removed, treating with  $\text{HCl}$  aq. which dissolves  $\text{CaO}$ , and dissolving the residual  $\text{MgO}$  in  $\text{H}_2\text{SO}_4$  aq., evaporating, crystallising out  $\text{MgSO}_4 \cdot 7\text{aq}$ , drying this salt, and heating it gradually to  $c. 300^\circ$  till it ceases to lose weight. A white solid; S.G. 2.709 at  $15^\circ$  (Thorpe & Watts, *C. J.* 37, 102); 2.77 at  $2.795$  at  $14^\circ$  (Petersson, *Upsala, Nova Acta*, 1876). H.F.  $[\text{Mg}, \text{S}, \text{O}] = 802,300$  (*Th.* 3, 516).  $[\text{MgSO}_4 \cdot \text{Aq}] = 20,765$  (Pickering, *C. J.* 47, 100). Decomposed to  $\text{MgO}$ ,  $\text{SO}_2$ , and  $\text{O}$  at  $c. 360^\circ$  (v. Bailey, *C. J.* 51, 682). Not acted on by  $\text{HCl}$  gas below incipient red heat (Hensgen, *B.* 9, 1671; 10, 259). The heptahydrate  $\text{MgSO}_4 \cdot 7\text{aq}$  (*Epsom salt*) occurs in many mineral springs, in sea water, and in some rocks. It crystallises at the ordinary temperature from solutions of  $\text{MgO}$  or  $\text{MgCO}_3$  in  $\text{H}_2\text{SO}_4$  aq. Translucent, rhombic prisms; from supersaturated solutions crystallises in hexagonal forms, and from solutions containing some  $\text{FeSO}_4$  in monoclinic forms (v. Marignac, *Ann. M.* [5] 12, 50). S.G. 1.678 at  $15^\circ$  (Thorpe & Watts, *C. J.* 37, 102); 1.683 at  $4^\circ$  (Playfair & A. Joule, *C. J.* 1, 138). H.F.  $[\text{Mg}, \text{S}, \text{O}, 7\text{H}_2\text{O}] = 326,400$  (*Th.* 3, 516). Melts at  $70^\circ$  (Tilden, *C. J.* 45, 267); gives up  $6\text{H}_2\text{O}$  by prolonged heating at  $150^\circ$ – $160^\circ$ , and all water of crystallisation at  $c. 280^\circ$  (v. Pickering, *C. J.* 47, 100). The following data for solubility in water are calculated by Mulder from observations by Gay-Lussac, Tobler, and others:—

Temp.	S.	Temp.	S.
$0^\circ$	25.76	$60^\circ$	55.0
5	29.3	65	57.3
10	31.5	70	59.6
15	33.8	75	61.9
20	36.2	80	64.2
25	38.5	85	66.5
30	40.9	90	68.9
35	43.3	95	71.4
40	45.6	100	73.8
45	48.0	105	76.2
50	50.3	108.4	77.9
55	52.7		

Gerlach (*Fr.* 8, 287) gives the following:—

P.p. $\text{MgSO}_4$	S.G. $\text{MgSO}_4 \cdot \text{Aq}$	P.p. $\text{MgSO}_4$	S.G. $\text{MgSO}_4 \cdot \text{Aq}$

S. at  $15^\circ$  in 10 p.c. alcohol 39.3, 20 p.c. alcohol 21.3, 40 p.c. alcohol 1.62 (Schiff, *A.* 118, 365). Heated with  $\text{NaCl}$  gives off  $\text{HCl}$ , leaving  $\text{Na}_2\text{SO}_4$ ,  $\text{MgCl}_2$ , and some  $\text{MgSO}_4$  (Ramon de Luna, *J. pr.* 66, 256). Decomposed, almost entirely, by heating in steam, giving off  $\text{H}_2\text{SO}_4$  and leaving  $\text{MgO}$  (Clemm, *J.* 1864, 764). Strongly heated with charcoal gives off  $\text{SO}_2$  and  $\text{CO}_2$  (or  $\text{CO}$ ), and leaves  $\text{MgO}$ . Mixed with  $\text{NaCl}$  and heated in steam gives  $\text{Na}_2\text{SO}_4$ ,  $\text{MgO}$ , and  $\text{HCl}$ .

Other hydrates of magnesium sulphate. (1)

$\text{MgSO}_4 \cdot \text{aq}$  occurs native as *kieserite*, S.G. 2.281 at  $16^\circ$  (Pape, *P.* 120, 369); dissolves slowly in cold water, easily in boiling water, forming  $\text{MgSO}_4 \cdot 7\text{aq}$ ; prepared by heating the heptahydrate for a long time at  $150^\circ$ – $160^\circ$  (Pickering, *C. J.* 47, 100); S.G. 2.445 (Thorpe & Watts, *C. J.* 37, 102). (2)  $\text{MgSO}_4 \cdot 6\text{aq}$ , by crystallising a solution of the heptahydrate above  $40^\circ$ ; S.G. 1.734 (*T. a. W., l.c.*). (3)  $\text{MgSO}_4 \cdot 5\text{aq}$ , by drying the heptahydrate over conc.  $\text{H}_2\text{SO}_4$ ; S.G. 1.869 (*T. a. W., l.c.*). (4)  $\text{MgSO}_4 \cdot 2\text{aq}$ , by boiling powdered  $\text{MgSO}_4 \cdot 7\text{aq}$  with absolute alcohol; S.G. 2.373 (*T. a. W., l.c.*). (5) According to Jacquelin (A. Ch. [3] 32, 201), the hydrates  $4\text{M} \cdot 7\text{aq}$ ,  $4\text{M} \cdot 9\text{aq}$ , and  $2\text{M} \cdot 5\text{aq}$  exist ( $\text{M} = \text{MgSO}_4$ ). Acid salts. Schiff (*A.* 106, 115) obtained deliquescent, hexagonal plates,  $\text{MgSO}_4 \cdot \text{H}_2\text{SO}_4$ , from a solution of  $\text{MgSO}_4$  in hot conc.  $\text{H}_2\text{SO}_4$ ; according to Schultz (*P.* 130, 149), the crystals are  $\text{MgSO}_4 \cdot 3\text{H}_2\text{SO}_4$ .

Double salts. With  $\text{K}_2\text{SO}_4$ , or  $(\text{NH}_4)_2\text{SO}_4$ , to form compounds  $\text{MgSO}_4 \cdot \text{M}_2\text{SO}_4 \cdot 6\text{aq}$ ; by crystallising mixtures of the component salts in proper proportion. For solubility and S.G. of solution of the  $\text{K}_2\text{SO}_4$  compound, v. Tobler (*A.* 95, 193), Schiff (*A.* 113, 183), Gerlach (*Fr.* 8, 287). The compound of  $\text{MgSO}_4$  and  $\text{Na}_2\text{SO}_4$  contains  $4\text{aq}$  (cf. van't Hoff & Deventer, *B.* 19, 2144). The compound  $\text{MgSO}_4 \cdot \text{KCl} \cdot 3\text{aq}$  occurs native as *kainite* (v. Reichardt, *Ar. Ph.* 159, 204; Erlenmeyer, *B.* 2, 283). A double salt  $\text{MgSO}_4 \cdot \text{Al}_2(\text{SO}_4)_3 \cdot x\text{H}_2\text{O}$  occurs as *feather alum*, and *pickeringite*. Some triple salts of  $\text{MgSO}_4$ , with  $\text{CaSO}_4$  and  $\text{K}_2\text{SO}_4$ , occur as minerals (v. Reichardt, *Ar. Ph.* 159, 204; Frecht, *B.* 14, 2138).

Manganese sulphates. I. Manganous salts. The normal salt  $\text{MnSO}_4$  is obtained by dissolving  $\text{MnCO}_3$  or  $\text{Mn}$  in warm dilute  $\text{H}_2\text{SO}_4$  aq., crystallising out  $\text{MnSO}_4 \cdot 5\text{aq}$ , drying this salt, and heating to  $c. 280^\circ$  until it ceases to lose weight. A white salt, with very faint rose tint; S.G. 3.282 (Thorpe & Watts, *C. J.* 37, 113). H.F.  $[\text{Mn}, \text{S}, \text{O}] = 249,900$  (*Th.* 3, 516). S.  $56.5$  at  $6.3^\circ$ ,  $60$  at  $18.7^\circ$ ,  $68.7$  at  $37.5^\circ$ ,  $67$  at  $75^\circ$  (Brandes, *P.* 20, 575). Decomposed by heating to full redness, giving off  $\text{SO}_2$  and  $\text{O}$ , and leaving  $\text{Mn}_2\text{O}_3$ ; heated in steam is said to give an oxysulphide  $\text{Mn}_2\text{OS}$  (Arfvedson, *P.* 1, 50).

Hydrates of manganous sulphate. (1)  $\text{MnSO}_4 \cdot 7\text{aq}$  separates from solutions of  $\text{Mn}$  or  $\text{MnCO}_3$  in  $\text{H}_2\text{SO}_4$  aq. below  $6^\circ$  (Mitscherlich, *P.* 25, 287; Claassen, *Ar. Ph.* [3] 25, 310). Very pale rose-coloured, monoclinic crystals; isomorphous with  $\text{FeSO}_4 \cdot 7\text{aq}$ . Very sol. water; S. at  $18.5^\circ$   $c. 200$  (Jahn, *A.* 28, 110). According to Etard (*C. R.* 86, 1399), solubility increases from  $0^\circ$ – $55^\circ$ , and decreases from  $55^\circ$ – $145^\circ$ ; the changes are probably due to the formation of different hydrates. (2)  $\text{MnSO}_4 \cdot 5\text{aq}$ , obtained by crystallising between  $7^\circ$  and  $20^\circ$ , or by treating a conc. solution of  $\text{MnSO}_4$  with 95 p.c. alcohol and allowing to crystallise slowly (Claassen, *Ar. Ph.* [3] 25, 310). S.G. 2.103 (Thorpe & Watts, *C. J.* 37, 113). H.F.  $[\text{Mn}, \text{S}, \text{O}, 5\text{H}_2\text{O}] = 263,600$  (*Th.* 3, 516). (3)  $\text{MnSO}_4 \cdot 4\text{aq}$ , obtained by crystallising between  $20^\circ$  and  $30^\circ$  (*C., l.c.*; Mitscherlich, *P.* 25, 287). S.G. 2.261 (Topsoe, *C. C.* 4, 76). This is the main constituent of ordinary manganous sulphate. Mulder gives solubilities as follows:—

Temp.	S. $\text{MnSO}_4$ , 4aq	Temp.	S. $\text{MnSO}_4$ , 4aq
0°	55.4	50°	74.8
5	58.2	54	75.3
10	63.8	58.5	61.3
20	66.3	64	61.5
25	68.5	85	61.3
30	70.4	90	60.3
35	71.9	95	57.9
40	73.1	100	52.9
45	74.0		

Insol. absolute alcohol (*cf.* Schiff, *A.* 118, 365).

(4)  $\text{MnSO}_4 \cdot 2\text{aq}$ , obtained by boiling the powdered pentahydrate with absolute alcohol; also by pouring a saturated solution of the pentahydrate into conc.  $\text{H}_2\text{SO}_4$ ; S.G. 2.526 (T. a. W., *l.c.*).

(5)  $\text{MnSO}_4$ , aq, obtained by heating the pentahydrate at  $100^\circ$  till it ceases to lose weight; S.G. 2.845 (T. a. W., *l.c.*).

Linebarger (*Am.* 15, 225) has obtained hydrates of  $\text{MnSO}_4$  with 1, 2, 3, 4, 5, 6, and 7  $\text{H}_2\text{O}$ . Below  $-10^\circ$  mixtures of the heptahydrate and ice separate from  $\text{MnSO}_4$ , aq; above  $117^\circ$  only  $\text{MnSO}_4$  separates. The solubilities of the various hydrates are discussed; the more water in the hydrate, the more soluble it is.

*Acid salts*  $\text{MnSO}_4 \cdot \text{H}_2\text{SO}_4$  and  $\text{MnSO}_4 \cdot 3\text{H}_2\text{SO}_4$  were obtained by Schultz (*P.* 130, 149) by dissolving the normal salt in hot conc.  $\text{H}_2\text{SO}_4$ .

*Basic salts* are formed by adding a little warm  $\text{KOH}$  aq to a large excess of boiling  $\text{MnSO}_4$ , aq (*v.* Gorgeu, *C. R.* 94, 1425).

*Double salts*; (1) with sulphates of Cu, Fe, Mg, and Zn to form salts  $\text{MnSO}_4 \cdot \text{MSO}_4 \cdot x\text{H}_2\text{O}$  (*v.* Rammelsberg, *P.* 91, 321; Vohl, *A.* 94, 73). (2) With  $\text{Al}(\text{SO}_4)_3$ ,  $\text{Fe}(\text{SO}_4)_3$ , and  $\text{Cr}(\text{SO}_4)_3$ , *v.* Etard (*C. R.* 86, 1399; 87, 602). (3) With alkali sulphates to form  $\text{MnSO}_4 \cdot \text{M}_2\text{SO}_4 \cdot 4\text{aq}$  or  $6\text{aq}$  (*v.* Marignao, *Ann. M.* [5] 9, 1; Pierre, *A. Ch.* [3] 16, 239; von Hauer, *J. pr.* 74, 431). For various *triple salts* of  $\text{MnSO}_4$  with alkali sulphates and  $\text{CuSO}_4$ ,  $\text{MgSO}_4$ , &c.; *v.* Vohl (*A.* 94, 57).

**II. Manganic salts.**—The normal salt  $\text{Mn}_2(\text{SO}_4)_3$  is obtained by the action of hot conc.  $\text{H}_2\text{SO}_4$  on  $\text{MnO}_2$ . Carius (*A.* 98, 53) recommends to prepare pure  $\text{MnO}_2$  by passing Cl into  $\text{NaOH}$  aq containing  $\text{MnCO}_3$  in suspension, to wash and dry the  $\text{MnO}_2$ , to rub up to a paste with conc.  $\text{H}_2\text{SO}_4$ , and heat gradually to  $110^\circ$  till O is given off and the mass becomes grey-violet, then to heat to c.  $135^\circ$ – $140^\circ$  till the whole is liquid, to pour the solid that forms as the liquid partially cools on to warm unglazed porcelain, after  $\text{H}_2\text{SO}_4$  has become absorbed to mix with a little conc.  $\text{HNO}_3$  aq and allow to drain on the porcelain, to repeat this treatment with  $\text{HNO}_3$  six or eight times, and finally to heat at  $150^\circ$  till all  $\text{HNO}_3$  is removed. Franke (*J. pr.* [2] 36, 451) obtained  $\text{Mn}_2(\text{SO}_4)_3$  by heating 8 g.  $\text{KMnO}_4$  with 100 c.c. conc.  $\text{H}_2\text{SO}_4$  at  $100^\circ$  for some time. A dark-green powder; Franke describes it as green crystals. Decomposed above  $160^\circ$ , giving  $\text{MnSO}_4$ . Insol. conc.  $\text{H}_2\text{SO}_4$  or conc.  $\text{HNO}_3$  aq. Sol. conc.  $\text{HCl}$  aq to a brown liquid, which gives off Cl when warmed.  $\text{Mn}_2(\text{SO}_4)_3$  is very hygroscopic; quickly decomposed by water, with separation of  $\text{MnO}_2 \cdot x\text{H}_2\text{O}$  (Carius, *l.c.*).

Forms *double salts* with  $\text{Al}_2(\text{SO}_4)_3$ ,  $\text{Fe}_2(\text{SO}_4)_3$ , and  $\text{Cr}_2(\text{SO}_4)_3$  (*v.* Etard, *C. R.* 86, 1399). The *double compounds* of  $\text{Mn}_2(\text{SO}_4)_3$  with alkali sul-

phates— $\text{Mn}_2(\text{SO}_4)_3 \cdot \text{M}_2\text{SO}_4 \cdot 24\text{aq}$ —are alums. According to Frey (*C. R.* 82, 1231), the salt  $\text{Mn}(\text{SO}_4)_2$ , *manganese disulphate*, corresponding with  $\text{MnO}_2$ , is formed by decomposing  $\text{KMnO}_4$  by a considerable excess of cold conc.  $\text{H}_2\text{SO}_4$  (*cf.* Franke, *J. pr.* [2] 36, 453).

**Mercury sulphates.** **I. Mercurous salts.** The normal salt  $\text{Hg}_2\text{SO}_4$  is obtained by gently warming equal weights of Hg and conc.  $\text{H}_2\text{SO}_4$ , removing the white solid so produced before the whole of the Hg is changed, washing with cold water, and drying at a low temperature. Divers a. Shimidzu (*C. J.* 47, 639) recommend to mix Hg with fuming sulphuric acid rich in  $\text{SO}_3$  in a covered dish, in a cool place, adding a little more Hg from time to time till there is sufficient to saturate the  $\text{SO}_3$  in the acid, but avoiding excess, and when the Hg is all converted into  $\text{Hg}_2\text{SO}_4$  to set the dish in a warm place to expel  $\text{SO}_3$ .  $\text{Hg}_2\text{SO}_4$  is also obtained by adding 6 pts. water to 18 pts.  $\text{HgSO}_4$  and rubbing with 11 pts. Hg (Planché, *A.* 66, 168). Also by ppg.  $\text{HgNO}_3$  aq by dilute  $\text{H}_2\text{SO}_4$  aq or solution of a sulphate; or by rubbing together  $\text{HgNO}_3$  and  $\text{Na}_2\text{SO}_4$  and washing with cold water (H. Rose; Stoedeler, *A.* 87, 129). A white powder, consisting of monoclinic prisms (*S.*, *l.c.*); S. G. 7.56 (Playfair a. Joule, *C. S. Mem.* 2, 401). Sl. sol. water; S. in cold water 2; in boiling water 33; more sol. dilute  $\text{HNO}_3$  aq; sol. conc. hot  $\text{H}_2\text{SO}_4$ , crystallising out on cooling.  $\text{Hg}_2\text{SO}_4$  becomes grey on exposure to light (*v.* Buchner, *Chem. Zeitung*, 10, 759); hence the salt should be kept in the dark.  $\text{Hg}_2\text{SO}_4$  melts to a reddish liquid, and decomposes at a higher temperature, giving off  $\text{SO}_2$  and O, and also partially subliming. Slowly changed by boiling water to an acid salt, and a yellow powder which is probably a basic salt (*v.* Kane, *P.* 42, 367). An *acid salt*  $\text{Hg}_2\text{SO}_4 \cdot \text{H}_2\text{SO}_4$  is said to be formed by the prolonged reaction of conc.  $\text{H}_2\text{SO}_4$  containing a drop of  $\text{HNO}_3$  aq on Hg (Braham, *C. N.* 42, 163). A *double salt*  $\text{Hg}_2\text{SO}_4 \cdot 2\text{HgSO}_4$  was obtained by Brooks (*P.* 66, 63) by gently warming mercurous-mercuric nitrate (formed by warming 2 pts. Hg with 3 pts.  $\text{HNO}_3$  aq S.G. 1.2) with  $\text{Na}_2\text{SO}_4$  aq.

**II. Mercuric salts.** The normal salt  $\text{HgSO}_4$  is obtained by the reaction of 6 pts. boiling conc.  $\text{H}_2\text{SO}_4$  with 5 pts. Hg, till  $\text{SO}_2$  ceases to be evolved, and a little of the white solid produced gives no pp. of  $\text{HgCl}$  when dropped into dilute  $\text{HCl}$  aq; the white mass is gently warmed till acid fumes cease to be given off. A white powder; S.G. 6.466 (Playfair a. Joule, *C. S.*, *Mem.* 2, 401). Becomes yellow, then red when heated; decomposes at red heat to Hg, O, and  $\text{SO}_2$ , a little  $\text{HgSO}_4$  subliming (Mohr, *A.* 31, 180). Decomposed by water to a yellow basic salt and  $\text{H}_2\text{SO}_4$  aq. Hot  $\text{HgSO}_4$  absorbs  $\text{HCl}$  and  $\text{HBr}$  gases; according to Ditté (*A. Ch.* [5] 17, 120) the compounds  $\text{HgSO}_4 \cdot 2\text{HCl}$  and  $\text{HgSO}_4 \cdot 2\text{HBr}$  are formed; these bodies are said to be sol. water without formation of basic salts, and  $\text{HgSO}_4 \cdot 2\text{HCl}$  is said to sublime unchanged when heated. Solution of  $\text{HgSO}_4$  in  $\text{H}_2\text{SO}_4$  aq is said to react with  $\text{PH}_3$  to form the compound  $2(\text{HgO} \cdot \text{SO}_3) \cdot \text{Hg}_2\text{P}$  (H. Rose, *P.* 40, 75). *Mono-hydrated mercuric sulphate*  $\text{HgSO}_4 \cdot \text{aq}$  was obtained by Eisefeldt (*Ar. Ph.* [2] 76, 16) by covering a thin layer of  $\text{HgSO}_4$  with the calculated quantity of water. The *basic salt*  $\text{HgSO}_4 \cdot 2\text{HgO}$

( $=3\text{HgO}\cdot\text{SO}_3$ ) is obtained by the action of hot water on  $\text{HgSO}_4$ , also by adding  $\text{Na}_2\text{SO}_4$  to hot  $\text{Hg}(\text{NO}_3)_2$  aq; a citron-yellow powder, S.G. 6.44; nearly insol. water (v. Cameron, *Ann.* 880, 144). Decomposed by Cl at the ordinary temperature. Absorbs HCl and HBr, forming  $\text{HgSO}_4\cdot 2\text{H}_2\text{O}$  (or 6HBr) (Ditte, l.c.). This acid salt was formerly known as *mineral turpethum* or *turbith mineral* (from its resemblance to a coloured gum obtained from an oriental creeping plant [*Ipomoea turpethum*]). Hopkins (*Am. S.* 18, 364) described another basic salt  $3\text{HgSO}_4\cdot\text{HgO}=4\text{HgO}\cdot 3\text{SO}_3$ . *Double salts.* — (1)  $\text{HgSO}_4\cdot(\text{NH}_4)_2\text{SO}_4\cdot x\text{H}_2\text{O}$  and  $\text{HgSO}_4\cdot\text{K}_2\text{SO}_4\cdot x\text{H}_2\text{O}$  (v. Hirzel, *J.* 1860, 322). (2)  $\text{HgSO}_4\cdot\text{HgI}_2$  (v. Souville, *J. Ph.* 26, 474). (3)  $2\text{HgSO}_4\cdot\text{HgS}$  (v. Jacobsen, *P.* 68, 411).

**Molybdenum sulphates.** By evaporating a solution of  $\text{MoO}_3$  in conc.  $\text{H}_2\text{SO}_4$ , Schultz-Sellack (*B.* 4, 14) obtained white lustrous crystals of  $\text{MoO}_3\cdot\text{SO}_3$ ; the compound  $\text{MoO}_3\cdot 3\text{SO}_3$ , 2aq, described by Anderson (*B. J.* 22, 161), could not be obtained by S.S.

**Nickel sulphates.** The normal salt  $\text{NiSO}_4$  is formed, as a clear yellow powder, by heating powdered  $\text{NiSO}_4$  2aq (v. *infra*) to c.  $300^\circ$ . The salt is obtained in crystals, regular octahedra, by heating  $\text{NiSO}_4$ ,  $\text{NiO}$ , or  $\text{NiCO}$ , with five or six times its weight of fused  $(\text{NH}_4)_2\text{SO}_4$ , separating the yellow crystals of the double salt  $8\text{NiSO}_4\cdot 2(\text{NH}_4)_2\text{SO}_4$ , that form, and heating these in presence of some  $(\text{NH}_4)_2\text{SO}_4$  in a partly closed crucible out of contact with the gases of the flame till all the ammonium salt is removed; S.G. of crystals 3.67 at  $20^\circ$  (Lepierre a. Lachaud, *C. R.* 115, 115; Klobb, *C. R.* 114, 836). Tobler (*A.* 95, 193) gives solubilities of  $\text{NiSO}_4$  as follows:—

Temp.	S.	Temp.	S.
$2^\circ$	80.4	$41^\circ$	49.1
16	87.4	50	52.0
20	89.4	53	54.4
23	41.0	60	57.2
31	45.8	70	61.9

The *hexahydrate*  $\text{NiSO}_4\cdot 6\text{aq}$  is obtained by dissolving Ni, NiO, or NiCO, in excess of  $\text{H}_2\text{SO}_4$  aq, evaporating, and crystallising. At the ordinary temperature; bluish tetragonal pyramids separate (Brooke a. Phillips, *P.* 6, 193); greenish monoclinic crystals separate from warm solutions (Pierre, *A. Ch.* [3] 16, 252). The salt is, therefore, dimorphous (Marignac, *A.* 97, 294; cf. Mitscherlich, *P.* 12, 144; also Lecoq de Boisbaudran, *A. Ch.* [4] 9, 173). By dissolving this hydrate in water, and crystallising at  $15^\circ$ – $20^\circ$ , emerald-green rhombic prisms of the *heptahydrate*  $\text{NiSO}_4\cdot 7\text{aq}$  are obtained, isomorphous with  $\text{MgSO}_4\cdot 7\text{aq}$ ; melts at  $98^\circ$ – $100^\circ$  (Tilden, *C. J.* 45, 267). When this hydrate is heated to  $-103^\circ$  it loses  $6\text{H}_2\text{O}$  and leaves the *monohydrate*  $\text{NiSO}_4\cdot \text{aq}$ . By passing  $\text{NH}_3$  into  $\text{NiSO}_4$  aq, compounds of the form  $\text{NiSO}_4\cdot x\text{NH}_3\cdot y\text{H}_2\text{O}$  are obtained ( $x=4, 5$ , and 6; v. F. Rose, *Ammon. Kobaltverbind.* [Heidelberg, 1871] 27; also *P.* 20, 156).

**Double salts.** (1) With  $(\text{NH}_4)_2\text{SO}_4$ ,  $\text{K}_2\text{SO}_4$ , and  $\text{Ti}_2\text{SO}_4$  to form  $\text{NiSO}_4\cdot \text{M}_2\text{SO}_4\cdot 6\text{aq}$  (v. F. Rose, l.c.; Link, *Crell's Ann.* 1796 [1] 32; Werther, *J. pr.* 92, 132). (2) With  $\text{BeSO}_4$  to form various compounds (Klatzo, *Über die Constant. der*

*Beryllus*, *Lorpat*, 1858). (3) With  $\text{CuSO}_4$ ,  $\text{CoSO}_4$ ,  $\text{FeSO}_4$ ,  $\text{MgSO}_4$ ,  $\text{MnSO}_4$ , and with some of these and also alkali sulphates (v. Pierre, *A. Ch.* [3] 16, 253; Lecoq de Boisbaudran, *C. R.* 66, 497).

**Basic salts** are formed by the gradual reaction of  $\text{NiSO}_4$  aq with  $\text{NiCO}$ , and by adding a little  $\text{NH}_4$  aq to boiling  $\text{NiSO}_4$  aq (Habermann, *M.* 5, 440).

**Palladium sulphates.** The normal palladium salt  $\text{PdSO}_4\cdot 2\text{aq}$  is obtained in brown crystals by evaporating a solution of Pd in  $\text{H}_2\text{SO}_4$  aq containing  $\text{HNO}_3$ . Addition of a little KOH aq to a conc. solution in water of the normal salt ppts. a *basic salt*  $\text{PdSO}_4\cdot 7\text{PdO}\cdot 6\text{aq}$  (v. Kane, *B. J.* 24, 236).

**Platinum sulphates.** By dissolving  $\text{PtO}_2$  in dilute  $\text{H}_2\text{SO}_4$  aq, Berzelius (*Lehrbuch* [5th ed.] 8, 987) obtained a dark syrup which probably contained *platinous sulphate*  $\text{PtSO}_4$ . *Platinic sulphate*  $\text{Pt}(\text{SO}_4)_2$  was obtained by Berzelius (l.c., p. 989) by evaporating  $\text{PtCl}_4$  with conc.  $\text{H}_2\text{SO}_4$  (1 part acid for 1 part Pt), as an almost black solid. E. Davy (*T.* 1820) obtained the salt by oxidising  $\text{PtS}$ , by fuming  $\text{HNO}_3$ . Prost (*Bl.* [2] 46, 156) obtained a *basic salt* by allowing an acid solution of  $\text{Pt}(\text{SO}_4)_2$  to stand for some days; Prost also describes several *double salts* of  $\text{Pt}(\text{SO}_4)_2$  with alkali sulphates.

**Potassium sulphates.** The normal salt  $\text{K}_2\text{SO}_4$  is found in the lava from Vesuvius, in small quantities in sea water, and in some mineral springs, in combination with  $\text{MgSO}_4$  and  $\text{MgCl}_2$ , as *kainite* ( $\text{K}_2\text{SO}_4\cdot \text{MgSO}_4\cdot \text{MgCl}_2\cdot 6\text{aq}$ ), in combination with  $\text{MgSO}_4$  and  $\text{CaSO}_4$  as *polyhalite* ( $\text{K}_2\text{SO}_4\cdot \text{MgSO}_4\cdot 2\text{CaSO}_4\cdot 2\text{aq}$ ), and as *alum.*  $\text{K}_2\text{SO}_4$  is prepared by decomposing KCl by  $\text{H}_2\text{SO}_4$ , by neutralising  $\text{H}_2\text{SO}_4$  aq by KOH or  $\text{K}_2\text{CO}_3$ , and evaporating (for the preparation of  $\text{K}_2\text{SO}_4$  on the large scale v. *DICTIONARY OF APPLIED CHEMISTRY*, vol. iii. p. 279).  $\text{K}_2\text{SO}_4$  forms in white, hard, four-sided, trimetric prisms, unchanged in air. S.G. 2.656 at  $4^\circ$  (Playfair a. Joule, *C. J.* 1, 132); for S.G. at various temperatures from  $0^\circ$  to  $100^\circ$  v. Spring, *B.* 15, 1940. Melts above  $861^\circ$  (Carnelley, *Melting and Boiling-Point Tables*, 1, 33); melts at  $1073^\circ$  according to V. Meyer a. Riddle (*B.* 26, 2443). H.F. [ $\text{K}_2\text{SO}_4$ ] = 344,600 (*Th.* 3, 516); [ $\text{K}_2\text{SO}_4$  aq] = -6167 (Pickering, *C. J.* 47, 98). Mulder (*Scheikund. Verhandel.* 1864. 49) gives solubilities in water as follows:—

Temp.	S.	Temp.	S.
$5^\circ$	0.1	$55^\circ$	16.8
10	9.7	60	17.8
15	10.3	65	18.8
20	10.9	70	19.8
25	11.6	75	20.8
30	12.3	80	21.8
35	13.1	85	22.8
40	14.0	90	23.9
45	14.9	95	25.0
50	15.8	100	26.2

Gerlach (*Fr. S.* 827) gives S.G. of  $\text{K}_2\text{SO}_4$  aq as follows:—

Pctge. $\text{K}_2\text{SO}_4$	S.G. $\text{K}_2\text{SO}_4$ aq	Pctge. $\text{K}_2\text{SO}_4$	S.G. $\text{K}_2\text{SO}_4$ aq
1	1.00829	6	1.04947
2	1.01635	7	1.05790
3	1.02450	8	1.06644
4	1.03277	9	1.07499
5	1.04105	9.92 (satd.)	1.08305

**Insol. absolute alcohol; sol. aqueous alcohol** in proportion to amount of water present (v. Schiff, *A.* 118, 362). **Insol.** KOHAq 1:32 S.G.; sl. sol. KOHAq 20 p.c. S. in saturated  $\text{NH}_4\text{Aq}$  = 0.365 (Giraud, *Bl.* [2] 43, 552). S. in glycerin (S.G. 1.225) at ordinary temperature = 1.32 (Vogel, *N. R.* P. 16, 557). More sol. in solution of  $\text{CuSO}_4$ ,  $\text{MgSO}_4$ , or  $\text{Na}_2\text{SO}_4$  than in water. Reacts with strong acids to give  $\text{KHSO}_4$  (for thermal measurements v. Berthelot, *Essai de m c. chimique*, 1, 389). Dissolves in hot conc.  $\text{HNO}_3\text{Aq}$ ,  $\text{KHSO}_4$  separates on cooling, then  $\text{KNO}_3$ , and then a compound of  $\text{K}_2\text{SO}_4$  with  $\text{HNO}_3$ ;  $\text{H}_3\text{PO}_4\text{Aq}$  reacts similarly (v. Jacquelin, Biedermann's *Techn. Chem.* J. 4, 62). Absorbs  $\text{HCl}$  gas when heated, forming  $\text{KCl}$  and  $\text{KHSO}_4$  (Thomas, *C. J.* 33, 372; Hengen, *B. J.* 9, 1671; 10, 259). Decomposed by heating with  $\text{NH}_4\text{Cl}$ , giving  $\text{KCl}$  (H. Rose, *P.* 64, 568). Heated to redness with iron filings gives  $\text{KOH}$  mixed with  $\text{Fe}_2\text{O}_3$  and  $\text{FeS}$  (d'Heureuse, *P.* 75, 255). Reduced to sulphide (or  $\text{KSH}$ ) by heating in  $\text{CO}$ ; to  $\text{KSH}$  and  $\text{KOH}$  by heating in  $\text{H}$  (v. Berthelot, *C. R.* 110, 1106). Sulphur reacts at full red heat, giving  $\text{SO}_2$  and polysulphides of  $\text{K}$  (Berthelot, *C. R.* 96, 303).  $\text{SO}_2$  is without action at a red heat.

**Double salts.** (1) With  $\text{Al}_2(\text{SO}_4)_3$ ,  $\text{Cr}_2(\text{SO}_4)_3$ , and  $\text{Fe}_2(\text{SO}_4)_3$  to form  $\text{K}_2\text{SO}_4 \cdot \text{M}_2(\text{SO}_4)_3 \cdot 24\text{aq}$ ; v. *potash alum*, *potash chrome-alum* and *potash iron-alum*, under ALUMINIUM SULPHATES (p. 568), CHROMIUM SULPHATES (p. 570), and IRON SULPHATES (p. 572). (2) With sulphates of  $\text{Ce}$  and  $\text{Di}$  respectively, to form  $3\text{K}_2\text{SO}_4 \cdot \text{M}_2(\text{SO}_4)_3$  (v. Cleve, *Bl.* [2] 43, 359; Czudnowitz, *J. pr.* 82, 129; Hermann, *J. pr.* 82, 385); also the salt  $2\text{K}_2\text{SO}_4 \cdot \text{Ce}(\text{SO}_4)_2 \cdot 2\text{aq}$  (Marignac, *Ann. M.* [5] 15, 275). (3) With sulphates of  $\text{Cd}$ ,  $\text{Co}$ ,  $\text{Cu}$ ,  $\text{Fe}$ ,  $\text{Mg}$ ,  $\text{Mn}$ ,  $\text{Ni}$ ,  $\text{Zn}$  to form  $\text{K}_2\text{SO}_4 \cdot \text{MSO}_4 \cdot 6\text{aq}$  (v. Graham, *P. M.* 1835, 327, 417; Brunner, *P.* 15, 476; 32, 221; Pickering, *C. J.* 49, 1; Tobler, *A.* 95, 193; Schiff, *A.* 108, 326; 113, 183; Gerlach, *Tr.* 8, 287; Marignac, *Ann. M.* [5] 9, 19; Wilm, *A. Ch.* [4] 5, 56; Pierre, *A. Ch.* [3] 16, 239; von Hauer, *J. pr.* 74, 431; Werther, *J. pr.* 92, 132). (4)  $\text{K}_2\text{SO}_4 \cdot \text{BeSO}_4 \cdot 2\text{aq}$  (Awdejoff, *P.* 56, 101). (5)  $\text{K}_2\text{SO}_4 \cdot \text{Na}_2\text{SO}_4$  (Penny, *P. M.* [4] 10, 401; Mitscherlich, *P.* 58, 468; von Hauer, *J. pr.* 83, 856).

The **acid salt**  $\text{KHSO}_4$  occurs in some volcanic districts as *misenerite*; it is formed by heating 13 parts  $\text{K}_2\text{SO}_4$  with 8 parts conc.  $\text{H}_2\text{SO}_4$ , or by heating  $\text{KNO}_3$  and conc.  $\text{H}_2\text{SO}_4$  in the ratio  $\text{KNO}_3:\text{H}_2\text{SO}_4$ . Crystallises in white rhombic forms, S.G. 2.273; also in monoclinic forms, S.G. 2.245 (v. Wyruboff; abstract in *C. J.* 50, 665). Melts at c. 200°. Easily sol. water; Kremers gives S. 33.9 at 0°, 48 at 20°, 62.9 at 40°, 114 at 100°. An aqueous solution is said to deposit, first  $\text{K}_2\text{SO}_4$ , then  $\text{KHSO}_4$ ,  $\text{K}_2\text{SO}_4$ , and then  $\text{KHSO}_4$ ; by evaporating  $\text{KHSO}_4\text{Aq}$  at a low temperature until a solid mass formed on removing the flame, arborescent and very deliquescent crystals formed on the surface of the solid, which were  $2\text{KHSO}_4 \cdot 11\text{H}_2\text{O}$  according to Senderens (*Bl.* [8] 2, 728).

**Other acid salts.** (1)  $\text{KHSO}_4 \cdot \text{K}_2\text{SO}_4$  obtained by evaporating  $\text{KHSO}_4\text{Aq}$ . (2)  $2\text{KHSO}_4 \cdot \text{K}_2\text{SO}_4$  crystallising from  $\text{K}_2\text{SO}_4$  in  $\text{H}_2\text{SO}_4\text{Aq}$  (Phillips, *J. pr.* [2] 1, 429; Marignac, *Ann. M.* [5] 9, 7). (3)  $\text{KHSO}_4 \cdot \text{H}_2\text{SO}_4$  formed by heating  $\text{K}_2\text{SO}_4$  with

less than 5 parts conc.  $\text{H}_2\text{SO}_4$  (Schultz, *P.* 133, 137).

**Rhodium sulphates.** The **normal rhodic sulphate**  $\text{Rh}_2(\text{SO}_4)_3$  is obtained by dissolving  $\text{Rh}_2\text{O}_3$  in  $\text{H}_2\text{SO}_4\text{Aq}$ , evaporating, and heating to 400° till excess of acid is removed; a red powder, decomposed by hot water to the yellow **basic salt**  $\text{Rh}_2(\text{SO}_4)_3 \cdot \text{Rh}_2\text{O}_3$  (Leidi , *C. R.* 107, 234). Claus (*Beitr ge zur Chemie der Platinmetalle* [Dorpat, 1854]) obtained the **hydrate**  $\text{Rh}_2(\text{SO}_4)_3 \cdot 12\text{aq}$ , as a pale-yellow crystalline salt, by crystallising a solution of  $\text{Rh}_2\text{O}_3$  in  $\text{H}_2\text{SO}_4\text{Aq}$  and washing with alcohol. The **double salt**  $\text{Rh}_2(\text{SO}_4)_3 \cdot 3\text{K}_2\text{SO}_4$  was obtained by Claus (*l.c.*) by evaporating a solution of the constituent salts in the ratio  $\text{Rh}_2(\text{SO}_4)_3:5\text{K}_2\text{SO}_4$ . The **double salt**  $\text{Rh}_2(\text{SO}_4)_3 \cdot \text{Na}_2\text{SO}_4$  was obtained by Bunsen (*A.* 146, 265; v. also Seubert a. Kobb , *B.* 23, 2556) by the action of hot conc.  $\text{H}_2\text{SO}_4$  on  $\text{RhSO}_4 \cdot 6\text{Na}_2\text{SO}_4 \cdot 9\text{aq}$  (formed by heating  $\text{RhCl}_3\text{Aq}$  for some time with  $\text{NaHSO}_4$ ).

**Rubidium sulphates.** The **normal salt**  $\text{Rb}_2\text{SO}_4$  is obtained by neutralising  $\text{H}_2\text{SO}_4\text{Aq}$  by  $\text{Rb}_2\text{CO}_3$  and evaporating; it crystallises in transparent, hexagonal forms, unchanged in air. S. 42.4 at 70°. S.G. 3.6438 at 0°; 3.6256 at 50°; 3.6036 at 100° (Spring, *B.* 15, 1940). If excess of  $\text{H}_2\text{SO}_4\text{Aq}$  is used, the **acid salt**  $\text{RbHSO}_4$  separates in rhombic prisms (Kirchoff a. Bunsen, *P.* 115, 534).

**Double salts.** (1) With  $\text{Li}_2\text{SO}_4$  to form  $\text{RbLiSO}_4$  (Wyruboff, *Bl.* [2] 43, 184, 630). (2) With  $\text{CaSO}_4$  and  $\text{PbSO}_4$  to form the compounds  $\text{Rb}_2\text{SO}_4 \cdot 2\text{MSO}_4 \cdot 2\text{aq}$  (Ditte, *C. R.* 89, 641). (3) With  $\text{Al}_2(\text{SO}_4)_3$  to form **rubidium alum**  $\text{Al}(\text{SO}_4)_3 \cdot \text{Rb}_2\text{SO}_4 \cdot 24\text{aq}$  (Bunsen, *P.* 119, 1; Godeffroy, *A.* 181, 176; Redtenbacher, *J. pr.* 95, 143).

**Ruthenium sulphate.** **Normal ruthenic sulphate**  $\text{Ru}(\text{SO}_4)_3$  is obtained by oxidising  $\text{RuS}_2$  (formed by prolonged action of  $\text{H}_2\text{S}$  on  $\text{RuCl}_3\text{Aq}$ ) by conc.  $\text{HNO}_3\text{Aq}$  and evaporating off excess of acid. An amorphous, brownish-yellow, very hygroscopic solid. Strongly heated gives  $\text{RuO}_3$  (Claus, *J. pr.* 42, 364).

**Silver sulphates.** The **normal salt**  $\text{Ag}_2\text{SO}_4$  is obtained by heating finely divided  $\text{Ag}$  with excess of conc.  $\text{H}_2\text{SO}_4$ , by neutralising  $\text{H}_2\text{SO}_4\text{Aq}$  by  $\text{Ag}_2\text{O}$  or  $\text{Ag}_2\text{CO}_3$  and evaporating, by evaporating  $\text{AgNO}_3$  with  $\text{H}_2\text{SO}_4\text{Aq}$ , or by ppg.  $\text{AgNO}_3\text{Aq}$  by  $\text{Na}_2\text{SO}_4\text{Aq}$ . Small, white, lustrous, rhombic crystals, isomorphous with  $\text{Na}_2\text{SO}_4$  (Mitscherlich, *P.* 12, 138; 25, 301). S. 1.15 cold water, 1.45 at 100° (Wenzel, *P.* 82, 136). S.G. 5.322 (Playfair a. Joule, *C. S. Mem.* 2, 401), 5.425 when fused (Schr der, *P.* 106, 228). Decrepitates when heated to 300°; melts at 645° (Carnelley, *C. J.* 33, 279). Decomposed at very high temperature, giving  $\text{Ag}$ ,  $\text{SO}_2$ , and  $\text{O}$ . Reduced to  $\text{Ag}$  by heating in  $\text{H}$ , with  $\text{O}$ , or in  $\text{CO}$  (Stammer, *J. pr.* 11, 70). Absorbs  $2\text{NH}_3$  (H. Rose, *P.* 20, 153).

**Acid salts** are obtained by dissolving  $\text{Ag}_2\text{SO}_4$  in different quantities of  $\text{H}_2\text{SO}_4\text{Aq}$  and crystallising; Schultz (*P.* 133, 137) describes (1)  $\text{AgHSO}_4$ , (2)  $2\text{Ag}_2\text{SO}_4 \cdot 3\text{H}_2\text{SO}_4 \cdot 2\text{aq}$ , (3)  $\text{Ag}_2\text{SO}_4 \cdot 3\text{H}_2\text{SO}_4 \cdot 2\text{aq}$ . Carey Lea (*Am. S.* [3] 44, 322) describes a **hemisulphate**  $\text{Ag}_2\text{SO}_4 \cdot \text{Ag}_2\text{SO}_4 \cdot \text{aq}$ , but this salt was not obtained free from  $\text{Ag}_2\text{PO}_4$ .

Forms a **double salt**  $\text{Ag}_2\text{SO}_4 \cdot \text{Al}(\text{SO}_4)_3 \cdot 24\text{aq}$ ; this salt is an **alum** (v. Church a. Northcote, *P.* 115, 534).

C. N. 9, 155). Also combines with  $\text{Ag}_2\text{S}$  and with  $\text{K}_2\text{SO}_4$  (Berzelius; H. Rose, P. 53, 463).

**S diam sulphates.** The normal salt  $\text{Na}_2\text{SO}_4$  occurs native as *thenardite*, in combination with  $\text{CaSO}_4$  as *glauconite*, and with  $\text{MgSO}_4$  as *l'ewite*; the salt also occurs in sea water and in many mineral springs. It is prepared by adding  $\text{H}_2\text{SO}_4$  to  $\text{NaCl}$  in the ratio  $\text{NaCl}:\text{H}_2\text{SO}_4$ , and strongly heating the  $\text{NaHSO}_4$  thus produced; also by the reaction between  $\text{NaCl}$ ,  $\text{SO}_3$ , steam and  $\text{O}$  at  $400^\circ\text{--}450^\circ$ :  $2\text{NaCl} + \text{SO}_3 + \text{O} + \text{H}_2\text{O} = \text{Na}_2\text{SO}_4 + 2\text{HCl}$  (for the application of these processes on the large scale v. *DICTIONARY OF APPLIED CHEMISTRY*, vol. iii. p. 439).  $\text{Na}_2\text{SO}_4$  is also obtained in the decomposition of  $\text{NH}_4\text{Cl}$ , or  $\text{NaNO}_3$ , by  $\text{H}_2\text{SO}_4$ ; it is formed by neutralising  $\text{H}_2\text{SO}_4$  aq by  $\text{NaOHAq}$  or  $\text{Na}_2\text{CO}_3$ , evaporating, and heating to redness the crystals of  $\text{Na}_2\text{SO}_4$  that separate.  $\text{Na}_2\text{SO}_4$  is a white amorphous powder; S.G. 2.597 (Playfair a. Joule, C. S. *Mem.* 2, 401); 2.631 (Karsten, S. 65, 894). Obtained in rhombic crystals, isomorphous with  $\text{Ag}_2\text{SO}_4$  (Mitscherlich, P. 12, 138; 25, 301), by heating to  $40^\circ$  a solution saturated at  $33^\circ$ ; S.G. 2.6618, or 2.6637 crystallised at  $110^\circ$  (Nicol, P. M. [5] 15, 94). Dissolves in water with production of heat; according to Berthelot (C. R. 78, 1722)  $[\text{Na}^+\text{SO}_4^-\text{Aq}] = 780$  at  $21.2^\circ$ , but  $-100$  at  $8^\circ$ ; Pickering (C. J. 45, 686) thinks that two modifications of  $\text{Na}_2\text{SO}_4$  exist; the salt dried at  $100^\circ$  or  $150^\circ$  gave  $[\text{Na}^+\text{SO}_4^-\text{Aq}] = 57$  at  $20.4^\circ$ , but after heating to temperatures varying from  $250^\circ$  to the melting-point the heat of solution was  $[\text{Na}^+\text{SO}_4^-\text{Aq}] = 760$ . Thomsen (Th. 3, 516) gives H.F.  $[\text{Na}^+\text{S}_2\text{O}_7] = 328,600$ . Tilden (Pr. 35, 345) gives solubilities as follows: 5 at  $0^\circ$ , 7.8 at  $84^\circ$ , 42.7 at  $100^\circ$ , 41.95 at  $120^\circ$ , 42 at  $140^\circ$ , 42.9 at  $160^\circ$ , 44.25 at  $180^\circ$ , 46.4 at  $230^\circ$ . Etard (C. R. 113, 854) says that S. increases from  $33^\circ$  to  $80^\circ$ , remains constant to  $230^\circ$ , and then decreases to  $320^\circ$  (v. also Löwel, A. Ch. [3] 33, 334; 49, 32; Gernez, C. R. 60, 833; de Coppet, Bl. [2] 17, 146). For S.H. and expansion of  $\text{Na}_2\text{SO}_4$  aq v. Thomsen (P. 142, 837) and Marignao (A. Ch. [4] 22, 415).  $\text{Na}_2\text{SO}_4$  melts at  $861^\circ$  (Carnelley, C. J. 33, 280); at  $843^\circ$  (V. Meyer a. Riddle, B. 26, 2445). S.G. at melting-point = 2.104 (Braun, B. 7, 958).

Heated with charcoal out of air  $\text{Na}_2\text{SO}_4$  is reduced to  $\text{Na}_2\text{S}$ ; Gay-Lussac (A. Ch. [2] 11, 312) says polysulphides are also formed;  $\text{CO}_2$  is evolved, but no  $\text{CO}$  (Unger, A. 63, 240; Scheurer-Kestner, A. Ch. [4] 1, 412; Stromeyer, A. 107, 361); heated to bright redness with  $\text{O}$  in a vessel containing air,  $\text{Na}_2\text{S}$  is formed and  $\text{CO}$  evolved (Berthelot, C. R. 1.0, 1106). Reduced to sulphide by heating to bright redness in carbon monoxide (B., l.c.); reduction by hydrogen begins at c.  $500^\circ$ , the products are  $\text{Na}_2\text{S}$ ,  $\text{NaSH}$ ,  $\text{NaOH}$ ,  $\text{H}_2\text{O}$ , and  $\text{H}_2\text{S}$  (B., l.c.). Heated with hydrogen chloride,  $\text{NaCl}$  is formed (Bousingault, C. R. 78, 593); boiling  $\text{HClAq}$  produces  $\text{NaCl}$  and  $\text{NaHSO}_4$  (Thomas, C. J. 33, 373). A little  $\text{NaCl}$  is formed by heating with ammonium chloride (Nicholson, C. N. 26, 47). Boiled with barium carbonate some  $\text{Na}_2\text{CO}_3$  and  $\text{BaSO}_4$  are formed; after a time a condition of equilibrium is attained. A very little  $\text{NaOHAq}$  is produced by boiling for some time with milk of lime; under increased pressure  $\text{NaOHAq}$  is formed

(v. Scheurer-Kestner, A. Ch. [4] 1, 412). Not decomposed by heating strongly with calcium carbonate (S.-K., l.c.). When a mixture of  $\text{Na}_2\text{SO}_4$  and alumina is heated in steam,  $\text{SO}_3$  is given off and sodium aluminate remains; presence of charcoal hastens the reaction (Wagner). According to Stromeyer (A. 107, 361) fusion with iron produces  $\text{Fe}_2\text{O}_3$ ,  $\text{Na}_2\text{O}$ , and  $\text{Na}_2\text{S}_2\text{FeS}$ . The final products of heating with silica and carbon in a closed crucible are  $\text{Na}_2\text{O}$ ,  $2\text{SiO}_2$ ,  $\text{S}$ ,  $\text{CO}$ , and  $\text{CO}$  (S.-K., C. R. 114, 117).

**Hydrates of  $\text{Na}_2\text{SO}_4$ .** (1) The heptahydrate  $\text{Na}_2\text{SO}_4 \cdot 7\text{aq}$  is obtained by melting Glauber's salt  $\text{Na}_2\text{SO}_4 \cdot 10\text{aq}$  in its water of crystallisation, heating to boiling, at once closing the vessel, and shaking repeatedly as the liquid cools till  $18^\circ$  is reached;  $\text{Na}_2\text{SO}_4$  separates at first but dissolves again, and below  $18^\circ$   $\text{Na}_2\text{SO}_4 \cdot 7\text{aq}$  separates (Löwel, A. Ch. [3] 33, 334; 49, 32). The following method gives better results (L., l.c.): 22 parts  $\text{Na}_2\text{SO}_4 \cdot 10\text{aq}$  are dissolved in 10 parts water, the solution is heated to boiling, and the flask is then closed with a cork carrying two narrow tubes bent at right angles; when the liquid is cold the outer end of one of the tubes is dipped into 30 p.c. alcohol at  $40^\circ$ , and the alcohol is caused to run into and fill the flask by sucking at the outer end of the other tube. As the alcohol withdraws water, large, translucent, rhombic or tetragonal crystals of  $\text{Na}_2\text{SO}_4 \cdot 7\text{aq}$  gradually separate. The crystals must be quickly pressed between filter paper. They rapidly absorb water from the air, changing to  $\text{Na}_2\text{SO}_4 \cdot 10\text{aq}$ ; exposed to air, even under dilute alcohol, they soon change to the decahydrate. According to Löwel (l.c.) the heptahydrate is much more soluble in water between  $0^\circ$  and  $26^\circ$  than the decahydrate. The temperature of maximum solubility is  $27^\circ$ ; the solution then contains 56 p.c.  $\text{Na}_2\text{SO}_4$ , which is the same quantity as is present in solution of  $\text{Na}_2\text{SO}_4 \cdot 10\text{aq}$  saturated at  $34^\circ\text{--}36^\circ$ . If a crystal of  $\text{Na}_2\text{SO}_4 \cdot 7\text{aq}$  is added to the saturated solution of this salt at  $27^\circ$  it does not dissolve, but crystals of  $\text{Na}_2\text{SO}_4$  separate until a concentration is reached corresponding with a saturated solution of  $\text{Na}_2\text{SO}_4$  at the temperature. The heptahydrate is able to form supersaturated solutions, but less readily than the decahydrate; addition of a crystal of  $\text{Na}_2\text{SO}_4 \cdot 7\text{aq}$  causes separation of the heptahydrate. These results were confirmed by de Coppet (Bl. [2] 17, 146).

(2) The decahydrate  $\text{Na}_2\text{SO}_4 \cdot 10\text{aq}$  crystallises from a hot saturated solution of  $\text{Na}_2\text{SO}_4$  cooled to at least  $32^\circ$ ; a supersaturated solution may be cooled in a closed vessel to  $0^\circ$ . If a crystal of  $\text{Na}_2\text{SO}_4 \cdot 10\text{aq}$  is dropped in, a mass of crystals of the decahydrate is formed, and the temperature rises to c.  $18^\circ$ . Large, white, striated, monoclinic prisms; isomorphous with  $\text{Na}_2\text{CrO}_4 \cdot 10\text{aq}$  and  $\text{Na}_2\text{SeO}_4 \cdot 10\text{aq}$ . S.G. 1.469 (Playfair a. Joule, C. S. *Mem.* 2, 401); 1.485 at  $19^\circ$ , 1.492 at  $20^\circ$  (Pettersson, Upsala, *Nova Acta*, 1874).  $[\text{Na}^+\text{S}_2\text{O}_7 \cdot 10\text{H}_2\text{O}] = 347,800$  (Th. 3, 516). Melts at  $34^\circ$  (Tilden, C. J. 45, 267). Effloresces in air. When melted in the water of crystallisation, boiled, and allowed to cool in a closed vessel,  $\text{Na}_2\text{SO}_4$  separates, but on shaking, this salt dissolves till  $18^\circ$  is reached, after which crystals of  $\text{Na}_2\text{SO}_4 \cdot 7\text{aq}$  separate (v. *supra*).  $\text{Na}_2\text{SO}_4 \cdot 10\text{aq}$  is insol. absolute alcohol; alcohol of S.G. .976 dis-

solves 14.86 p.c., of S.G. .979 dissolves 5.6 p.c., and of S.G. .939 dissolves 1.3 p.c. Solubility in water increases with temperature to 33°-34°, whereat the solution contains 55 parts  $\text{Na}_2\text{SO}_4$  in 100 of water; a crystal of  $\text{Na}_2\text{SO}_4 \cdot 10\text{aq}$  dropped into the solution dissolves, and  $\text{Na}_2\text{SO}_4$  separates till 49.53 parts  $\text{Na}_2\text{SO}_4$  are in solution in 100 parts water, which is the same quantity of  $\text{Na}_2\text{SO}_4$  as is present in a solution made by saturating water with  $\text{Na}_2\text{SO}_4$  at 34° (Löwel, *A. Ch.* [3] 33, 334; 49, 32). As temperature is increased above 34°  $\text{Na}_2\text{SO}_4$  seems to be formed, and the solubility of this salt decreases as temperature rises to the b.p. of saturated  $\text{Na}_2\text{SO}_4\text{Aq}$ . There appear to be three temperatures of maximum solubility for  $\text{Na}_2\text{SO}_4$  and its hydrates: (1) at 34°, which is the maximum for  $\text{Na}_2\text{SO}_4 \cdot 10\text{aq}$ , (2) at 26°-27° for  $\text{Na}_2\text{SO}_4 \cdot 7\text{aq}$ , (3) at 17°-18° for  $\text{Na}_2\text{SO}_4$ . The quantity of salt in solution, calculated as  $\text{Na}_2\text{SO}_4$ , is about the same at these temperatures. Löwel (*l.c.*) gives the following table:—

Temp.	100 parts water contain, when solution is saturated,		
	$\text{Na}_2\text{SO}_4$ Sol. made with $\text{Na}_2\text{SO}_4$	$\text{Na}_2\text{SO}_4 \cdot 10\text{aq}$ Sol. made with $\text{Na}_2\text{SO}_4 \cdot 10\text{aq}$	$\text{Na}_2\text{SO}_4 \cdot 7\text{aq}$ Sol. made with $\text{Na}_2\text{SO}_4 \cdot 7\text{aq}$

*Acid salts.* (1)  $\text{NaHSO}_4$ ; by adding 7 parts  $\text{H}_2\text{SO}_4\text{Aq}$  S.G. 1.85, to 10 parts  $\text{Na}_2\text{SO}_4$ , and heating gently till the mass melts and water-vapour ceases to be given off. By dissolving in water, or by evaporating  $\text{Na}_2\text{SO}_4$  in  $\text{H}_2\text{SO}_4\text{Aq}$  at 50°, crystals of  $\text{NaHSO}_4\text{aq}$  are obtained (Mitscherlich, *P.* 12, 138; H. Rose, *P.* 82, 545). (2)  $\text{Na}_2\text{SO}_4 \cdot \text{NaHSO}_4$  ( $= \text{Na}_2\text{H}(\text{SO}_4)_2$ ); by crystallising  $\text{Na}_2\text{SO}_4$  from half as much  $\text{H}_2\text{SO}_4$  in water as is required to form  $\text{NaHSO}_4$  (*M., l.c.*; R., *l.c.*). (3)  $\text{NaHSO}_4 \cdot \text{H}_2\text{SO}_4$  ( $(\text{NaH}(\text{SO}_4))_2$ ); by crystallising  $\text{Na}_2\text{SO}_4$  from solution in almost 7 parts  $\text{H}_2\text{SO}_4$  (Schulz-Sellack, *J. pr.* [2] 2, 459; Lescœur, *C. R.* 78, 1044).

*Double salts.* (1)  $\text{Na}_2\text{SO}_4 \cdot \text{K}_2\text{SO}_4$  (Penny, *P. M.*

[4] 10, 401; Mitscherlich, *P.* 58, 468; von Hauer, *J. pr.* 83, 356). (2)  $\text{Na}_2\text{SO}_4 \cdot (\text{NH}_4)_2\text{SO}_4$ ; by the interaction of  $(\text{NH}_4)_2\text{SO}_4$  and  $\text{NaCl}$  with a little water (Schiff). (3) Various double salts with  $\text{Li}_2\text{SO}_4$  (Rammelsberg, *P.* 128, 811; Wyrnboff, *Bl.* [2] 9, 35). (4) With sulphates of Cd, Ca, Cu, Di, In, Fe, La, Mn, and Mg; references under CADMIUM SULPHATES, CALCIUM SULPHATES, &c. (5) The compounds  $\text{Na}_2\text{SO}_4 \cdot \text{M}_2(\text{SO}_4)_2 \cdot 24\text{aq}$ , where M = Al or Cr, are *alums* (references under ALUMINIUM SULPHATES and CHROMIUM SULPHATES). Strontium sulphates. The *normal salt*  $\text{SrSO}_4$  occurs native as *celestine*. It is obtained by adding  $\text{H}_2\text{SO}_4\text{Aq}$  or solution of an alkali sulphate to solution of a strontium salt; large crystals are formed by dissolving *ppd.*  $\text{SrSO}_4$  in conc.  $\text{H}_2\text{SO}_4$ , adding dilute  $\text{HClAq}$ , heating to 150°, allowing to cool, again heating to 150° with  $\text{HClAq}$ , and repeating this treatment three or four times (Bourgeois, *C. R.* 105, 1072).  $\text{SrSO}_4$  is also obtained crystalline by fusing  $\text{K}_2\text{SO}_4$  with excess of  $\text{SrCl}_2$  (Manross, *A.* 82, 850). A white solid; S.G. 3.927 to 3.955 crystalline (*M., l.c.*; Neumann, *P.* 23, 1); 3.7 *ppd.* (Schröder, *P.* 106, 226; v. also Clarke's *Table of Spec. Gravs.* [New Ed.] 82). H.F. [ $\text{Sr}_2\text{SO}_4$ ] = 830,300 (*Th.* 8, 516). Almost insol. water; S. .0145

ordinary temperature,  $-0.104$  at  $100^\circ$  (Fresenius); insol. dilute  $\text{H}_2\text{SO}_4$ ; S. conc.  $\text{H}_2\text{SO}_4$  at  $70^\circ - 14^\circ$  (Garside, *C. N.* 81, 245); for S. in solutions of  $\text{NaCl}$ ,  $\text{KCl}$ ,  $\text{MgCl}_2$ , and  $\text{CaCl}_2$  v. Virek (*C. C.* 1862, 402). Melts when strongly heated; is decomposed to  $\text{SrO}$ ,  $\text{SO}_2$ , and  $\text{O}$  at full white heat (Bousingault, *J.* 1867, 161). Reduced by heating strongly with  $\text{C}$ ,  $\text{Fe}$ , or  $\text{Zn}$  (d'Heureuse, *P.* 75, 277), or in a steam of  $\text{H}$  or moist  $\text{CO}$  (Jacquemin, *C. R.* 46, 1164). Loses  $\text{SO}_2$  when heated with  $\text{As}_2\text{O}_3$  (Moretti, *S.* 9, 169), or when heated continuously to redness in  $\text{HCl}$  (Bousingault, *C. R.* 78, 593). Decomposed by heating with solutions of alkali carbonates. Forms double salts,  $\text{SrSO}_4 \cdot \text{M}_2\text{SO}_4$ , with alkali sulphates (*H. Rose*, *P.* 93, 604; 110, 296). An acid salt  $\text{SrH}_2(\text{SO}_4)_2$  ( $= \text{SrSO}_4 \cdot \text{H}_2\text{SO}_4$ ) is formed by digesting  $\text{SrSO}_4$  in conc.  $\text{H}_2\text{SO}_4$  with excess of  $\text{SrSO}_4$  (Schultz, *P.* 113, 147).

**Thallium sulphates.** The normal thallous salt  $\text{Tl}_2\text{SO}_4$  is obtained by dissolving  $\text{Tl}$  in hot  $\text{H}_2\text{SO}_4$ , or by neutralising  $\text{H}_2\text{SO}_4$  by  $\text{TiOH}$  or  $\text{TiCO}_3$ , and evaporating (Crookes, *C. N.* 24, 38). Forms white rhombic prisms, isomorphous with  $\text{K}_2\text{SO}_4$  (von Lang, *P. M.* [4] 25, 348); S.G. 6.77 (Lamy, *Bl.* [2] 11, 210; v. also Clarke's *Table of Spec. Grav.* [new ed.] 79). H.F. [ $\text{Tl}_2\text{SO}_4$ ] = 221,000 (*Th.* 3, 516). S.  $4.74$  at  $15^\circ$ ,  $18.5$  at  $100^\circ$  (Lamy, *l.c.*). Not decomposed by heating to full redness in absence of air; heated more strongly in air gives  $\text{Tl}_2\text{O}_3$ ,  $\text{SO}_2$ , and  $\text{O}$  (Carstanjen, *J.* 1867, 279). Reduced to  $\text{Tl}_2\text{S}$  by heating with  $\text{KCN}$ . The acid thallous salt  $\text{THSO}_4$  3aq separates from a solution of the normal salt in  $\text{H}_2\text{SO}_4$  after some months. When strongly heated yields  $\text{Tl}_2\text{SO}_4$  and  $\text{H}_2\text{SO}_4$  (Carstanjen, *l.c.*). Double salts,  $\text{Tl}_2\text{SO}_4 \cdot \text{M}_2\text{SO}_4$ , 6aq, are formed when  $\text{M} = \text{Cu}$ ,  $\text{Fe}$ ,  $\text{Mg}$ ,  $\text{Ni}$ , or  $\text{Zn}$  (Willm, *A. Ch.* [4] 9, 5; Werther, *Bl.* [2] 2, 272). The salt  $\text{Tl}_2\text{SO}_4 \cdot \text{Al}_2(\text{SO}_4)_3$ , 24aq is an alun (v. Lamy, *Bl.* [2] 11, 210). Normal thallic sulphate  $\text{Ti}_2(\text{SO}_4)_3$ , 7aq is obtained as thin, white leaflets by dissolving  $\text{Ti}_2\text{O}_3$  in fairly conc.  $\text{H}_2\text{SO}_4$  and evaporating. Loses 6aq when heated to  $200^\circ$ , at higher temperatures  $\text{SO}_2$  and  $\text{O}$  are given off and  $\text{Ti}_2\text{SO}_4$  remains (Strecker, *A.* 135, 207; Crookes, *C. N.* 8, 243). The double salts  $\text{Ti}_2(\text{SO}_4)_3 \cdot \text{M}_2\text{SO}_4$  ( $= \text{TiM}(\text{SO}_4)_2$ ), where  $\text{M} = \text{K}$  or  $\text{Na}$ , are described by Strecker (*l.c.*).

**Thorium sulphates.** The hydrated normal sulphate  $\text{Th}(\text{SO}_4)_2 \cdot 9\text{aq}$  is obtained by dissolving  $\text{ThO}_2$  in slight excess of  $\text{H}_2\text{SO}_4$  and crystallising at  $10^\circ - 15^\circ$ . The anhydrous salt is obtained by heating the hydrated salt to  $c. 400^\circ$  (v. Chydenius, *P.* 119, 43; Delafontaine, *A.* 131, 100; Cleve, *Bl.* [2] 21, 115; Demarçay, *C. R.* 96, 1860). For a full discussion of the conditions of formation, relations, and solubilities of the various hydrates of  $\text{Th}(\text{SO}_4)_2$  v. Roozeboom (*Z. P. C.* 5, 198).  $\text{Th}(\text{SO}_4)_2$  has S.G. 4.053 at  $22.8^\circ$  (Clarke, *Am.* 2, 175);  $4.2252$  at  $17^\circ$  (Krüss a. Nilson, *B.* 20, 1675). The S.G. of  $\text{Th}(\text{SO}_4)_2 \cdot 9\text{aq}$  is 2.767 according to Topsøe (*Bl.* [2] 21, 120). The hydrate  $\text{Th}(\text{SO}_4)_2 \cdot 9\text{aq}$  is isomorphous (monoclinic) with  $\text{U}(\text{SO}_4)_2 \cdot 9\text{aq}$  (Rammelsberg, *B.* 1886, 603). Double salts  $\text{Th}(\text{SO}_4)_2 \cdot \text{M}_2\text{SO}_4$ , 2aq are known, where  $\text{M} = \text{an alkali metal}$  (Cleve, *l.c.*; Chydenius, *l.c.*).

**Tin sulphates.** The normal stannous salt  $\text{SnSO}_4$  is obtained, in very small white crystals, by dissolving  $\text{Sn}$  in warm fairly conc.  $\text{H}_2\text{SO}_4$ , taking care that  $\text{Sn}$  is in excess, dissolving the

white solid so formed in water, and allowing to crystallise out of contact with air (Marignac, *Ann. M.* [5] 15, 221).  $\text{SnSO}_4$  is very sol. water; the solution soon deposits basic salts. The normal stannic salt  $\text{Sn}(\text{SO}_4)_2$ , 2aq was obtained by Ditte (*C. R.* 104, 178) by dissolving  $\text{SnO}_2$ , 2aq (ppd. from  $\text{SnCl}_4$  by alkali) in dilute  $\text{H}_2\text{SO}_4$  and evaporating (v. also Kraskowitz, *P.* 35, 518). It forms white rhombic leaflets; very sol. water; decomposed by much water with separation of  $\text{SnO}_2$ . A basic salt  $\text{SnO}(\text{SO}_4)$ , aq is said to be formed (Ditte, *l.c.*) by dissolving the normal salt in  $\text{H}_2\text{SO}_4$ , warming, adding excess of  $\text{Sn}$ , and then ether.

**Titanium sulphates.** Normal titanous sulphate  $\text{Ti}_2(\text{SO}_4)_3$ , 8aq is obtained, as violet crystals, by evaporating a solution of  $\text{Ti}$  in  $\text{H}_2\text{SO}_4$ ; sol. water, solution gives a black pp. when warmed (Glatzel, *B.* 9, 1833; Ebelmen, *J. pr.* 42, 76). Normal titanic sulphate  $\text{Ti}(\text{SO}_4)_2$ , 5aq was obtained by Glatzel (*l.c.*) by oxidising the titanous salt by  $\text{HNO}_3$ , adding a drop or two  $\text{H}_2\text{SO}_4$ , and evaporating; a white, translucent mass. A double salt  $\text{Ti}(\text{SO}_4)_2 \cdot \text{K}_2\text{SO}_4$ , 3aq was obtained by Warren (*P.* 102, 449), by fusing  $\text{TiO}_2$  with  $\text{KHSO}_4$ , treating with conc.  $\text{H}_2\text{SO}_4$ , evaporating, and washing the residue with cold water (v. also Glatzel, *l.c.*). By dissolving  $\text{TiO}_2$  in hot  $\text{H}_2\text{SO}_4$ , evaporating, drying the residue on a porous tile at  $180^\circ$ , and then heating to  $c. 350^\circ$ , Merz (*J. pr.* 99, 157) obtained the acid salt  $\text{TiO}(\text{SO}_4)$ , as a hard white solid.

**Uranium sulphates.** Normal uranic sulphate  $\text{U}(\text{SO}_4)_2$ , 9aq is obtained, as green monoclinic crystals isomorphous with  $\text{Th}(\text{SO}_4)_2$ , 9aq (Rammelsberg, *B.* 1886, 603), by evaporating a solution of  $\text{UO}_2$  in excess of  $\text{H}_2\text{SO}_4$  (R., *l.c.*; Ebelmen, *J. pr.* 27, 385). Unchanged in air; slowly loses water of crystallisation when heated; at higher temperatures gives yellow  $(\text{UO}_2)_2\text{SO}_4$ , and when strongly heated leaves  $\text{U}_2\text{O}_5$ . Heated in  $\text{H}$  gives  $\text{UO}_2$ . Easily sol. dilute  $\text{H}_2\text{SO}_4$  or  $\text{HCl}$  aq. Decomposed by water, giving basic salts (v. R., *l.c.*; Athanasesco, *C. R.* 103, 271). Forms double salts with alkali sulphates (R., *l.c.*). The uranyl salt  $(\text{UO}_2)_2\text{SO}_4$ , 2aq is obtained, in citron-yellow crystals, by dissolving  $\text{U}_2\text{O}_5$  in  $\text{H}_2\text{SO}_4$  with a little  $\text{HNO}_3$ , or by decomposing  $\text{UO}_2(\text{NO}_3)_2$  by conc.  $\text{H}_2\text{SO}_4$ , evaporating nearly to dryness, dissolving in water, evaporating to a syrup, and allowing to crystallise slowly (Ebelmen, *A.* 56, 230). By evaporating a solution of the hydrated salt in conc.  $\text{H}_2\text{SO}_4$ , Schultz-Selack obtained the anhydrous salt  $(\text{UO}_2)_2\text{SO}_4$  (B., 4, 13). Forms double salts with alkali sulphates  $(\text{UO}_2)_2\text{SO}_4 \cdot \text{M}_2\text{SO}_4$ , 2aq (Rammelsberg, *B.* 5, 1005).

**Vanadium sulphates.** Vanadyl sulphate  $(\text{VO})\text{SO}_4$ , 2aq is obtained by heating a solution of  $\text{V}_2\text{O}_5$  in conc.  $\text{H}_2\text{SO}_4$ . Gerlach (*B.* 11, 98) prepared several compounds of  $\text{V}_2\text{O}_5$  and  $\text{SO}_2$  by dissolving  $\text{V}_2\text{O}_5$  in  $\text{H}_2\text{SO}_4$ . For more details and descriptions of various salts v. VANADIUM TETROXIDE and PENTOXIDE (*infra*).

**Zinc sulphates.** The normal salt  $\text{ZnSO}_4$  is obtained by dissolving  $\text{Zn}$ ,  $\text{ZnO}$ , or  $\text{ZnCO}_3$  in dilute  $\text{H}_2\text{SO}_4$ , evaporating, drying the crystals of  $\text{ZnSO}_4$ , 7aq, and gradually heating to  $c. 280^\circ$  till water ceases to be given off; it is difficult to drive off every trace of water without decomposing some of the  $\text{ZnSO}_4$ , and forming

**basic sulphates.** Klobb (*C. R.* 114, 836) obtained  $\text{ZnSO}_4$  in crystals by heating  $\text{ZnSO}_4 \cdot 7\text{aq}$  mixed with excess of  $(\text{NH}_4)_2\text{SO}_4$  in a partly-closed crucible, protected from the gases of the flame, till all  $(\text{NH}_4)_2\text{SO}_4$  was volatilised. A white solid; S.G. 3.435 at  $16^\circ$  (Pape, *P.* 120, 367); 3.6235 at  $15^\circ$  (Thorpe & Watts, *C. J.* 37, 108). H.F.  $[\text{Zn}, \text{S}, \text{O}] = 230, 100$  (*Th.* 3, 516). Decomposed to  $\text{ZnO}$ ,  $\text{SO}_2$ , and  $\text{O}$  at c.  $400^\circ$  (Bailey, *C. J.* 51, 681). Heated with charcoal,  $\text{SO}_2$  and  $\text{CO}_2$  are evolved and  $\text{ZnO}$  remains; if the temperature is rapidly raised to a white heat,  $\text{SO}_2$  and  $\text{CO}$  are given off and  $\text{ZnS}$  is formed. Heating in  $\text{H}$  produces an oxysulphide of  $\text{Zn}$ . For solubility in water *v. infra*.  $[\text{ZnSO}_4, \text{Aq}] = 9,950$  (*Th.* 3, 516). For compounds of  $\text{ZnSO}_4$  with  $\text{NH}_3$ , *v.* Schindler (*Mag. Pharm.* 81, 167; 36, 43), Kane (*A. Ch.* [2] 72, 290), Müller (*Z.* [2] 5, 250; 6, 96). **Hydrated zinc sulphate.** Several hydrates are known. The **heptahydrate**  $\text{ZnSO}_4 \cdot 7\text{aq}$  crystallises, at ordinary temperatures, in white, right rhombic, prisms, isomorphous with  $\text{MgSO}_4 \cdot 7\text{aq}$ . S.G. 1.964 (Thorpe & Watts, *C. J.* 37, 110). H.F.  $[\text{Zn}, \text{S}, \text{O}, 7\text{H}, \text{O}] = 252, 700$  (*Th.* 3, 516). Melts at  $50^\circ$  (Tilden, *C. J.* 45, 267). At  $100^\circ$  loses  $6\text{H}_2\text{O}$ . Poggiale (*A. Ch.* [3] 8, 467) gives solubility in water as follows:—

Temp.	$\text{ZnSO}_4 \cdot 7\text{aq}$	$\text{ZnSO}_4$
$0^\circ$	115.22	43.03
10	138.21	48.36
20	161.49	53.13
30	190.90	58.40
40	224.05	63.52
50	263.84	68.75
60	313.48	74.20
70	369.36	79.25
80	442.62	84.60
90	532.02	89.78
100	653.59	95.03

Gerlach (*Fr.* 8, 260) and Schiff (*A.* 110, 72) give the following data for  $\text{ZnSO}_4 \cdot \text{aq}$ :—

S.G.		
Gerlach, at $16^\circ$	Schiff, at $20.5^\circ$	Petge, $\text{ZnSO}_4 \cdot 7\text{aq}$
1.0288	1.0289	5
1.0593	1.0588	10
1.0905	1.0899	15
1.1236	1.1222	20
1.1574	1.1560	25
1.1933	1.1914	30
1.2315	1.2285	35
1.2709	1.2674	40
1.3100	1.3083	45
1.3532	1.3511	50
1.3986	1.3964	55
1.4451	1.4439	60

Almost insol. absolute alcohol; 100 parts of a saturated solution in alcohol of 40 p.c. contain 8.48 parts  $\text{ZnSO}_4 \cdot 7\text{aq}$  (Schiff, *J.* 1861, 87).

**Hexahydrate**,  $\text{ZnSO}_4 \cdot 6\text{aq}$ ; obtained by crystallising  $\text{ZnSO}_4 \cdot \text{aq}$  at  $40^\circ$ ; S.G. 2.07 (*T. a. W.*, *l.c.*; *v.* also Marignac, *J.* 1855, 389). **Pentahydrate**,  $\text{ZnSO}_4 \cdot 5\text{aq}$ ; obtained by boiling the finely-powdered heptahydrate with alcohol of S.G. 825; S.G. 2.206 (*T. a. W.*, *l.c.*; *v.* also Kühn, *J.* 1830, 300; Schindler, *Mag. Pharm.* 81, 167; 36, 43; Pierre, *A. Ch.* [3] 16, 242). **Dihydrate**,  $\text{ZnSO}_4 \cdot 2\text{aq}$ ; formed by pouring cold saturated  $\text{ZnSO}_4 \cdot \text{aq}$  into conc.  $\text{H}_2\text{SO}_4$  and wash-

ing the pp. with absolute alcohol; S.G. 2.959 (*T. a. W.*, *l.c.*). **Monohydrate**,  $\text{ZnSO}_4 \cdot \text{aq}$ ; obtained by heating  $\text{ZnSO}_4 \cdot 7\text{aq}$  to  $100^\circ$ – $110^\circ$  till it ceases to lose weight; S.G. 8.28 (*T. a. W.*, *l.c.*; *v.* also Graham, *P. M.* [3] 6, 827, 417).

An **acid salt**  $\text{ZnSO}_4 \cdot \text{H}_2\text{SO}_4 \cdot 8\text{aq}$  is described by von Kobell (*J. pr.* 28, 492). Several **basic salts** are formed by boiling solutions of  $\text{ZnSO}_4 \cdot 7\text{aq}$  with  $\text{ZnO}$  or  $\text{ZnO} \cdot \text{H}_2$  (*v.* Schindler, *l.c.*; Kühn, *l.c.*; Kane, *A. Ch.* [2] 72, 290; Reindel, *Z.* [2] 5, 508; Habermann, *M.* 5, 432; Athanasesco, *C. R.* 103, 271).

**Double salts** are numerous: (1) With alkali sulphates,  $\text{ZnSO}_4 \cdot \text{M}_2\text{SO}_4 \cdot 2\text{aq}$  (*v.* Pierre, *Ph. C.* 1846, 410; Tobler, *A.* 95, 193; Graham, *P. M.* [3] 6, 827, 417; Karsten, *B. B.* 1841). (2) With  $\text{CoSO}_4$ ,  $\text{FeSO}_4$ ,  $\text{MgSO}_4$ ,  $\text{NiSO}_4$ , &c., to form  $\text{ZnSO}_4 \cdot \text{MSO}_4 \cdot 2\text{aq}$  (*v.* Rummelsberg, *P.* 91, 321; Pierre, *l.c.*; Etard, *C. R.* 86, 1399; 87, 602).

**Zirconium sulphates.** The **normal salt**  $\text{Zr}(\text{SO}_4)_2$  is obtained by dissolving  $\text{ZrO}_2$  in slightly diluted  $\text{H}_2\text{SO}_4$ , evaporating, and driving off excess of acid at a temperature below red heat.  $\text{Zr}(\text{SO}_4)_2$  is decomposed by heating to redness, giving  $\text{ZrO}_2$ . By concentrating a solution of  $\text{Zr}(\text{SO}_4)_2$  containing some free  $\text{H}_2\text{SO}_4$ , Paykull (*B.* 6, 1467) obtained crystals of the **tetrahydrate**  $\text{Zr}(\text{SO}_4)_2 \cdot 4\text{aq}$  (confirmed by Weibull, *B.* 20, 1394).

**Basic salts** are obtained by digesting a solution of a salt of  $\text{Zr}$  with saturated  $\text{K}_2\text{SO}_4 \cdot \text{aq}$  (*v.* Berzelius, *P.* 4, 117; Warren, *J. pr.* 75, 861).

**Double salts** with  $\text{K}_2\text{SO}_4$  are formed by fusing  $\text{KH}_2\text{SO}_4$  and  $\text{ZrO}_2$  (*B.*, *l.c.*; *W.*, *l.c.*).

**DITHIOPIERSULPHATES.** Under the name of **sodium dithiopiersulphate**, Villiers (*C. R.* 106, 851, 1354) described a salt  $\text{Na}_2\text{S}_2\text{O}_4 \cdot 5\text{aq}$ . This salt was said to be obtained by adding to sodium thiosulphate insufficient water to dissolve all the salt, saturating with  $\text{SO}_2$ , adding a little more water, again saturating with  $\text{SO}_2$ , keeping the yellow solution at the ordinary temperature for two or three days, passing in  $\text{SO}_2$  as long as it was absorbed, and, after standing a day or two, evaporating *in vacuo* over  $\text{H}_2\text{SO}_4$ . A mixture of  $\text{Na}_2\text{S}_2\text{O}_3$  and  $\text{Na}_2\text{S}_2\text{O}_4$  was thus obtained; on exposure to air the crystals of  $\text{Na}_2\text{S}_2\text{O}_4$  effloresced, and the  $\text{Na}_2\text{S}_2\text{O}_3$  was then picked out. The salt  $\text{Na}_2\text{S}_2\text{O}_4$  was described as white, lustrous, rhombic prisms; unchanged in air; melting at c.  $125^\circ$ , and giving off  $\text{SO}_2$  at c.  $140^\circ$ , leaving  $\text{Na}_2\text{SO}_3$  mixed with  $\text{S}$ . In a later paper (*C. R.* 108, 402) V. announced that the salt supposed by him to be  $\text{Na}_2\text{S}_2\text{O}_4$  was only hydrated sodium tetrathionate  $\text{Na}_2\text{S}_4\text{O}_{10} \cdot \text{H}_2\text{O}$ .

**NITROSOSULPHATES.** In 1800 Davy (*Researches, chiefly concerning Nitrous Oxide*) noticed that  $\text{NO}$  was absorbed by a mixture of  $\text{Na}_2\text{SO}_4 \cdot \text{aq}$  and  $\text{NaOH} \cdot \text{aq}$ , a compound being formed which, on addition of an acid, gave off  $\text{N}_2\text{O}$  while  $\text{Na}_2\text{SO}_4$  remained in solution; he supposed that the  $\text{NO}$  was reduced to  $\text{N}_2\text{O}$ , the  $\text{Na}_2\text{SO}_4$  being oxidised to  $\text{Na}_2\text{S}_2\text{O}_8$ , and that the  $\text{N}_2\text{O}$  combined with the  $\text{NaOH}$ . Pelouze (*A. Ch.* [2] 60, 151) found that a salt containing  $\text{N}$ ,  $\text{S}$ , and  $\text{O}$  was formed in the reaction examined by Davy; to this salt he gave the composition  $\text{Na}_2\text{SO}_4(\text{NO})_2$ .

A mixture of 1 vol.  $\text{SO}_2$  and 3 vols.  $\text{NO}$  is gradually absorbed by conc.  $\text{KOH} \cdot \text{aq}$  or  $\text{NaOH} \cdot \text{aq}$ , forming  $\text{K}_2(\text{NO})_2\text{SO}_4$  or  $\text{Na}_2(\text{NO})_2\text{SO}_4$ .

**Ammonium nitrosulphate**  $(\text{NH}_4)_2(\text{NO})_2\text{SO}_4$  is best prepared by passing NO for some hours into cold conc.  $(\text{NH}_4)_2\text{SO}_4$  mixed with 5 to 6 times its volume of  $\text{NH}_4\text{Aq}$ . White crystals of the salt gradually form; they are washed with ice-cold  $\text{NH}_4\text{Aq}$ , dried *in vacuo*, and kept in a well-stoppered bottle (Pelouze, *l.c.*). **Potassium nitrosulphate** and **sodium nitrosulphate**,  $\text{M}_2(\text{NO})_2\text{SO}_4$ , are prepared similarly to the ammonium salt. **Barium** and **lead nitrosulphates** are obtained by ppg. aqueous solutions of the K salt by conc.  $\text{BaO Aq}$  and solution of basic acetate of lead, respectively (Divers a. Haga, *C. J.* 47, 864). The nitrosulphates readily decompose; they are stable in solution only in presence of excess of alkali. Heated moist they give off  $\text{N}_2\text{O}$ , leaving pure sulphate; heated dry they give NO and sulphite (v. D. a. H., *C. J.* 47, 208). With acids, and also with most metallic salts in solution, also in contact with spongy Pt, charcoal,  $\text{Ag}_2\text{O}$ ,  $\text{MnO}_2$ , &c., they give  $\text{N}_2\text{O}$  and sulphates. Solution of an alkali nitrosulphate has no reaction with  $\text{KMnO}_4\text{Aq}$  (D. a. H., *l.c.* p. 205). An alkaline solution of the K or Na salt is slowly reduced by Na amalgam, giving  $\text{K}_2\text{SO}_4\text{Aq}$  and  $\text{K}_2\text{N}_2\text{O}_4\text{Aq}$ , or the corresponding Na salts (D. a. H., *l.c.* p. 208).

**PERSULPHATES.** Persulphuric anhydride  $\text{S}_2\text{O}_8$  is formed at the anode during the electrolysis of fairly conc.  $\text{H}_2\text{SO}_4\text{Aq}$  (v. *Sulphuric peroxide*, under SULPHUR OXIDES, p. 616). The acid corresponding with this oxide would be  $\text{H}_2\text{S}_2\text{O}_8$  or  $\text{HSO}_4$ ; this acid has not been isolated, but some of its salts have been prepared by Marshall (*C. J.* 59, 771 [1891]).

**Potassium persulphate**  $\text{K}_2\text{S}_2\text{O}_8$  is obtained by passing a current of 3 to 3½ amperes, for some days, through saturated  $\text{KHSO}_4\text{Aq}$  contained in a Pt dish, wherein is suspended a porous cell containing dilute  $\text{H}_2\text{SO}_4\text{Aq}$ ; the Pt dish stands in a vessel of copper, through which runs a stream of cold water, and which is connected with the battery so that the Pt dish becomes the anode; the cathode consists of a stout wire of Pt dipping into the dilute  $\text{H}_2\text{SO}_4\text{Aq}$  in the porous cell (for description, and diagram, of the apparatus v. Marshall, *C. J.* 59, 765-6). The granular salt that slowly separates during electrolysis is collected by filtering through Pt foil, dried on a porous plate, treated with hot water so as to obtain a nearly saturated solution, which is at once rapidly cooled (the mother-liquor yields more  $\text{K}_2\text{S}_2\text{O}_8$  when again electrolysed).  $\text{K}_2\text{S}_2\text{O}_8$  forms small, white, prismatic crystals; by spontaneous evaporation of a solution, large, flat tables are obtained, probably asymmetric. Slightly sol. cold water;  $\text{S. at } 0^\circ = 1.77$ ; insol. absolute alcohol, hot or cold. Measurements of the electrical conductivities of solutions of the salt indicated the formula  $\text{KSO}_4$ , and not  $\text{K}_2\text{S}_2\text{O}_8$ ; but Bredig (*Z. P. C.* 12, 230) showed that Marshall's results were based on data, given by Ostwald, which were not quite accurate (the data were afterwards corrected in Ostwald's *Lehrbuch* (2nd ed.) 2, 730). Bredig's measurements established the formula  $\text{K}_2\text{S}_2\text{O}_8$ ; and this was confirmed by Löwenberg's determinations of the freezing-points and conductivities of solutions of the salt (*Chem. Zeitung*, 1892, 838).  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$  very slowly decomposes at the ordinary temperature, giving  $\text{KHSO}_4\text{Aq}$  and O; in contact with

zinc, decomposition is still very slow; with a Cu-Zn couple the rate of change is hastened; heating also hastens the reaction. After keeping for some time in a closed bottle a peculiar smell is noticed on opening the bottle, perhaps due to  $\text{H}_2\text{S}_2\text{O}_8$  or  $\text{S}_2\text{O}_8$ ; ozone is sometimes also given off. Heat decomposes  $\text{K}_2\text{S}_2\text{O}_8$ ;  $\text{K}_2\text{SO}_4$  remains and  $\text{SO}_2$  and O are given off; decomposition is marked at a little above  $100^\circ$ , but is not complete at  $250^\circ$ . When gently warmed with conc.  $\text{HNO}_3\text{Aq}$  or  $\text{H}_2\text{SO}_4$ , much ozone is given off; Cl is evolved when conc.  $\text{HClAq}$  is used.  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$  does not yield pps. of persulphates with solutions of metallic salts; when pps. are formed they are due to reactions with  $\text{K}_2\text{SO}_4\text{Aq}$  formed by the decomposition of the  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ . Solution of a salt of Ba slowly throws down  $\text{BaSO}_4$ ; the reaction is very slow, even when the solution is boiled. Solution of a salt of Pb also slowly forms  $\text{PbSO}_4$ , when heated with  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ ; if alkali is added,  $\text{PbO}_2$  is ppd.  $\text{AgNO}_3\text{Aq}$  produces no pp. at once, but after a time black  $\text{Ag}_2\text{O}$ , the solution becoming acid; several other metallic salts in presence of alkali yield pps. of peroxides with  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ , e.g. salts of Co, Cu, Mn, and Ni.  $\text{KIAq}$  is slowly decomposed by  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ , with separation of I; litmus and turmeric solutions are gradually bleached; paper and cloth become rotten when dipped in  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ .  $\text{KFeCyAq}$  is oxidised to  $\text{K}_3\text{FeCyAq}$ , and alcohol yields aldehyde, by warming with  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ .

**Ammonium persulphate**  $(\text{NH}_4)_2\text{S}_2\text{O}_8$ . Prepared, similarly to  $\text{K}_2\text{S}_2\text{O}_8$ , by electrolysis dilute  $\text{H}_2\text{SO}_4\text{Aq}$  (ca. 1 to 6 by volume) with  $(\text{NH}_4)_2\text{SO}_4$ ; the salt is purified by cooling by ice a solution saturated at a little above the ordinary temperature. Crystallises in transparent lozenge-shaped, apparently mono-symmetric tables. Very sol. water;  $\text{S. at } 0^\circ = 58.2$ . Reacts similarly to  $\text{K}_2\text{S}_2\text{O}_8$  (*cf.* Elbs, *J. pr.* [2] 48, 185).

**Barium persulphate**  $\text{Ba}_2(\text{SO}_4)_2\text{Aq}$ . Prepared by rubbing in a mortar saturated  $(\text{NH}_4)_2\text{S}_2\text{O}_8\text{Aq}$  with excess of pure  $\text{BaO}_2\text{H}_2 - \text{Ba}_2(\text{SO}_4)_2$ , goes into solution, and  $\text{BaSO}_4$  also forms—passing a rapid stream of air till most of the  $\text{NH}_4$  set free in the reaction is removed, placing *in vacuo* over  $\text{H}_2\text{SO}_4$  till no free  $\text{NH}_3$  remains, passing in  $\text{CO}_2$  to remove excess of  $\text{BaO}_2\text{H}_2$ , keeping *in vacuo* for a short time (to decompose Ba bicarbonate to  $\text{BaCO}_3$ ), filtering from  $\text{BaSO}_4$  and  $\text{BaSO}_3$ , evaporating *in vacuo* till crystallisation begins (with addition from time to time of a little  $\text{BaO Aq}$  to neutralise  $\text{H}_2\text{S}_2\text{O}_8$  that is set free during evaporation), dissolving the crystals that first separate in as little water as possible, filtering, cooling by ice, and drying the small prismatic crystals that form on a porous plate. The crystals of  $\text{Ba}_2(\text{SO}_4)_2\text{Aq}$  gradually become milky from formation of  $\text{BaSO}_3$ , the change soon spreads, and the crystals crumble to a moist, powdery mass of  $\text{BaSO}_3$ .  $\text{Ba}_2(\text{SO}_4)_2\text{Aq}$  is very sol. cold water;  $\text{S. at } 0^\circ = 52.2$ . Sol. absolute alcohol; on standing white crystals are deposited, probably  $\text{Ba}_2(\text{SO}_4)_2\text{Aq}$ .

**Lead persulphate**  $\text{Pb}_2(\text{SO}_4)_2\text{Aq}$ ;  $\alpha = 4$  or 6, probably 6. Obtained by adding a slight excess of  $\text{H}_2\text{SO}_4\text{Aq}$  to conc.  $\text{Ba}_2(\text{SO}_4)_2\text{Aq}$ , neutralising with  $\text{PbCO}_3$ , filtering after some time, evaporating *in vacuo* over  $\text{H}_2\text{SO}_4$  (removing  $\text{PbSO}_4$  from time to time by filtration) till a solid mass is obtained, which is at once dried between filter paper and

placed *in vacuo*.  $\text{Pb}(\text{SO}_4)_2$  was not obtained quite free from  $\text{PbSO}_4$ ; it decomposes very readily, giving off pungent fumes, that separate I from  $\text{KI}(\text{Aq})$  on paper.

*Zinc persulphate* was obtained, but not pure, by adding  $\text{ZnSO}_4(\text{Aq})$  to  $\text{Ba}_2(\text{SO}_4)_2(\text{Aq})$  in the proper proportions, filtering, and evaporating *in vacuo* over  $\text{H}_2\text{SO}_4$ . The copper salt was also obtained, but not free from  $\text{CuSO}_4$ . For thermal data concerning the formation and solution of the persulphates of  $\text{NH}_4$ ,  $\text{Ba}$ ,  $\text{K}$ , and  $\text{Na}$  v. Berthelot (*C. R.* 114, 875; abstract in *C. J.* 62, 931).

**PYROSULPHATES.** (*Disulphates.* *Anhydrosulphates.*) Salts of the acid  $\text{H}_2\text{S}_2\text{O}_7$  (v. *Pyrosulphuric acid*, under *Sulphuric acid*, p. 620). These salts bear to the sulphates a relation similar to that of the dichromates to the chromates. The sulphates may be written  $\text{SO}_4(\text{OM})_2$ , and the pyrosulphates  $\text{OM}.\text{SO}_2.\text{O}.\text{SO}_2.\text{OM}$ . The sulphates and pyrosulphates may also be regarded as compounds of the acidic radicle  $\text{SO}_3$  with basic radicles  $\text{MO}$ ; thus sulphates  $\text{MO}.\text{SO}_3$ , pyrosulphates  $\text{MO}.\text{SO}_2\text{SO}_3$ . Inasmuch as  $\text{H}_2\text{S}_2\text{O}_7$  may be regarded as a partial anhydride of  $\text{H}_2\text{SO}_4$  ( $2\text{H}_2\text{SO}_4 - \text{H}_2\text{O} = \text{H}_2\text{S}_2\text{O}_7$ ), the acid  $\text{H}_2\text{S}_2\text{O}_7$  is sometimes called anhydrosulphuric (cf. *Acids*, vol. i. p. 50).

*Potassium pyrosulphate*  $\text{K}_2\text{S}_2\text{O}_7$  is formed by heating  $\text{K}_2\text{SO}_4$  with half its weight of  $\text{H}_2\text{SO}_4$  till acid ceases to come off at an incipient red heat. Prismatic needles; *S.G.* 2.277 (Jacquelin, *A. Ch.* [2] 70, 811). Melts at  $300^\circ$ , according to Schultze-Sellack (*B.* 4, 109). Cannot be crystallised from water. Solution in fuming  $\text{H}_2\text{SO}_4$  gives crystals of the acid salt  $\text{KHS}_2\text{O}_7$ , melting at  $168^\circ$  (*S.-S.*, l.c.). Heated with alcoholic solution of  $\text{KSH}$  gives  $\text{K}_2\text{SO}_4$ ,  $\text{K}_2\text{S}_2\text{O}_8$ , and  $\text{H}_2\text{S}$ ; boiled with  $\text{C}_2\text{H}_5\text{ONa}$  in alcohol gives  $\text{KNaSO}_4$  and  $\text{KHSO}_4$  (Drechsel, *J. pr.* [2] 5, 367). The pyrosulphates of  $\text{NH}_4$ ,  $\text{Ba}$ ,  $\text{Ag}$ , and  $\text{Na}$  are prepared similarly to  $\text{K}_2\text{S}_2\text{O}_7$  (v. Schulze, *B.* 17, 2707; *J.*, l.c.; *S.-S.*, l.c.). M. M. P. M.

#### SULPHAZIDES $\text{X.NH.NH.SO}_2\text{Y}$ .

**Formation.**—1. By the action of alcoholic  $\text{SO}_2$  upon diazo-compounds.—2. By the action of hydrazines upon sulphonic chlorides  $\text{Y.SO}_2\text{Cl}$ . 3. By the action of hydrazine hydrochlorides upon sulphonic acids  $\text{Y.SO}_2\text{H}$ .—4. By reduction of the compounds  $\text{X.N}_2\text{SO}_2\text{Y}$ .

**Reaction.**—By heating with aqueous alkalis (e.g. baryta-water) they are decomposed into a sulphinic acid, a hydrocarbon, and nitrogen:  $\text{X.NH.NH.SO}_2\text{Y} = \text{XH} + \text{Y.SO}_2\text{H} + \text{N}_2$ .

**References:** Koenigs, *B.* 10, 1531; Wessinger, *B.* 10, 1715; Fischer, *A.* 190, 132; Escales, *B.* 18, 893; Limpriht, *B.* 20, 1238.

**SULPHAZOTISED ACIDS** v. **SULPHUR OXYACIDS**, **NITROGEN DERIVATIVES** of (p. 619).

**SULPHIDES.** Binary compounds of sulphur. The name is generally applied only to binary compounds of  $\text{S}$  with elements less negative than itself—that is, to compounds with elements other than  $\text{Br}$ ,  $\text{Cl}$ ,  $\text{F}$ ,  $\text{I}$ , or  $\text{O}$ ; thus  $\text{SO}_2$  and  $\text{SO}_3$  are called oxides of sulphur rather than sulphides of oxygen. Compounds of  $\text{S}$  with organic radicles, which compounds react similarly to sulphides of metals, must be regarded as binary compounds if the definition of the term sulphide is to be made as wide as possible. In the present article, however, only binary compounds of  $\text{S}$  with less negative elements are included. Sulphides of

all the metals, and also of the non-metals  $\text{H}$ ,  $\text{B}$ ,  $\text{C}$ ,  $\text{N}$ ,  $\text{Si}$ ,  $\text{P}$ ,  $\text{Se}$ , and  $\text{Te}$ , are known.

Many sulphides of metals occur native. Sulphides are frequently prepared by the direct union of the elements; sometimes by heating metallic oxides with excess of  $\text{S}$ , e.g.  $\text{As}_2\text{S}_3$ —in many cases a mixture of sulphide and oxide is formed in this way; addition of alkali carbonate to the mixture of metallic oxide and  $\text{S}$  sometimes brings about formation of sulphides, e.g. formation of sulphides of  $\text{Cr}$  and  $\text{U}$ ; polysulphides mixed with sulphates are produced by heating the hydroxides or carbonates of alkali metals with  $\text{S}$ . Most heavy metals give sulphides when their oxides are heated in  $\text{H}_2\text{S}$  gas, also when  $\text{H}_2\text{S}$  is passed into solutions of their salts. Heating metals in  $\text{H}_2\text{S}$  gas often produces sulphides. Sulphides are also formed by heating one metal with the sulphide of another, more negative, metal. Reduction of sulphates, generally by heating in  $\text{H}$  or with  $\text{C}$ , frequently yields sulphides. Some metallic oxides yield sulphides when strongly heated in vapour of  $\text{CS}_2$ . Sulphides of many heavy metals are formed by immersing the metals in  $(\text{NH}_4)_2\text{SAq}$  containing excess of  $\text{S}$  (v. Prioznik, *A.* 164, 46). Many metallic oxides yield sulphides by heating with dry  $\text{Na}_2\text{S}_2\text{O}_3$  (v. Landauer, *Fr.* 1872, 427).

The sulphides of the alkali and alkaline earth metals are soluble in water; other sulphides are insoluble, or only very slightly soluble, in water.

Very dilute aqueous solutions of several metallic sulphides, in the colloidal form, were obtained by Winssinger (*Bl.* [2] 49, 452) by the following methods: (1) ppg. the sulphide by  $\text{H}_2\text{S}$  from an extremely dilute solution, and dialysing; (2) washing the ppg. sulphide for a long time with cold water, or with dilute  $\text{H}_2\text{SAq}$ ; (3) forming the sulphide in a solution free from all substances capable of causing coagulation. In these ways W. obtained colloidal soluble sulphides of  $\text{Bi}$ ,  $\text{Co}$ ,  $\text{Au}$ ,  $\text{Fe}$ ,  $\text{In}$ ,  $\text{Pb}$ ,  $\text{Hg}$ ,  $\text{Mo}$ ,  $\text{Ni}$ ,  $\text{Pd}$ ,  $\text{Pt}$ ,  $\text{Ag}$ ,  $\text{Ti}$ ,  $\text{W}$ , and  $\text{Zn}$ . For preparation of colloidal soluble  $\text{CdS}$  v. Prost (*C. C.* 1888, 32), and of colloidal soluble  $\text{CuS}$  v. Spring a. de Boeck (*Bl.* [2] 48, 165).

Metallic sulphides are decomposed by strong acids, giving salts and  $\text{H}_2\text{S}$ ; secondary reactions frequently occur,  $\text{S}$  almost invariably separating. Several sulphides, e.g.  $\text{As}_2\text{S}_3$  and  $\text{HgS}$ , are sublimable out of contact with air; all sulphides are oxidised by heating to redness in air. The sulphides of the very positive metals yield sulphates, and the sulphides of the heavy metals generally form oxides (the sulphides of  $\text{Au}$ ,  $\text{Hg}$ ,  $\text{Pt}$ , and  $\text{Ag}$  form metal) and give off  $\text{SO}_2$ . All sulphides of metals yield metallic chlorides and  $\text{S}_2\text{Cl}_2$  when heated in a stream of  $\text{Cl}$ . Many metallic sulphides are decomposed by water, at different temperatures, giving oxides or hydroxides and  $\text{H}_2\text{S}$  (cf. de Clermont a. Frommel, *C. R.* 87, 330). Sulphides of non-metals are decomposed by water, generally to oxyacids and  $\text{H}_2\text{S}$ ;  $\text{NS}$  gives  $\text{NH}_3$ , salts of  $\text{H}_2\text{S}_2\text{O}_8$  and  $\text{H}_2\text{S}_2\text{O}_7$ . Many sulphides of heavy metals are decomposed by heating with water and  $\text{I}$ , giving iodides,  $\text{S}$ , and a little sulphate (v. Filhol a. Mellies, *A. Ch.* [4] 22, 58).

The double sulphides, formed by the union of sulphides of more positive elements with sulphides of less positive elements, are comparable

with the double oxides or oxyalts; most of these double sulphides are probably best regarded as salts of thio-acids corresponding with salts of oxyacids, but it is customary to apply this conception generally only to those compounds which contain sulphides of non-metals or of Sb, As, or Sn. The double sulphides, or thio-salts, are generally decomposed by water, forming oxides and  $H_2S$ . Many double sulphides, containing  $K_2S$  or  $Na_2S$  as one constituent, are formed by fusing metals or metallic sulphates with  $K_2CO_3$ , or  $Na_2CO_3$ , and  $S$  (v. Schneider, *J. pr.* [2] 7, 214; 9, 209; 10, 55). The sulphides may be classified, like the oxides, as monosulphides, disulphides, &c. It is better, however, to divide them into *basic*, *acidic*, *indifferent*, and *persulphides*; but this classification has been less developed and applied than in the case of the oxides. Basic sulphides react with acids to form salts and  $H_2S$ , just as basic oxides react with acids to form salts and  $H_2O$ . Acidic sulphides react with the basic sulphides to form thio-salts, as acidic oxides react with basic oxides to form oxy-salts; but few compounds have been isolated of acidic sulphides with  $H_2S$ , corresponding with the compounds of acidic oxides with water which are oxyacids. The more strongly acidic sulphides—that is, the sulphides of non-metals—are decomposed by water, generally giving  $H_2S$  and oxyacids. The persulphides have not been much studied; any sulphide of an element containing more  $S$  than the basic or acidic sulphide of the same element may be placed provisionally among the persulphides. A sulphide which does not react as basic or acidic, and which from its composition cannot well be called a persulphide, may be classed as an indifferent sulphide. The sulphides of  $C$  and  $P$  combine with several metallic sulphides to form thio-salts; double sulphides (or thio-salts) have not been isolated containing sulphides of  $B$ ,  $N$ ,  $Si$ ,  $Se$ , or  $Te$ ; the sulphides of  $Sb$ ,  $As$ , and  $Sn$  combine with the sulphides of the alkali metals, and with some other sulphides of positive metals, to form thio-salts. The greater number of the double sulphides are formed by the union of two sulphides, both of which are metallic. The sulphide of that metal which, on the whole, is the more positive is regarded as the basic radicle; and the sulphide of the metal which, on the whole, is the less positive is regarded as the acidic radicle of the double sulphide. Some metallic sulphides must be classed both as basic and acidic;  $Cu_2S$ , for example, combines with  $As_2S_3$ , and is therefore basic towards the distinctly acidic sulphide of  $As$ , but it also combines with  $K_2S$ , and is therefore acidic towards the distinctly basic sulphide of  $K$ . It is impossible to divide the metallic sulphides into two distinctly-marked classes; the relativity of the terms 'basic' and 'acidic' becomes even more apparent in dealing with sulphides than in dealing with oxides. The sulphides  $BaS$ ,  $BaS_2$ ,  $CaS$ , and  $CaS_2$  may be taken as examples of those which are loosely put together under the name persulphides. As examples of indifferent sulphides  $NS$  and  $Cr_2S_3$  may be mentioned. Many metallic sulphides which have been little studied—and which must, therefore, for a time be called indifferent—are very probably basic in their reactions; such are  $Al_2S_3$  and  $CdS$ . M. M. F. M.

**SULPHIDO-DIACETIC ACID**  $C_2H_3SO_4$ , *i.e.*  $S(CH_2.CO_2H)_2$ . *Thiodiglycollic acid*. [129°].  $S$ . 42 at 18°. Formed from chloro-acetic acid and alcoholic ammonium sulphide, aqueous  $Ca(SH)_2$ , or  $Na_2S$  (Schulze, *Z.* 1865, 73; 1866, 184; Schreiber, *J. pr.* [2] 13, 472; Lovén, *B.* 17, 2818). Formed also by heating bromo-acetic acid with benzyl sulphide, allyl sulphide, or ethylene sulphide (Letts, *Tr. E.* 28, 612). Tri-metric tables, v. sol. alcohol. Oxidised by  $KMnO_4$  to  $SO_2(CH_2.SO_3H)_2$ . The  $Na$  salt is converted by treatment with sodium chloro-acetate into  $CO_2H.CH_2.SMe < \underset{CH_2}{O} > CO$  [150°] (Delisle, *B.* 25, 2450). The analogous compound  $(CO_2H.CH_2)_2S < \underset{CH_2}{O} > CO$  [158°] is formed from chloro-acetic acid,  $Na_2CO_3$ , and  $Na_2S$  (Delisle), and yields  $Na_2A''$  3aq.

**Salts.**— $K_2A'$  aq.: deliquescent prisms.— $KHA'$ .— $CaA'$ .  $S$ . 2 at 21°.— $BaA'$ .— $BaA''$  5aq.— $ZnA''$  4aq.— $PbA'$ .— $Pb_2A''O$ .— $CuA'$  aq.— $AgA'$ .

**Methyl ether**  $Me_2A'$ . (135° at 11 mm.).

**Ethyl ether**  $Et_2A'$ . (268° cor.). Formed from chloroacetic ether and alcoholic  $KSH$  (Wislicenus, *A.* 146, 153).

**Amide**  $S(CH_2.CO.NH)_2$ . Formed from chloro-acetic acid and alcoholic  $(NH_4)_2S$ .

**Amic acid**  $S(CH_2.CO_2H).CH_2.CO.NH_2$ . [125°]. Prisms, m. sol. cold water.— $BaA_2$  aq.— $CaA'$  aq.— $AgA'$ : needles (from hot water).

**Imide**  $S < \underset{CH_2}{CH_2}{CO} > NH$ . [128°]. Formed by heating the ammonium salt at 200°. Crystals.

**Anhydride**  $S < \underset{CH_2}{CH_2}{CO} > O$ . [102°]. (158° at 10 mm.). Formed by boiling the acid with  $AcCl$  (Anschütz, *A.* 273, 68). Needles (from  $CHCl_3$ ).

**Chloride**  $S(CH_2.COCl)_2$ .

**Mono-anilide**  $\dot{S}(CH_2.CO_2H).CH_2.CONHPh$ . [103°].

**Di-anilide**  $S(CH_2.CO.NHPh)_2$ . [168°].

**p-Toluide**  $S(CH_2.CO_2H).CH_2.CO.NHC_6H_4$ . [95°]. Needles.

**Di-sulphido-di-acetic acid (di-thio-di-glycollic acid)**  $S_2(CH_2.CO_2H)_2$  [100° uncor.]. Formed from thio-glycollic acid  $CH_2(SH).CO_2H$  by  $FeCl_3$  or by atmospheric oxidation of the alkaline solution (Claesson, *B.* 14, 410; Ginsburg a. Bondzynski, *B.* 19, 114). White plates or prisms. V. sol. water, alcohol, and ether, sl. sol. benzene. Gives with  $AgNO_3$  a white pp.  $AgHA'$ . By tin and  $HCl$  it is reduced to thio-glycollic acid.— $K_2A''$  1½aq.: easily soluble crystals.— $KHA''$  aq.— $BaA''$  4aq.: amorphous pp.

**Ethyl ether**  $Et_2A''$ . (c. 280°).

**Amide** [155°]. Crystalline.

#### SULPHIDO-DI-ACETOACETIC ETHER

$C_2H_5SO_4$ , *i.e.*  $S(CH_3.CO_2Et)_2$ . [90°] ( $S$ ); [84°] ( $D$ ); [76°] ( $B$ ). Formed by the action of  $S_2Cl_2$  (2 mols.) or of  $SCl_2$  on sodium acetoacetic ether (1 mol.) suspended in benzene (Buchka, *B.* 18, 2092; 22, 2545, 2555; Delisle, *B.* 22, 306). Formed also from cupric acetoacetic ether and  $S$  in benzene (Schönbrodt, *A.* 253, 197). Needles, v. s. sol. benzene. Converted by  $KOH$  into sulphido-di-acetic acid. Yields a crystalline phenyl-hydrazide  $C_{10}H_{11}N_3SO_4$ , converted by warming with an alcoholic solution of phenyl-hydrazine into oxy-phenyl-methyl-pyrazole-azo-

benzene  $\text{NPh.CO} > \text{C:N.NPh}$  (Michaelis & Phillips, *B.* 23, 560). Phenyl-hydrazine (2 mols.) added to sulphido-di-acetoacetic ether dissolved in cooled HOAc forms  $\text{C}_{10}\text{H}_8\text{N}_2\text{SO}_2$ , which yields B'HOAc [161°] and B'HOEt (Michaelis, *B.* 23, 2476; Sprague, *C. J.* 59, 332).

**SULPHIDO-ANILINE** v. DI-AMIDO-DI-PHENYL SULPHIDE.

#### DISULPHIDO-DI-BENZOIC ACID

$\text{S}_2(\text{C}_6\text{H}_4.\text{CO}_2\text{H})_2$ . [244°]. Formed by oxidation of  $\text{C}_6\text{H}_4(\text{SH}).\text{CO}_2\text{H}$  by moist air or by bromine water (Frerichs, *B.* 7, 794; Hübner & Upmann, *Z.* 1870, 294). Formed also from *m*-diazobenzoic acid and H<sub>2</sub>S (Griess, *J. pr.* [2] 1, 102) and, in small quantity, by fusing sodium sulphobenzonate with sodium formate (Ador, *B.* 4, 622; Meyer, *B.* 6, 1150). Needles, nearly insol. hot water, sl. sol. alcohol. —  $(\text{NH}_4)_2\text{A}''$  2aq. —  $\text{CaA}''$  3aq. —  $\text{BaA}''$  3aq. —  $\text{PbA}''$  aq. —  $\text{Cu}_2(\text{OH})_2\text{A}''$  5aq. —  $\text{Ag}_2\text{A}''$  1½aq: yellowish-white pp.

#### γ-SULPHIDO-DIBUTYRIC ACID

$\text{S}(\text{CH}_2\text{CH}_2.\text{CH}_2.\text{CO}_2\text{H})_2$ . [90°]. Formed by warming its nitrile with fuming HClAq (Gabriel, *B.* 23, 2492). Flat crystals.

*Nitrile*  $\text{S}(\text{CH}_2\text{CH}_2.\text{CH}_2.\text{CN})_2$ . (above 300°). Formed by boiling γ-chloro-butyronitrile with alcoholic K<sub>2</sub>S. Thick liquid.

*α*-Sulphido-dibutyric acid  $\text{S}(\text{CHET}.\text{CO}_2\text{H})_2$ . [105°]. Formed by heating *α*-bromo-butyric ether (2 mols.) with an alcoholic solution of KSH (1 mol.) and KOH (1 mol.), and saponifying the product (Lovén, *J. pr.* [2] 33, 102). Tufts of needles (from water). —  $\text{BaA}''$ .

*α*-Sulphido-di-isobutyric acid  $\text{S}(\text{CMe}_2.\text{CO}_2\text{H})_2$ . Formed from *α*-bromo-isobutyric ether and alcoholic K<sub>2</sub>S, the product being saponified. Tablets (from water), insol. dilute H<sub>2</sub>SO<sub>4</sub>. —  $\text{BaA}''$  2aq.

#### Di-γ-sulphido-dibutyric acid

$\text{S}_2(\text{CH}_2\text{CH}_2.\text{CH}_2.\text{CO}_2\text{H})_2$ . [109°]. Formed by boiling the amide with conc. HClAq (Gabriel). Flat plates, v. sol. alkalis.

*Amide*  $\text{S}_2(\text{C}_4\text{H}_9.\text{CO}.\text{NH}_2)_2$ . [167°]. Formed by dissolving  $\text{Cy}.\text{C}_4\text{H}_9.\text{S}.\text{Cy}$  in cold conc. H<sub>2</sub>SO<sub>4</sub>.

**SULPHIDO-DICINNAMIC ACID**  $\text{C}_{18}\text{H}_{14}\text{SO}_2$ , i.e.  $(\text{Ph}.\text{CH}:\text{C}(\text{CO}_2\text{H}))_2\text{S}$ . Formed by boiling sulphido-diacetic acid with Ac<sub>2</sub>O and NaOAc (Lovén, *B.* 18, 3242). Small needles (from alcohol), insol. water. Yields  $\text{C}_{18}\text{H}_{14}\text{Br}_2\text{SO}_4$ . —  $\text{NaA}''$  2½aq: silvery plates.

*Di-α-sulphido-di-cinnamic acid*  $\text{C}_{22}\text{H}_{16}\text{S}_2\text{O}_4$ , i.e.  $(\text{Ph}.\text{CH}:\text{C}(\text{CO}_2\text{H}))_2\text{S}_2$ . [179°]. Formed by the oxidation of sulphhydro-cinnamic acid  $\text{Ph}.\text{CH}:\text{C}(\text{SH}).\text{CO}_2\text{H}$  by iodine in alcoholic solution. Long yellowish needles, v. sol. alcohol, less in benzene (Ginsburg & Bondzynski, *B.* 19, 123).

#### DI-SULPHIDO-DI-METHENYL-DI-AMIDO-DI-NAPHTHYL MERCAPTAN

$\text{S}_2(\text{C} \begin{smallmatrix} \text{N} \\ \text{S} \end{smallmatrix} > \text{C}_{10}\text{H}_7)_2$ . Formed by oxidation of  $\text{C}_{10}\text{H}_7.\text{C} \begin{smallmatrix} \text{N} \\ \text{S} \end{smallmatrix} > \text{C}_6\text{H}_5$  with alkaline K<sub>2</sub>FeCy<sub>4</sub> (Jacobson & Frankenbacher, *B.* 24, 1408). The (α)-compound melts at 194°, the (β)-isomeride at 180°.

**DISULPHIDO-DI-METHENYL-DI-AMIDO-DI-PHENYL MERCAPTAN**  $\text{S}_2(\text{C} \begin{smallmatrix} \text{N} \\ \text{S} \end{smallmatrix} > \text{C}_6\text{H}_5)_2$ . [186°]. Formed by oxidising sulphhydro-methenyl-amido-phenyl mercaptan with K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and HOAc (Jacobson & Frankenbacher, *B.* 24,

1404; cf. Hofmann, *B.* 20, 1789). Plates (from benzene).

#### DI-SULPHIDO-DI-METHENYL-DI-BENZENYL-DI-AMIDOSULPHIM

$\text{S}_2(\text{C} \begin{smallmatrix} \text{N} \\ \text{S} \end{smallmatrix} > \text{C}_6\text{H}_5)_2$ . [120°]. Formed by oxida-

tion of  $\text{C}_6\text{H}_5.\text{C} \begin{smallmatrix} \text{N} \\ \text{S} \end{smallmatrix} > \text{C}_6\text{H}_5$  (Crayen, *B.* 24, 889).

Stellate groups of needles, insol. water, sl. sol. alcohol. Reduced by sodium-amalgam to the parent substance.

#### DI-SULPHIDO-DI-METHENYL-DI-*p*-TOLENYL-DI-AMIDOSULPHIM

$\text{S}_2(\text{C} \begin{smallmatrix} \text{N} \\ \text{S} \end{smallmatrix} > \text{C}_6\text{H}_4(\text{Me}))_2$ . [169°]. Formed by

oxidation of  $\text{C}_6\text{H}_4(\text{Me}).\text{C} \begin{smallmatrix} \text{N} \\ \text{S} \end{smallmatrix} > \text{C}_6\text{H}_5$  with HNO<sub>3</sub>, free from nitrous acid (Crayen, *B.* 24, 392). Needles, insol. alcohol and ether, sol. hot C<sub>6</sub>H<sub>6</sub>.

#### DI-SULPHIDO-DI-METHYL-ANILINE v. TETRA-METHYL-DI-AMIDO-DI-PHENYL-DI-SULPHIDE.

**DI-SULPHIDO-DI-NAPHTHALENE-DI-(β)-SULPHONIC ACID**  $\text{S}_2(\text{C}_{10}\text{H}_7.\text{SO}_3\text{H})_2$ . Formed from the product of the action of potassium xanthate on diazotised (β)-naphthylamine (β)-sulphonic acid by treatment with alcoholic potash (Leuckart, *J. pr.* [2] 41, 223). Colourless plates, v. sol. water and alcohol. Reduced by zinc-dust and dilute H<sub>2</sub>SO<sub>4</sub> to  $\text{C}_{10}\text{H}_7(\text{SH}).\text{SO}_3\text{H}$ . —  $\text{K}_2\text{A}''$ . —  $\text{PbA}''$ : amorphous pp., sl. sol. water.

#### SULPHIDO-DI-(β)-NAPHTHYL-CARBAMIC ACID. Phenyl ether

$\text{S} \begin{smallmatrix} \text{C}_{10}\text{H}_7 \\ \text{C}_{10}\text{H}_7 \end{smallmatrix} > \text{N.CO.OPh}$ . [215°]. S. (96 p.c. alcohol) 20 at 16°; S. (benzene) 1-20 at 16°. Formed from the chloride and alcoholic NaOPh (Paschkowezky, *B.* 24, 2916). Needles.

#### Chloride $\text{S}(\text{C}_{10}\text{H}_7)_2.\text{N.COCl}$ . [255°].

Formed by heating β-imido-di-naphthyl sulphide with COCl<sub>2</sub> in toluene at 170°. Needles (from benzene-alcohol), v. sl. sol. ether. Converted by aniline into  $\text{S}(\text{C}_{10}\text{H}_7)_2.\text{N.CO.NHPh}$ , which is crystalline, S. (96 p.c. alcohol) 04; S. (benzene) 18 at 17-5°, converted by boiling aniline into  $\text{S}(\text{C}_{10}\text{H}_7.\text{NH}_2)_2$  and CO(NHPh). The chloride is converted by alcoholic NH<sub>3</sub> at 145° into  $\text{S} \begin{smallmatrix} \text{C}_{10}\text{H}_7 \\ \text{C}_{10}\text{H}_7 \end{smallmatrix} > \text{N.CO.NH}_2$ , crystallising in needles, S. (96 p.c. alcohol) 06; S. (benzene) 10 at 17-5°.

The chloride  $\text{S} \begin{smallmatrix} \text{C}_{10}\text{H}_7 \\ \text{C}_{10}\text{H}_7 \end{smallmatrix} > \text{N.COCl}$  is converted

by β-imido-di-naphthyl sulphide in xylene at 280° into  $(\text{S} \begin{smallmatrix} \text{C}_{10}\text{H}_7 \\ \text{C}_{10}\text{H}_7 \end{smallmatrix} > \text{N})_2\text{CO}$ , crystallising in yellowish plates and tables [over 350°].

#### SULPHIDO-DI-PHENYL-AMINE v. IMIDO-DI-PHENYL SULPHIDE.

#### SULPHIDO-DI-PHENYL-CARBAMIC ACID.

*Ethyl ether*  $\text{S} \begin{smallmatrix} \text{C}_6\text{H}_5 \\ \text{C}_6\text{H}_5 \end{smallmatrix} > \text{N.CO}_2\text{Et}$ . [110°].

Formed from imido-di-phenyl-sulphide and ClCO<sub>2</sub>Et (Fränckel, *B.* 19, 1845). Silky plates.

*Phenyl ether*  $\text{S}(\text{C}_6\text{H}_5)_2.\text{N.CO}_2\text{Ph}$ . [164°]. S. (96 p.c. alcohol) 24 at 16°; S. (benzene) 1-9 at 16°.

Formed by heating the chloride with NaOPh in alcohol on the water-bath (Paschkowezky, *B.* 24, 2908). Needles.

*Chloride*  $\text{S}(\text{C}_6\text{H}_5)_2.\text{N.COCl}$ . [172°]. Formed from  $\text{S}(\text{C}_6\text{H}_5)_2.\text{NH}$  and COCl<sub>2</sub> at 100°. Colourless prisms, sol. chloroform, and hot HOAc.

**p-SULPHIDO-DI-PHENYL-DI-HYDRAZINE**  
 $S(C_6H_5.NH.NH_2)_2$ . [115°]. Formed from  $S(C_6H_5.NH_2)_2$  by diazotisation, treatment with  $NaHSO_4$ , and reduction with zinc-dust (Ruhl, B. 23, 3482; A. 270, 149). Yellowish leaflets, decomposing at 130°, sl. sol. cold water and ether, v. sol. alcohol. Reduces Fehling's solution in the cold. Benzoic aldehyde yields  $S(C_6H_5.NH.CHPh)_2$ . —  $B''HCl$ . [209°]. —  $B''H_2SO_4$ . [219°]. —  $B''H_2CO_3$ .

**SULPHIDO-PHENYL-NAPHTHYLAMINE**  
 $S(C_6H_5.NH.C_{10}H_7)_2$ . Imido-phenyl-naphthylamine. Formed by heating phenyl-naphthyl-amine with S at 240° (Kym, B. 23, 2454). The (α)-compound melts at 139°, the (β)-isomer at 178°. Both form yellow crystals, m. sol. hot alcohol, and give a deep blue solution in conc.  $H_2SO_4$ .

**SULPHIDO-DI-PHENYL-DI-(β)-NAPHTHYL-UREA**  $N(C_{10}H_7)_2.CO.N(C_6H_5)_2$ . S. [225°]. S. (96 p.c. alcohol) 12; S. (benzene) 55 at 16°. Formed from  $S(C_6H_5)_2.N.COCl$  and  $(C_{10}H_7)_2NH$  at 260° (Paschkowesky, B. 24, 2914). White nodules, sl. sol. hot alcohol, sol. hot benzene.

**Sulphido-tri-phenyl-(β)-naphthyl-urea**  $NPh(C_6H_5).CO.N(C_6H_5)_2$ . S. [170°]. S. (96 p.c. alcohol) 52; S. (benzene) 338 at 15°. Formed by heating sulphido-di-phenyl-carbamic chloride with phenyl-(β)-naphthylamine at 250° (P.).

**SULPHIDO-DI-PHENYL-DI-TOLYL-DI-GUANIDINE**  $(NHPh.C(NH).NH.C_6H_5)_2$ . S. [153°]. Formed from the corresponding thio-urea,  $HgO$ , and alcoholic  $NH_3$  (Truhlar, B. 20, 675). Needles (from ether ligroin). —  $C_{10}H_7.SN.H.PtCl_6$ .

**Sulphido-tetra-phenyl-di-tolyl-di-guanidine**  $(NHPh.C(NH).NH.C_6H_5)_2$ . S. [106°]. Formed by warming an alcoholic solution of  $(NHPh.CS.NHC_6H_5)_2S$  with aniline and  $HgO$ . Grey amorphous powder, v. e. sol. alcohol.

**Disulphido-di-phenyl-tolyl-di-guanidine**  $NPh.C(NH.C_6H_5)_2.S.C_6H_5.NH.C(NH).NH.C_6H_5$ . [119°]. Formed by heating the corresponding thio-urea with excess of aniline and  $HgO$ . Resinous mass, v. e. sol. alcohol.

**SULPHIDO-DI-PHENYL-DI-TOLYL-DI-THIO-DI-UREA**  $(NHPh.CS.NH.C_6H_5)_2$ . S. [134°]. Formed from  $S(C_6H_5.NH_2)_2$  and phenyl-thio-carbimide (Truhlar, B. 20, 670). Needles.

**SULPHIDO-DI-PHENYL-UREA**  $C_{10}H_7.N_2SO$ .  $S(C_6H_5)_2.N.CO.NH_2$ . [202°]. S. (96 p.c. alcohol at 17.5°) 3; S. (benzene) 2.7 at 17.5°. Formed from  $S(C_6H_5)_2.N.COCl$  and alcoholic  $NH_3$  (Paschkowesky, B. 24, 2908). Plates.

**Sulphido-tri-phenyl-urea**  $S(C_6H_5)_3.N.CO.NHPh$ . [169°]. S. (96 p.c. alcohol) 26 at 17.5°; S. (benzene) 3.74 at 17.5°. Formed from  $S(C_6H_5)_2.N.COCl$  and aniline. Bluish needles, sol. alcohol.

**Sulphido-tetra-phenyl-urea**  $S(C_6H_5)_4.N.CO.NPh$ . Formed in like manner, using  $NPh.H$ . Hexagonal plates.

**Di-sulphido-tetra-phenyl-urea**  $CO(N(C_6H_5)_2)_2$ . [225°] (F.); [231°] (P.). S. (96 p.c. alcohol) 0.48 at 17°; 4.16 at 78°. Formed by heating  $NH(C_6H_5)_2S$  with

$S(C_6H_5)_2.N.COCl$  (Fränkel, B. 18, 1846). Plates (from  $HOAc$ ), v. sl. sol. ether and hot alcohol.

**DI-SULPHIDO-DI-PROPYL-DI-PHTHALAMIC ACID**  $C_6H_5.N_2S_2O_6$ .  $S_2(C_6H_5.NH.CO.C_6H_5)_2$ . [136°]. Formed by boiling (γ)-phthalimido-propyl sulphocyanide with a 10 p.c. solution of  $KOH$  (Gabriel, A. Lauer, B. 23, 89). Plates (from  $HOAc$ ), v. sol. alkalis. —  $K_2A''$ : crystalline pp.

(a). **SULPHIDO-DIPROPIONIC ACID**  $S(CHMe.CO_2H)_2$ . Thiodilactylic acid. [125°]. Formed, together with  $CH_3.CH(SH).CO_2H$ , by boiling potassium α-chloro-propionate with  $KSH$  (Schacht, A. 129, 4; Böttlinger, A. 196, 106). Formed also by passing  $H_2S$  into a solution of potassium pyruvate (Böttlinger, B. 12, 1425) and by the action of  $CH_3.CH(SK).CO_2K$  on  $CH_3.CHCl.CO_2K$  (Lovén, J. pr. [2] 29, 373). Monoclinic prisms, v. e. sol. water, alcohol, and ether. Not affected by nascent hydrogen. Oxidised by dilute  $HNO_3$  to  $SO_3(CHMe.CO_2H)_2$ . —  $K_2A''$ : deliquescent. —  $BaA''$ : amorphous, v. sol. water (S.). Its solution on boiling deposits a crystalline salt, S. 1 (L.). —  $Ag_2A''$ : amorphous pp.

**Dj-(a)-sulphido-dipropionic acid**  $S_2(CHMe.CO_2H)_2$ . [142°]. Formed by oxidation of  $CH_3.CH(SH).CO_2H$  by  $I$  or  $FeCl_3$  (S.; Böttlinger, A. 196, 103; B. 16, 1047; Lovén, J. pr. [2] 29, 372). Needles, sl. sol. cold water, v. sol. alcohol and ether. Reduced by zinc and  $HClAq$  to  $CH_3.CH(SH).CO_2H$ . —  $(NH_4)_2A''$ . —  $K_2A''$  2aq. —  $Ag_2A''$ : amorphous pp.

**Di-β-sulphido-dipropionic acid**  $S_2(CH_2.CH_2.CO_2H)_2$ . Formed by oxidation of  $CH_2(SH).CH_2.CO_2H$  (L.). Thin silvery plates.

**Tri-sulphido-di-propionic acid**  $S_3(CHMe.CO_2H)_2$ . [95°]. Formed from  $CH_3.CO.CO_2H$  and  $H_2S$  (Lovén, J. pr. [2] 47, 173). Plates, v. sol. hot water. Yields α-sulpho-propionic acid on oxidation.

**SULPHIDO-TOLUIDINE** v. **DI-AMIDO-DI-TOLYL SULPHIDE**.

**SULPHIDO-DI-TOLYL-DI-CARBAMIC ETHER**  $S(C_6H_5.Me.NH.CO_2Et)_2$ . [113°]. Formed from imido-di-tolyl sulphide and  $ClCO_2Et$  (Truhlar, B. 20, 668). Needles, v. sol. alcohol.

**DI-SULPHIDO-TETRA-TOLYL-DI-GUANIDINE**  $C(NH)(NH.C_6H_5)_2.S.C_6H_5.NH.C(NH).NH.C_6H_5$ . [196°]. Formed by boiling the corresponding thio-urea with alcoholic  $NH_3$  and  $HgO$  (Truhlar, B. 20, 673). White amorphous powder, v. sol. benzene and hot alcohol. —  $B_2H_4PtCl_6$ : brown amorphous powder.

**SULPHIDO-DI-TOLYL-THIO-UREA**  $S(C_6H_5.NH)_2.CS$ . [235°]. Formed from  $S(C_6H_5.NH_2)_2$  and alcoholic  $CS_2$ .

**Sulphido-di-tolyl-di-thio-di-urea**  $S(C_6H_5.NH.CS.NH)_2$ . [121°]. Formed by evaporating the hydrochloride of di-amido-di-tolyl sulphide with ammonium sulphocyanide (Truhlar, B. 20, 669). Amorphous powder, sl. sol. ether.

**Di-sulphido-tetra-tolyl-di-thio-di-urea**  $CS(NH.C_6H_5)_4$ .  $S_2(C_6H_5.NH)_4$ . [231°]. Formed by boiling an alcoholic solution of di-p-amido-di-tolyl sulphide with  $CS_2$  (Truhlar, B. 20, 672).

white amorphous powder, nearly insol. ordinary solvents.

#### SULPHIDO-DI-TOLYL-DI-UREA

$S(O_2H_2Me.NH.CO.NH_2)_2$ . Formed from di-amido-di-tolyl sulphide, hydrochloride and potassium cyanate (Truhlar, B. 20, 669). Crystallises from benzene in needles [ $161^\circ$ ] containing  $C_6H_5$ .

#### Di-sulphido-tetra-tolyl-di-urea

$CO < \begin{smallmatrix} NH.C_6H_4.S.O_2.C_6H_4.NH \\ NH.C_6H_4.S.O_2.C_6H_4.NH \end{smallmatrix} > CO$ . Formed from  $S(C_6H_4.NH_2)_2$  and  $COCl_2$  (Truhlar, B. 20, 671). White amorphous powder, sol. hot alcohol.

#### SULPHIDO-DI-ISOVALEERIC ACID

$S(C_4H_7.CO_2H)_2$ . Formed from bromo-isovaleric acid and  $K_2S$  (Lövén, J. pr. [2] 33, 102). Crystals. —BaA": in soluble powder.

**SULPHIMIDE**  $SO_2.NHAq$ . Obtained only in aqueous solution, which is prepared by decomposing the Ag derivative,  $SO_2.NAg$ , with the proper quantity of dilute  $HClAq$ , and filtering. The compound  $SO_2.NAg$  is prepared by saturating well-cooled  $SO_2Cl_2$  in 15–20 vols.  $CHCl_3$ , with dry  $NH_3$ , dissolving the pp. in water, acidifying with  $HNQ_3$ , ppg. all Cl by  $AgNO_3Aq$ , filtering, neutralising with  $KOHAq$ , and adding more  $AgNO_3Aq$ ; the pp. thus obtained is purified by recrystallisation from water. The compound  $SO_2.NAg$  is also obtained by heating  $SO_2(NH_3)_2$  (v. SULPHAMIDE, p. 567) to  $200^\circ$ – $210^\circ$ , dissolving in water, ppg. by  $AgNO_3Aq$ , and recrystallising the pp. from water. The solution in water of  $SO_2.NH$  is strongly acid; when dilute it may be boiled for a short time without decomposition;  $NI_2.HSO_3$  is formed on evaporation, even below  $40^\circ$ ; the solution is decomposed by warming with acids, giving  $H_2SO_4Aq$  and  $NH_4Aq$ ; excess of alkali reacts slowly even on boiling (W. Traube, B. 25, 2472; 26, 607). Metallic derivatives of  $SO_2.NH$  wherein H is replaced by  $NH_4$ , Ba, Ca, Pb, K, Ag, and Na are described by T. (cf. Imido-sulphonic acid and salts, under SULPHONIC ACIDS AND DERIVATIVES, p. 600). M. M. P. M.

#### SULPHIMIDO-AMIDE $SO_2.NH.NH_2.SO_2$ . (Imido-sulphamide. Imido-sulphonamide. Imido-sulphurylamide).

Prepared by adding ammonium carbamate very slowly to  $S_2O_3Cl_2$ , well cooled in a small closed flask, allowing to stand for some time with a  $CaCl_2$  tube fitted through the cork, then heating to  $60^\circ$  for some hours, washing out  $NH_4Cl$  by repeated treatment with dry alcohol saturated with  $NH_3$ , dissolving the residue in a little  $NH_4Aq$ , and placing the solution in ice. Forms white lustrous crystals; boiling  $NH_4Aq$  transforms it wholly to ammonium imidosulphonate; with boiling conc.  $HClAq$  is completely changed to  $(NH_4)_2SO_3$ ; when boiled with  $NaOHAq$  gives off two-thirds of its  $N$  as  $NH_3$ , and forms sodium imidosulphonate (Mente, A. 248, 268). M. M. P. M.

#### SULPHINDIGOTIC ACID v. INDIGO DI-SULPHONIC ACID.

**SULPHINES**. Alkyl iodides combine with di-alkyl sulphides forming compounds  $R_2SR'I$ , from which moist  $Ag_2O$  produces strong bases  $R_2SR'.OH$ . In these bases the group  $(SR'_2R')$  may be looked upon as a monovalent basylous radicle derived from the hypothetical sulphine  $(SH_2)$ . Thus  $Me_3SEtI$  may be called di-methyl-ethyl-sulphine iodide, but in this dictionary it

is described as the ethyl-iodide of Di-methyl sulphide. In the same manner  $Me_3SCl$  may be called tri-methyl-sulphine chloride, but in this dictionary it is described as the methyl-chloride of Di-methyl-sulphide.

**SULPHINIC ACIDS**. Organic acids containing the group  $SO(OH)$  where S is united to carbon. They may be obtained by reducing the chlorides of the sulphonic acids, in alcoholic or ethereal solution, with zinc-dust (Otto, B. 9, 1584). Fatty sulphinic acids are formed by the action of  $SO_2$  or of  $SO_3$  on zinc alkyls (Hofmann, A. 102, 72; 106, 287). They are readily oxidised to sulphonic acids. The aromatic sulphinic ethers are readily oxidised by  $KMnO_4$  and  $HOAc$  to sulphonic ethers (Otto a. Rossing, B. 19, 1224). By zinc and dilute  $H_2SO_4$ , sulphinic acids are reduced to mercaptans. The aromatic sulphinic acids yield  $K_2S_2O_8$  and hydrocarbons when fused with potash. The alkyl ethers of sulphinic acids  $X.SO_2OR$  are formed by passing  $HCl$  into a solution of the acid in the corresponding alcohol, and also by the action of chloro-carbonic ethers  $Cl.CO_2R$  upon the sodium sulphinate  $X.SO_2ONa$  in cold alcohol,  $CO_2$  being evolved. The ethers are not formed by the action of alkyl halogenides upon sulphinates, for by this reaction the isomeric sulphones  $X.SO_2R$  are produced instead (Otto a. Rossing, B. 18, 2493).  $H_2S$  passing through benzene sulphinic ether at  $50^\circ$  forms mercaptan, benzene sulphinic acid, benzene sulphonic acid, and other products. (Otto a. Rossing, B. 20, 2275).  $COCl_2$  converts sodium benzene sulphinate into the anhydride  $(Ph.SO_2)_2O$ , which is v. sol. ether and benzene, and decomposed by water and alcohol into benzene sulphinic acid and ether respectively (Otto, B. 20, 3337).

#### SULPHITES AND HYPOSULPHITES.

SULPHITES are salts of sulphurous acid formed by replacing H in  $H_2SO_3$  by metals. All sulphites may be represented by the formula  $xMO.ySO_3$ , where MO stands for an equivalent of a metallic oxide; the normal sulphites belong to the forms  $M^+SO_3$ ,  $M^{++}SO_3$ ,  $M^{+++}(SO_3)_3$ , and  $M^{IV}(SO_3)_2$ ; the greater number of the acidic sulphites are of the forms  $M^+HSO_3$  and  $M^{++}(HSO_3)_2$ , a few which contain more than one equivalent of acidic radicle to one of basic radicle may be represented as  $M^+SO_3.xSO_3$ . Double sulphites are fairly numerous.

Many sulphites are prepared by passing  $SO_2$  into water wherein metallic hydroxides or carbonates are dissolved or suspended; some are formed by double decomposition from the alkali sulphites. Several metallic sulphites that are insoluble in water can be prepared by the reaction between solutions of the sulphates and solution of  $Na_2SO_3$ ; two main reactions occur, approximately in accordance with the equations (1)  $M^{++}SO_4Aq + Na_2SO_3Aq = M^{++}SO_3 + Na_2SO_4Aq$ , (2)  $M^{++}SO_4Aq + 2H_2O = MO_2H_2 + H_2SO_4Aq$ , so that normal sulphites are formed in some cases and basic sulphites in other cases. This method of forming sulphites has been examined by Seubert a. Elten (Zeit. f. anorg. Chem. 4, 44); they find that normal sulphites are always formed when  $M = Ba, Cd, Ca, Fe^{++}, Pb, Ag, Sr$ , or  $Tl$  (with  $Hg^{++}$  a double sulphite  $HgSO_3.Na_2SO_3.H_2O$  was formed); that normal sulphites are formed at low temperatures, using the salts in the ratio

of equal molecules, when  $M = \text{Mg, Mn, Sn, U}(\text{O}_2)$ , or Zn, but that at higher temperatures, or with more dilute solutions, basic sulphites of these metals are produced; and that basic sulphites are always obtained when  $M = \text{Al, Be, Bi, Cr, Co, Cu, Fe}^{\text{III}}, \text{ or Ni}$ .

The sulphites of the alkali metals, and the acid sulphites of the alkaline earths, are soluble in water; most other sulphites are insoluble. Sulphites in aqueous solution, and many in moist air, readily oxidise to sulphates; salts of other S oxyacids are sometimes formed, and S is frequently separated (*cf.* Pierre, *C. R.* 62, 460; 73, 749). Oxidisers, such as  $\text{ClAq}$ ,  $\text{HNO}_3\text{Aq}$ , &c., quickly convert sulphites into sulphates; sulphite solutions are, therefore, energetic reducers. Solutions of sulphites are readily reduced, giving  $\text{H}_2\text{S}$  or metallic sulphides, by  $\text{SnCl}_2\text{Aq}$ , Zn and  $\text{HClAq}$ , &c. Heated with C, they are reduced to sulphides, sometimes to oxides. Sulphites decompose at a red heat to sulphides and sulphates, or to oxides and  $\text{SO}_2$ . Sulphites are decomposed by almost all acids, not by  $\text{CO}_2\text{Aq}$  of boric acid, giving off  $\text{SO}_2$ . Solutions of sulphites generally form thiosulphates by reacting with  $\text{S}$ ,  $\text{H}_2\text{S}$  or alkali hydrosulphides. Sulphites give sulphates and thiosulphates when heated in  $\text{SO}_2$  (Divers, *C. J.* 47, 205). Sulphites scarcely react with  $\text{POCl}_3$ , according to Divers (*l.c.*); a little metallic chloride and phosphate are formed, but no  $\text{SOCl}_2$ . Divers (*l.c.*; also *C. J.* 49, 577) contends that the normal sulphites have the constitution  $\text{SO}_2\text{OM.M}$ —that is, that they contain the sulphonic group  $\text{SO}_2\text{OM}$ —and that they are not thionyl compounds,  $\text{SO}(\text{OM})_2$ .

**Aluminium sulphites.** The only salt that has been definitely isolated is the *basic sulphite*  $\text{Al}_2\text{O}_3\cdot\text{SO}_2\cdot 4\text{aq}$ ; obtained by dissolving freshly ppt.  $\text{Al}_2\text{O}_3\cdot\text{H}_2$  in  $\text{SO}_2\text{Aq}$ , and heating to  $74^\circ$ , when the salt separates as a white powder. Heated in air gives off  $\text{H}_2\text{O}$  and  $\text{SO}_2$ , and leaves sulphate (Gougginsberg, *A.* 45, 132; confirmed by Röhrig, *J. pr.* [2] 37, 217).

**Ammonium sulphites.** The *normal salt*  $(\text{NH}_4)_2\text{SO}_3\cdot\text{aq}$  was found in the fumes from the residues from gas-works used in the preparation of  $(\text{NH}_4)_2\text{SO}_4$  (Scheitz, *Ar. Ph.* [3] 5, 332); it is prepared by adding absolute alcohol to  $\text{SO}_2\text{Aq}$  made alkaline by  $\text{NH}_3\text{Aq}$ , or by passing moist  $\text{SO}_2$  and moist  $\text{NH}_3$  into absolute alcohol (Muspratt, *P. M.* [3] 30, 414). White monoclinic leaflets; sol. in 1 part water at  $12^\circ$  with disappearance of heat. Does not deliquesce in air, but oxidises gradually to sulphate (Marignac, *Ann. M.* [5] 12, 25). The *acid salt*  $\text{NH}_4\cdot\text{HSO}_3$  is obtained, as very deliquescent rhombic crystals, by saturating a solution of the normal salt with  $\text{SO}_2$  and allowing to crystallise *in vacuo*; loses  $\text{SO}_2$  at the ordinary temperature; S separates on exposure to light; a saturated solution heated to  $150^\circ$  in a sealed tube decomposes to  $\text{S}$ ,  $\text{H}_2\text{SO}_4\text{Aq}$ , and  $(\text{NH}_4)_2\text{SO}_4\text{Aq}$  (Barbaglia a. Gucci, *B.* 13, 2825). The *basic salt*  $3(\text{NH}_4)_2\text{O}\cdot 2\text{SO}_2\cdot 2\text{aq}$  described by Muspratt could not be obtained by Marignac. *Double salts* are described under the various sulphites.

**Barium sulphites.** The *normal salt*  $\text{BaSO}_3$  is prepared by double decomposition from  $\text{BaCl}_2\text{Aq}$  and  $\text{Na}_2\text{SO}_3\text{Aq}$ ; a white powder, insol. water; may be crystallised in hexagonal forms

from warm saturated  $\text{SO}_2\text{Aq}$ ; heated in a closed tube decomposes to  $\text{BaSO}_4$  and BaS (Rammelsberg, *P.* 67, 391). Easily sol.  $\text{HClAq}$  (Johnson, *C. N.* 58, 155; *cf.* Hodges, *ibid.* 128).

**Beryllium sulphites.** No salt has been isolated; a solution of a sulphite (?  $\text{BeSO}_3$ ) is obtained by dissolving  $\text{BeO}\cdot\text{H}_2$  in  $\text{SO}_2\text{Aq}$ , but crystals do not form on evaporation alone or over  $\text{H}_2\text{SO}_4$ ; addition of alcohol causes formation of a thick syrup (Atterberg, *Bl.* [2] 24, 358; *cf.* Berthier, *A. Ch.* [3] 7, 77).

**Bismuth sulphites.** A *basic salt*  $2\text{Bi}_2\text{O}_3\cdot 3\text{SO}_2\cdot 5\text{aq}$  is formed by the action of conc.  $\text{SO}_2\text{Aq}$  on  $\text{BiO}_3\text{H}$  (Röhrig, *J. pr.* [2] 37, 217; *cf.* Muspratt, *P. M.* [3] 30, 414).

**Cadmium sulphites.** The *normal salt*  $\text{CdSO}_3$  is obtained by dissolving  $\text{CdCO}_3$  in  $\text{SO}_2\text{Aq}$ , and crystallising; white, indistinctly crystalline salt; scarcely sol. water; heated gives  $\text{SO}_2$ , CdO, CdS, and  $\text{CdSO}_4$  (Rammelsberg, *P.* 67, 256). By treating Cd with  $\text{SO}_2\text{Aq}$ , filtering from CdS, and concentrating carefully, Fordos a. Gélis obtained the *dihydrate*  $\text{CdSO}_3\cdot 2\text{aq}$ ; the same salt was obtained by Muspratt (*l.c.*); confirmed by Röhrig (*l.c.*). Denigès (*Bl.* [3] 7, 569) failed to obtain this hydrate, but states that a *trihydrate* is produced by mixing equal vols. of 10 p.c. solutions of  $\text{CdSO}_4$  acidified with acetic acid and  $\text{Na}_2\text{SO}_3$ . A *double ammonium-cadmium sulphite*  $\text{CdSO}_3\cdot(\text{NH}_4)_2\text{SO}_3$  was obtained by Rammelsberg (*l.c.*).

**Calcium sulphites.** The *normal salt*  $\text{CaSO}_3\cdot 2\text{aq}$  is prepared by ppg.  $\text{CaCl}_2\text{Aq}$  by  $\text{Na}_2\text{SO}_3\text{Aq}$ , dissolving in  $\text{SO}_2\text{Aq}$ , and crystallising; it forms small lustrous crystals (Muspratt, *l.c.*). Also obtained by passing  $\text{SO}_2$  into water with  $\text{CaCO}_3$  in suspension (Röhrig, *l.c.*). Heated to  $80^\circ$  gives  $2\text{CaSO}_3\cdot\text{aq}$ , and loses all water at  $100^\circ$  (R., *l.c.*). R. failed to isolate any acid salt.

**Chromium sulphites.** A *basic chromic salt*  $2\text{Cr}_2\text{O}_3\cdot 3\text{SO}_2\cdot 16\text{aq}$  was obtained by Muspratt (*P. M.* [3] 30, 414), as a pale-green pp., by adding alcohol to solution of  $\text{CrO}_3\cdot\text{H}_2$  in  $\text{SO}_2\text{Aq}$ ; composition confirmed by Röhrig (*J. pr.* [2] 37, 217). Alkali sulphite solutions do not ppt. solutions of chromic salts even after long boiling (Berthier, *A. Ch.* [3] 7, 77). By adding  $\text{K}_2\text{SO}_4\text{Aq}$  to  $\text{CrCl}_3\text{Aq}$ , Moberg (*J.* 1847–8, 413) obtained a reddish pp. which was perhaps a *chromous sulphite*.

**Cobalt sulphites.** The *normal cobaltous salt*  $\text{CoSO}_3\cdot 5\text{aq}$  was obtained by Muspratt (*l.c.*), as a red granular pp., by passing  $\text{SO}_2$  into water with  $\text{CoCO}_3$  in suspension, boiling out air from the solution, and letting cool in a closed vessel. By evaporating in H, Rammelsberg (*P.* 67, 391) obtained the *trihydrate*; the existence of both hydrates has been confirmed by Röhrig (*l.c.*). *Double salts*  $\text{CoSO}_3\cdot\text{K}_2\text{SO}_3$  and  $2\text{CoSO}_3\cdot\text{Na}_2\text{SO}_3\cdot\text{CoO}$  were obtained by Schultz (*J.* 1865, 270) by heating  $\text{CoSO}_3$  or  $\text{CoCl}_2$  with alkali sulphite solutions. *Double salts of cobaltic sulphite*  $\text{Co}_2(\text{SO}_3)_2\cdot\text{M}_2\text{SO}_3$ , where  $M = \text{K or Na}$ , were obtained by Geuther (*A.* 128, 157) by continued heating of  $\text{CoO}\cdot\text{H}_2$  with fresh quantities of conc.  $\text{M}_2\text{SO}_4\text{Aq}$ .

**Copper sulphites.** Neither cuprous nor cupric sulphite has been isolated, but several double salts of cuprous sulphite are known. The green liquid obtained by dissolving  $\text{CuCO}_3$  (Berthier, *A. Ch.* [3] 7, 86) or  $\text{CuO}\cdot\text{H}_2$  (Böttger, *A.* 39, 178)

in  $\text{SO}_2\text{Aq}$  probably contains  $\text{Cu}_2\text{SO}_3$ ; but this solution rapidly decomposes with separation of a red pp. and formation of  $\text{CuSO}_4\text{Aq}$ . The red solution formed by passing  $\text{SO}_2$  into water with freshly prepared  $\text{Cu}_2\text{SO}_3(\text{NH}_4)_2\text{SO}_4$  (*v. infra*) in solution was supposed to contain  $\text{Cu}_2\text{SO}_3$  by Rogojski (*J. pr.* 53, 403); but Péan de Saint-Gilles obtained only  $\text{Cu}_2\text{SO}_3 \cdot \text{CuSO}_4 \cdot 2\text{aq}$  from this solution (*A. Ch.* [3] 42, 23), and this was confirmed by Svensson (*B.* 4, 713).

According to Newbury (*Am.* 14, 232), a *basic cupric sulphite*  $6\text{CuO} \cdot 4\text{SO}_3 \cdot 3\text{aq}$  is formed by passing  $\text{SO}_2$  into cold water with  $\text{CuO} \cdot \text{H}_2$  in suspension, and sending a stream of air into the green solution so formed until a bright-yellow pp. is produced. When this basic salt is boiled with water for a few minutes  $\text{CuSO}_4\text{Aq}$  is formed, and a brown pp. is thrown down. The brown pp. is thought by N. to be  $\text{Cu}_2\text{SO}_3$ ; on continued boiling with water it gives off  $\text{SO}_2$ , and  $\text{Cu}_2\text{O}$  remains.

*Double cupro-cupric sulphites.* The *dihydrated salt*  $\text{Cu}_2\text{SO}_3 \cdot \text{CuSO}_4 \cdot 2\text{aq}$  was obtained by Chevreul (*A. Ch.* 83, 183) by heating  $\text{CuO}$  or  $\text{CuCO}_3$  with  $\text{SO}_2\text{Aq}$ ; it is also prepared by boiling  $\text{CuSO}_4\text{Aq}$  with solution of an alkali sulphite or thiosulphate, by boiling the green double salt  $\text{Cu}_2\text{SO}_3(\text{NH}_4)_2\text{SO}_4$  (*infra*) with water (P. de St.-G., *l.c.*), by passing  $\text{SO}_2$  into conc.  $\text{Cu}(\text{C}_2\text{H}_3\text{O}_2)_2\text{Aq}$  at  $65^\circ$  till the yellow pp. that forms is dissolved, and then letting stand in air (Étard, *C. R.* 93, 725), and by passing a slow stream of  $\text{SO}_2$  into 10 p.c.  $\text{CuSO}_4\text{Aq}$  containing a roll of thin sheet Cu till the liquid is almost colourless (the salt deposits on the Cu) (Newbury, *Am.* 14, 232). Translucent, garnet-red octahedra; S.G. 3.57; gives up  $2\text{H}_2\text{O}$ , and also  $\text{SO}_2$ , above  $150^\circ$ , and at a higher temperature leaves  $\text{Cu}_2\text{O}$  with some  $\text{CuSO}_4$  (Rammelsberg, *P.* 67, 391). Soluble  $\text{SO}_2\text{Aq}$ ,  $\text{HClAq}$ , and  $\text{NH}_4\text{Aq}$ ;  $\text{KOH Aq}$  ppts. hydrates of  $\text{CuO}$  and  $\text{Cu}_2\text{O}$ ; heated with water to  $200^\circ$  gives  $\text{CuSO}_4\text{Aq}$  and Cu in crystalline leaflets (Geitner, *A.* 129, 350). The *pentahydrate*  $\text{Cu}_2\text{SO}_3 \cdot \text{CuSO}_4 \cdot 5\text{aq}$  separates, as a greenish-yellow pp., from conc.  $\text{Cu}(\text{C}_2\text{H}_3\text{O}_2)_2\text{Aq}$ , into which a slow stream of  $\text{SO}_2$  has been passed till the liquid has become emerald-green (P. de St.-G., *l.c.*). Easily sol.  $\text{SO}_2\text{Aq}$  or acetic acid, also in solutions of cupric salts and in  $\text{NH}_4\text{Aq}$ ; when boiled with water the red dihydrate is formed.

*Double salts of cuprous sulphite with alkali sulphites* are readily produced by the reaction of conc. solutions of alkali sulphites with solutions of cupric salts. These double salts are colourless and crystalline; their composition is  $x\text{Cu}_2\text{SO}_3 \cdot y\text{M}_2\text{SO}_3 \cdot z\text{aq}$  ( $x$  generally = 1), where  $\text{M} = \text{NH}_4$ , K, or Na (for details of preparation, composition, and properties *v.* Rogojski, *J. pr.* 53, 403; Péan de Saint-Gilles, *A. Ch.* [3] 42, 23; Vohl, *J. pr.* 95, 218; and Svensson, *B.* 4, 713). Some *acid salts* of the form  $\text{Cu}_2\text{SO}_3 \cdot x\text{M}_2\text{SO}_3 \cdot y\text{SO}_2 \cdot z\text{aq}$  have also been prepared (S., *l.c.*), and some *salts* of alkali sulphites with both  $\text{Cu}_2\text{SO}_3$  and  $\text{CuSO}_4$  (P. de St.-G., *l.c.*; R., *l.c.*).

*Didymium sulphites.* The *normal salt*  $\text{Dl}_2(\text{SO}_3)_2$  was obtained, as a reddish-white powder, by passing  $\text{SO}_2$  into water with  $\text{Dl}_2\text{O}_3$  in suspension, and boiling off excess of  $\text{SO}_2$  (Marignac, *A. Ch.* [3] 58, 148; Cleve, *Bt.* [2] 89, 161).

*Gold sulphites.* No gold sulphite has been isolated. *Double salts* of  $\text{Au}_2\text{SO}_3$  with  $\text{Am}_2\text{SO}_3$  and  $\text{Na}_2\text{SO}_3$  of the form  $\text{Au}_2\text{SO}_3 \cdot 3\text{M}_2\text{SO}_3 \cdot 3\text{aq}$  are known; also a Ba salt  $\text{Au}_2\text{SO}_3 \cdot 3\text{BaSO}_3 \cdot \text{aq}$ . The Na salt is obtained by adding  $\text{Na}_2\text{SO}_3\text{Aq}$  to a boiling alkaline solution of  $\text{NaAuO}_2$ , or by saturating  $\text{NaAuO}_2\text{Aq}$  at  $50^\circ$  with  $\text{SO}_2$ , then carefully adding  $\text{BaCl}_2\text{Aq}$  to the solution till free  $\text{H}_2\text{SO}_4$  and  $\text{H}_2\text{SO}_3$  are p.p.d., filtering, adding more  $\text{BaCl}_2\text{Aq}$ , quickly filtering off the purple-red  $\text{Au}_2\text{SO}_3 \cdot 3\text{BaSO}_3 \cdot \text{aq}$  that separates, washing the pp. rapidly out of contact with air, decomposing it by the proper quantity of  $\text{Na}_2\text{CO}_3\text{Aq}$ , adding some alcohol to the solution, filtering off any Ba salt that ppts., and adding more alcohol, when the Na salt separates as an orange-red, very easily decomposed, pp. (*v.* Himly, *A.* 56, 252; 59, 95). When  $\text{AuCl}_3\text{Aq}$  is added, drop by drop, to a warm solution of  $(\text{NH}_4)_2\text{SO}_3$  in conc.  $\text{NH}_4\text{Aq}$ , white, lustrous, six-sided plates separate of the salt  $(\text{NH}_4)_2\text{SO}_3 \cdot 3(\text{NH}_4\text{Au})_2\text{SO}_3 \cdot 3\text{aq}$ ; the mother-liquor from this salt yields the salt  $\text{Au}_2\text{SO}_3 \cdot 3(\text{NH}_4)_2\text{SO}_3 \cdot 3\text{aq}$ , very similar to the corresponding Na salt (Haase, *Z.* 1869, 535).

*Indium sulphites.* The only salt that has been isolated is a *basic salt*  $2\text{In}_2\text{O}_3 \cdot 3\text{SO}_2 \cdot 8\text{aq}$ . Obtained by boiling a solution of a salt of In with excess of  $\text{NaHSO}_4\text{Aq}$ ; insol. water, sol. in dilute acids; loses  $3\text{H}_2\text{O}$  at  $100^\circ$ , and all water at  $260^\circ$ ; decomposed at  $280^\circ$ , giving off  $\text{SO}_2$  and leaving  $\text{In}_2\text{O}_3$  (Bayer, *A.* 158, 372).

*Iridium sulphites.* The *normal iridic salt*  $\text{Ir}_2(\text{SO}_3)_3 \cdot 6\text{aq}$  is obtained, in yellow crystals, by passing  $\text{SO}_2$  into water with  $\text{IrO}_2\text{H}_3$  in suspension, filtering and evaporating. The salt loses all water at  $160^\circ$ – $180^\circ$ ; at a higher temperature  $\text{Ir}_2\text{O}_3$  remains; sl. sol. water, easily sol. acids; decomposed by boiling with  $\text{KOH Aq}$  with separation of  $\text{Ir}_2\text{O}_3$  (Birnbbaum, *A.* 136, 179). The insoluble matter that remains on treating  $\text{IrO}_2\text{H}_3$  in water with  $\text{SO}_2$  is a *basic salt*  $\text{Ir}_2\text{O}_3 \cdot \text{SO}_3 \cdot 4\text{aq}$  (Birnbbaum, *l.c.*). *Double salts of iridous sulphite* were obtained by Seubert (*B.* 11, 1761) in separating Ir from Rh by means of  $\text{Na}_2\text{SO}_3$  (by Bunson's method, *A.* 146, 274). Seubert gave the formulae  $\text{IrSO}_3 \cdot 3\text{Na}_2\text{SO}_3 \cdot 10\text{aq}$  and  $\text{IrH}_2(\text{SO}_3)_2 \cdot 3\text{Na}_2\text{SO}_3 \cdot x\text{aq}$ ,  $x$  being = 4 and 10, to the salts he prepared.

*Iron sulphites.* The *normal ferrous salt*  $\text{FeSO}_3 \cdot 3\text{aq}$  is formed, along with  $\text{FeSO}_4$ , by dissolving iron wire in  $\text{SO}_2\text{Aq}$  out of contact with air; on evaporating (out of air) the sulphite crystallises out, leaving the thiosulphate in solution (Fordos, *A. Gélis, J. Ph.* [3] 4, 333; *cf.* Koene, *P.* 63, 245, 631; also Muspratt, *P. M.* [3] 80, 414). Sl. sol. water, easily sol.  $\text{SO}_2\text{Aq}$ ; loses  $\text{H}_2\text{O}$ , and then (at  $250^\circ$ )  $\text{SO}_2$ , on heating. *Lusic ferric salts* are formed by reacting on ferric salt solutions with alkali sulphites; on adding alcohol to the red liquids thus formed, Koene (*P.* 63, 245, 481) obtained the salts  $\text{Fe}_2\text{O}_3 \cdot \text{SO}_3 \cdot 6\text{aq}$  and  $2\text{Fe}_2\text{O}_3 \cdot 3\text{SO}_3$  (*cf.* Muspratt, *l.c.*). By passing  $\text{SO}_2$  into water with  $\text{FeO} \cdot \text{H}_2$  in suspension, and adding  $\text{KOH Aq}$ , Muspratt (*l.c.*) obtained the *double salt*  $\text{Fe}_2\text{O}_3 \cdot \text{SO}_3 \cdot 2\text{K}_2\text{SO}_3 \cdot 5\text{aq}$ .

*Lead sulphites.* Only the *normal salt*  $\text{PbSO}_3$  has been obtained; a white powder, insol. water, formed by adding  $\text{Na}_2\text{SO}_3\text{Aq}$  to solution of a salt of Pb (confirmed by Röhrig, *J. pr.* [2] 87, 217).

**Lithium sulphites.** The normal salt  $\text{Li}_2\text{SO}_3$ , aq. is prepared by passing  $\text{SO}_2$  into water with  $\text{Li}_2\text{CO}_3$  in suspension, till  $\text{CO}_2$  ceases to be given off, and evaporating on a water-bath or over  $\text{H}_2\text{SO}_4$  (Röhrig, *J. pr.* [2] 37, 217). Danson (*C. J.* 2, 206) represented the salt as a *hexahydrate*. By adding ether to the solution obtained from  $\text{Li}_2\text{CO}_3$ , as described, R. got the *dihydrate*  $\text{Li}_2\text{SO}_3 \cdot 2\text{aq}$ . Easily sol. water, somewhat sol. alcohol, very sl. sol. ether; oxidised in moist air. Röhrig failed to obtain an acid salt. By adding the proper quantity of  $\text{K}_2\text{CO}_3$  to the acid solution of  $\text{Li}_2\text{CO}_3$  in  $\text{SO}_2$  aq. evaporating to a syrup, and placing in a freezing mixture of snow and salt, R. obtained the *double salt*  $2\text{LiKSO}_3$ , aq.; by a similar process he got monoclinic crystals of  $6\text{Li}_2\text{SO}_3 \cdot \text{Na}_2\text{SO}_3 \cdot 8\text{aq}$  (*J. pr.* [2] 37, 217).

**Magnesium sulphites.** The normal salt  $\text{MgSO}_3$ , aq. is formed by suspending *magnesia alba* in water, passing in  $\text{SO}_2$ , and concentrating the solution (Rammelsberg, *P.* 52, 89); if evaporation is carried on over  $\text{H}_2\text{SO}_4$  (Röhrig, *l.c.*), or *in vacuo* below  $100^\circ$  (Hartog, *C. R.* 104, 1793), the *hexahydrate* separates; if evaporation proceeds above  $100^\circ$  the *trihydrate* is obtained (Muspratt, *l.c.*; R., *l.c.*; H., *l.c.*). Slowly oxidises in air to sulphate; loses all water at  $200^\circ$ ; when more strongly heated the salt loses  $\text{SO}_2$  and leaves  $\text{MgO}$ .

**Double salts** with  $(\text{NH}_4)_2\text{SO}_3$  are formed by mixing the constituents and evaporating; also by dissolving  $\text{MgO} \cdot \text{H}_2$  in cold  $(\text{NH}_4)_2\text{SO}_3$  aq. (Rammelsberg, *P.* 94, 507; Hartog, *l.c.*).

**Manganese sulphites.** Several hydrates of the normal *manganous salt*  $\text{MnSO}_3$  have been described. By adding alkali sulphite solution to dilute  $\text{MnCl}_2$  aq. so long as the pp. that forms dissolves again, and then letting stand, monoclinic crystals of the *trihydrate*  $\text{MnSO}_3 \cdot 3\text{aq}$  are obtained; this hydrate is also formed by mixing 10 p.c. of  $\text{MnSO}_4$  aq. acidified with acetic acid, and  $\text{Na}_2\text{SO}_3$  (Denigès, *Bt.* [3] 7, 569); if  $\text{Na}_2\text{SO}_3$  aq. is added to hot dilute  $\text{MnCl}_2$  aq. the *monohydrate* is said to be produced. (Rammelsberg (*P.* 67, 245, 391) gives the formula  $2\text{MnSO}_3 \cdot 5\text{aq}$  to the salt obtained by reacting on Mn acetate solution with  $\text{Na}_2\text{SO}_3$  aq. and this is confirmed by Röhrig (*J. pr.* [2] 37, 217; cf. also Muspratt, *P. M.* [3] 30, 414). **Double salts**  $\text{MnSO}_3 \cdot \text{K}_2\text{SO}_3$  and  $2\text{MnSO}_3 \cdot \text{K}_2\text{SO}_3$  were prepared by Gorgeu (*C. R.* 96, 376) by saturating 20 p.c.  $\text{K}_2\text{SO}_3$  aq. with  $\text{SO}_2$ , adding 4 p.c.  $\text{MnSO}_3$  3aq. and evaporating over an absorbent of  $\text{SO}_2$ ; double Mn-Na salts are also described by G. (*l.c.*).

**Mercury sulphites.** According to Péan de Saint-Gilles (*C. R.* 34, 905) the normal *mercuric salt*  $\text{HgSO}_3$  is formed by adding dilute  $\text{Na}_2\text{SO}_3$  aq. to a very conc. solution of  $\text{Hg}(\text{NO}_3)_2$  free from excess of acid; it is, however, difficult to obtain the salt free from basic sulphites. The *basic mercuric sulphite*  $2\text{HgO} \cdot \text{SO}_3$  was obtained pure by P. de St.-G. by using solution of basic mercuric nitrate. The normal salt is easily decomposed; boiling water produces  $\text{Hg}_2\text{SO}_3$  and  $\text{Hg}$ . Boiling water is said (P. de St.-G., *l.c.*) to convert the basic salt into the isomeric compound  $\text{Hg}_2\text{SO}_3$  ( $2\text{HgO} \cdot \text{SO}_3 = \text{Hg}_2\text{O} \cdot \text{SO}_3$ ). Divers a. Shimidzu (*C. J.* 49, 538) say that normal mercuric sulphite cannot be isolated; the reaction of  $\text{Na}_2\text{SO}_3$  aq. with  $\text{Hg}(\text{NO}_3)_2$  aq. produces at first the basic salt  $2[2\text{HgO} \cdot \text{SO}_3]$  aq. and then a

salt which is most simply represented as  $\text{HgSO}_3 \cdot \text{Hg}_2\text{SO}_3 \cdot 4\text{aq}$ , and which is called *mercurous* (or *mercurio-mercuric*) *sulphite* by D. a. S., and represented by them as

$\text{Hg} \left\langle \begin{smallmatrix} \text{SO}_3 \cdot \text{O} \\ \text{SO}_3 \cdot \text{O} \end{smallmatrix} \right\rangle \text{Hg}_2 \cdot 4\text{aq}$ . D. a. S. represent the basic salt as  $\text{Hg} \left\langle \begin{smallmatrix} \text{SO}_3 \cdot \text{OHgO} \\ \text{SO}_3 \cdot \text{OHgO} \end{smallmatrix} \right\rangle \text{Hg}$ , aq. and call it *mercuric oxyulphite*.

For the best conditions of preparation of  $2\text{HgO} \cdot \text{SO}_3$ , v. D. a. S., *l.c.*, p. 550, and for the reactions of this salt v. *ibid.* pp. 546-50; for preparation of mercurous sulphite v. *ibid.* p. 564, and for the reactions of this salt, pp. 559-63.

By adding dilute  $\text{Na}_2\text{SO}_3$  aq. to moist  $\text{Hg}_2\text{SO}_4$  or to  $\text{HgNO}_3$  aq., D. a. S. (*l.c.*, p. 572) obtained a greyish-black amorphous solid to which they gave the formula  $\text{Hg}_2(\text{SO}_3)_2$  aq. the constitution  $\text{Hg} \left\langle \begin{smallmatrix} \text{SO}_3 \cdot \text{O} \\ \text{SO}_3 \cdot \text{O} \end{smallmatrix} \right\rangle \text{Hg}_2$ , aq. and the name *mercuric hypomercurous sulphite* or *hypomercurous sulphite*.

For the best method of preparing this salt (action of  $\text{SO}_2$  aq. on  $\text{Hg}_2\text{SO}_4$  or  $\text{HgNO}_3$ ) v. D. a. S., *l.c.*, p. 571; for the reactions of the salt v. pp. 567-70. It is evident that the formula given to this salt is the same as that of normal *mercurous sulphite* ( $\text{Hg}_2(\text{SO}_3)_2 = 2\text{Hg} \cdot \text{SO}_3$ ); the salt is produced from mercurous compounds, and in many of its reactions yields mercurous compounds; D. a. S. insist that the salt belongs to a new class of Hg compounds that contain what they call the 'hypomercurous radicle.'

By treating solid  $\text{HgCl}_2$  with  $\text{NaHSO}_3$  aq., Wicke (*A.* 95, 176) obtained a solution that deposited a white crystalline powder to which he gave the composition  $\text{Hg}(\text{HSO}_3)_2$ —i.e. *acid mercuric sulphite*. According to D. a. S. (*l.c.*, p. 554) the pp. is  $\text{HgSO}_3 \cdot \text{Na}_2\text{SO}_3$  aq. By reacting on  $\text{HgO}$  with  $\text{SO}_2$  aq. a white solid is formed, together with a solution containing a compound of Hg. Rammelsberg thought that the white solid was a basic mercurous sulphite of varying composition, and that the solution contained  $\text{Hg}_2\text{SO}_3$  (*P.* 67, 405; the reaction was also examined by P. de St.-G. and by Vogel). D. a. S. say that the white residue is  $\text{HgSO}_3 \cdot \text{Hg}_2\text{SO}_3 \cdot 4\text{aq}$  (mercurous sulphite, according to D. a. S.); by using freshly ppd.  $\text{HgO}$  suspended in water, and adding a little of this to  $\text{SO}_2$  aq. (nearly free from  $\text{H}_2\text{SO}_4$ ), D. a. S. obtained a clear solution which reacted as a solution of  $\text{HgSO}_3$  in  $\text{H}_2\text{SO}_4$ , and which they regarded as a *solution of acid mercuric sulphite*,  $\text{Hg}(\text{HSO}_3)_2$  (v. *l.c.*, pp. 554-8). Several *double salts of mercuric sulphite with alkali sulphites* have been isolated. The chief are  $\text{HgSO}_3 \cdot \text{M}_2\text{SO}_3 \cdot x\text{aq}$ , where  $\text{M} = \text{NH}_4$ , K, or Na, and  $2\text{HgSO}_3 \cdot \text{Na}_2\text{SO}_3$  aq. (v. P. de St.-G., *C. R.* 34, 905; Hirtzel, *A.* 84, 258; D. a. S., *l.c.*, pp. 538-46). D. a. S. regard these double salts as alkali derivatives of the hypothetical acid

$\text{Hg} \left\langle \begin{smallmatrix} \text{SO}_3 \cdot \text{OH} \\ \text{SO}_3 \cdot \text{OH} \end{smallmatrix} \right\rangle$  (they greatly doubt the existence of the salt  $2\text{HgSO}_3 \cdot \text{Na}_2\text{SO}_3$ , described by P. de St.-G.); this view is confirmed by Barth's measurements of the electrolytic conductivities, and the freezing-points, of solutions of these salts (*Z. P. C.* 9, 176); Barth's results point to the dissociation in dilute aqueous solution of these salts into three ions,  $\text{Hg}_2\text{SO}_3$ , R. and B'.

**Nickel sulphites.** The normal salt  $\text{NiSO}_3$ , 6aq. separates, in green tetrahydrocrys.

als, on slowly evaporating a solution formed by passing  $\text{SO}_2$  into water with  $\text{NiO}$ . 2aq in suspension (Rammelsberg, *P.* 67, 391). By boiling the solution of  $\text{NiO}$ . 2aq in  $\text{SO}_2$ aq, Muspratt (*P. M.* [8] 30, 414) obtained a tetrahydrate  $\text{NiSO}_4 \cdot 4\text{aq}$ ; this hydrate was also obtained by Röhrig (*J. pr.* [2] 37, 217) by quickly evaporating the solution at c.  $150^\circ$ . The compound with ammonia,  $\text{NiSO}_4 \cdot 3\text{NH}_3 \cdot 3\text{aq}$ , separates, as a blue crystalline pp., on adding alcohol to an ammoniacal solution of  $\text{NiSO}_4$  (Rammelsberg, *l.c.*).

**Osmium sulphites.** The normal salt  $\text{OsSO}_4$  was obtained by Claus (*J. pr.* 90, 65) by treating  $\text{OsO}_4$ aq with excess of  $\text{SO}_2$ , and evaporating or adding  $\text{Na}_2\text{CO}_3$  or  $\text{Na}_2\text{SO}_4$ ; after drying the salt is a blackish-blue powder, insol. water, sol.  $\text{HCl}$ aq without giving off  $\text{SO}_2$ , reppd. from this solution by  $\text{KOH}$  or  $\text{K}_2\text{CO}_3$ , decomposed to  $\text{K}_2\text{SO}_4$  and  $\text{OsO}_4$ . 2aq by long boiling with conc.  $\text{KOH}$ aq. When moist the salt oxidises in air to  $\text{OsSO}_4$ . The double salt  $\text{OsSO}_4 \cdot 2\text{K}_2\text{SO}_4 \cdot 2\text{KH}_2\text{SO}_4 \cdot 4\text{aq}$  was obtained by Claus (*A.* 63, 355) as a pale rose-red crystalline powder, by heating  $\text{K}_2\text{OsCl}_6$  with  $\text{K}_2\text{SO}_4$ aq.

**Palladium sulphites.** Only the double pallado-sodium salt  $\text{PdSO}_4 \cdot 3\text{Na}_2\text{SO}_4 \cdot 2\text{aq}$  has been isolated; a white pp. obtained by dropping  $\text{NaOH}$ aq into  $\text{PdCl}_4$ aq, after adding  $\text{SO}_2$  (Wöhler, *A.* 174, 199).

**Platinum sulphites.** Neither platinosulphite  $\text{PtSO}_4$  nor platinisulphite  $\text{Pt}(\text{SO}_3)_2$  has been isolated. Several salts which may be regarded as double compounds of  $\text{PtSO}_4$ , but are better classed as platinosulphonates or platino-sulphites, have been obtained; they are shortly described under PLATINO-SULPHONATES (this vol., p. 285). By passing  $\text{SO}_2$  into water with  $\text{PtO}_2 \cdot \text{H}_2$  in suspension, and adding alkali sulphites to the dark-red liquid so formed, Birnbaum (*A.* 139, 172) obtained double salts of the form  $\text{PtO} \cdot \text{SO}_3 \cdot x\text{M}_2\text{SO}_4 \cdot y\text{aq}$ , where  $\text{M} = \text{K}$  or  $\text{Na}$ ,  $x$  varied from 1 to 2, and  $y$  also from 1 to 2. These salts gave no pp. of  $\text{BaSO}_4$  with  $\text{BaCl}_2$ aq, with  $\text{HCl}$ aq  $\text{SO}_2$  was given off and  $\text{PtCl}_2$  formed; hence they are better classed as double salts of platinyli sulphite,  $\text{PtO} \cdot \text{SO}_3$ , than of platinous sulphate  $\text{PtSO}_4$ .

**Potassium sulphites.** The normal salt  $\text{K}_2\text{SO}_3 \cdot 2\text{aq}$  is obtained, in large, deliquescent, monoclinic prisms, by passing  $\text{SO}_2$  into  $\text{K}_2\text{CO}_3$ aq as long as  $\text{CO}_2$  is given off, and evaporating over  $\text{H}_2\text{SO}_4$  at the ordinary temperature (Muspratt, *P. M.* [3] 30, 414). More soluble cold than hot water; decomposed by heat to  $\text{K}_2\text{S}$  and  $\text{K}_2\text{SO}_4$  (Rammelsberg, *A.* 50, 259; results of M. and R. confirmed by Röhrig, *J. pr.* [2] 37, 217; v. also Hartog, *C. R.* 109, 179, 221, 436). The acid salt  $\text{KHSO}_3$  separates in white needles on adding alcohol to a solution of the normal salt saturated with  $\text{SO}_2$  (M., *l.c.*; confirmed by Röhrig, *l.c.*). By passing  $\text{SO}_2$  into hot saturated  $\text{K}_2\text{CO}_3$  till  $\text{CO}_2$  ceased to come off and the solution was greenish, and then allowing to cool, Muspratt (*l.c.*) obtained hard monoclinic crystals of the acid salt  $\text{K}_2\text{SO}_3 \cdot \text{SO}_2 (= \text{K}_2\text{S}_2\text{O}_5)$ , sometimes called *pyrosulphite*; only sl. sol. water; decomposed by heat to  $\text{K}_2\text{SO}_4$ ,  $\text{SO}_2$ , and S (confirmed by Röhrig, *l.c.*). Dilute  $\text{K}_2\text{SO}_3$ aq heated in a closed tube to  $100^\circ$  and then let stand is very slowly decomposed to  $\text{K}_2\text{SO}_4$ ,  $\text{H}_2\text{S}$ ,  $\text{O}_2$ , and S (Saint-Pierre, *C. R.* 62, 460; 73, 749).  $\text{K}_2\text{SO}_3$ aq with  $\text{KNO}_3$ aq

gives K salts of various acids; v. SULPHUR OXACIDS, NITROGEN DERIVATIVES OF (p. 619).

**Double sulphites of potassium and sodium.** Schwicker (*B.* 22, 1728) obtained two distinct salts  $\text{KNaSO}_3 \cdot 2\text{aq}$ ; one by neutralising conc.  $\text{KHSO}_3$ aq by the proper quantity of  $\text{Na}_2\text{CO}_3$ , and evaporating over  $\text{H}_2\text{SO}_4$ , the other by adding  $\text{K}_2\text{CO}_3$  to  $\text{NaHSO}_3$ aq. Röhrig (*J. pr.* [2] 37, 217) ppts. the salts by adding alcohol, or better ether. The first salt, heated with  $\text{EtI}$  to  $140^\circ$ , gives  $4(\text{SO}_3 \cdot \text{Et} \cdot \text{OK}) \cdot \text{NaI}$ , the second gives  $4(\text{SO}_3 \cdot \text{Et} \cdot \text{ONa}) \cdot \text{KI}$ ; hence the first salt seems to be  $\text{NaSO}_3 \cdot \text{OK}$  and the other  $\text{KSO}_3 \cdot \text{ONa}$ . Schwicker assigns different quantities of crystalline water to the salts, viz.  $\text{NaSO}_3 \cdot \text{OK} \cdot 2\text{aq}$  and  $\text{KSO}_3 \cdot \text{ONa} \cdot \text{aq}$ ; Röhrig (*l.c.*) gives 2aq to both salts. The two salts seem to be isomeric. Aqueous solutions of these salts have identical electrolytic conductivities, as would be expected (Barth, *Z. P. C.* 9, 176). Schwicker (*l.c.*) also describes the salts  $\text{KNa} \cdot \text{H}(\text{SO}_3)_2 \cdot 4\text{aq}$  and  $\text{K} \cdot \text{NaH}(\text{SO}_3)_2 \cdot 3\text{aq}$ . Hartog (*C. R.* 109, 179, 221, 436) describes the salts  $\text{K}_2\text{SO}_3 \cdot 2\text{Na}_2\text{SO}_3 \cdot \text{SO}_2 \cdot 9\text{aq} (= \text{K}_2\text{O} \cdot 2\text{Na}_2\text{O} \cdot \text{ASO}_2 \cdot 9\text{aq})$  and  $2\text{K}_2\text{SO}_3 \cdot (\text{NH}_4)_2\text{SO}_3 \cdot \text{SO}_2 \cdot 9\text{aq} (= 2\text{K}_2\text{O} \cdot (\text{NH}_4)_2\text{O} \cdot \text{ASO}_2 \cdot 9\text{aq})$ .

For other double salts of potassium sulphite v. *supra*, cobalt sulphites, copper sulphites, iron sulphites, lithium sulphites, manganese sulphites, mercury sulphites, osmium sulphites, and platinum sulphites; and *infra*, ruthenium sulphites and silver sulphites.

**Rhodium sulphites.** The normal rhodic salt  $\text{Rh}_2(\text{SO}_3)_3 \cdot 6\text{aq}$  is prepared, as a yellowish crystalline mass, by dissolving  $\text{RhO}_2 \cdot \text{H}_2$  in  $\text{SO}_2$ aq and evaporating; fairly sol. water, insol. alcohol (Bunsen, *A.* 146, 265). The double rhodous salt  $4\text{RhSO}_3 \cdot 6\text{Na}_2\text{SO}_3 \cdot 9\text{aq}$  is obtained by treating  $\text{Na}_2\text{RhCl}_6 \cdot 12\text{aq}$  with excess of  $\text{NaHSO}_3$ aq (Bunsen, *l.c.*); it has been examined by Seubert a. Kobbé (*B.* 23, 2556), who prepared it by heating a solution of  $\text{RhCl}_3 \cdot 4\text{aq}$  with excess of  $\text{NaHSO}_3$ aq for some time, washing the pp. with cold water, and drying over  $\text{P}_2\text{O}_5$ . Pale-yellow solid; very sl. sol. hot water; dissolves in dilute  $\text{HNO}_3$ aq, giving off  $\text{SO}_2$ ; warmed with conc.  $\text{H}_2\text{SO}_4$  forms  $\text{Rh}_2(\text{SO}_4)_3 \cdot \text{Na}_2\text{SO}_4$  (B., *l.c.*; S. a. K., *l.c.*).

**Ruthenium sulphites.** Only the double rutheno-potassium salt  $\text{RuSO}_3 \cdot \text{K}_2\text{SO}_3$  has been isolated; prepared by heating  $\text{K}_2\text{RuCl}_6$ aq with  $\text{K}_2\text{SO}_3$ aq till a dark-red solution is formed, evaporating to dryness, dissolving, again evaporating to dryness, and repeating these processes till a pure white residue is obtained (Claus, *J. pr.* 42, 351).

**Silver sulphites.** The normal salt  $\text{Ag}_2\text{SO}_3$  forms small, white lustrous crystals; obtained by treating  $\text{AgNO}_3$ aq with alkali sulphite solution or with  $\text{SO}_2$ aq; if excess of  $\text{SO}_2$ aq is allowed to remain in contact with the salt for some time  $\text{Ag}$  is formed (H. Rose, *P.* 88, 240). Darkens in air (Muspratt, *P. M.* [3] 30, 414; Sodeau, *C. R.* 65, 102?); products depend on method of preparation of the salt (v. *Stas*, *Stas Nouv. R.*). Heated alone, or with water, to  $100^\circ$  gives  $\text{Ag}_2\text{SO}_3$ ,  $\text{Ag}$ , and  $\text{SO}_2$  (Berthier, *A. Ch.* [3] 7, 82; cf. Geitner, *J.* 1864, 142, who says that decomposition begins at  $200^\circ$ ). Scarcely sol. water or  $\text{SO}_2$ aq; sol.  $\text{NH}_3$ aq (Berthier, *l.c.*), also in alkali sulphite solutions.

**Double salts.**  $\text{AgNaSO}_3$ , 2aq; small lustrous needles, formed by dissolving  $\text{Ag}_2\text{SO}_3$  in hot saturated  $\text{Na}_2\text{SO}_3$  aq, letting cool, and pressing salt that separates (cannot be washed with water) (Svensson, *B.* 4, 714).  $\text{AgKSO}_3$ , 2aq, prepared like the Na salt. Svensson (*l.c.*) describes three double salts with  $(\text{NH}_4)_2\text{SO}_3$ , obtained by dissolving  $\text{Ag}_2\text{SO}_3$  or  $\text{AgCl}$  in  $(\text{NH}_4)_2\text{SO}_3$  aq; he gives the formulæ  $\text{Ag}(\text{NH}_4)_2\text{SO}_3$ ,  $\text{Ag}_2\text{SO}_3 \cdot 6(\text{NH}_4)_2\text{SO}_3$ , 19aq, and  $\text{Ag}_2\text{SO}_3 \cdot 3(\text{NH}_4)_2\text{SO}_3 \cdot 4(\text{NH}_4)_2\text{HSO}_3$ , 18aq.

**Sodium sulphites.** The normal salt  $\text{Na}_2\text{SO}_3$  is prepared by completely saturating  $\text{Na}_2\text{CO}_3$  aq with  $\text{SO}_2$ , warming, adding an equal quantity of the same  $\text{Na}_2\text{CO}_3$  aq, evaporating, and crystallising above  $33^\circ$  (Rammelsberg, *P.* 56, 298; Schultze-Sellack, *J. pr.* [2] 2, 459). Also obtained by heating the hydrate  $\text{Na}_2\text{SO}_3 \cdot 7\text{aq}$  to  $150^\circ$ .  $\text{Na}_2\text{SO}_3$  also crystallises from solution of  $\text{NaHSO}_3$ , that has been made strongly alkaline. Heated above  $150^\circ$  melts to a yellowish-red mass containing sulphide and sulphate in the ratio  $\text{Na}_2\text{S} : 3\text{Na}_2\text{SO}_3$  (R., *P.* 67, 246; 94, 507). The heptahydrate  $\text{Na}_2\text{SO}_3 \cdot 7\text{aq}$  is obtained by crystallising at the ordinary temperature a solution of  $\text{Na}_2\text{CO}_3$  saturated with  $\text{SO}_2$ , warmed, and mixed with an equal quantity of the same  $\text{Na}_2\text{CO}_3$  aq; monoclinic prisms; S.G. 1.561 (Buignet, *J.* 14, 15). Effloresces and partially oxidises in air. Very sol. water; maximum solubility at  $33^\circ$ . Another hydrate,  $\text{Na}_2\text{SO}_3 \cdot 10\text{aq}$ , was described by Muspratt (*P. M.* [3] 30, 414) as formed by evaporating  $\text{Na}_2\text{SO}_3$  aq over  $\text{H}_2\text{SO}_4$ ; according to Röhrig (*J. pr.* [2] 37, 217) only the heptahydrate exists.

The acid salt  $\text{NaHSO}_3$  is formed by saturating  $\text{Na}_2\text{CO}_3$  aq with  $\text{SO}_2$  and cooling; better crystals are obtained by treating  $\text{Na}_2\text{CO}_3 \cdot 10\text{aq}$  with  $\text{SO}_2$  and evaporating the liquid so produced in  $\text{SO}_2$ . Easily sol. water, but less sol. than  $\text{Na}_2\text{SO}_3 \cdot 7\text{aq}$ . (For heat of solution v. De Forcrand, *C. R.* 98, 738.) Gives off  $\text{SO}_2$  on exposure to air;  $\text{SO}_2$  is also removed from  $\text{NaHSO}_3$  aq by passage of an indifferent gas (Gernez, *C. R.* 61, 606). When heated gives off  $\text{H}_2\text{O}$ ,  $\text{SO}_2$ , and S, leaving  $\text{Na}_2\text{SO}_3$ ; heated in a closed tube forms  $\text{Na}_2\text{SO}_3$ ,  $\text{H}_2\text{SO}_4$ , S, and  $\text{H}_2\text{O}$  (Barbaglia a. Gucci, *B.* 13, 2325). Reacts with I to give  $\text{NaHSO}_4$  and NaI (Spring a. Bourgeois, *Ar. Ph.* 229, 707, where references are given to other experiments). Another acid salt  $\text{Na}_2\text{SO}_3 \cdot \text{SO}_2$  (=  $\text{Na}_2\text{S}_2\text{O}_5$ ), sometimes called *pyrosulphite*, is said to separate, in lustrous prisms, from conc. hot  $\text{NaOH}$  aq saturated with  $\text{SO}_2$  (v. Röhrig, *l.c.*).

**Double salts with ammonium sulphite.** Marignac (*Ann. M.* [5] 12, 30) described a double salt obtained by passing  $\text{NH}_3$  into conc.  $\text{NaHSO}_3$  aq; the salt is probably identical with that described by Schwicker (*B.* 22, 1728), to which he gives the formula  $\text{Na}_2\text{SO}_3 \cdot (\text{NH}_4)_2\text{HSO}_3 \cdot 4\text{aq}$ . By partially saturating conc.  $(\text{NH}_4)_2\text{HSO}_3$  with  $\text{Na}_2\text{CO}_3$  aq, Trauber (*J. C. T.* 1888, 44) obtained the salt  $2\text{Na}_2\text{SO}_3 \cdot (\text{NH}_4)_2\text{S}_2\text{O}_5 \cdot 10\text{aq}$ ; Hartog writes the formula of this salt  $2\text{Na}_2\text{O} \cdot (\text{NH}_4)_2\text{O} \cdot 4\text{SO}_2$ , and says it crystallises with 9aq (*C. R.* 109, 179, 221, 486). For other double salts of  $\text{Na}_2\text{SO}_3$ , v. *supra*, **cobalt sulphites, copper sulphites, gold sulphites, iridium sulphites, lithium sulphites, manganese sulphites, mercury sulphites, palladium sul-**

**phites, platinum sulphites, potassium sulphites, rhodium sulphites, and silver sulphites.**

**Strontium sulphites.** The normal salt  $\text{SrSO}_3$  is formed by passing  $\text{SO}_2$  over  $\text{SrO}$  at  $290^\circ$  (Birnbbaum a. Wittich, *B.* 13, 651); also by decomposing  $\text{SrCl}_2$  aq by alkali sulphite solution. Small white crystals; slowly oxidises in air to sulphate (Muspratt, *P. M.* [3] 30, 414); gives  $\text{SrS}$  and  $\text{SrSO}_4$  on heating (Forster, *P.* 133, 106).

**Thallium sulphites.** The normal thallous salt  $\text{Tl}_2\text{SO}_3$  is prepared by adding  $\text{Na}_2\text{SO}_3$  aq to  $\text{Tl}_2\text{SO}_4$  aq, and crystallising the pp. from warm water. White crystals; S.  $3:34$  at  $15^\circ$ ; insol. alcohol; S.G. 6.427 at  $20^\circ$  (Seubert a. Elten, *Zeit. f. anorg. Chem.* 2, 434). The same salt was obtained by Röhrig (*J. pr.* [2] 37, 217) by passing  $\text{SO}_2$  into solution of a thallous salt, evaporating at  $100^\circ$  or over  $\text{H}_2\text{SO}_4$ , or adding alcohol.

**Tin sulphites.** Basic stannous salts,  $x\text{SnO}_2 \cdot 2\text{SO}_3$ , 20aq,  $x$  being probably 5, 8, and 11, were obtained by Röhrig (*J. pr.* [2] 37, 217) by treating freshly ppd.  $\text{SnO}$  2aq with  $\text{SO}_2$  aq.

**Titanium sulphites.** Berthier (*A. Ch.* [3] 7, 77) made some observations, but described no definite salts.

**Uranium sulphites.** A basic uranous salt  $\text{UO}_2 \cdot \text{SO}_3$ , 2aq =  $\text{U}(\text{OH})_2\text{SO}_3$  aq is obtained, as a greyish-green pp., by adding  $\text{Na}_2\text{SO}_3$  aq to  $\text{UCl}_4$  aq (Rammelsberg, *P.* 56, 125; confirmed by Röhrig, *J. pr.* [2] 37, 217). The uranyl salt  $\text{UO}_2 \cdot \text{SO}_3$ , 2aq was obtained, in yellow prisms, by Muspratt (*P. M.* [3] 30, 414), by passing  $\text{SO}_2$  into water with  $\text{UO}_2$  in suspension, and allowing the solution so formed to evaporate at the ordinary temperature; Muspratt gave  $x=3$ , according to Röhrig (*l.c.*)  $x=4$  (cf. Girard, *C. R.* 34, 22; and Reineke, *P.* 125, 238).

**Zinc sulphites.** The normal salt  $2\text{ZnSO}_3 \cdot 5\text{aq}$  is prepared by evaporating, or by adding alcohol to, a solution of  $\text{ZnCO}_3$  in  $\text{SO}_2$  aq (Rammelsberg, *P.* 52, 90); also by mixing cold 25 p.c.  $\text{ZnSO}_4$  acidified with acetic acid with cold 25 p.c.  $\text{Na}_2\text{SO}_3$  aq, and letting stand (Denigès, *Bl.* [3] 7, 569). Muspratt (*l.c.*), Fordos a. Gélis (*J. Ph.* [3] 4, 333), and Koene (*P.* 63, 245, 431) give the formula  $\text{ZnSO}_3 \cdot 2\text{aq}$ ; but Röhrig (*J. pr.* [2] 37, 217) confirms Rammelsberg's formula.

**Zirconium sulphites.** Compositions of salts obtained by ppq. Zr salt solutions by alkali sulphites are doubtful (v. Berthier, *A. Ch.* [3] 7, 77; Hermann, *J. pr.* 31, 77).

**HYPOSULPHITES. (Hydrosulphites.)** Salts of the acid  $\text{H}_2\text{S}_2\text{O}_4$ . Hyposulphurous acid is known only in aqueous solution. Schützenberger (*A. Ch.* [4] 70, 351) obtained the Na salt, and an aqueous solution of the acid, in 1869; he gave the formula  $\text{H}_2\text{SO}_3$  to the acid; but Bernthsen (*A.* 203, 142; 209, 235; 211, 285) in 1881 showed that the acid has the composition  $\text{H}_2\text{S}_2\text{O}_4$ . This acid corresponds with the oxide  $\text{S}_2\text{O}_3$  ( $\text{S}_2\text{O}_3 + \text{H}_2\text{O} = \text{H}_2\text{S}_2\text{O}_4$ ). Schützenberger prepared the Na salt by digesting conc.  $\text{NaHSO}_3$  aq with zinc shavings in a closed flask for c. half an hour, pouring the liquid from the crystals of the double Na-Zn sulphite which formed (this is a basic Zn-Na sulphite, according to Bernthsen, *A.* 211, 297) into a flask about three-fourths filled with conc. alcohol, allowing to stand for

some time in the closed flask, and then pouring off into flasks, each flask being quite filled with the liquid and then sealed; after a time crystals of the hyposulphite were formed, to which S. gave the composition  $\text{NaHSO}_3$ . Bernthsen (*l.c.*) after reducing  $\text{NaHSO}_3\text{Aq}$  by Zn, pouring off from the double sulphite formed, &c., removed sulphite and sulphate by adding  $\text{BaCl}_2\text{Aq}$ ; he then filtered and titrated the solution by ammoniacal  $\text{CuSO}_4\text{Aq}$ , which is decolourised by  $\text{Na}_2\text{S}_2\text{O}_4\text{Aq}$  to a cuprous salt (and eventually to  $\text{Cu}_2\text{I}_2$  and  $\text{Cu}_2\text{S}$ ). For details of the method of analysis v. Bernthsen (*B.* 13, 2277; *A.* 211, 292 note). B. failed to obtain  $\text{Na}_2\text{S}_2\text{O}_4$  free from  $\text{Na}_2\text{SO}_4$ ,  $\text{Na}_2\text{SO}_3$ ,  $\text{Na}_2\text{S}_2\text{O}_5$  and Zn salts.

B. expresses the first part of the reduction of  $\text{NaHSO}_3$  by the equation  $4\text{NaHSO}_3\text{Aq} + \text{Zn} = \text{Na}_2\text{S}_2\text{O}_4\text{Aq} + \text{ZnSO}_3 + \text{Na}_2\text{SO}_4\text{Aq} + 2\text{H}_2\text{O}$ , and the complete change by the equation  $10\text{NaHSO}_3\text{Aq} + 3\text{Zn} =$

$3\text{Na}_2\text{S}_2\text{O}_4\text{Aq} + \text{Na}_2\text{SO}_4\text{Aq} + \text{Zn}_3\text{Na}_2\text{S}_2\text{O}_8 + 5\text{H}_2\text{O}$ . Moist sodium hyposulphite is rapidly oxidised in air to  $\text{Na}_2\text{SO}_3$ ; when dry it is unchanged in O; it is easily sol. water, less sol. dilute alcohol, and insol. conc. alcohol; but according to B. even approximately pure  $\text{Na}_2\text{S}_2\text{O}_4$  has not been isolated.  $\text{Na}_2\text{S}_2\text{O}_4\text{Aq}$  is oxidised by iodine solution to  $\text{Na}_2\text{SO}_4\text{Aq}$ .

By heating  $\text{Na}_2\text{S}_2\text{O}_4\text{Aq}$  with an equivalent quantity of  $\text{H}_2\text{SO}_4\text{Aq}$  or  $\text{H}_2\text{C}_2\text{O}_4\text{Aq}$ , an aqueous solution of *hyposulphurous acid*  $\text{H}_2\text{S}_2\text{O}_4\text{Aq}$  is obtained; this solution is an energetic reducer, decolourising indigo, and reducing salts of Cu, Hg, Ag, &c.; the solution rapidly decomposes in air with separation of S. M. M. P. M.

**SULPHO.**—Use of this prefix applied to inorganic compounds: for *sulpho-* compounds and *sulpho-* salts v. the compounds or salts to the names of which *sulpho-* is prefixed; thus *sulpho-molybdates* are described under *MOLYBDATES*; but the prefix *thio-* is used in almost every case in preference to *sulpho-* to denote the replacement of O by S. *Sulphocyanides* and similar compounds are described under *CYANIDES*; *sulphocyanic anhydride* is described as *CYANOGEN SULPHIDE*.

**SULPHO-ACETIC ACID**  $\text{C}_2\text{H}_3\text{SO}_3$ , i.e.  $\text{SO}_3\text{H.CH}_2\text{CO}_2\text{H}$ . [75].

**Formation.**—1. By adding  $\text{SO}_2$  to cooled  $\text{HOAc}$  (Melsens, *A. Ch.* [3] 5, 392; 10, 370; *A.* 52, 276).—2. By the action of fuming  $\text{H}_2\text{SO}_4$  on acetamide or acetonitrile (Buckton & Hofmann, *C. J.* 9, 247).—3. By boiling chloro-acetic acid with aqueous  $\text{K}_2\text{SO}_3$  (Strecker, *Z.* [2] 4, 214; Collmann, *A.* 148, 109).—4. By heating  $\text{Ag}_2\text{SO}_3$  with  $\text{AcCl}$  at  $120^\circ$  (Kämmerer & Carius, *A.* 131, 165).—5. By boiling chloro-acetic acid with ammonium sulphite solution (Hemilian, *A.* 168, 145).—6. By heating  $\text{Ac}_2\text{O}$  with  $\text{H}_2\text{SO}_4$  at  $130^\circ$  (Franchimont, *C. R.* 92, 1054; cf. Baumstark, *A.* 140, 83).—7. By heating  $\text{ClSO}_3\text{H}$  with  $\text{HOAc}$  at  $140^\circ$  (Baumstark).—8. By oxidation of isethionic acid by  $\text{CrO}_3$  (Carl, *B.* 14, 63).

**Properties.**—Deliquescent crystals (containing  $1\frac{1}{2}\text{aq}$ ) giving off water of crystallisation at about  $160^\circ$  and decomposed at  $230^\circ$  into  $\text{CO}_2$ ,  $\text{SO}_2$ , acetic acid, and other products (Franchimont, *R. T. C.* 7, 25). V. sol. water. Its salts are sol. water, insol. alcohol.  $\text{PCl}_5$  acting on the Nasalt forms  $\text{CHCl}(\text{SO}_2\text{Cl})\text{COCl}$  (R. Siemens, *B.* 6, 659).

VOL. IV.

**Salts.**— $\text{KA}'\text{aq}$ : hard crystals. — $\text{KHA}'$ : six-sided tables. — $\text{BaA}'\text{aq}$ . S.  $267$  at  $20^\circ$ . — $\text{BaA}'\text{Et}_2\text{SO}_4$  (Laube, *A.* 218, 258). — $\text{CaA}'\text{aq}$ . — $\text{PbA}'$ : radiating needles. — $\text{Ag}_2\text{A}'\text{aq}$ : flat prisms.

*Mono-ethyl ether EtHA'*. Formed by passing  $\text{HCl}$  into the  $\text{Ag}$  salt suspended in alcohol. Syrup, v. sol. water. — $\text{AgEtHA}'$ : plates. • *Ethyl ether EtA'*. Oil. Formed, together with  $\text{C}_2\text{H}_5\text{Ag}_2\text{S}_2\text{O}_8$  by the action of  $\text{Ag}_2\text{A}'$  on  $\text{EtI}$  (F.). May be distilled (Mauzelius, *B.* 21, 1550).

**Sulpho-diacetic acid v. DI-METHYL SULPHONE DICARBOXYLIC ACID.**

**Di-sulpho-acetic aldehyde**  $\text{C}_2\text{H}_2\text{S}_2\text{O}_4$ , i.e.  $\text{CH}(\text{SO}_3\text{H})_2\text{CHO}$ . By adding chloral hydrate to conc.  $\text{KHSO}_4\text{Aq}$  at  $80^\circ$  there are formed crystals of  $\text{C}_2\text{H}_2\text{K}_2\text{S}_2\text{O}_4$ ,  $\text{KHSO}_4$ , and these when boiled with  $\text{HClAq}$  yields  $\text{C}_2\text{H}_2\text{K}_2\text{S}_2\text{O}_4\text{aq}$ , from which  $\text{C}_2\text{H}_2\text{BaS}_2\text{O}_4$  2aq may be prepared (Hahlke, *A.* 161, 154). Boiling  $\text{K}_2\text{CO}_3$  yields  $\text{CH}_3(\text{SO}_3\text{K})_2$  potassium formate, and  $\text{K}_2\text{SO}_4$ .

**SULPHO-AMIDO-BENZOIC ACID v. AMIDO-SULPHO-BENZOIC ACID.**

**DI-SULPHO-ANILINE v. DI-AMIDO-DI-PHENYL DISULPHIDE.**

(B.) - **SULPHO-ANTHRACENE**  $\cdot (A) \cdot \text{CARBOXYLIC ACID}$   $\text{C}_{14}\text{H}_7\text{O}_4$ ,  $\text{C}(\text{CO}_2\text{H})_2\text{C}_6\text{H}_4(\text{SO}_3\text{H})$ .

[above  $360^\circ$ ]. Obtained by dissolving anthracene-(A)-carboxylic acid in cold conc.  $\text{H}_2\text{SO}_4$  and allowing to stand for 12 hours on ice (Bühla, *B.* 20, 706). Minute yellowish prisms (from alcohol). V. sol. water and alcohol, insol. benzene and ether. The aqueous solutions of the acid and its salts have a strong blue fluorescence. — $\text{BaA}'$ : very soluble yellowish minute prisms.

**Di-sulpho-anthracene-(A)-carboxylic acid**  $\text{C}_{14}\text{H}_6(\text{SO}_3\text{H})_2\text{CO}_2\text{H}$ . [above  $360^\circ$ ]. Formed by dissolving anthracene-(A)-carboxylic acid in cold fuming  $\text{H}_2\text{SO}_4$  (Behla). Yellow prisms (from alcohol). V. sol. water and alcohol, insol. benzene. Its aqueous solution scarcely fluoresces, but the conc.  $\text{H}_2\text{SO}_4$  solution has a strong yellowish-green fluorescence. — $\text{A}'\text{Ba}$ : very sparingly soluble crystalline powder.

**SULPHOBENZIDE v. DI-PHENYL SULPHONE.**  
**o-SULPHO-BENZOIC ACID**  $\text{C}_6\text{H}_4\text{SO}_3$ , i.e.  $\text{C}_6\text{H}_4(\text{SO}_3\text{H})\text{CO}_2\text{H}$ . S. 50 in the cold.

**Formation.**—1. Together with its imide, by oxidation of toluene *o*-sulphonic amide with  $\text{KMnO}_4$  (Remsen & Fahlberg, *Am.* 1, 433).—2. By heating the imide with  $\text{HClAq}$  at  $100^\circ$  (Fahlberg & Remsen, *B.* 12, 472; Fahlberg & Barge, *B.* 22, 754; Brackett & Hayes, *Am.* 9, 399). By this means the acid ammonium salt is first obtained (F.; Remsen & Dohme, *Am.* 11, 332).—3. By boiling *o*-diazo-benzoic acid with alcoholic  $\text{SO}_2$  (Wiesinger, *B.* 12, 1349).—4. By oxidation of toluene *o*-sulphonic acid by  $\text{KMnO}_4$ .

**Properties.**—Trimetric crystals (containing  $3\text{aq}$  or  $4\text{aq}$ );  $a:b:c = .55:1:1.812$ , v. e. sol. water, sol. alcohol, insol. ether. According to Fahlberg (*B.* 22, 754), it crystallises with  $3\text{aq}$ , and is decomposed at  $105^\circ$ . According to Remsen (*Am.* 11, 332), it crystallises with  $4\text{aq}$ , melts at  $69^\circ$  in its water of crystallisation, melts at  $180^\circ$  when anhydrous, and gives a sublimate of long needles (containing  $2\text{aq}$ ). Resorcin (1.2 pts.) at  $195^\circ$  forms 'sulphofluorescein'  $\text{C}_{15}\text{H}_{10}\text{SO}_4$ , 2aq, which fluoresces in aqueous and alkaline solutions (Remsen & Hayes, *Am.* 9, 872). By condensa-

Q Q

don of resorcin (4 mols.) with *o*-sulpho-benzoic acid there is likewise formed a similar body  $C_6H_2SO_3 \cdot 4aq$  (Fahlberg a. Barge, *B.* 22, 765). Potash-fusion gives salicylic acid.

**Salts.**—KHA': transparent plates, sol. water.— $K_2A''$  2aq.— $Ba(HA'')_2$  2aq: needles, sol. water.— $Ba(HA'')_2$  2aq.— $BaHA''$  4aq.— $BaA''$  2aq.— $Ca(HA'')_2$  6aq.— $CaA''$  5aq.— $CuA''$  3aq.— $Ag_2A''$ — $C_6H_4(SO_3NH_2)CO_2H$ . Formed by heating the imide with  $HCl$  aq at  $100^\circ$ .

**Anhydride**  $C_6H_4\langle\frac{CO}{SO_2}\rangle O$ . [119°] (F.).

[128°] (Remsen a. Dohme, *Am.* 11, 332). Formed by heating the K salt with  $PCl_5$  at  $180^\circ$  or the acid with  $P_2O_5$  at  $130^\circ$ . Monoclinic tables, insol. cold water.  $NH_3$  passed into its solution in benzene forms  $C_6H_4(CONH_2)SO_3NH_4$  [256°], which crystallises from alcohol in needles.

**Chloride**  $C_6H_4(SO_2Cl)COCl$ . [73°]. Prisms (from ether). When reduced by zinc-dust and  $H_2SO_4$  it yields  $C_6H_4(SH)CO_2H$  (Delisle, *B.* 22, 2205).

**Amic acid**  $C_6H_4(CO.NH_2)SO_3H$ . Crystals (containing aq), v. sol. alcohol and water. Got by the action of  $H_2S$  on  $C_6H_4(CONH_2)SO_3Ag$  aq, which is obtained by adding silver nitrate to  $C_6H_4(CONH_2)SO_3NH_4$  prepared as above (Fahlberg a. Barge, *B.* 22, 760).

**Amic acid**  $C_6H_4(SO_3NH_2)CO_2H$ . *Sulphaminic-benzoic acid*. Formed by boiling toluene *o*-sulphonic amide with  $K_2FeC_4$  and aqueous potash (Noyes, *Am.* 8, 178; cf. Fahlberg, *Am.* 1, 170). Slender needles or prisms, v. sol. water, alcohol, and ether. Melts at  $155^\circ$  when slowly heated, and at  $167^\circ$  when quickly heated. At  $180^\circ$  it is completely converted into imide. Gives rise to the salts  $MgA'$ , 6aq,  $BaA'$ , 4aq,  $BaA'$ , 9aq,  $AgA'$ , and  $Ag_2C_6H_4NSO_3$ . By passing  $HCl$  into an alcoholic solution of the imide, the ether  $C_6H_4(SO_3NH_2)CO_2Et$  [83°] is formed. The methyl and propyl ethers have also been obtained and may be converted by aniline into  $C_6H_4(SO_3NH_2)CONHPh$  [189°], by *o*-toluidine into  $C_6H_4(SO_3NH_2)CONHC_6H_3$  [193°], and by means of *p*-toluidine into the isomeric *p*-toluide  $C_6H_4(SO_3NH_2)CONHC_6H_4$  [202°].

**Imide**  $C_6H_4\langle\frac{SO}{CO}\rangle NIl$ . *Saccharin*. [220°]

(Remsen a. Fahlberg, *Am.* 1, 432). Formed by oxidising  $CH_3C_6H_4SO_3NH_2$  with  $KMnO_4$  in neutral solution (Remsen a. Fahlberg, *B.* 12, 469; Remsen a. Palmer, *Am.* 8, 223; Fahlberg a. List, *B.* 20, 1597; 21, 242; Remsen a. Linn, *Am.* 11, 73). Elongated triangular plates (by sublimation), sl. sol. cold water, v. sol. alcohol and ether. Has a very sweet taste (500 times that of cane sugar). The solubility of commercial saccharin is given by Gravill (*Ph.* [8] 18, 337) as S. (water) .2 at  $15^\circ$ ; .6 at  $100^\circ$ ; S. (alcohol) .5-4 at  $15^\circ$ ; S. (ether) 1-8 at  $15^\circ$ . According to Stitt (*B. C.* 18, 468) and Aducco and Mosso (*C. C.* 1887, 1148) it retards digestion, and is antiseptic. The imide is converted into  $C_6H_4(SO_3NH_2)CO_2H$  on evaporation with  $KOHAq$ . Conc. hydrochloric acid at  $150^\circ$  forms  $C_6H_4(SO_3NH_2)CO_2H$ . The imide gives rise to salts of the form  $C_6H_4\langle\frac{SO}{CO}\rangle NAg$ , of which the following have been described.—KA' aq: prisms, v. sol. water.— $NaA'$  2aq: tables.—

$BaA'$ , 1aq.— $BaA'$ , 4aq (Noyes, *Am.* 8, 180).— $AgA'$ : needles (from hot water). To detect 'saccharin,' a suspected liquid may be acidified, extracted with ether, the ether evaporated, the residue fused with  $NaOH$ , and the product tested for salicylic acid and for sulphate (C. Schmitt, *Fr.* 27, 396; Allen, *Am.* 13, 105; Börnstein, *Fr.* 27, 165). 'Saccharin' evaporated to dryness on a water-bath leaves a residue which, when warmed with alcoholic potash, exhibits yellow, blue, and red colours (Lindo, *C. N.* 58, 51, 155).

**Methylimide**  $C_6H_4\langle\frac{SO}{CO}\rangle NMe$ . [132°].

Formed by heating  $C_6H_4\langle\frac{SO}{CO}\rangle NAg$  with  $MeI$  at  $100^\circ$  (Brackett, *Am.* 9, 406). Long flat needles, sol. ether, alcohol, and hot water.

**Ethylimide**  $C_6H_4\langle\frac{SO}{CO}\rangle NEt$ . [97°].

Needles (from water). Converted by boiling alcoholic potash into  $C_6H_4(SO_3NH_2)CO_2H$  [116°], which yields  $C_6H_4(SO_3NKEt)CO_2K$  crystallising in nacreous scales,  $Na_2C_6H_4NSO_3$ ,  $CuA'$  2aq, and  $AgA'$  (Fahlberg a. List, *B.* 20, 1596).

**Propylimide**  $C_6H_4\langle\frac{SO}{CO}\rangle NPr$ . [60°–70°].

***m*-Sulpho-benzoic acid**  
[1:3] $C_6H_4(SO_3H)CO_2H$ .

**Formation.**—1. By mixing benzoic acid (2 pts.) with  $SO_3$  (1 pt.) (Mitscherlich, *P.* 31, 287; 32, 227; Barth, *A.* 148, 33).—2. By heating  $BzCl$  with  $Ag_2SO_3$  at  $150^\circ$  (Kämmerer a. Carius, *A.* 131, 153; *B.* 4, 219).—3. By heating  $BzCl$  with  $H_2SO_4$  (Oppenheim, *B.* 3, 735).—4. By the action of an alcoholic solution of  $SO_2$  on *m*-diazobenzoic acid (Wiesinger a. Vollbrecht, *B.* 10, 1715).—5. By oxidation of *m*-sulpho-benzoic aldehyde with air at  $95^\circ$  (Kafka, *B.* 24, 796).

**Properties.**—Deliquescent crystalline mass. Yields *m*-oxy-benzoic acid when fused with potash.

**Salts.**— $NaHA''$  2aq: triclinic crystals.— $Na_2A''Me_2SO_3$  (Stengel, *A.* 218, 260). Crystals.— $Na_2A''Et_2SO_3$ : v. sol. water.— $KHA''$  2aq.— $KHA''$  5aq (Otto, *A.* 122, 155).— $BaA''$  3aq: v. sol. water (Fehling, *A.* 27, 322).— $BaHA''$  3aq. White monoclinic prisms. S. 5 at  $20^\circ$  (M.).— $BaA''Me_2SO_3$ — $BaA''Me_2SO_3$  3aq. S. 34 at  $21^\circ$ .— $BaA''Et_2SO_3$  3aq. S. 31 at  $21^\circ$ . Formed from the acid,  $NaHSO_4$ , and alcohol (Stengel). Long needles.— $BaA''Pr_2SO_3$  7aq. S. 11 at  $19^\circ$ .— $PbA''$  2aq: stellate groups of white needles.— $PbA''Et_2SO_3$  2aq.— $CuA''Me_2SO_3$  2aq. Crystals.— $CuA''Et_2SO_3$  2aq.— $AgHA''$ : nodules (Limpriht a. Usilar, *A.* 106, 50).— $AgA''$  aq: small yellowish prisms.

**Mono-ethyl ether**  $EtHA''$ . Formed by the action of alcoholic  $NH_3$  on  $EtA''$  or on the chloride (Limpriht a. Usilar, *A.* 102, 252). The free acid is unstable.— $EtNH_4A''$ : four-sided triclinic tables (Kefenstein, *A.* 106, 385).— $NaEtA''$  2aq.— $Ba(EtA'')_2$  2aq: efflorescent tables.

**Ethyl ether**  $EtA''$ . Formed from the chloride and alcohol. Syrup, miscible with water. Saponified by heating with water.

**Semi-chloride**  $C_6H_4SO_3Cl$ . Formed by heating the acid (1 mol.) with  $PCl_5$  (1 mol.) (L. a. S.). Formed also by leaving the chloride  $C_6H_4(SO_3Cl)COCl$  in contact with water for

several weeks. Crystalline powder, sol. ether. Converted by hot water into the acid.

**Chloride**  $C_6H_4(SO_2Cl)COCl$ . Formed by heating the acid (1 mol.) with  $PCl_5$  (2 mols.) at  $100^\circ$ . Thick oil, slowly decomposed by water. Yields  $C_6H_4ClCOCl$  on distillation and on heating with  $PCl_5$  at  $150^\circ$  (Kämmerer a. Carius, A. 131, 159).

**Benzoyl derivative**  $C_6H_5SO_2$ . The first product of the action of  $BzCl$  (2 mols.) on  $Ag_2SO_4$  (1 mol.) (K. a. C.). Amorphous, sol. ether. Resolved by water into benzoic and sulphobenzoic acids.

**Amic acid**  $C_6H_4(SO_2NH_2)CO_2H$ . *m*-Sulphaminebenzoic acid. [235° uncor.] (R. a. P.); [247°] (N. a. W.). Formed by the action of conc. KOHAq at  $100^\circ$  on the amide (Limpricht a. Usler, A. 106, 27). Prepared by oxidation of [1:3]  $C_6H_4MeSO_2NH_2$  with alkaline  $KMnO_4$ , with chromic acid mixture (Remsen a. Palmer, Am. 4, 143), or with alkaline  $K_2FeO_4$  (Noyes a. Walker, Am. 8, 188). Scales (from water), sl. sol. cold water, v. sol. alcohol. Converted by  $PCl_5$  at  $150^\circ$ – $200^\circ$  into the oily chloride  $C_6H_4(SO_2NH_2)COCl$ .— $BaA'$ , 1aq.— $AgA'$  aq.— $Ag_2C_6H_4NSO_4$ ; amorphous pp., sol. hot water.— $EtA'$ . Monoclinic crystals, sl. sol. hot water.

**Amide**  $C_6H_4(SO_2NH_2)CONH_2$ . [170°]. Formed from the chloride and conc.  $NH_4Aq$ . Small anhydrous crystals (from alcohol) or needles (containing aq.). V. sol. hot water and alcohol.  $PCl_5$  at  $100^\circ$  forms  $C_6H_4(SO_2NH_2)COClNH_2$ , which is decomposed by distillation into *m*-chloro-benzonitrile,  $SO_2$ , and  $NH_3$ ; and by treatment with  $NH_4Aq$  into  $C_6H_4(SO_2NH_2)CN$  [152°] (Wallach a. Huth, B. 9, 428).

**Anilide**  $C_6H_4(SO_2NHPh)CONHPh$ . Formed from the chloride and aniline. Small crystals (from alcohol).

**Isomeride of the amic acid**  $C_6H_4(CNH)N.SO_2H$ . *Benzamidine-v-sulphonic acid*. [247°]. Mol. w. 200 (obs.). Formed by passing  $SO_2$  into cold benzonitrile (Engelhardt, J. pr. 75, 363; Eitner, B. 25, 471). Prisms and rhombohedra. Converted by  $HClAq$  into benzamidine sulphate.— $CaA'_2$ .— $BaA'_2$  4aq.

**Amorphous isomeride of the amic acid**. A product of the action of  $PCl_5$  on the amic acid (L. a. U.). Insol. water, alcohol, and ether. Forms amorphous salts. Water at  $180^\circ$  reconverts it into the ordinary amic acid.— $BaA'_2$  4aq; brittle mass.

#### *p*-Sulpho-benzoic acid

[1:4]  $C_6H_4(SO_2H)CO_2H$ . [c.  $200^\circ$ ]. Formed, in small quantity, together with the *m*-isomeride, by the action of  $SO_2$  on benzoic acid (Remsen, A. 178, 275; Z. [2] 7, 81, 199). Formed also by oxidation of toluene-*p*-sulphonic acid with  $KMnO_4$  (Hart, Am. 1, 342), and by the action of an alcoholic solution of  $SO_2$  on diazotised *p*-amido-benzoic acid (Wiesinger, B. 10, 1715). Needles, not deliquescent, decomposed by heat. Potash-fusion converts it into *p*-oxy-benzoic acid. The K salt heated with potassium formate yields terephthalic acid.

**Salts**.— $NaA$ .  $2\frac{1}{2}$ aq. Stellate groups of prisms, m. sol. cold water.— $BaA'$  2aq; groups of needles, m. sol. cold water.— $BaH_2A''$ , 3aq; flat needles, v. sl. sol. cold water.

**Amic acid**  $C_6H_4(SO_2NH_2)CO_2H$ . [c.  $280^\circ$ ]. Formed by oxidation of  $C_6H_4Me.SO_2NH_2$  and of

*p*-sulpho-cinnamic amide (Remsen, A. 178, 299; Fahlberg, Am. 1, 170; Palmer, Am. 4, 164; Noyes, Am. 7, 145; 8, 182). Flat prisms (from water), sl. sol. hot water, v. sol. alcohol. Decomposed on fusion.— $NH_4A'$ ; needles or long laminas, v. sol. water.— $BaA'$ , 5aq.— $AgA'$ ; v. sl. sol. hot water.— $C_6H_4(SO_2NHAg).CO_2Ag$ ; v. sol. hot water.— $EtA'$ . [111°].

#### *Di*-sulpho-benzoic acid $C_6H_2S_2O_4$ , i.e.

$C_6H_2(SO_2H)_2CO_2H$  [4:2:1]. [above  $285^\circ$ ]. Formed by oxidation of toluene disulphonic acid with chromic acid mixture (Blomstrand a. Hakansson, B. 5, 1088; Brunner, Sitz. W. [2] 78, 665) and by digesting  $C_6H_2(SO_2NH_2)<\frac{SO_2}{CO}>NH$  with  $HClAq$  at  $160^\circ$  (Fahlberg, Am. 2, 190). Large crystals (from  $HClAq$ ), sol. cold water, insol. alcohol and ether. Yields (4,2,1)-di-oxy-benzoic acid on fusion with potash.

**Salts**.— $K_2A''$  2aq; prisms, v. e. sol. water.— $K_2HA''$  aq; large crystals, sl. sol. water.— $Ba_2A''$ , 7aq.— $Ca_2A''$ , 7aq; minute crystals.

**Amic acid**  $C_6H_2(SO_2H)(SO_2NH_2)CO_2H$  [2:4:1]. [165°]. Formed by boiling the imide of the amic acid with dilute  $HClAq$  for five hours. Large crystals, v. e. sol. water, sl. sol.  $HClAq$ , insol. ether.— $HA'$ ; crystals (from dilute  $HClAq$ ), v. e. sol. water.

**Di-amic acid**  $C_6H_2(SO_2NH_2)_2CO_2H$ . [183°]. Formed by heating  $C_6H_4Me(SO_2NH_2)_2$  with aqueous potassium permanganate and by evaporating  $C_6H_2(SO_2NH_2)<\frac{SO_2}{CO}>NH$  with  $KOHAq$  (Fahlberg, Am. 2, 186; B. 21, 246). Minute satiny needles, v. e. sol. water and alcohol, sl. sol. ether. Tastes acid. Decomposes completely at  $250^\circ$ – $260^\circ$ . Its salts are crystalline. Those of alkalis and alkaline earths are v. sol. water.— $BaA'$ , 5aq; monoclinic prisms.— $CaA'_2$  2aq; pale-blue silky needles.— $AgA'$ ; white needles.— $EtA'$ . [200°]. Silky needles (from water).

#### *Imide of the amic acid*

$C_6H_2(SO_2NH_2)<\frac{SO_2}{CO}>NH$ . [285°]. Formed by warming  $C_6H_2(SO_2NH_2)_2CO_2Et$  with  $KOHAq$  (Fahlberg a. List, B. 20, 1603; 21, 242). Tables, sl. sol. cold water, v. e. sol. alcohol and ether.— $K.C_6H_2N_2S_2O_4$ ; deliquescent crystalline mass.— $(C_6H_2(SO_2NH_2)_2SCO_2N)_2Ba$  3aq; crystals.— $Cu(C_6H_2N_2S_2O_4)_2$  4aq; minute blue needles.— $AgC_6H_2N_2S_2O_4$ .

#### *s*-Di-sulpho-benzoic acid $C_6H_2(SO_2H)_2CO_2H$

Formed by heating benzoic acid with  $H_2SO_4$ ,  $SO_3$ , and  $P_2O_5$  (Barth a. Senhofer, A. 159, 217). Hygroscopic prisms (containing aq.). Turns brown at  $140^\circ$ . Yields *s*-di-oxy-benzoic acid on fusion with potash. The K salt forms isophthalic acid when fused with potassium formate.— $K_2A''$  1½aq; needles.— $BaHA''$  2aq; minute needles.— $Ba_2A''$ , 7aq; white prisms.— $Ca_2A''$ , 8½aq.— $Ag_2A''$  2aq; crystalline pp.

**References**.—Bromo-, Nitro-, Oxy-amido, and Oxy-, SULPHO-BENZOIC ALDEHYDE

#### *m*-SULPHO-BENZOIC ALDEHYDE

$C_6H_4(SO_2H)CHO$ . *Sulphonic acid of benzoic aldehyde*. Formed from benzoic aldehyde and fuming  $H_2SO_4$  below  $50^\circ$  (Wallach a. Wüsten, B. 16, 150; cf. Engelhardt, J. 1864, 850). The Na salt reacts with (α)-naphthylamine forming  $C_6H_4(SO_2Na).CH.NC_{10}H_7$ , and forms with sodium naphthionate  $C_6H_4(SO_2Na).CH.NC_{10}H_7.SO_2Na$ .

Yields *m*-sulpho-benzoic acid on oxidation.-- $\text{MgA}'_2$  (dried at  $170^\circ$ ).-- $\text{BaA}'_2$  (dried at  $170^\circ$ ). Nodules.

*Oxim.* The salt  $\text{C}_6\text{H}_4(\text{SO}_3\text{Na})\text{CH:NHOH}$  crystallises in plates, v. s. sol. water, m. sol. alcohol (Kafka, *B.* 24, 791).

*Phenyl-hydrazide.*

The salt  $\text{C}_6\text{H}_4(\text{SO}_3\text{Na})\text{CH:N.NHPh}$  crystallises in needles, sl. sol. cold water, v. sol. alcohol.

*Di-phenyl-hydrazide.*

The salt  $\text{C}_6\text{H}_4(\text{SO}_3\text{Na})\text{CH:N.NPh}_2$  crystallises from water in plates.

**SULPHOBENZOLIC ACID** *v.* BENZENE SULPHONIC ACID.

**SULPHO-BENZYL-SULPHAMIC ACID**  
 $\text{C}_6\text{H}_4\text{CH}(\text{SO}_3\text{H})\text{NH}_2\text{SO}_3\text{H}$ . The salt  $\text{Na}_2\text{A}$  3aq is formed from  $\text{C}_6\text{H}_4\text{CH:NHOH}$  and aqueous  $\text{Na}_2\text{SO}_3$  (Pechmann, *B.* 20, 2541). It crystallises in needles and is decomposed by  $\text{NaOH}$  aq into benzoic aldehyde,  $\text{Na}_2\text{SO}_3$ , and  $\text{H}(\text{NH}_4)\text{SO}_3$ .

(*a*)-**SULPHO-BUTYRIC ACID**  $\text{C}_4\text{H}_7\text{SO}_3$ , *i.e.*  $\text{CH}_3\text{CH}_2\text{CH}(\text{SO}_3\text{H})\text{CO}_2\text{H}$ . Formed from butyric acid and  $\text{ClSO}_3\text{H}$ ; and also by the action of  $(\text{NH}_4)_2\text{SO}_3$  on  $\alpha$ -bromo-butyric acid (Hemilian, *B.* 6, 196, 562; *A.* 176, 1; Franchimont, *R. T. C.* 7, 27). Formed also from crotonic acid and  $\text{KHSO}_3$  at  $130^\circ$  (Heilstein, *A.* Wiegand, *B.* 18, 483). Syrup. The Ba salt is converted by  $\text{PCl}_5$  into  $\text{CH}_3\text{CH}_2\text{CHClCOCl}$ .— $\text{CaA}''$  2aq: needles (from ether-alcohol), insol. alcohol.— $\text{BaA}''$  2aq. S. 7-1 at  $16^\circ$ .— $\text{PbA}''$  2aq.— $\text{CuA}''$  4aq.— $\text{ZnA}''$  5aq.— $\text{Ag}_2\text{A}''$ : prisms, insol. alcohol.

*a*-Sulpho-isobutyric acid  $\text{C}_4\text{H}_7\text{SO}_3$ , *i.e.*

$\text{CMe}_2(\text{SO}_3\text{H})\text{CO}_2\text{H}$ . Formed by the action of  $\text{ClSO}_3\text{H}$  on isobutyric acid and also by oxidation of  $\text{C}_4\text{H}_9\text{N}_2\text{SO}$ , which is prepared by heating thio-urea with  $\alpha$ -bromo-isobutyric acid (Andreasch, *M.* 8, 412).— $\text{Na}_2\text{H}$  1/2 aq.— $\text{BaA}''$  4aq.

Ammonium sulphite appears to convert  $\alpha$ -bromo-isobutyric acid into an isomeride which yields  $\text{BaC}_4\text{H}_7\text{SO}_3$  2aq, crystallising in needles, v. sol. water.

*$\beta$* -Sulpho-butyric acid

$\text{CH}_3\text{CH}(\text{SO}_3\text{H})\text{CH}_2\text{CO}_2\text{H}$ . Formed from  $\beta$ -chloro-butyric ether and  $(\text{NH}_4)_2\text{SO}_3$  (H.). Got also by oxidising barium oxy-butane disulphonate with chlorine-water (Haubner, *M.* 12, 547). Amorphous.— $\text{BaA}''$  aq (H.).— $\text{BaC}_4\text{H}_7\text{SO}_3$ . White amorphous mass, v. sol. water, almost insol. alcohol. Yields acetic acid by potash-fusion.

**Sulphodibutyric acid** *v.* DI-PROPYL SULPHONE DICARBOXYLIC ACID.

**SULPHOBUTYRIC ALDEHYDE**  $\text{C}_4\text{H}_6\text{SO}_3$ , *i.e.*  $\text{CH}_2\text{CH}(\text{SO}_3\text{H})\text{CH}_2\text{CHO}$ . Got by saturating a solution of crotonic aldehyde with  $\text{SO}_2$  and distilling *in vacuo*, afterwards distilling with steam. On neutralisation of the residue with baryta the salt  $\text{BaA}'$  is got (Haubner, *M.* 12, 546). The barium salt is converted by hydroxylamine into  $(\text{CH}(\text{NOH})\text{CH}_2\text{CHMeSO}_3)_2\text{Ba}$ , which is reduced by sodium-amalgam to  $(\text{CH}_2(\text{NH}_2)\text{CH}_2\text{CHMeSO}_3)_2\text{Ba}$ , which on distillation with lime yields butylamine and a little  $\text{CH}_3\text{CH}:\text{CHCH}_2\text{NH}_2$ . Sodium-amalgam reduces the sulpho-butyric aldehyde to oxy-butane sulphonic acid  $\text{CH}_3\text{CH}(\text{SO}_3\text{H})\text{CH}_2\text{CH}_2\text{OH}$ , whence  $\text{NaA}'$ , which when distilled with lime gives a mixture of butyl and crotyl alcohols.

**SULPHOCAMPHORIC ACID** *v.* CAMPHORIC ACID.

**SULPHOCAMPHYLIC ACID** *v.* CAMPHORIC ACID.

**SULPHO-CHLORO-BENZOIC ACID** *v.* CHLORO-SULPHO-BENZOIC ACID.

*o*-**SULPHO-CINNAMIC ACID**  $\text{C}_9\text{H}_7\text{SO}_3$ , *i.e.*  $\text{C}_6\text{H}_4(\text{SO}_3\text{H})\text{CH}:\text{CHCO}_2\text{H}$ . Formed, together with the *p*-isomeride, by the action of  $\text{SO}_2$  or fuming  $\text{H}_2\text{SO}_4$  on cinnamic acid (Marchand, *J. pr.* 16, 60; Herzog, *J. pr.* 29, 51; Rudneff, *A.* 173, 8). Prisms (containing 3aq), v. s. sol. water and alcohol. Yields *m*-oxy-benzoic acid on fusion with potash.— $\text{KA}''$ : amorphous, v. sol. water.— $\text{KHA}''$ : groups of needles.— $\text{CaA}''$  1 1/2 aq.— $\text{BaH}_2\text{A}''_2$ . S. 45 at  $20^\circ$ .— $\text{BaA}''$  1 1/2 aq. S. 4-2 at  $16^\circ$ .— $\text{Ag}_2\text{A}''$ .

*m*-Sulpho-cinnamic acid

[1:3]  $\text{C}_6\text{H}_4(\text{SO}_3\text{H})\text{CH}:\text{CHCO}_2\text{H}$ . Formed from *m*-sulpho-benzoic aldehyde,  $\text{NaOAc}$ , and  $\text{Ac}_2\text{O}$  (Kafka, *B.* 24, 791).— $\text{BaA}''$ : nodules, v. sol. water, sl. sol. alcohol.

*p*-Sulpho-cinnamic acid

[1:4]  $\text{C}_6\text{H}_4(\text{SO}_3\text{H})\text{CH}:\text{CHCO}_2\text{H}$ . Formed as above. Monoclinic prisms (containing 5aq). Yields *p*-oxy-benzoic acid by potash-fusion.— $\text{KA}''$  1/2 aq. Nodules (from alcohol). Reduces  $\text{KMnO}_4$  in the cold (Liebermann, *B.* 22, 782).— $\text{CaA}''$  1/2 aq.— $\text{BaA}''$  3aq. S. (of  $\text{BaA}''$ ) 12 at  $20^\circ$ .— $\text{BaA}''$  aq. S. 4 at  $18^\circ$ .— $\text{CuA}''$  6aq: greenish-prisms, v. sol. water.

*Amide*  $\text{C}_9\text{H}_7(\text{SO}_3\text{NH}_2)\text{CH}:\text{CHCONH}_2$ . [218°]. Needles, v. sol. hot water (Palmer, *Am.* 4, 163).

*Amic acid*  $\text{C}_9\text{H}_7(\text{SO}_3\text{NH}_2)\text{CH}:\text{CHCO}_2\text{H}$ . S. 558 at  $21^\circ$ . Formed by heating the amide with  $\text{NaOH}$  aq. Needles (from water), sol. alcohol, sl. sol. ether. Decomposes at  $250^\circ$ . Yields  $\text{CaA}'_2$  aq and  $\text{BaA}'_2$  2aq, both crystallising in needles.

**SULPHO-CUMINIC ACID**  $\text{C}_{10}\text{H}_{12}\text{SO}_3$ , *i.e.*  $\text{C}_6\text{H}_4\text{Pr}(\text{SO}_3\text{H})\text{CO}_2\text{H}$  [4:3:1]. [160°]. Formed by sulphonating cuminic acid (Widman, *B.* 22, 2276). Crystalline.— $\text{BaA}''$  aq: sl. sol. water.— $\text{BaH}_2\text{A}''_2$  4 1/2 aq. Prisms, m. sol. water.

*Chloride*  $\text{C}_6\text{H}_4\text{Pr}(\text{SO}_3\text{Cl})\text{COCl}$ . [56°].

*Amide*  $\text{C}_{10}\text{H}_{12}\text{Pr}(\text{SO}_3\text{NH}_2)\text{CONH}_2$ . [225°]. Tables, sol. hot water.

*Amic acid*  $\text{C}_{10}\text{H}_{12}\text{Pr}(\text{SO}_3\text{NH}_2)\text{CO}_2\text{H}$ . [246° cor.]. Formed by heating the amide with  $\text{KOH}$  aq at  $100^\circ$ . Formed also by oxidising (*\beta*)-cymene sulphonic amide [148°] with chromic acid mixture, an isomeric change taking place (Romsen a. Day, *Am.* 5, 158). Needles, sol. hot water. Yields  $\text{BaA}'_2$  3aq, v. s. sol. water.

*Sulpho-n-cuminic acid*

$\text{C}_6\text{H}_3\text{Pr}(\text{SO}_3\text{H})\text{CO}_2\text{H}$  [4:3:1]. Formed by sulphonation of *n*-cuminic acid (W.). V. sol. alcohol, ether, and water.— $\text{BaA}''$  aq: needles, sl. sol. Aq.

*Chloride*  $\text{C}_6\text{H}_3\text{Pr}(\text{SO}_3\text{Cl})\text{COCl}$ . [43°].

*Amide*  $\text{C}_6\text{H}_3\text{Pr}(\text{SO}_3\text{NH}_2)\text{CONH}_2$ . [203°].

Tables (from water).

*Amic acid*  $\text{C}_6\text{H}_3\text{Pr}(\text{SO}_3\text{NH}_2)\text{CO}_2\text{H}$ . [216° cor.]. Formed from the amide (W.), and also by oxidation of *p*-di-*n*-propyl-benzene sulphonic amide [103°] (Romsen, *Am.* 5, 158). Long needles (from water).— $\text{CaA}'_2$  6aq.— $\text{CuHA}'_2$  2aq.— $\text{AgA}'$ : flocculent pp.

*Sulpho-cuminic acid. Amic acid*

$\text{C}_6\text{HMe}_2(\text{SO}_3\text{NH}_2)\text{CO}_2\text{H}$  [5:3:2:1]. Formed by oxidation of isodurene sulphonic amide by alkaline  $\text{KMnO}_4$  (Jacobsen, *B.* 15, 1855). The K salt is amorphous.

**Sulpho-cuminic acid. *Amic acid***  
 $C_9H_8Me_2(SO_3NH_2).CO_2H$  [6:4:2::1]. Formed by oxidation of the corresponding isodurene sulphonic amide (J.). The K salt is crystalline.

*Reference.*—Oxy-sulpho-cuminic acid.

**SULPHO-CYANIC ACID** v. vol. ii. p. 303.

**SULPHOCYANO-ACETIC ACID**  $C_2H_3NSO_2$ , i.e.  $Cy.S.CH_2.CO_2H$ . Formed from potassium sulphocyanide and sodium chloro-acetate (Claesson, *B.* 10, 1347). Thick oil, changing to a solid polymeride when heated.— $NaA'$  aq: prisms. Converted by  $AgNO_3$  into  $HS.CH_2.CO_2Na$ .  $CuSO_4$  forms, after a time, a black pp. of cuprous thioglycollate. —  $KA'$  aq. —  $BaA'$  4aq: tables. —  $BaA'$  aq: prisms. —  $CaA'$  2aq. —  $MnA'$  2aq.

**Ethyl ether**  $EtA'$ . (225°). S.G. 1.174. Formed by boiling chloro-acetic ether with potassium sulphocyanide (Heintz, *A.* 136, 223). Liquid. Yields thioglycollic acid and thioglycollic ether on distillation with phosphoric acid. Polymerised by repeated distillation, many other products being formed at the same time. Boiling dilute  $HClAq$  forms  $NH_4.CO_2S.CH_2.CO_2H$  [143°], which is v. sol. alcohol and ether, yields  $MeA'$  [75°–80°] and  $CaA'$  2aq, and is resolved by heat into cyanic and thioglycollic acids (Nencki, *J. pr.* [2] 16, 11).  $EtA'$  at 120° forms ethyl sulphocyanide and iodo-acetic acid.

**Isoamyl ether**  $C_5H_{11}A'$ . (255°).

**Amide**  $CH_2(S.CN).CONH_2$ . Needles.

**Polymeride**  $(C_2H_3NSO_2)_n$ . [200°]. Formed from potassium sulphocyanurate and potassium chloro-acetate (Claesson, *J. pr.* [2] 33, 121; *B.* 14, 732). Needles, sol. alcohol and ether. Decomposed by  $HClAq$  at 100° into thioglycollic acid and cyanuric acid.— $BaA''$  2aq: small prisms, nearly insol. water.— $BaHA''$  2aq: large prisms.— $EtA'''$ . [81°]. Formed by distilling sulphocyanic-acetic ether. Needles, nearly insol. hot water.

**Persulphocyanodiacetic acid**

$C_2N_2S(S.CH_2.CO_2H)_2$ . [177°]. Formed from sodium chloro-acetate, iso-persulphocyanic acid, and  $KOHAq$  (Klason, *J. pr.* [2] 38, 381). Plates.— $BaA''$  3aq.— $CaA''$  3aq.— $ZnA''$  aq.— $CdA''$ .— $CuA''$  3aq.— $EtA''$ . Oil.

**Amide**. [125°]. Prisms.

**SULPHOCYANO-ACETIC ALDEHYDE**

$CH_2(SCy).COH$ . [below –20°]. S.G. 1.47. Formed by heating iodo-acetic aldehyde with  $AgSCy$  and ether (Chautard, *A. Ch.* [6] 16, 193; *C. R.* 106, 1169). Oil, miscible with alcohol and ether. Decomposed by distillation, by treatment with  $Cl_2$  and by  $HClAq$ .  $HNO_3$  forms acetic acid, sulphocyanic-acetic acid, and thio-carbimido-acetic acid [128°]. Rectified by alkalis.

**SULPHOCYANO-ACETONE**  $C_2H_3NSO_2$ , i.e.  $CH_2.CO.CH_2.SCy$ . S.G. 1.2; 22 1.18. S. 7 at 16°. Formed from chloro-acetone and barium sulphocyanide (Tscherniac, *C. R.* 96, 587; *B.* 16, 349; 25, 2607, 2623). Liquid, v. e. sol. ether, v. sl. sol. ligroin. Decomposed by heat. Dissolves in aqueous  $KHSO_4$ . Boiling dilute  $HClAq$  converts it into oxy-methyl-thiazole. Ammonium sulphocyanide forms 'propimine sulphocyanide'  $CH_2.C(NH).CH_2.SCy$  [42°] (231°), which yields  $B'H.PtCl_6$ ,  $B'HNO_3$  [183°],  $B'H_2SO_4$  2aq,  $B'HSy$  [115°],  $B'MeI$  [160°], and  $CH_2.C(NH).CH_2.SCy$  [134°].

**Oxim**  $CH_2.C(NOH).CH_2.SCy$ . [135°]. Yellowish prisms (Arapides, *A.* 249, 18). Produces great irritation on the skin.

**SULPHOCYANO-ACETOPHENONE** v. PHENACYL SULPHOCYANIDE.

**SULPHOCYANO-BARBITURIC ACID**

$C_5H_4N_2SO_2$ , i.e.  $CO < \begin{smallmatrix} NH.CO \\ NH.CO \end{smallmatrix} > CH_2.SCy$ . Formed from di-bromo-barbituric acid and alcoholic  $KSCy$  in the cold (Trzeinski, *B.* 16, 1058). The free acid splits up into thiodialuric acid and other products. Hot  $KOH$  aq also forms thiodialuric acid.— $NH_4A'$ .— $KA'$ : tables (from water).— $AgA'$ : crystalline pp.

**$\gamma$ -SULPHOCYANO-BUTYRIC ACID. Nitrile.**  
 $CH_2(SCy).CH_2.CH_2.CN$ . (c. 195° at 40 mm.). Formed by boiling potassium sulphocyanide (1 pt.) with  $\gamma$ -chloro-butyrionitrile (1 pt.) and alcohol (Gabriel, *B.* 23, 2190). Liquid. Partially decomposed by distillation under atmospheric pressure. Converted by conc.  $H_2SO_4$  into  $S_2(CH_2.CH_2.CH_2.CO.NH_2)_2$ .

**$\alpha$ -SULPHOCYANO-ISOBUTYRIC ALDEHYDE.**  
 $CH_2(SCy).CHO$ . S.G. 1.63. Formed from  $\alpha$ -iodo-isobutyric aldehyde and  $AgSCy$  (Chautard, *A. Ch.* [6] 16, 198). Liquid with nauseous odour, decomposed by heat, by acids, and by alkalis.

**SULPHOCYANO-ETHANE. SULPHONIC ACID**  $C_2H_3NSO_3$ , i.e.  $CH_2(SCy).CH_2.SO_3H$ . Formed from  $CH_2(SCy).CH_2Cl$  and aqueous  $Na_2SO_3$  in sunlight (James, *J. pr.* [2] 26, 381).

**SULPHOCYANO-FORMIC ETHER**  
 $CyS.CO_2Et$ . The compound  $(CyS.CO_2Et)EtOH$  is got by mixing chloro-formic ether with ammonium sulphocyanide and alcohol (Delitsch, *J. pr.* [2] 10, 118; cf. Henry, *J. pr.* [2] 9, 464). It crystallises in prisms [41°], insol. water, v. e. sol. alcohol. Alcoholic potash forms  $C_2H_3KNSO_2$ , crystallising from alcohol in plates.  $KOH$  aq forms  $KSCy$ , alcohol, and  $K_2CO_3$ .

**SULPHOCYANO-HEPTOIC ALDEHYDE.**

Formed from iodo-heptioic aldehyde and  $AgSCy$  in ether (Chautard, *A. Ch.* [6] 16, 198). Yellowish liquid with fætid odour. Decomposed by heat, by acids, and by alkalis.

**$\beta$ -SULPHOCYANO-PROPIONIC ALDEHYDE**  $CH_2(SCy).CH_2.CHO$ . Formed by treating  $\beta$ -iodo-propionic aldehyde dissolved in ether with  $AgSCy$  (Chautard, *A. Ch.* [6] 16, 197). Liquid with fætid odour. Decomposed by heat, and resinified by alkalis and by mineral acids.

**$\omega$ -SULPHOCYANO-TOLUIC ACID. Nitrile.**  
 $CH_2(SCy).C_6H_4.CN$ . (86°). Formed from  $\omega$ -cyano-benzyl chloride and  $KSCy$  in alcohol (Gabriel & Day, *B.* 23, 2179). Needles. Converted by conc.  $HClAq$  at 180° into thiophthalide  $C_6H_4SO$  [57°]. Conc.  $H_2SO_4$  at 30°–70° forms cyano-benzylmercaptan  $C_6H_4NS$  [62°].

**SULPHOCYANO-ISOVALERIC ALDEHYDE.**

Formed from iodo-isovaleric aldehyde and  $AgSCy$  in ether (Chautard, *A. Ch.* [6] 16, 198). Liquid, with fætid odour, easily decomposed by heat, by  $HClAq$ , and by alkalis.

**SULPHO-DURIDE** v. DI-DURYL SULPHONE.

**SULPHO-ETHYL-BENZOIC ACID. *Amic acid***  
 $C_8H_7NSO_2$ , i.e.  $C_6H_5Et(SO_2NH_2).CO_2H$  [262° cor.]. Formed by oxidising the sulphonic amide of *p*-di-ethyl-benzene with  $CrO_3$  (Remsen & Noyes, *Am.* 4, 202). Needles.— $BaA'$  3aq.

**SULPHO-FUMARIC ACID**  $C_4H_4SO_4$ , *i.e.*  $CO_2H.CH:C(SO_3H).CO_2H$ . Formed by the action of Br or of  $HNO_3$  on the salts of (8)-bromo-(8)-sulpho-pyromucic acid (Hill a. Palmer, *Am.* 10, 409).— $BaA''$ , 2aq: v. sl. sol. water.— $AgA''$  2aq.

**SULPHO-HIPPURIC ACID**  $C_8H_8NSO_4$ , *i.e.*  $C_6H_5(SO_3H).CO.NH.CH_2.CO_2H$ . Formed from hippuric acid and  $SO_3$  (Schwanert, *A.* 112, 59). Amorphous, deliquescent mass. Converted by nitrous acid into sulpho-benzoic acid.— $BaA''$  aq: needles.— $Pb.OA''$ .

**SULPHO-ISATIC ACID** *v.* ISATIC ACID.

**SULPHO-TRIMELLITIC ACID**  $C_6H_4SO_4$ , *i.e.*  $C_6H_2(SO_3H)(CO_2H)_3$  [5:4:2:1]. Formed, together with the amic acid  $C_6H_2(SO_3NH_2)(CO_2H)_3$ , by oxidation of  $C_6H_4Me(SO_3NH_2)(CO_2H)_3$  [2:5:4:1] by  $KMnO_4$  (Jacobsen a. H. Meyer, *B.* 16, 192).— $KH_2A''$  8aq: prisms, m. sol. cold water. Potash-fusion yields oxy-trimellitic acid.

**SULPHO-TRIMESIC ACID.** *Amic acid*  $C_6H_4NSO_4$ , *i.e.*  $C_6H_2(SO_3NH_2)(CO_2H)_3$  [x:5:3:1]. Formed by oxidation of the amic acid of *o*- or *p*-sulpho-mesitylenic acid (Jacobsen, *A.* 206, 203).— $KH_2A''$  2aq: crystalline mass, m. sol. cold water. Conc.  $HClAq$  at  $210^\circ$  forms  $NH_3$ ,  $H_2SO_4$ , and trimesic acid. Potash-fusion gives oxytrimesic acid.

**$\alpha$ -SULPHO-MESITYLENIC ACID**  $C_9H_8SO_4$ , *i.e.*  $C_6H_4Me_2(SO_3H).CO_2H$ . Formed, together with a ( $\beta$ )-isomeride which yields  $CaA''$  4aq, by the action of  $SO_3$  on mesitylenic acid (Remsen a. Brown, *Am.* 3, 218). Yields *o*-oxy-mesitylenic acid on fusion with potash. By successive treatment with  $PCl_5$  and  $NH_3$  it is converted into an amide [288°].— $CaA''$  4aq. Less sol. water than the salt of the ( $\beta$ )-isomeride.

**Sulpho-mesitylenic acid.** *Amic acid*  $C_9H_8NSO_4$ , *i.e.*  $C_6H_4Me_2(SO_3NH_2).CO_2H$  [5:3:6:1]. [262° cor.]. Formed, together with the (5:3:4:1)-isomeride, by oxidising mesitylene sulphonic amide with chromic acid mixture or alkaline  $KMnO_4$  (Hall a. Remsen, *Am.* 2, 131; *B.* 10, 1040; Jacobsen, *B.* 12, 604; *A.* 206, 167). Short prisms (from water), sl. sol. hot water, sol. alcohol and ether. Decomposed by heating with conc.  $HClAq$  at  $200^\circ$  into  $H_2SO_4$  and mesitylenic acid. Soda-fusion forms mesitylenic acid and *m*-xylene sulphonic amide [137°].— $CaA'$ , 6aq: long flat plates.— $CaA'$ , 5aq.— $BaA'$ , 3aq. *S.* 3:3 at  $0^\circ$ ; 1:4 at  $21^\circ$ .— $CaA'$ , 4aq: blue needles.— $CaA'$ , 3aq.— $AgA'$ : pp.

**Sulpho-mesitylenic acid.** *Amic acid*  $C_9H_8Me_2(SO_3NH_2).CO_2H$  [5:3:4:1]. [276° cor.]. Formed as above (J.). Long needles, v. sol. alcohol and ether, more sol. hot water than its isomeride. Conc.  $HClAq$  at  $200^\circ$  forms mesitylenic acid. Soda-fusion gives oxy-mesitylenic acid.— $BaA'$ , 2aq. *S.* 2:05 at  $0^\circ$ .— $CaA'$ , 2aq: prisms.— $CaA'$ , aq: blue monoclinic prisms.

**SULPHO-DI-METHYL-BENZOIC ACID.** *Amic acid*  $C_9H_8NSO_4$ , *i.e.*  $C_6H_4Me_2(SO_3NH_2).CO_2H$  [4:2:5:1]. [268°]. Formed by oxidation of the sulphonic amide of  $\psi$ -cumene (Jacobsen a. Meyer, *B.* 16, 190). Long needles (from water). Yields di-methyl-benzoic acid on heating with conc.  $HClAq$  at  $210^\circ$ .— $KA'$  aq.

**Sulpho-di-methyl-benzoic acid.** [180°–190°]. *Amic acid*  $C_9H_8Me_2(SO_3NH_2).CO_2H$  [1:2:5:3]. ( $\alpha$ )-*Sulphamine-hemimellitic acid.* [238°]. Formed, together with the more soluble ( $\beta$ )-iso-

meride, by oxidising the sulphonic amide of hemimellithene with alkaline  $KMnO_4$  (Jacobsen, *B.* 19, 2519). Needles, sl. sol. cold water.  $HClAq$  at  $150^\circ$  forms sulpho-di-methyl-benzoic acid and, finally, hemimellitic acid [144°]. Potash-fusion yields an oxy-hemimellitic acid.— $BaA'$ , 5aq: small tables, m. sol. water.

**Sulpho-di-methyl-benzoic acid.** *Amic acid*  $C_9H_8Me_2(SO_3NH_2).CO_2H$  [1:3:5:2]. [174°]. Formed as above. Stellate groups of minute needles. Converted by heating with  $HClAq$  into a very soluble sulphonic acid, and finally into *m*-xylene. Potash-fusion gives an easily soluble oxy-hemimellitic acid.— $BaA'$ , 4aq: needles.

**Isomeride v. SULPHO-MESITYLENIC ACID.**

**SULPHO-METHYL-TEREPHTHALIC ACID.** *Amic acid*  $C_9H_8Me(SO_3NH_2)(CO_2H)_2$  [2:5:4:1]. [295°–300°]. Formed by oxidation of  $\psi$ -cumene sulphonic amide by alkaline  $KMnO_4$  (Jacobsen a. H. Meyer, *B.* 16, 190). Small needles (from water).— $BaA''$  2aq: stellate groups of prisms.

**SULPHONAMIDE** *v.* SULPHAMIDE, p. 567; and IMIDO-SULPHONAMIDE *v.* SULPHIMIDO-AMIDE, p. 587.

**SULPHONAMIDES.** Amides of sulphonic acids. They contain the group  $SO_2NH_2$  attached by S to carbon.

**SULPHONAMIDO-** compounds *v.* *Amic acids* derived from Sulpho-compounds.

**SULPHO-NAPHTHALENE-AZO-** compounds *v.* Azo-compounds.

( $\alpha'$ )-**SULPHO-( $\alpha$ )-NAPHTHOIC ACID**  $C_{11}H_7SO_4$ , *i.e.*  $C_{10}H_7(SO_3H).CO_2H$ . [235°]. Formed, together with the ( $\beta$ )- and ( $\gamma$ )-isomerides, by warming ( $\alpha$ )-naphthoic acid with fuming  $H_2SO_4$  at  $70^\circ$  (Battershall, *A.* 168, 119; Stumpf, *A.* 188, 1). Prisms, v. sol. water. Not deliquescent. Yields ( $\alpha$ )-oxy-naphthoic acid by potash-fusion.— $K_2A''$  2aq.— $CaA''$  3aq.— $BaA''$  4aq. Monoclinic crystals, sl. sol. water.— $BaH_2A''$ , 2aq: prisms, more sol. than  $BaA''$ . ( $\beta$ )-Sulpho-( $\alpha$ )-naphthoic acid. [218°–222°]. Crystalline mass, v. e. sol. water.— $BaA''$  3aq: needles, m. sol. water.— $BaH_2A''$ , 4aq.

( $\gamma$ )-Sulpho-( $\alpha$ )-naphthoic acid. [182°–185°]. Needles, v. sol. water.— $KA''$ .— $BaA''$  1½aq: m. sol. water.— $BaH_2A''$ , aq: almost insol. cold Aq.

**Sulpho-( $\alpha$ )-naphthoic acid.** *Nitrile*  $C_{10}H_6Cy.SO_2NH$ . Formed by sulphonating ( $\alpha$ )-naphthonitrile (Dutt, *B.* 16, 1251; Armstrong a. Williamson, *C. J. Proc.* 3, 43).— $BaA'$ , 6aq: glistening plates.— $KA'$  3aq: prisms.

**Chloride of the nitrile**  $C_{10}H_6Cy.SO_2Cl$ . Prisms, sol. benzene.

( $\alpha'$ )-Sulpho-( $\beta$ )-naphthoic acid. [230°]. Formed, together with the ( $\beta'$ )-isomeride, by sulphonating ( $\beta$ )-naphthoic acid (B.; S.). Crystalline.— $BaA''$  aq.— $BaA''$  6½aq.— $BaH_2A''$ , 6½aq. ( $\beta'$ )-Sulpho-( $\beta$ )-naphthoic acid.— $BaA''$  2aq. Less sol. water than the acid salt.

**Reference.**—OXY-SULPHO-NAPHTHOIC ACID.

**SULPHO-NAPHTHYL ETHYL DI-THIO-CARBONATE.** The salt  $SO_3K.C_6H_4.S.CS.OEt$ , formed from potassium xanthate and diazotised naphthionic acid, crystallises from water in colourless plates, converted by boiling dilute alcoholic potash into  $S_2(C_6H_4.SO_3K)_2$  (Leuckart, *J. pr.* [2] 41, 218). The corresponding salt from ( $\beta$ )-naphthylamine ( $\beta$ )-sulphonic acid crystallises in small plates.

**SULPHO-( $\beta$ )-NAPHTHYL-PHOSPHORIC ACID**  $\text{SO}_2\text{H.C}_{10}\text{H}_7\text{.O.PO(OH).C}_{10}\text{H}_7\text{.SO}_2\text{H}$ . Formed, together with the anhydride  $\text{O.PO(OH).C}_{10}\text{H}_7\text{.SO}_2\text{H}$ , by heating potassium ( $\beta$ )-naphthol sulphionate (1 mol.) with  $\text{PCl}_5$  (2 mols.) at  $100^\circ$  (Claus a. Zimmermann, *B.* 14, 1482). Decomposed by boiling alkalis into phosphate and ( $\beta$ )-naphthol sulphionate. The Ba salt is a white powder, sl. sol. water.

**SULPHONES.** Compounds of the form  $\text{R.SO}_2\text{R'}$  where R and R' are attached by means of C to S. They may be formed from the corresponding sulphides and sulfoxides by oxidation with  $\text{KMnO}_4$  (Beckmann, *J. pr.* [2] 17, 475). Aromatic sulphones can be prepared by the action of  $\text{AlCl}_3$  on a mixture of a sulphonic chloride and an aromatic hydrocarbon (Beckurts a. Otto, *B.* 11, 472, 2066), and by heating a sulphonic acid with a hydrocarbon and  $\text{P}_2\text{O}_5$  at  $200^\circ$  (Michael a. Adair, *B.* 10, 583). Sulphones are often formed by the action of sulphuric acid on aromatic hydrocarbons. The sulphones are volatile, and are not reduced by nascent hydrogen. They are not attacked by  $\text{PCl}_5$  or  $\text{KMnO}_4$ . Chlorine in daylight converts di-phenyl-sulphone into chloro-benzene (1 mol.) and  $\text{C}_6\text{H}_5\text{.SO}_2\text{Cl}$ , while in sunlight it yields chloro-benzene (2 mols.) and  $\text{SO}_2\text{Cl}_2$ . Disulphones  $\text{CH}_3(\text{SO}_2\text{R})_2$  are not attacked by alcoholic potash at  $140^\circ$ , while disulphones of the form  $\text{R'.SO}_2\text{CH}_2\text{CH}_2\text{SO}_2\text{R'}$  are converted by alcoholic potash into a sulphonic acid and an oxy-sulphone (Otto a. Kossing, *B.* 20, 185). The disulphones  $\text{CMe}_2(\text{SO}_2\text{Et})_2$  (sulphonal),  $\text{CHMe}(\text{SO}_2\text{Me})_2$ ,  $\text{CHEt}(\text{SO}_2\text{Et})_2$ ,  $\text{CEt}_2(\text{SO}_2\text{Me})_2$ ,  $\text{CMeEt}(\text{SO}_2\text{Et})_2$  (trional), and  $\text{CEt}_2(\text{SO}_2\text{Et})_2$  (tetronal) are powerful hypnotics (Baumann a. Kast, *H.* 14, 52).

**SULPHONIC ACIDS (organic).** Acids containing the group  $\text{SO}_2\text{OH}$  united to C by S. Fatty sulphonic acids may be formed by the action of silver sulphite on alkyl iodides, the resulting ether being saponified. Fatty sulphonic acids may also be got by boiling alkyl iodides with  $\text{K}_2\text{SO}_3$  or  $(\text{NH}_4)_2\text{SO}_3$  for a long time. Both fatty and aromatic sulphonic acids may be got by oxidation of the corresponding mercaptans, sulphides, and sulphydrylides. The sulphonic acids of fatty acids and alcohols are formed by the action of  $\text{SO}_3$  or  $\text{ClSO}_3\text{H}$  on fatty acids and of  $\text{SO}_3$  on alcohols;  $\text{SO}_3\text{H}$  taking the  $\alpha$ -position (Hemilian, *A.* 176, 1). Aromatic compounds readily yield sulphonic acids on treatment with  $\text{SO}_3$ , with  $\text{H}_2\text{SO}_4$ , or with  $\text{ClSO}_3\text{H}$ . As a rule not more than two  $\text{SO}_3\text{H}$  groups enter a benzene nucleus. Aromatic sulphonic acids may also be obtained by the action of  $\text{SO}_3$  on diazo-compounds. On adding  $\text{NaCl}$  to the product of sulphonation of aromatic compounds, the Na salt of the sulphonic acid frequently separates in crystalline form (Gattermann, *B.* 24, 2121). Nitric acid does not attack fatty sulphonic acids, while usually it nitrates aromatic sulphonic acids, although it sometimes displaces  $\text{SO}_3\text{H}$  by  $\text{NO}_2$ .  $\text{PCl}_5$  forms sulphonic chlorides which are reduced by zinc and dilute  $\text{H}_2\text{SO}_4$  to mercaptans. Aromatic sulphonic acids are partially converted into the corresponding amido-compounds by fusion with  $\text{NaNH}_2$ . In this way benzene sulphonic acid yields 15 p.c. of aniline (Jackson a. Wing, *Am.* 9, 75). Aromatic sulphonic acids are decomposed by superheated steam at  $200^\circ$ -

$210^\circ$  into the hydrocarbon and  $\text{H}_2\text{SO}_4$  (Kelbe, *B.* 19, 92). Hydrolysis may also be effected by passing superheated steam into a solution of the sulphonic acid containing  $\text{H}_2\text{SO}_4$  or  $\text{H}_3\text{PO}_4$  (Armstrong; Friedel a. Crafts, *C. R.* 109, 96). Aromatic sulphonic acids when fused with potash yield  $\text{K}_2\text{SO}_4$  and phenols. Fusion with  $\text{KCN}$  or  $\text{KFeCy}_3$  yields the corresponding nitriles. Fusion with sodium formate displaces  $\text{SO}_3\text{H}$  by  $\text{CO}_2\text{H}$ .

#### SULPHONIC ACIDS AND DERIVATIVES.

Several inorganic acids, and derivatives of these acids, will be described here, most of which are regarded as derived from  $\text{SO}_2\text{OH.OH}$  by replacing one OH by a monovalent radicle—such as Cl, F, or  $\text{NH}_2$ —or as derived from  $\text{SO}_2\text{OH.H}$  by replacing H by a monovalent radicle. A few sulphonic acids must be formulated as derived from  $2(\text{SO}_2\text{OH.OH})$ , or  $2(\text{SO}_2\text{OH.H})$ , by replacing 2OH, or 2H, by a divalent radicle; and one as derived from  $3(\text{SO}_2\text{OH.OH})$ , or  $3(\text{SO}_2\text{OH.H})$ , by replacing 3OH, or 3H, by a trivalent radicle (\**v. supra*). The sulphonic acids, therefore, are all looked on as compounds of the monovalent radicle  $\text{SO}_2\text{OH}$ . The term sulphonic is also frequently applied to organic acids containing this radicle; but in this dictionary such acids are described as sulphonyl-acids, e.g. sulphonyl-benzoic acid  $\text{C}_6\text{H}_5(\text{SO}_2\text{OH})\text{CO}_2\text{H}$ . The compositions of the sulphonic acids are expressed by the formulae  $\text{R'SO}_2\text{OH}$ ,  $\text{R''}(\text{SO}_2\text{OH})_2$ , and  $\text{R'''(SO}_2\text{OH})_3$ , where  $\text{R'}$  =  $\text{NH}_2$ , Cl, F,  $\text{NO}_2$ ,  $\text{NH.OH}$ , or  $\text{N(NO.OH)}$ ;  $\text{R''}$  =  $\text{NH}$ , or  $\text{N.OH}$ ; and  $\text{R'''}$  = N.

**AMIDOSULPHONIC ACID AND SALTS**  $\text{NH}_2(\text{SO}_2\text{OH})$  and  $\text{NH}_2(\text{SO}_2\text{OM})$ . These compounds are described in the article **SULPHAMIC ACID AND SULPHAMATES** (q.v. p. 567).

**CHLOROSULPHONIC ACID AND SALTS**  $\text{Cl(SO}_2\text{OH)}$  and  $\text{Cl(SO}_2\text{OM)}$ . The acid has also been called *chlorohydrosulphurous acid*, *monochlorosulphuric acid*, *sulphuric chlorhydrate* or *hydrochloride*, *sulphuric chlorhydrin*, and *sulphuryl hydroxyl chloride*.

**Chlorosulphonic acid**  $\text{Cl(SO}_2\text{OH)}$ .

**Formation.**—1. By the direct union of  $\text{SO}_3$  and  $\text{HCl}$  (Williamson, *Pr.* 7, 11; Baumstark, *A.* 140, 75; Williams, *C. J.* [2] 7, 804; Dewar a. Cranston, *C. N.* 20, 174; Michaelis, *J. Z.* 6, 235, 292).—2. By the reaction of  $\text{PCl}_5$ ,  $\text{POCl}_3$ , or  $\text{PCl}_3$  with conc.  $\text{H}_2\text{SO}_4$  (Müller, *B.* 6, 227; Geuther, *D.* 5, 925; Thorpe, *C. J.* 37, 358).—3. By distilling fuming  $\text{H}_2\text{SO}_4$  with  $\text{P}_2\text{O}_5$  in a current of  $\text{HCl}$  (Müller, *loc. cit.*).—4. By the reaction of  $\text{HCl}$  with crystallised fuming  $\text{H}_2\text{SO}_4$  (Beckurts a. Otto, *B.* 11, 2058).—5. By the action of  $\text{Cl}$ ,  $\text{S}_2\text{Cl}_2$ , or  $\text{S}_2\text{O}_2\text{Cl}_2$  with conc.  $\text{H}_2\text{SO}_4$ ; or of  $\text{Cl}$  with moist  $\text{SO}_3$  in presence of  $\text{Pt}$  at a red heat. 6. By warming  $\text{S}_2\text{O}_2\text{Cl}_2$  with water (Billitz a. Heumann, *B.* 16, 602).

**Preparation.**—1. Three parts of the most conc.  $\text{H}_2\text{SO}_4$  (preferably the residue from preparing  $\text{SO}_3$ ) are warmed in a long-necked flask, and two parts  $\text{PCl}_5$  are added little by little; when  $\text{HCl}$  ceases to be given off the contents of the flask are fractionated, the part boiling between  $c. 152^\circ$ - $156^\circ$  being collected apart.—2. Very conc. oil of vitriol, 200 parts, is mixed with  $\text{POCl}_3$ , 226 parts, the mixture is gently heated and then distilled  $2(\text{SO}_2\text{OH.OH}) + \text{POCl}_3 = 2(\text{Cl.SO}_2\text{OH}) + \text{HPO}_3 + \text{HCl}$  (Thorpe, *loc. cit.*)—

3. A mixture of  $P_2O_5$  and fuming  $H_2SO_4$  is distilled in a current of  $HCl$ , and the product is fractionated; this method removes all traces of  $P$  chlorides (Müller, *loc.*).—4. Commercial crystalline fuming  $H_2SO_4$  (approximately pure  $H_2S_2O_7$ ) is placed in a retort connected with a good condenser, dry  $HCl$  gas is passed in so long as absorption occurs, the liquid is distilled, and the product fractionated; the yield is very satisfactory (Beckurts a. Otto, *B.* 11, 2058).

*Properties.*—A colourless liquid, fuming much in air, and having a powerful, penetrating odour. S.G.  $d_4^{20} = 1.78474$  (Thorpe, *C. J.* 37, 358); Michaelis (*J. Z.* 6, 235, 292) gives 1.776 at  $18^\circ$ . Boils at  $155.3^\circ$  at 760 mm. pressure (*l. c.*; v. also M., *loc.*; Clausnitzer, *B.* 11, 2008; Beckurts a. Otto, *loc.*; Behrend, *B.* 8, 1004). Ogier (*C. R.* 96, 616) gives H.F. [ $SO_4^+$  solid,  $HCl$ ] = 14,400. Baumstark (*A.* 140, 75) found V.D. 59.3 (calc. = 58.12) (temp. is not given); Williams (*C. J.* [2] 7, 304) found V.D. at  $216^\circ$  to be 32.8; Heumann a. Köchlin (*B.* 16, 602) found V.D. 34.7 at  $184^\circ$  and 30.4 at  $410^\circ$ . The gas is therefore dissociated at a temperature not much above its b.p. When  $ClSO_3OH$  is repeatedly heated above  $158^\circ$  it is partly resolved into  $SO_2Cl_2$ ; distilled, it gives  $SO_2Cl_2$  (Williamson, *C. J.* 10, 97). By boiling the compound for a long time with an inverted condenser, Clausnitzer (*B.* 11, 2008) obtained  $H_2SO_4$ ,  $SO_2$ , and  $Cl$ ; Beckurts a. Otto (*loc.*) heated  $ClSO_3OH$  for a long time in a sealed tube at  $c. 170^\circ$ , and found that part remained unchanged, and that  $Cl$  and  $SO_2$  were produced. Heumann a. Köchlin (*loc.*) think that the decomposition at  $c. 440^\circ$  is represented as follows:  $2(ClSO_3OH) = SO_2 + SO_3 + Cl_2 + H_2O$ ; they regard the high value obtained by Baumstark for the V.D. as due to presence of  $S_2O_7Cl_2$  (v. also Claesson, *J. pr.* [2] 19, 235).

*Reactions.*—1. Action of heat, v. *supra*, *Properties*.—2. Water produces  $HClAq$  and  $H_2SO_4Aq$ . 3. Hydrogen sulphide reacts at ordinary temperatures, forming  $HCl$ ,  $S_2Cl_2$ ,  $S$ , and  $H_2SO_4$  (Prinz, *A.* 223, 371).—4. Carbon disulphide, at  $100^\circ$ , produces  $HCl$ ,  $SO_2$ ,  $S$ , and  $COS$ .—5. Phosphorus pentoxide or pentachloride produces  $S_2O_7Cl_2$  (Billitz a. Heumann, *B.* 16, 482; Konswaloff, *C. R.* 96, 1146).—6. Heating with silver nitrate forms  $AgCl$  and  $NO_2SO_3OH$  (Thorpe, *C. J.* 41, 297).—7. Fusion with potassium sulphate forms  $K_2S_2O_7$  and  $HCl$ ; heating with sodium chloride forms  $HCl$  and  $ClSO_3ONa$  (Müller, *B.* 6, 227). 8. The reactions of  $ClSO_3OH$  with several elements were examined by Heumann a. Köchlin (*B.* 15, 416).

**Chlorosulphonates.** The salts of  $ClSO_3OH$ , which reacts as a monobasic acid, are formed by the reaction of the acid with metallic chlorides. It is very difficult to obtain these salts pure. When heated they form sulphates, giving off  $SO_2$  and  $Cl$ ; with water they decompose to chlorides and acid sulphates; and with alcohol  $HCl$  and salts of  $Et.H_2SO_4$  are formed (Müller, *B.* 6, 227). No accurate description of any salts has yet been given.

#### CHLOROSULPHONIC ANHYDRIDE

**Pyrosulphuryl chloride**, under SULPHUR OXY-  
SULPHIDES, p. 618.

**FLUOSULPHONIC ACID AND SALTS**  
 $F.SO_3OH$  and  $F.SO_3OM$ . Only the acid has been isolated.

**Fluosulphonic acid  $F.SO_3OH$ .** Isolated and examined by Thorpe a. Kirman (*C. J.* 61, 921 [1892]). Prepared by placing pure  $SO_2$  in a Pt vessel, surrounded by ice and  $CaCl_2$  (for description of apparatus v. Thorpe a. Hambly, *C. J.* 55, 163), leading in excess of pure  $HF$  (made by heating  $KHF_2$ ), and removing excess of  $HF$  by passing in a stream of dry  $CO_2$  for many hours, the liquid being kept at  $25^\circ-35^\circ$ . A thin, colourless liquid, with a slightly pungent smell, and fuming in air; boils at  $162.6^\circ$ , a little being decomposed with formation of  $H_2SO_4$ , and probably also  $SO_2F_2$ . Reacts rapidly with  $Pb$ , forming  $PbSO_4$  and  $PbF_2$ ; slowly attacks glass. Reacts violently, and sometimes explosively, with water, forming  $H_2SO_4Aq$  and  $HF Aq$ .

**IMIDOSULPHONIC ACID AND SALTS**  
 $NH(SO_3OH)_2$ ,  $NH(SO_3OM)_2$ , and  $NM(SO_3OM)_2$ . By passing dry  $NH_3$  into  $SO_3$ , H. Rose (*P.* 32, 81; 47, 41; 49, 183 [1831-40]) obtained two compounds, which he named *sulphatammon* and *parasulphatammon*, and to both of which he assigned the composition  $2NH_4SO_3$ . These compounds were examined by Jacquelin (*A. Ch.* [3] 8, 293 [1843]), Woronin (*J. R.* 3, 273 [1859]) and others; in 1875 Berglund (*Lunds Universitets Årsskrift*, 12 and 13; *Bl.* [2] 25, 455; 29, 422) showed that Rose's *parasulphatammon* was diammonium imidosulphonate  $NH(SO_3ONH)_2$ , and that *sulphatammon* was probably the triammonium salt  $N.NH_4(SO_3ONH)_2$ . Berglund's conclusions were confirmed, partly by Raschig (*A.* 241, 161 [1887]), and Mente (*A.* 248, 232 [1888]), and partly by Divers a. Haga (*C. J.* 61, 943 [1892]). A full discussion of the constitution of Rose's compounds, with reference to the work of other chemists and an historical summary of researches on the imidosulphonates, will be found in the memoir by D. a. H.

**Imidosulphonic acid  $NH(SO_3OH)_2Aq$ .** This acid is known only in solution, which is obtained by suspending lead imidosulphonate in water, decomposing by a stream of  $H_2S$ , and rapidly filtering from  $PbS$ . The solution gives a pp. with excess of  $BaOAc$ , soluble in  $HNO_3Aq$ ; and a pp. of  $NH(SO_3OK)_2$  with  $K.C_2H_3O_2Aq$ . The acid solution is very unstable, soon becoming changed to  $NH_4(SO_3OH)Aq$  and  $H_2SO_4Aq$  (Jacquelin, *loc.*; Fremy, *A. Ch.* [3] 15, 408; D. a. H., *loc.* p. 945).

**Imidosulphonates.** The normal salts are of the types  $NH(SO_3OM)_2$  and  $NM(SO_3OM)_2$ ; besides these many basic salts have been isolated. The di-alkali imidosulphonates are prepared by mixing solutions of alkali nitrites and sulphites, dissolving the pp. which forms in water, heating this solution for some time, allowing to crystallise, and then boiling the nitrisulphonate,  $N(SO_3OM)_2$ , thus obtained (v. p. 601, NITRISULPHONATES) with acidified water (for instance  $N(SO_3OK)_2 + H_2O = NH(SO_3OK)_2 + KHSO_4$ ); also by heating the alkali amidosulphonates (e.g.  $2(NH_4SO_3OK) = NH(SO_3OK)_2 + NH_3$ ); the diammonium salt  $NH(SO_3ONH)_2$  is also obtained by the reaction of  $NH_3$  with  $SO_3$ ,  $ClSO_3OH$ ,  $SO_2Cl_2$ , or  $S_2O_7Cl_2$ . Most of the other di- salts are obtained by double decomposition from the alkali salts. The tri- salts

are generally prepared by dissolving the di-salts in excess of an aqueous solution of the base and crystallising. A number of mixed salts, such as  $N(NH_4)(SO_3O)_2Ba$ , have been prepared, generally by double decomposition. Basic salts, chiefly of such slightly positive metals as Pb or Hg, have also been isolated. For references *v. Divers a. Haga* (*C. J.* 61, 943). The di-alkali salts give off  $NH_3$ , N, and  $SO_2$  when heated; water reacts to form amidosulphonates  $NH_2(SO_3OM)_2$  and sulphates.

The chief imidosulphonates are those of  $NH_3$ , Ba, Ca, Hg, Pb, K, Ag, and Na; basic salts of Pb and Hg are known; mixed salts containing  $NH_3$  and Na,  $NH_3$  and Ba, Ba and Hg, Ba and Na, Ca and Na, Hg and K, and Ag and Na have been isolated; some of the imidosulphonates also form double compounds with  $KNO_3$  and  $NaNO_3$ . Full accounts of the preparation and reactions of the chief imidosulphonates are given in the memoir of D. a. H.

**NITRILOSULPHONIC ACID AND SALTS**  $N(SO_3OH)_2$  and  $N(SO_3OM)_2$ . The acid has not been isolated, and only a few salts are known.

**Potassium nitrilosulphonate**  $N(SO_3OK)_2$ . Solutions of  $K_2SO_3$  and  $KNO_3$  are mixed in the ratio  $4K_2SO_3:KNO_3$ ; after crystallisation occurs the mixture is heated at  $100^\circ$  till the crystals dissolve, a little water is added, and heating at  $100^\circ$  is continued for a little; on cooling the salt crystallises in well-formed crystals with  $2H_2O$ . The water of crystallisation is removed at  $100^\circ$ – $110^\circ$ ; at a higher temperature decomposition occurs to  $K_2SO_4$ ,  $(NH_4)_2SO_4$ ,  $SO_3$ , and  $SO_2$ . The salt may be crystallised from dilute KOH aq; it is decomposed by water at  $40^\circ$  to  $NH_4(SO_3OK)_2$  and  $KHSO_4$ .

Claus prepared this salt in 1871 (*B. J.* 4, 186), giving it the formula  $NH_2(SO_3K)_2$ , and the name *potassium trisulphannionate*; Raschig (*B. J.* 20, 581 [1887]) showed that the salt was probably  $N(SO_3OK)_2$ , and this composition was confirmed both by the earlier work of Berglund (*B. J.* 9, 252, 1896 [1876]) and by the more recent work of Divers a. Haga (*C. J.* 61, 943).

For description of a salt  $NO(SO_3K)_2$ , *v. Raschig* (*A.* 241, 225); this is the *trisulpho-oxyazotate* of Claus and Raschig. R. regards it as  $(SO_3OK)_2N<\overset{O}{\underset{O}{\text{C}}}>N(SO_3OK)_2$ .

**Sodium nitrilosulphonate**  $N(SO_3ONa)_2$ . Formed by passing  $SO_2$  into a solution of  $NaNO_3$  and  $Na_2CO_3$  (in the ratio  $2NaNO_3:3Na_2CO_3:10aq$ ) until the solution is feebly acid to litmus (*v. D. a. H., l.c.*).

**NITROSULPHONIC ACID**  $NO_2(SO_3OH)$ , AND DERIVATIVES. The acid and its potassium salt have been isolated. The anhydride  $SO_2(NO_2)O(NO_2)SO_2$ , the chloride  $NO_2(SO_3Cl)$ , and an oxy-anhydride  $S_2O_5O(NO_2)_2$  have also been obtained.

**Nitrosulphonic acid**  $NO_2(SO_3OH)$ . (*Nitrosyl-sulphuric acid*  $SO_3OH.O(NO)$ . *Lead chamber crystals*. *Nitrosyl hydrogen sulphate*  $NO.H_2SO_4$ .) This acid is produced by the reaction between  $H_2SO_4$  and any oxide of nitrogen except  $N_2O$  (Henry, *P.* 7, 135; A. Rose, *P.* 50, 161; Reibling, *J.* 1861, 152; Kuhlmann, *A. Ch.* [3] 1, 116; Sestini, *Bl.* [2] 10, 226). It is also formed in the leaden chambers in making  $H_2SO_4$  (first observed by Clement a. Desormes,

*A. Ch.* [2] 59, 329). The acid is produced by the reaction of  $SO_2$  with  $NO$  or  $NO_2$  in presence of water (Davy); also by burning 1 part S mixed with 2.5–3 parts  $KNO_3$  in moist air (Girard a. Pabst, *Bl.* [2] 80, 531; Reinsch, *N. J. P.* 12, 8).

The acid is best prepared by leading  $NO_2$  into well-cooled fuming  $H_2SO_4$  till the whole solidifies, and then drying over  $H_2SO_4$  (Weber, *J. pr.* 85, 425; 100, 37; Tilden, *C. J.* 23, 630); or by adding  $NO_2$  in excess to conc.  $H_2SO_4$ , washing the crystals with liquid  $NO_2$ , and drying in a stream of dry air at  $20^\circ$ – $30^\circ$  or *in vacuo* (Müller, *A.* 122, 1; Gaultier de Claubry, *P.* 20, 467).

Colourless rhombic plates, melting at  $73^\circ$  (Tilden, *l.c.*, gives m.p.  $85^\circ$ – $87^\circ$ ), and easily remaining liquid below this temperature (Weltzien, *A.* 115, 213; De la Provostaye, *A. Ch.* [2] 73, 362). On melting in air the anhydride  $(S_2O_5(NO_2))_2$  is formed, and the water given off causes decomposition of part of the acid to  $H_2SO_4$  and oxides of N (Michaelis a. Schumann, *B.* 7, 1075; Fremy, *C. R.* 70, 61). With dry  $NaCl$  reacts to give  $NaHSO_4$  and  $NOCl$ ; on heating for a little  $HCl$  is given off (Tilden, *l.c.*). Dissolves unchanged in  $H_2SO_4$  (Döbereiner, *S.* 8, 239; *cf. Lunge, B.* 12, 1058; 21, 67).  $SO_2$  is without action on dry  $NO_2(SO_3OH)$ , but in presence of water, or  $H_2SO_4$  aq with S.G. less than 1.55, decomposition occurs with formation of  $H_2SO_4$ ,  $N_2O_5$ , and other oxides of N, according to Lunge (*l.c.*).

**Potassium nitrosulphonate**  $NO_2(SO_3OK)$  seems to be obtained by the reaction of  $SO_2$  on  $KNO_3$ , also by adding liquid  $SO_2$  to dry  $KNO_3$ ; the salt cannot be prepared by neutralising the acid by KOH aq. The salt is decomposed by water (Schultz-Sellack, *B. J.* 4, 113).

#### Nitrosulphonic anhydride

$S_2O_5(NO_2)_2 [O<\overset{O}{\underset{O}{\text{C}}}>SO_2(NO_2)]_2$ . Formed by heating  $NO_2(SO_3OH)$  (Michaelis a. Schumann, *B. J.* 7, 1075); also by the reaction of  $SO_2$  with  $NO$  in absence of O and moisture (H. Rose, *P.* 47, 605; Brüning, *A.* 98, 377); also by adding liquid  $NO_2$  to liquid  $SO_2$  without warming (De la Provostaye, *A. Ch.* [2] 73, 362); by passing electric sparks through a dry mixture of N, O, and  $SO_2$ , or of S vapour and  $N_2O$  or  $NO$  (Morren, *A. Ch.* [4] 4, 293; Chevrier, *C. R.* 69, 136). Hard, regular plates; S.G. 2.14; melts at  $217^\circ$ ; may be distilled unchanged at c.  $360^\circ$ . Decomposed by water to  $NO$ ,  $H_2SO_4$  aq, and  $HNO_3$  aq.  $NO_2(SO_3OH)$  crystallises from a solution in  $H_2SO_4$ .

#### OXYNITROSULPHONIC ANHYDRIDE

$S_2O_5O(NO_2)_2 [O<\overset{O}{\underset{O}{\text{C}}}>\overset{O}{\underset{O}{\text{C}}}>SO_2O(NO_2)]_2$ . A white, fusible, crystalline solid; formed by leading vapour of  $NO_2$  into  $SO_2$  till saturated. Gives  $S_2O_5O(NO_2)_2$  when heated (Weber, *P.* 123, 333; *cf. Thorpe, C. J.* 41, 297).

**Nitrosulphonic chloride**  $NO_2(SO_3Cl)$ . (*Nitrosulphuryl chloride*.) A white, crystalline solid; formed by the action of  $SO_2$  on  $NOCl$  in absence of moisture, also by the reaction of  $AgNO_3$  with  $SOCl_2$  (Thorpe, *C. J.* 41, 297); dissolves unchanged in fuming  $H_2SO_4$ ; dissolves in conc.  $H_2SO_4$ , giving off  $HCl$ , and forming  $Cl(SO_3OH)$  on heating; decomposed by moist air or by water, giving  $HCl$  aq,  $H_2SO_4$  aq,  $HNO_3$  aq, and  $NO$  (Weber, *l.c.*).

**NITROSO-OXY-AMIDOSULPHONIC ACID AND SALTS**  $N(NO.OH)(SO_2.OH)$ . (*Nitroso-hydroxylamine sulphonic acid*  $N(NO)(SO_2.OH).OH$ . *Dinitroso-sulphuric acid*  $SO(NO)_2(OH)_2$ , or  $(SO_2.OH)(NO)_2.H$ .) The acid has not been isolated, but the  $NH_4$ , Ba, Pb, K, and Na salts are known. These salts are described as *Nitrososulphates* under SULPHATES, p. 581.

**OXY-AMIDOSULPHONIC ACID AND SALTS**  $NH(OH)(SO_2.OH)$ . (*Hydroxylamine sulphonic acid* [Raschig]. *Sulphidroxylamic acid* [Claus]. *Sulphazilic acid* [Fremy].) The K salt of the acid is obtained by the action of water on  $N(OH)(SO_2.OK)_2$  (v. *Oxy-imidosulphonic acid* and SALTS, *infra*). The acid itself is known only in aqueous solutions. Two Ba salts, a K salt, and a Na salt have been isolated. The salts have been investigated by Fremy (*A. Ch.* [3] 15, 408), Claus a. Koch (*A.* 152, 336; 158, 52, 194), Raschig (*A.* 241, 161), and Divers a. Haga (*C. J.* 55, 760).

**Oxy-amidosulphonic acid**  $NH(OH)(SO_2.OH).Aq$ . An aqueous solution of this acid (the acid has not been isolated) is prepared by heating an aqueous solution of  $N(OH)(SO_2.OK)_2$  (v. *infra*) to boiling (whereby  $NH(OH)(SO_2.OK).Aq$ ,  $H_2SO_4.Aq$ , and  $KHSO_4.Aq$  are formed), neutralising by  $NH_3.Aq$ , adding  $BaCl_2.Aq$ , filtering off  $BaSO_4$ , adding  $BaO.Aq$  to ppt.  $Ba(N(OH)SO_2.O)_2.Ba.H_2O$ , washing this pp., adding enough  $H_2SO_4.Aq$  to ppt. half the Ba in the salt as  $BaSO_4$ , filtering, and so getting a solution of the (soluble) salt  $(NH(OH)SO_2.O)_2.Ba$ . On now heating this solution with an equivalent quantity of  $H_2SO_4.Aq$  (the Ba in solution must be estimated) and filtering, a solution of the acid is obtained (Fremy, modified by D. a. H.). The solution of  $NH(OH)(SO_2.OH)$  is fairly stable, but slowly decomposes; in presence of hot acid the decomposition is more rapid, giving  $2NH_4OH.H_2SO_4.Aq$  and  $H_2SO_4.Aq$  (Raschig, confirmed by D. a. H.).

**Oxy-amidosulphonates.** The normal salts are of the form  $NH(OH)(SO_2.OM')$  and  $(NH(OH)SO_2.O)_2.M''$ , where  $M' = K$  or Na, and  $M'' = Ba$ ; there is also a dibarium salt  $Ba \left\langle \begin{smallmatrix} N(OH).SO_2.O \\ N(OH).SO_2.O \end{smallmatrix} \right\rangle Ba.H_2O$ . The salts are best obtained from the solution of the soluble salt  $(NH(OH)SO_2.O)_2.Ba.H_2O$  (v. *supra*) by adding the equivalent quantity of a sulphate. The dibarium salt is itself prepared as described under the acid (*supra*); the monobarium salt is obtained by decomposing the di- salt by enough  $H_2SO_4.Aq$  to ppt. half the Ba, filtering, and evaporating over  $H_2SO_4$  (D. a. H.). The oxy-amidosulphonates are fairly stable; they are decomposed by heating with acid into hydroxylamine sulphate and  $H_2SO_4.Aq$ ; caustic alkalis produce only sulphite and hyponitrites (the latter rapidly undergo further change, giving off  $N_2O$ ) (D. a. H., *l.c.*; v. also *C. J.* 61, 988 note). Basic oxides, such as  $CuO$  and  $Ag_2O$ , in presence of alkali produce sulphite, sulphate, and  $N_2O$ , and at the same time the basic oxide is reduced (D. a. H., *l.c.*, p. 770).

Raschig's *sulphazinate* (*A.* 241, 197)  $(SO_2.OK)N(OH).O.(OK)N.(SO_2.OK)$  may be derived from  $2NH(OH)(SO_2.OH)$  by replacing 2H by O.

**OXY-IMIDOSULPHONIC ACID AND SALTS**  $N(OH)(SO_2.OH)_2$ . (*Hydroxylamine disulphonic acid*  $N(SO_2.OH)_2.OH$  [Raschig]. *Disulphidroxyl-amic acid* [Claus].) Only the potassium salt has been isolated.

**Potassium oxy-imidosulphonate**  $N(OH)(SO_2.OK)_2.2aq$  [Claus, *A.* 158, 83; Raschig, *B.* 20, 584; cf. Divers a. Haga, *C. J.* 51, 659]. Prepared by passing a rapid stream of  $SO_2$  through well cooled  $KNO_3.Aq$  made strongly alkaline by  $KOH.Aq$ ; allowing  $N(SO_2.OK)_2$  (v. *Nitrilosulphonates*, p. 601) to crystallise out, pouring off, and allowing to stand. Large, lustrous crystals; almost insol. cold water, more sol. water at  $40^\circ$ – $60^\circ$ ; heated with water gives  $KHSO_4.Aq$  and  $NH(OH)(SO_2.OK).Aq$  (v. *supra*, *Oxy-amidosulphonic acid*). Three Na salts and several other oxy-imidosulphonates have been prepared by D. a. H. (*C. J. Proc.* 1893–4, 61).

The salts described by Fremy (*l.c.*) as *sulphazotates*, and further examined by Raschig (*A.* 241, 211), and formulated by him as  $N(OH)(SO_2.OK)_2.N(OM)(SO_2.OK)_2$ , where  $M = K$  or Na, and  $N(OK)(SO_2.OK)_2.N(OK)(SO_2.OK)_2$ , may be regarded as derived from oxy-imidosulphonic acid  $N(OH)(SO_2.OH)_2$ .

The *oxysulphazotate* of Claus (*sulphazilate* of Fremy) examined by Raschig (*l.c.*, p. 223) and formulated by him as

$(SO_2.OK)_2.N \left\langle \begin{smallmatrix} O \\ N \end{smallmatrix} \right\rangle N(SO_2.OK)_2$ , may be looked on as derived from oxy-imidosulphonic acid by the removal of 2H from  $2N(OH)(SO_2.OH)_2$ .

M. M. P. M.

**SULPHONO-DI-ACETIC ACID** v. DI-METHYLSULPHONE DICARBOXYLIC ACID.

**SULPHONO-DI-BUTYRIC ACID**  $SO_2(CHEt.CO.H)_2$ . [152°]. Formed by oxidation of sulphido-dibutyric acid (5 g.) in neutral solution by  $KMnO_4$  (5 g.) in water (500 g.). Its ether is got from  $SO_2(CH_2.CO_2Et)_2$ , Na, and  $EtI$  (Lovén, *J. pr.* [2] 33, 104). Octahedra.

**Sulphono-di-isobutyric acid**  $SO_2(CMe.CO.H)_2$ . [182°–186°]. Formed by oxidising  $S(CMe.CO.H)_2$  (Lovén). Plates.— $BaA''2aq$ . Groups of needles (from hot water).

**SULPHONO-DIPROPIONIC ACID** v. DI-ETHYL-SULPHONE DICARBOXYLIC ACID.

**SULPHONO-DI-ISOVALERIC ACID**  $SO_2(C_4H_9.CO.H)_2$ . Formed by oxidation of  $S(C_4H_9.CO.H)_2$ , and by the action of  $PrI$  (2 mols.) on sulphono-di-acetic ether (1 mol.) and  $NaOEt$  (2 mols.) at  $120^\circ$ ; the product being saponified by baryta (Lovén, *J. pr.* [2] 33, 114).— $BaA''7aq$ .

**SULPHO-OXY-BENZOIC ACID** v. Oxy-SULPHO-BENZOIC ACID.

**SULPHO-PHENYL-ACETIC ACID**  $C_6H_5SO_3$ , i.e.  $CHPh(SO_3H).CO.H$ . Formed by saponifying the product of the action of  $K_2SO_3.Aq$  on  $\alpha$ -bromophenyl-acetic ether (Papilsky, *J.* 1880, 856). Very deliquescent mass.—Salts:  $KA''$ .— $CaA''$ .— $BaA''$ : plates, m. sol. hot water.— $ZnA''$ .— $PbA''$ .— $CuA''$ : blue plates.— $Me(NH_4)A''$ .— $CHPh(SO_3NH_4).CO.Et$ . Tables, v. sol. water.— $CHPh(SO_3K).CO.Et$ : thin plates, v. e. sol. Ag.

**SULPHO-PHENYL-AMIDO-ACETIC ACID**  $C_6H_5NSO_3.aq$  i.e.  $SO_3H.C_6H_4.NH.CO.H$ . [185°]. Formed by heating phenol (1 pt.) with hippuric acid (1 pt.) and  $H_2SO_4$  (8 pts.) at  $140^\circ$  (Zehenter, *M.* 5, 332; 6, 523). Monoclinic prisms (containing ag);  $a:b:c = 93:1:28$ . Sol.

water and alcohol. Coloured violet by  $\text{FeCl}_3$ . Decomposed by  $\text{HClAq}$  at  $140^\circ$  into phenol, glyccoll, and  $\text{H}_2\text{SO}_4$ . Aqua regia gives  $\text{C}_6\text{H}_4(\text{OH})\text{Cl}(\text{NO}_2)_2$  [1:2:3:5].— $\text{BaHA}''$  3aq.— $\text{AgHA}''$  3aq: concentric groups of needles.

#### p-SULPHO-PHENYL-CARBAMIC ACID.

The acid ether  $\text{C}_6\text{H}_4(\text{SO}_3\text{H})\text{NH}\cdot\text{CO}_2\text{Me}$  [188°] is formed by dissolving methyl phenyl-carbamate in fuming  $\text{H}_2\text{SO}_4$  (Hentschel, *B.* 18, 979) and also by adding  $\text{NaOH}$  to a cooled mixture of  $\text{ClCO}_2\text{Me}$  and aqueous *p*-amido-benzene sulphonic acid (Noelting, *Bl.* [2] 50, 622).

#### SULPHO-PHENYL-GLYCCOLL v. SULPHO-PHENYL-AMIDO-ACETIC ACID.

##### m-SULPHO-PHENYL-PROPIONIC ACID

$\text{C}_6\text{H}_4\text{SO}_3$ , i.e.  $\text{C}_6\text{H}_4(\text{SO}_3\text{H})\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$ . Formed by treating bromo-sulpho-phenyl-propionic acid with sodium-amalgam (Göring, *C. C.* 1877, 793, 808). Yields *m*-oxy-benzoic acid by potash-fusion.

##### exo-Sulpho-phenyl-propionic acid

$\text{C}_6\text{H}_4\cdot\text{C}_6\text{H}_5(\text{SO}_3\text{H})\cdot\text{CO}_2\text{H}$ . Formed by boiling cinnamic acid with aqueous  $\text{K}_2\text{SO}_3$  for 12 hours (Valet, *A.* 154, 62). Cinnamaldehyde is converted by  $\text{K}_2\text{SO}_3$  into  $\text{PhC}_6\text{H}_4(\text{SO}_3\text{K})\cdot\text{CH}(\text{OH})\cdot\text{SO}_3\text{K}$ , which crystallises in needles (containing 2aq) and is converted by boiling dilute  $\text{H}_2\text{SO}_4$  into *exo*-sulpho-phenyl-propionic acid (Heusler, *B.* 24, 1805). Crystals, v. sol. water and alcohol. Converted by boiling conc.  $\text{KOH}$  into cinnamic acid. Not affected by boiling dilute  $\text{H}_2\text{SO}_4$ .— $\text{KHA}''$ . S. 4 at  $15^\circ$ .— $\text{KA}''$  2aq. Efflorescent crystals.— $\text{CaA}''$  2aq. Plates.— $\text{BaA}''$  4aq.— $\text{K}_2\text{ZnA}''$ .— $\text{AgA}''$  1aq: white crystalline pp.

#### SULPHO-PHENYL-THIO-CARBAMIC ACID.

Anhydride  $\text{C}_6\text{H}_4\text{NSO}_2$ , i.e.  $\text{C}_6\text{H}_4\cdot\text{NH}\cdot\text{CS}\cdot\text{SO}_2$  [183°]. Formed from phenyl-thio-carbimide and  $\text{SO}_2$  (Magatti, *B.* 11, 2267). Crystals (from benzene), insol. water, alcohol, and ether. Insol. acids and alkalis. Decomposed by water at  $100^\circ$  into  $\text{H}_2\text{S}$ ,  $\text{CO}_2$ , and amido-benzene *p*-sulphonic acid.

**SULPHO-PHTHORETIC ACID**  $\text{C}_6\text{H}_4\text{SO}_3$ . Formed from phloretic (oxy-phenyl-propionic) acid and  $\text{SO}_2$  (Nachbaur, *J. pr.* 75, 45). Sour syrup.— $\text{NaA}''$  2aq.— $\text{BaA}''$  3aq.— $\text{MgA}''$  5aq.— $\text{CaA}''$  4aq. Crystalline.

#### c-SULPHO-PHTHALIC ACID

$\text{C}_6\text{H}_4(\text{SO}_3\text{H})(\text{CO}_2\text{H})_2$  [3:2:1]. (a)-*Sulpho-phthalic acid*. Formed by oxidising naphthalene (a)-sulphonic amide by  $\text{KMnO}_4$  (Remsen, *Am.* 5, 107), and got also, in small quantity, together with the (b)-acid, by the action of fuming  $\text{H}_2\text{SO}_4$  on phthalic acid (Rée, *C. J.* 49, 514). Minute crystals, v. sol. water, m. sol. alcohol. Soda-fusion gives *c*-oxy-phthalic acid.— $\text{BaA}''$  2aq. Needles, sl. sol. hot water.— $\text{PbHA}''$  1½aq.— $\text{AgKA}''$  2aq. Ppd. by adding  $\text{AgNO}_3$  to a solution of the K salt (Stokes, *Am.* 6, 280).

##### Amic acid $\text{C}_6\text{H}_4\text{NSO}_2$ , i.e.

$\text{C}_6\text{H}_4(\text{SO}_2\text{NH}_2)(\text{CO}_2\text{H})_2$  [155°–160°]. Formed by oxidation of naphthalene (a)-sulphonic amide by alkaline  $\text{KMnO}_4$ . Thick needles (containing aq). At  $155^\circ$  it splits up into  $\text{H}_2\text{O}$  and the anhydride. Conc.  $\text{HClAq}$  at  $150^\circ$  forms *c*-sulpho-phthalic acid.— $\text{KHA}''$ : slender needles, v. sl. sol. cold water.— $\text{KA}''$ . [300°]. Amorphous, v. s. sol. water. Yields, when heated, the compound  $\text{C}_6\text{H}_4(\text{COCl})_2\cdot\text{N}\cdot\text{POCl}_2$  [120°–126°] whence

$\text{MeOH}$  produces  $\text{C}_6\text{H}_4(\text{CO}_2\text{Me})_2\cdot\text{N}\cdot\text{H}\cdot\text{C}(\text{OMe})_2$  [144°] (Stokes, *Am.* 6, 274).— $\text{PbA}''$ .— $\text{AgHA}''$ : needles.— $\text{AgA}''$ . Insol. hot water.

##### Anhydride of the Amic Acid

$\text{C}_6\text{H}_4(\text{CO}_2\text{H})_2\cdot\text{N}\cdot\text{H}\cdot\text{C}(\text{CO})_2$ . Formed as above.

Begins to sublime at  $200^\circ$ , but is not melted at  $240^\circ$ . Its silver salt  $\text{C}_6\text{H}_4\text{AgNSO}_2$  is converted by  $\text{MeI}$  into  $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_2\cdot\text{NMe}$  [191° ocr.].

The compound  $\text{C}_6\text{H}_4(\text{CO}_2\text{Me})_2\cdot\text{NMe}$  [180° cor.] has also been prepared.

##### i-Sulpho-phthalic acid

$\text{C}_6\text{H}_4(\text{SO}_3\text{H})(\text{CO}_2\text{H})_2$  [4:2:1]. (b)-*Sulpho-phthalic acid*. (γ)-*Sulpho-phthalic acid*. [140°] (when hydrated). The chief product of the sulphonation of phthalic acid or anhydride at  $100^\circ$ – $200^\circ$  (Loew, *A.* 143, 257; Rée, *B.* 18, 1629). Formed also by oxidation of naphthalene (β)-sulphonic amide (Remsen, *Am.* 5, 110) and by the action of hot  $\text{HNO}_3$  (S.G. 1.3) on potassium di-nitro-(a)-naphthol sulphate (*naphthol yellow S*) (Graebe, *B.* 18, 1126; Rée, *C. J.* 49, 516). Crystalline (containing aq), very hygroscopic, v. sol. water and alcohol, insol. ether. At  $180^\circ$  it yields the anhydride  $\text{C}_6\text{H}_4\text{SO}_3$ . Soda-fusion forms *i*-oxy-phthalic acid. The K salt fused with sodium formate yields trimellitic acid. Heated with resorcin it yields fluorescein sulphonic acid.  $\text{PCl}_5$  forms  $\text{C}_6\text{H}_4(\text{SO}_3\text{Cl})(\text{CO}_2\text{H})_2$  [170°], oily  $\text{C}_6\text{H}_4(\text{SO}_3\text{Cl})_2\cdot\text{CO}$  and  $\text{C}_6\text{H}_4\text{Cl}_2\cdot\text{CO}$ .

The mono-chloride is converted by  $\text{NH}_3$  into  $\text{C}_6\text{H}_4(\text{SO}_3\text{NH}_2)(\text{CO}_2\text{H})_2$  [192°–202°] which crystallises in plates, sol. water, alcohol, and ether.

Salts.— $\text{KHA}''$  2aq. Needles, v. sol. water.— $\text{KA}''$  2aq.— $(\text{NH}_4)_2\text{HA}''$  1½aq. At  $200^\circ$  it yields  $\text{C}_6\text{H}_4(\text{SO}_3\text{NH}_2)_2\cdot\text{N}\cdot\text{H}$  [c. 300°]. Crystallising in monoclinic prisms.— $\text{BaA}''$  2aq.— $\text{BaHA}''$  5aq. S. 5 at  $15^\circ$ ; 50 at  $100^\circ$ . At  $250^\circ$  it yields  $\text{Ba}(\text{C}_6\text{H}_4\text{SO}_3)_2$ .— $\text{BaHA}''$  2aq.

##### s-Sulpho-isophthalic acid

$\text{C}_6\text{H}_4(\text{SO}_3\text{H})(\text{CO}_2\text{H})_2$  [5:3:1]. [258°]. Obtained by sulphonation of isophthalic acid (Aronstein a. Kramps, *B.* 13, 459; Lönnies, *B.* 13, 704). Long deliquescent needles (containing 2aq). Potash-fusion yields *s*-isophthalic acid.— $\text{KHA}''$  3aq: long needles.— $\text{KA}''$  2aq: prisms.— $\text{BaA}''$  2aq: needles, v. sol. water.

##### i-Sulpho-isophthalic acid

$\text{C}_6\text{H}_4(\text{SO}_3\text{H})(\text{CO}_2\text{H})_2$  [4:3:1]. [244°]. Formed by oxidation of *m*-xylene (a)-sulphonic acid (Jacobsen a. Lönnies, *B.* 13, 1556), and by oxidation of  $\text{C}_6\text{H}_4\text{Me}(\text{SO}_3\text{NH}_2)_2\cdot\text{CO}_2\text{H}$  (Remsen a. Iles, *Am.* 1, 114; Remsen a. Coale, *Am.* 3, 206). Hygroscopic needles (containing 2aq), v. s. sol. water. Potash-fusion yields (a)-oxy-isophthalic acid.—Salts:  $\text{KHA}''$  2aq: needles, sl. sol. cold water. S. 1.59 at  $26^\circ$ .— $\text{KA}''$ .— $\text{CaHA}''$  4½aq. Crystals.— $\text{BaHA}''$  3aq: small needles. S. 0.73 at  $23.5^\circ$ .— $\text{BaHA}''$  4aq.— $\text{BaA}''$  3aq.

##### Amic acid $\text{C}_6\text{H}_4\text{NSO}_2$ , i.e.

$\text{C}_6\text{H}_4(\text{SO}_2\text{NH}_2)(\text{CO}_2\text{H})_2$ . Formed by oxidation of  $\text{C}_6\text{H}_4\text{Me}(\text{SO}_3\text{NH}_2)_2\cdot\text{CO}_2\text{H}$  by  $\text{KMnO}_4$  (Remsen, *B.* 11, 464; 12, 1436; *Am.* 1, 122; 3, 209). When set free from its salts it changes at once to the anhydride  $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_2\cdot\text{N}\cdot\text{H}\cdot\text{C}(\text{CO})_2$  [284°], S. 45

at 10°.—KHA" aq. S. 2.3 at 26°.—K<sub>2</sub>A" 4aq. v. e. sol. water.—CaH<sub>2</sub>A" 2aq.—CaA" 5aq.—BaH<sub>2</sub>A" 2aq.; monoclinic tables.—BaA" 3aq.—Ag<sub>2</sub>C<sub>2</sub>H<sub>3</sub>NSO<sub>4</sub>; crystalline pp. (Jacobsen, *B.* 12, 2820).

**c-Sulpho-isophthalic acid.** *Amic acid* C<sub>6</sub>H<sub>3</sub>(SO<sub>2</sub>NH<sub>2</sub>)(CO<sub>2</sub>H)<sub>2</sub> [2:3:1]. Formed by oxidation of the corresponding *m*-xylene sulphonic amide (Jacobsen, *B.* 11, 902). Its acid potassium salt is sl. sol. water.

**a-SULPHO-PROPIONIC ACID** C<sub>3</sub>H<sub>5</sub>SO<sub>3</sub>, *i.e.* CH<sub>3</sub>CH(SO<sub>2</sub>H).CO<sub>2</sub>H. Formed by boiling *α*-chloro-propionyl chloride with aqueous ammonium sulphite and also by warming propionic acid with ClSO<sub>3</sub>H (Kurbatoff, *B.* 6, 563; *A.* 173, 5). Syrup, v. sol. water and alcohol.—K<sub>2</sub>A" aq.; needles (Rosenthal, *A.* 233, 27).—(NH<sub>4</sub>)<sub>2</sub>A" aq.; prisms.—BaA" 2aq. S. (of BaA") 7.45 at 18°.—CaA" 2aq.—CdA" 2aq.—Ag<sub>2</sub>A" 1; small needles. Got also by mixing propionic anhydride with SO<sub>2</sub> (Franchimont, *R. T. C.* 7, 27).

**β-Sulpho-propionic acid** CH<sub>3</sub>(SO<sub>2</sub>H).CH<sub>2</sub>.CO<sub>2</sub>H. [68°]. Formed by boiling β-iodo-propionic acid with an aqueous solution of (NH<sub>4</sub>)<sub>2</sub>SO<sub>3</sub>. Got also by the action of ammoniacal AgNO<sub>3</sub> on the compound of acrolein with NaHSO<sub>3</sub> (Rosenthal, *A.* 233, 15) and obtained likewise by the oxidation of thiohydantoic acid NH<sub>2</sub>C(NH<sub>2</sub>).S.CH<sub>2</sub>.CH<sub>2</sub>.CO<sub>2</sub>H (Andreasch, *M.* 6, 838; *J.* 169). Hygroscopic crystals, sol. water and alcohol. Decomposes at 160°. Successive treatment with PCl<sub>5</sub> and with tin and HCl aq converts it into sulphydro-propionic acid.

**Salts.**—K<sub>2</sub>A" aq.—KHA" aq.—Na<sub>2</sub>A" aq.—(NH<sub>4</sub>)<sub>2</sub>A" 4aq. Hygroscopic.—HNH<sub>4</sub>A"—BaA" 5aq.—BaH<sub>2</sub>A"—SrA" 6aq.—CaA" 2½aq.—CaA" aq.—MgA" 4aq.—ZnA" 4aq.—CuA"—MnA" 4aq.—PbA"—CdA" aq.—Ag<sub>2</sub>A" ½aq.—HAgA" ½aq.

**Ethyl ether Et<sub>2</sub>A".** Liquid.

**Sulpho-dipropionic acid** is DI-ETHYL-SULPHONE DICARBOXYLIC ACID.

**SULPHO-PROPYL-BENZOIC ACID** v. SULPHO-CUMINIC ACID.

**SULPHO-ISOPROPYL-SUCCINIC ACID** CMe<sub>2</sub>(SO<sub>2</sub>H).CH(CO<sub>2</sub>H).CH<sub>2</sub>.CO<sub>2</sub>H. [*c.* 167°]. Got by action of HNO<sub>3</sub> on sulphocamphyllic acid (Königs a. Hoerlin, *B.* 26, 2044). When heated *in vacuo* at 170° it splits up into water, SO<sub>2</sub>, and terebic acid. Tables (containing 3aq), v. e. sol. water.

**SULPHO-PYROMUCIC ACID** C<sub>6</sub>H<sub>4</sub>SO<sub>3</sub>, *i.e.* CH:O(CO<sub>2</sub>H)CH:O(CO<sub>2</sub>H)O. Formed by dissolving pyromucic acid in cold fuming H<sub>2</sub>SO<sub>4</sub>, and got also by the action of zinc-dust and ammonia on dibromo-sulpho-pyromucic acid (Schwanert, *A.* 116, 268; Hill a. Palmer, *B.* 18, 2095; *Am.* 10, 373, 409). Deliquescent prisms.—K<sub>2</sub>A" 4aq.—KHA"—Na<sub>2</sub>A" 5aq.—NaHA" aq.—BaA" 4aq. Small prisms. Yields fumaric acid when heated with excess of bromine.—Salts: BaH<sub>2</sub>A" 4aq.—BaH<sub>2</sub>A" 6aq.—CaA" 3aq.—PbA" 2aq.—Ag<sub>2</sub>A".

**Amide** C<sub>6</sub>H<sub>4</sub>SO<sub>3</sub>(NH<sub>2</sub>)<sub>2</sub> [218°]. Crystalline.

**(β)-Sulpho-pyromucic acid** C<sub>6</sub>H<sub>3</sub>O(SO<sub>2</sub>H)(CO<sub>2</sub>H). Formed by sulphonation of bromo-pyromucic acid and debromination of the product by zinc-dust and NH<sub>3</sub> (H. a. P.).—Salts: K<sub>2</sub>A" 2½aq.—CaA" 2aq.—BaH<sub>2</sub>A" 5aq.—BaA" 3aq.—BaA" aq.; small concentric prisms.

**SULPHO-PYROTARTARIC ACID** C<sub>4</sub>H<sub>4</sub>SO<sub>4</sub>, *i.e.* C<sub>2</sub>H<sub>2</sub>(SO<sub>2</sub>H)(CO<sub>2</sub>H)<sub>2</sub>. Formed by boiling ita-, citra-, and meso- conic acids with aqueous K<sub>2</sub>SO<sub>3</sub> (Wieland, *A.* 157, 34). Crystalline, v. e. sol. water.—Ca<sub>2</sub>A" 7aq. Sl. sol. cold water.

**SULPHO-QUINOLINE CARBOXYLIC ACID** C<sub>9</sub>H<sub>7</sub>N(SO<sub>2</sub>H).CO<sub>2</sub>H. (*a*)-*Sulpho-cinchoninic acid*. Formed by heating cinchonic acid with SO<sub>2</sub> or with H<sub>2</sub>SO<sub>4</sub> and P<sub>2</sub>O<sub>5</sub> at 180° (Weidel a. Cobenzl, *M.* 1, 814). Triclinic crystals (containing aq), m. sol. hot water, insol. alcohol and ether. Tastes bitter. Potash-fusion gives (*a*)-oxy-cinchoninic acid.—(NH<sub>4</sub>)<sub>2</sub>A" 2aq. Monoclinic crystals; *a:b:c* = 1.19:1.3:53; β = 95°14'.—CaA" 2½aq. Monoclinic crystals.—BaA" 3aq.—PbA" aq.—CuA" aq.; minute sea-green crystals.

(*B.* 2)-*Sulpho-quinoline* (*Py.* 1)-carboxylic acid SO<sub>2</sub>H.C<sub>6</sub>H<sub>4</sub>.C(CO<sub>2</sub>H):CH

CH:CH.CN.—CH' (*β*)-*Sulpho-cinchoninic acid*. Formed at the same time as the preceding acid (Weidel, *M.* 2, 565) and prepared by heating cinchoninic acid (1 pt.) with H<sub>2</sub>SO<sub>4</sub> (7 pts.) at 300° (Von Georgievitch, *M.* 3, 639). The same acid (crystallising with aq) appears to be formed by oxidation of benzylidene-lepidine sulphonic acid by alkaline KMnO<sub>4</sub> (Busch a. Koenigs, *B.* 23, 2683). Colourless needles (containing 2aq), v. sol. hot water. Very bitter. Potash-fusion yields (*β*)-oxy-cinchoninic acid.—(NH<sub>4</sub>)<sub>2</sub>A" 2aq.—BaA" aq.—PbA" 4aq.

**SULPHO-SALICYLIC ACID** v. OXY-SULPHO-BENZOIC ACID.

**SULPHO-SUCCINIC ACID** C<sub>4</sub>H<sub>4</sub>SO<sub>3</sub>, *i.e.* CO<sub>2</sub>H.CH<sub>2</sub>.CH(SO<sub>2</sub>H).CO<sub>2</sub>H.

**Formation.**—1. By exposing cooled succinic acid to SO<sub>2</sub> vapour (Fehling, *A.* 38, 285; 49, 203).—2. By boiling fumaric and maleic acids with aqueous K<sub>2</sub>SO<sub>3</sub> (Credner, *Z.* [2] 6, 77; Strecker a. Messel, *A.* 157, 15; *Z.* [2] 6, 459, 671).—3. From succinyl chloride and Ag<sub>2</sub>SO<sub>4</sub> (Carius a. Kämmerer, *A.* 131, 167).—4. By oxidation of thio-malic acid with HNO<sub>3</sub> (Carius, *A.* 129, 9).

**Properties.**—Deliquescent mass, v. e. sol. water, alcohol, and ether. Yields fumaric acid when fused with potash.

**Salts.**—K<sub>2</sub>A" aq.; efflorescent crystals.—K<sub>2</sub>A" 2½aq.—K<sub>2</sub>A" 1½aq. Crystals.—KHA"—K<sub>2</sub>HA" 2aq.—K<sub>2</sub>HA" 1½aq.—(NH<sub>4</sub>)<sub>2</sub>A" aq.—(NH<sub>4</sub>)<sub>2</sub>HA" aq.; crystals.—Ba<sub>2</sub>A" (dried at 100°). Pp.—Ca<sub>2</sub>A" 6aq.—Pb<sub>2</sub>A" 4aq.—Pb<sub>2</sub>A" 3aq.—Pb<sub>2</sub>OA"—Pb<sub>2</sub>O<sub>2</sub>A"—Ag<sub>2</sub>A"; m. sol. water.

**SULPHO-TEREPHTHALIC ACID** C<sub>8</sub>H<sub>4</sub>SO<sub>3</sub>, *i.e.* C<sub>6</sub>H<sub>2</sub>(SO<sub>2</sub>H)(CO<sub>2</sub>H)<sub>2</sub> [3:4:1].

**Formation.**—1. By heating terephthalic acid with fuming H<sub>2</sub>SO<sub>4</sub> at 250° (Ascher, *A.* 161, 2; Schoop, *B.* 14, 223).—2. By oxidation of sulpho-*p*-toluic acid (Remsen a. Burney, *Am.* 2, 410; Weber, *B.* 25, 1740), of *p*-xylene sulphonic acid (Remsen a. Kuhara, *Am.* 2, 414), and of C<sub>6</sub>H<sub>4</sub>Me(SO<sub>2</sub>NH<sub>2</sub>).CO<sub>2</sub>H (Hall a. Remsen, *B.* 12, 1432; *Am.* 2, 56).

**Properties.**—Hygroscopic needles or tables.

**Salts.**—KHA"—KHA" ½aq. Needles (Remsen a. Keiser, *Am.* 5, 170).—KHA" aq (W.).—K<sub>2</sub>A" aq.—BaHA" aq.—CaHA" 1½aq.—BaHA" 1½aq.—BaHA" aq.—BaA" 8aq.—BaH<sub>2</sub>A" 5aq.—PbHA" 2aq.—Ag<sub>2</sub>HA".

**Amic acid** C<sub>6</sub>H<sub>3</sub>(SO<sub>2</sub>NH<sub>2</sub>)(CO<sub>2</sub>H). Formed by oxidising *p*-xylene sulphonic amide with alkaline K<sub>2</sub>FeC<sub>4</sub> (Noyes a. Walker, *Am.* 9, 94).

Concentric needles, sol. hot water. Not melted at  $810^{\circ}$ .— $\text{KHA}''$  3aq.— $\text{BaA}''$  aq: nodules.

*Imide*  $\text{C}_6\text{H}_3(\text{CO}_2\text{H})_2 < \text{SO}_2 > \text{NH}$ . [284'] (W.); [299° cor.] (N. a. W.). Formed by oxidation of  $\text{C}_6\text{H}_3\text{Me}(\text{SO}_2\text{NH}_2)_2\text{CO}_2\text{H}$  by  $\text{KMnO}_4$ . Short thin prisms (from ether), in. sol. cold water.  $\text{AgNO}_3$  gives a pp. insol.  $\text{HNO}_3$ .— $\text{KC}_6\text{H}_3\text{N}_2\text{SO}_4$  aq.— $\text{BaC}_6\text{H}_3\text{N}_2\text{SO}_4$  3aq. Scales, v. sl. sol. water.— $\text{Ag}_2\text{C}_6\text{H}_3\text{N}_2\text{SO}_4$ .

**SULPHO-TOLUENE DICARBOXYLIC ACID.** *Amic acid*  $\text{C}_6\text{H}_3\text{Me}(\text{SO}_2\text{NH}_2)(\text{CO}_2\text{H})_2$  [1:4:3:5]. [c.  $300^{\circ}$ ]. Formed by oxidation of  $\psi$ -cumene sulphononic amide (Jacobsen a. Meyer, *B.* 16, 190). Needles, sol. water, alcohol, and ether.— $\text{BaA}''$  2½aq: small prisms, sl. sol. water.

**SULPHO-o-TOLUIC ACID**  $\text{C}_6\text{H}_4\text{SO}_3$ , i.e.  $\text{C}_6\text{H}_3\text{Me}(\text{SO}_2\text{H})(\text{CO}_2\text{H})$  [2:3:1]. Formed by heating o-toluic acid with  $\text{H}_2\text{SO}_4$  (5 pts.) for 3 hours at  $160^{\circ}$  (Jacobsen a. Wierss, *B.* 16, 1960). Crystalline, v. e. sol. water. Potash-fusion yields o-oxy-toluic acid.

**Sulpho-o-toluic acid.** *Amic acid*  $\text{C}_6\text{H}_3\text{Me}(\text{SO}_2\text{NH}_2)(\text{CO}_2\text{H})_2$  [2:5:1]. [243°]. Formed, together with about an equal quantity of the (2,4,1)-isomeride, by oxidation of *m*-xylene o-sulphononic amide by alkaline  $\text{KMnO}_4$  (Jacobsen, *B.* 14, 38). Long needles, sol. alcohol, ether, and water. Potash-fusion yields the corresponding oxy-toluic acid. Further oxidised by  $\text{KMnO}_4$  to  $\text{C}_6\text{H}_2(\text{SO}_2\text{NH}_2)(\text{CO}_2\text{H})_2$ .

**Sulpho-o-toluic acid.** *Amic acid*  $\text{C}_6\text{H}_3\text{Me}(\text{SO}_2\text{NH}_2)(\text{CO}_2\text{H})_2$  [2:4:1]. [217°]. Formed as above. Long needles, sl. sol. cold water, v. sol. alcohol and ether.— $\text{KA}'$ : crystals.

**s-Sulpho-m-toluic acid**  $\text{C}_6\text{H}_3\text{Me}(\text{SO}_2\text{H})(\text{CO}_2\text{H})_2$  [3:5:1]. Formed, together with the (3,4,1)-isomeride, by sulphonating *m*-toluic acid with fuming  $\text{H}_2\text{SO}_4$  at  $180^{\circ}$  (Jacobsen, *B.* 14, 2355).

**Sulpho-m-toluic acid.** *Amic acid*  $\text{C}_6\text{H}_3\text{Me}(\text{SO}_2\text{NH}_2)(\text{CO}_2\text{H})_2$  [3:4:1]. [248°]. S. 2 at  $15^{\circ}$ . Formed by oxidation of *m*-xylene sulphononic amide (Riemsen, *Am.* 1, 37; 3, 205; Jacobsen, *B.* 11, 895). Needles (from water), m. sol. alcohol, sl. sol. ether. Potash-fusion gives (4,3,1)-oxy-*m*-toluic acid.  $\text{KMnO}_4$  yields sulpho-isophthalic acid.— $\text{CaA}'$  1½aq: small concentric needles.— $\text{BaA}'$  4aq.— $\text{BaA}'$  5aq.— $\text{AgA}'$ : needles (from hot water).

**Sulpho-m-toluic acid.** *Amic acid*  $\text{C}_6\text{H}_3\text{Me}(\text{SO}_2\text{NH}_2)(\text{CO}_2\text{H})_2$  [3:2:1]. [203°]. Formed by oxidation of the corresponding *m*-xylene sulphononic amide [96°] (J.). Converted by potash-fusion into the corresponding oxy-toluic acid.

**Sulpho-p-toluic acid**  $\text{C}_6\text{H}_4\text{Me}(\text{SO}_2\text{H})(\text{CO}_2\text{H})$  [4:3:1].

**Formation.**—1. By oxidation of thio-carvacrol (Fiesch, *B.* 6, 480; Bechler, *J. pr.* [2] 8, 170).—2. By oxidation of cymene sulphononic acid (Riemsen, *Am.* 2, 411; R. Meyer a. Baur, *A.* 220, 18).—3. From *p*-toluic acid and  $\text{SO}_2$  (Fischli, *B.* 12, 616).—4. By oxidation of *p*-xylene sulphononic acid (Riemsen, *Am.* 8, 264). Needles (containing 2aq). Not hygroscopic. V. sol. water, insol. ether. Decomposes at  $185^{\circ}$ – $190^{\circ}$  without melting. Potash-fusion gives oxy-*p*-toluic acid [204°]. Conc.  $\text{HClAq}$  at  $190^{\circ}$  forms *p*-toluic acid.

**Salts.**— $\text{KHA}''$  3aq.— $\text{KHA}''$  2aq.—

$\text{K}_2\text{A}''$  1½aq.— $\text{MgA}''$  8aq.— $\text{MgA}''$  7aq.— $\text{BaA}''$  8aq.— $\text{BaA}''$  4aq.— $\text{PbA}''$  aq.— $\text{PbA}''$  3aq.— $\text{PbA}''$  8½aq.— $\text{AgA}''$  aq.

*Amide*  $\text{C}_6\text{H}_3\text{Me}(\text{SO}_2\text{NH}_2)(\text{CONH}_2)_2$  [218°]. *Amic acid*  $\text{C}_6\text{H}_3\text{Me}(\text{SO}_2\text{NH}_2)(\text{CO}_2\text{H})_2$  [267°].

Formed by oxidation of cymene sulphononic amide and of *p*-xylene sulphononic amide by chromic acid mixture (Riemsen a. Hall, *Am.* 2, 50; *B.* 11, 229; Noyes a. Walker, *Am.* 9, 98). Needles, sol. cold alcohol, insol. ether, sl. sol. cold water.— $\text{BaA}'$  2aq.— $\text{CaA}'$  4aq.— $\text{MnA}'$  5aq: needles. Probably the same amic acid [242°] is formed by oxidising *p*-butyl-toluene sulphononic amide by  $\text{KMnO}_4$  (Kelbe a. Baur, *B.* 16, 2565). Sl. sol. water, nearly insol. alcohol.

**Sulpho-p-toluic acid**  $\text{C}_6\text{H}_4\text{Me}(\text{SO}_2\text{H})(\text{CO}_2\text{H})$  [4:2:1]. [182°] (W.); [190°] (R.). Got by oxidising thio-thymol (Fittica, *A.* 172, 329) and by evaporating its imide with  $\text{HClAq}$  (Weber, *B.* 25, 1741). Crystals (containing 3aq).— $\text{NH}_4\text{HA}''$ .— $\text{MgA}''$ .— $\text{Ag}_2\text{A}''$ .

**Anhydride**  $\text{C}_6\text{H}_3\text{Me} < \text{CO} > \text{O}$ . [97°]. Got by treating the acid with  $\text{AcCl}$ .

*Amic acid*  $\text{C}_6\text{H}_3\text{Me}(\text{SO}_2\text{H})(\text{CONH}_2)_2$  [186°]. Prisms (containing aq).— $\text{NH}_4\text{A}'$ . Got from the anhydride in benzene by the action of dry  $\text{NH}_3$ .— $\text{AgA}'$  aq: scales (from water).

*Amic acid*  $\text{C}_6\text{H}_3\text{Me}(\text{SO}_2\text{NH}_2)(\text{CO}_2\text{H})_2$  [185°]. Got by boiling the imide with water (Weber, *B.* 25, 1739). Yellowish crystals. Probably identical with the preceding amic acid.— $\text{BaA}'$  2aq.— $\text{AgA}'$ .— $\text{MeA}'$ . [145°].— $\text{EtA}'$ . [95°].

*Imide*  $\text{C}_6\text{H}_3\text{Me} < \text{SO}_2 > \text{NH}$ . *Methyl-saccharin*. [246°]. Got from *p*-toluidine sulphononic acid *via*  $\text{C}_6\text{H}_3\text{MeCySO}_2\text{H}$ ,  $\text{C}_6\text{H}_3\text{MeCySO}_2\text{Cl}$ ,  $\text{C}_6\text{H}_3\text{MeCySO}_2\text{NH}_2$ ,  $\text{C}_6\text{H}_3\text{Me}(\text{CO}_2\text{H})(\text{SO}_2\text{NH}_2)$ , the last body being heated (Kreis, *Ch.* P. 48, 583; *B.* 22, Ref. 719; Weber, *B.* 25, 1737). Sl. sol. cold water, v. sol. alcohol, ether, and alkalis.

Yields  $\text{C}_6\text{H}_3\text{Me} < \text{SO}_2 > \text{NAg}$ , whence  $\text{MeI}$  forms

$\text{C}_6\text{H}_3\text{Me} < \text{SO}_2 > \text{NMe}$  [153°], while  $\text{EtI}$  gives

$\text{C}_6\text{H}_3\text{Me} < \text{SO}_2 > \text{NEt}$  [106°] (Weber). The imide is converted by warming with aqueous  $\text{KOH}$  into *p*-toluidine sulphononic acid.

**Di-sulpho-o-toluic acid**  $\text{C}_6\text{H}_3\text{Me}(\text{SO}_2\text{H})(\text{CO}_2\text{H})_2$  [2:3:5:1]. Formed by sulphonation of o-toluic acid with  $\text{H}_2\text{SO}_4$  containing  $\text{SO}_2$  (Jacobsen a. Wierss, *B.* 16, 1960). Minute needles, v. e. sol. water.— $\text{BaA}'$ : amorphous, v. sol. water.

**Di-sulpho-p-toluic acid**  $\text{C}_6\text{H}_4\text{Me}(\text{SO}_2\text{H})(\text{CO}_2\text{H})_2$ . Formed by heating *p*-toluic acid with fuming  $\text{H}_2\text{SO}_4$  and  $\text{P}_2\text{O}_5$  (Weinreich, *B.* 20, 982).— $\text{BaHA}''$  5aq. Crystals.

**Reference.**—NITRO-SULPHO-TOLUIC ACID.

**SULPHO-UVITIC ACID**  $\text{C}_6\text{H}_3\text{I}_2\text{SO}_3$ , i.e.  $\text{C}_6\text{H}_2\text{Me}(\text{SO}_2\text{H})(\text{CO}_2\text{H})_2$  [5:6:3:1]. Formed by evaporating its amic acid with conc.  $\text{HClAq}$  (Jacobsen, *A.* 206, 185). Needles (from dilute  $\text{H}_2\text{SO}_4$ ). Potash-fusion yields oxy-uvitic acid.— $\text{KH}_2\text{A}''$  2aq.— $\text{Ba}_2\text{A}''$ . S. 3–23 at  $12^{\circ}$ – $5^{\circ}$ . Needles.

*Amic acid*  $\text{C}_6\text{H}_3\text{Me}(\text{SO}_2\text{NH}_2)(\text{CO}_2\text{H})_2$ . A product of oxidation of mesitylene sulphononic amide with  $\text{KMnO}_4$  (Hall a. Riemsen, *Am.* 2, 136; Jacobsen). When set free from its salts it changes at once into the anhydride  $\text{C}_6\text{H}_2\text{N}_2\text{SO}_4$  [270°], S. 5 at  $100^{\circ}$ .— $\text{KHA}''$ .— $\text{BaA}''$ .— $\text{BaA}''$  3aq.

**SULPHO-ISOVALERIC ACID**  $C_4H_9SO_3$ , i.e.  $C_4H_9(SO_3H).CO_2H$ . Formed by heating isovaleric acid (1 pt.) with  $ClSO_3H$  (1 pt.) at  $150^\circ$  (De Varda, G. 18, 91). Deliquescent crystalline mass. Its aqueous solution partially decomposes when heated.—BaA" aq.—PbA" 2aq.

**SULPHOXIDES**. Organic compounds  $R.SO.R'$  formed by the action of conc.  $HNO_3$  on sulphides. Decomposed by heat. Reduced by Zn and  $H_2SO_4$  and by HI to sulphides. Attacked by  $PCl_5$ , sulphides being formed. They reduce  $KMnO_4$ , being converted into sulphones. Sulphoxides containing monovalent alcohol radicles form unstable compounds with  $HNO_3$ , such as  $Et_2SO.HNO_3$  (Beckmann, J. pr. [2] 17, 475).

**SULPHO-XYLENE CARBOXYLIC ACID**. *Amic acid*  $C_8H_7Me_2(SO_3NH_2).CO_2H$  [1:3:4:5]. [ $268^\circ$  cor.]. Formed by oxidising  $\psi$ -cumene sulphonic amide (Jacobsen a. Meyer, B. 16, 190). Long needles, sl. sol. hot water.—KA' aq.—BaA' 2aq.

**SULPHUR**. S. At. w. 31.98. Mol. w. 63.96; probably also 191.88 and 255.84 (v. *infra*). The following data apply to ordinary rhombic S. Melts at  $c. 115^\circ$ ; different observers give from  $111^\circ$  to  $115^\circ$  (v. Helff, Z. P. C. 12, 219; Spring, A. Ch. [5] 22, 170; Kopp, A. 93, 129; Brodie, J. pr. 62, 336; Gernez, C. R. 83, 217; for m.p. at high pressures v. Hopkins, J. 1854, 48). Boils at  $440^\circ$  (Dumas, A. Ch. [2] 36, 83; Troost a. Hautefeuille, C. R. 76, 76, 219). Callendar a. Griffiths (T. 182, 119) give  $444.53^\circ$  as within  $\cdot 1^\circ$  of the true temperature of the vapour of sulphur boiling freely under a pressure of 760 mm. (This determination was made with Pt resistance thermometers with great care, but unfortunately no special precautions were taken to insure the purity of the S used. For other determinations v. Carnelley's *Melting- and Boiling-point Tables*, 1, 11. For b.p. under different pressures from 1 to 760 mm. v. Monckman, Tr. 46, 136.) S.G. c. 2.03 (for numerous data v. Clarke's *Table of Specific Gravities*, 2nd ed., 9). S.G. molten S  $1.801$  to  $1.815$  (Playfair a. Joule, C. S. Mem. 3, 76); S.G. at b.p.  $1.46$  to  $1.51$  (Ramsay, C. J. 35, 471). V.D. varies from c. 122 to c. 62; v. *infra*, *Molecular Weight of S*. S.H. ( $17^\circ$ – $45^\circ$ )  $\cdot 163$  (Kopp, T. 1865, 71); ( $0^\circ$ – $100^\circ$ )  $\cdot 1776$  (Bunsen, P. 141, 1). S.H. (liquid)  $\cdot 2346$  (Person, A. Ch. [3] 21, 295). Latent heat of fusion =  $9.368$  (for 1 g. S) (Person, Lc.). S.V.S.  $15.9$ . S.V. of S in combination varies from  $28.6$  to  $22.6$ ; S.V. at b.p.  $21.6$  (Ramsay, C. J. 35, 471). C.E. (linear)  $\cdot 00006413$  (at  $40^\circ$ ) (Fizean, C. R. 68, 1125; v. also Kopp, A. 93, 129; Pisati, G. 1874, 29; Spring, J. 1881, 1035; Moitessier, J. 1866, 27, who gives C.E. for each  $c. 20^\circ$  from  $110^\circ$  to  $440^\circ$ ). S. in  $CS_2$ ,  $16.54$  at  $-11^\circ$ ,  $18.75$  at  $-6^\circ$ ,  $23.99$  at  $0^\circ$ ,  $37.15$  at  $+15^\circ$ ,  $41.65$  at  $18.5^\circ$ ,  $46.05$  at  $22^\circ$ ,  $94.57$  at  $38^\circ$ ,  $146.21$  at  $48.5^\circ$ ,  $181.84$  at  $65^\circ$  (Cossa, B. 1, 138; Payen, C. R. 84, 456, 508). For S.G. of solutions in  $CS_2$ , v. Macagno (C. N. 43, 192). For S. in  $C_6H_6$  and other solvents v. Pelouze (C. R. 68, 1179; 79,

56). Refraction-equivalent ( $\frac{\mu-1}{d}$  at w.) for

D line  $16.0$  (solid),  $16.47$  (liquid),  $16.1$  (gaseous, for C line),  $16.0$  (in solution),  $16.0$  (calculated from data for  $SO_2$ ),  $16.1$  (from data for  $S_2Cl_2$ )

(Gladstone, P. M. [5] 35, 204). H.C.  $[S.O] = 71.080$  (Th. 2, 247). The E.C. of S is very small; it varies much with temperature (v. Monckman, Pr. 46, 136). The fundamental form of rhombic S is a simple pyramid, or elongated octahedron;  $a:b:c = 8106:1:1.898$ . For emission-spectrum v. Salet, C. R. 68, 404; 78, 559; Bl. [2] 11, 302; Mulder, J. pr. 91, 112; Barrett, J. 1865, 138; Seguin, C. R. 53, 1272; Chautard, C. R. 79, 1123; Plücker a. Hittorf, J. 1863, 109. For absorption-spectrum of S vapour v. Salet, C. R. 74, 865; Gernez, C. R. 74, 803; Ciamician, W. A. B. 77 [2] 839. For vapour-pressures of S vapour v. Regnault (J. 1863, 65). Ignition point c.  $250^\circ$  (Hill, C. N. 61, 125; Blount, C. N. 61, 153).

The following data apply to monoclinic S. Melts at  $117.4^\circ$  (Gernez, C. R. 83, 217); at  $120^\circ$  (Brodie, J. pr. 62, 336). S.G.  $1.982$  (Marchand a. Scheerer, J. pr. 24, 129);  $1.958$  (Deville, J. 1, 365). S.V.S.  $16.4$ . H.C.  $[S.O] = 71.720$  (Th. 2, 247; Petersen, Z. P. C. 8, 601). For volumes occupied at different temperatures v. Toepler (W. 47, 169). Crystallises in secondary forms of a monoclinic prism;  $a:b:c = 1.004:1:1.004$ , angle  $b:c = 84^\circ 14'$ . Sol.  $CS_2$ , from which solution rhombic S crystallises out.

Insoluble sulphur is amorphous; insol.  $CS_2$ ; S.G. c.  $2.04$  (Troost a. Hautefeuille, C. R. 69, 248); S.G. after compression at 8,000 atmos.  $1.9556$  at  $0^\circ$ ,  $1.9643$  at  $100^\circ$  (Spring, Bl. Acad. Belg. [3] 2, 83).

Cf. *Allotropy of Sulphur* (p. 609).

**Occurrence**.—Native, in beds, in Sicily, Mexico, New Zealand, &c.; in the lava fissures of volcanic districts; in small quantities in the mud from the sea-bottom (Buchanan, Pr. E. 1891, 1). Many metallic sulphides also occur native—e.g. sulphides of Sb, As, Cu, Fe, Pb, Hg, and Zn. Sulphates occur in large quantities—e.g. gypsum, celestine, heavy spar; these and other sulphates are found in the earth's crust, in the sea, and in many river and spring waters. (For more details v. *DICTIONARY OF APPLIED CHEMISTRY*, iii. 682.) S is a constituent of albumen, hair, feathers, horn, and some other parts of animals; it is also found in many plants. Small quantities of S compounds are found in the atmosphere near volcanoes. According to Young sulphur occurs in the solar atmosphere (Am. S. [3] 4, 356).

Sulphur has been known from very early times. The quantitative work of Lavoisier, in 1772, on burning S showed this substance to be an element, but it was not finally placed on the list of elements until after the experiments of Gay-Lussac and Thénard in 1809.

**Formation**.—1. By the interaction of  $SO_2$  and  $H_2S$ ;  $2SO_2 + 4H_2S = 3S_2 + 4H_2O$ .—2. By the partial oxidation of  $H_2S$ , either by incomplete combustion or by exposure of  $H_2SAq$  to a limited quantity of air;  $2H_2S + O_2 = 2H_2O + S_2$ . Also by the oxidation of FeS by exposure to moist air;  $2FeS + 3O = Fe_2O_3 + S_2$ .—3. By distilling certain metallic sulphides out of contact with air, e.g.  $3FeS_2 = Fe_3S_4 + S_2$ .—4. By decomposing solution of an alkali or alkaline polysulphide by acid; e.g.  $CaS_2Aq + 2HClAq = CaCl_2Aq + H_2S = 2S_2$ .

Also by adding acid to solution of a thiosulphate; e.g.  $Na_2S_2O_3Aq + 2HClAq = 2NaClAq + H_2O + SO_2Aq + S$ .—5. By decom-

posing  $S_2Cl_2$  by water ( $2S_2Cl_2 + 2H_2O + Aq = 4HClAq + SO_2 + 3S$ ).—6. When sulphates, e.g.  $CaSO_4$ , are in prolonged contact with decaying organic matter (such as plant-leaves) they are reduced to sulphides, and if these come into contact with acids  $S$  is among the products of the reactions that occur. For a fuller account of some of these processes, whereby native  $S$  is probably formed, v. *DICTIONARY OF APPLIED CHEMISTRY*, iii. 683. For methods of forming the various varieties of  $S$  v. *infra*, *Preparation*.

*Preparation*.—1. Ordinary  $S$  is dissolved in pure, dry  $CS_2$ ; a part of the  $CS_2$  is distilled off, and the rest is allowed to deposit crystals of  $S$ . This process is repeated once or twice; the  $S$  crystals are powdered, kept *in vacuo* for some days to remove all  $CS_2$ , and then repeatedly distilled *in vacuo*, the middle portion of the distillate being collected each time.—2. Ppd.  $S$  is distilled several times in  $S_2Cl_2$  to remove  $H$  compounds; the distillate is then repeatedly distilled *in vacuo*, the middle portion only being collected; the distilled  $S$  is finely powdered, repeatedly washed with water, dried, distilled over a few small pieces of pure  $Zn$  *in vacuo* (to remove traces of  $S_2Cl_2$ ), and then repeatedly distilled *in vacuo*.—3.  $S$  is ppd. by adding  $HClAq$  to pure  $Na_2S_2O_3Aq$ , the pp. is repeatedly washed till free from chlorides, dried, distilled repeatedly, and finally distilled several times *in vacuo* (v. Monckman, *Pr.* 46, 149).

Ordinary rhombic sulphur is prepared by melting  $S$  and allowing to cool *very slowly* at  $90^\circ$  (Schützenberger, *C. R.* 66, 746), or by melting and throwing in a crystal of rhombic  $S$  when the liquid has cooled nearly to the crystallisation point (Gernez, *C. R.* 83, 217); also by crystallising from  $CS_2$ ; and, in very well formed crystals, by saturating pyridine or picoline with  $H_2S$  and allowing to stand (Ahrens, *B.* 23, 2708).

Monoclinic sulphur is prepared by melting a considerable quantity of roll sulphur in a Hessian crucible, allowing to cool till a crust forms on the surface, piercing this crust, and pouring out the  $S$  that is still liquid; the walls of the crucible are covered with monoclinic crystals. This form of  $S$  can also be prepared by evaporating alcoholic solutions of  $(NH_4)_2S$  (Mallard, *J.* 1885, 383; Ruys, *J.* 1884, 336; Gernez, *C. R.* 100, 1539; 101, 312); also, along with rhombic crystals, from solution of  $S$  in boiling alcohol, benzene, &c. (Maquenne, *B.* [2] 41, 238). By melting  $S$ , and throwing in a crystal of the monoclinic form when the liquid is near the crystallisation point, the  $S$  solidifies in monoclinic crystals (Gernez, *C. R.* 83, 217).

Soft soluble sulphur is prepared by decomposing  $S_2Cl_2$  by water, or  $Na_2S_2O_3Aq$  or a soluble polysulphide by a limited quantity of acid, or many metallic sulphides by fuming  $HNO_3$ , or  $SO_2Aq$  by  $HSAq$  (Weber, *A.* 141, 432; Rose, *P.* 47, 166; Deville, *Ph. C.* 1848, 200; Fordos a. Gélis, *Ph. C.* 1854, 294). This preparation is not homogeneous; it contains both soluble and insoluble  $S$ .

Insoluble sulphur (insol. in  $CS_2$ ) is prepared by heating ordinary  $S$  nearly to boiling and then cooling rapidly (most easily by slowly pouring into a large quantity of cold water), rubbing the plastic mass so obtained with a glass rod, under water, till it becomes hard, and

removing soluble  $S$  by treatment with warm  $CS_2$  (cf. Deville, *Ph. C.* 1848, 200). Insoluble  $S$  is generally present in 'flowers of sulphur' (which is formed by rapidly cooling vapour of  $S$ ); by treating this with  $CS_2$ , the soluble  $S$  is removed, and the insoluble form remains. Soluble  $S$  becomes covered with a film of the insoluble variety by exposure to sunlight or electric light when melted (Berthelot, *J. pr.* 31, 396; Lallemand, *C. R.* 70, 182). Insoluble  $S$  is also said to be obtained by decomposing  $Na_2S_2O_3Aq$  by  $HClAq$ , dissolving the ppd.  $S$  in  $CHCl_3$ , evaporating, and keeping the crystals that separate for some time (for details v. Engel, *C. R.* 112, 866; Friedel, *C. R.* 112, 834). Insoluble  $S$  is also formed, mixed with the soluble variety, by the incomplete combustion of  $H_2S$  or  $CS_2$ ; by decomposing  $H_2S$  by fuming  $HNO_3$ , aqua regia,  $FeCl_3Aq$ ,  $S_2Cl_2$ , or  $CrO_3Aq$ ; and by the reaction of  $HNO_3Aq$ ,  $SO_2$ , or halogens with melted  $S$  (v. Wöhler, *A.* 86, 373; Vogel, *J. Ph.* [3] 29, 433; Schiff, *A.* 115, 68; Nöllner, *A.* 108, 49; Dietzenbacher, *C. R.* 56, 39). Insoluble  $S$  is also formed by decomposing thiosulphates by acid, or  $S_2Cl_2$  or  $S_2Br_2$  by water, &c., and washing the soft magma so obtained with  $CS_2$  to remove soluble  $S$  (cf. *Preparation of soft soluble sulphur, supra*; and v. Weber, *A.* 141, 432; Rose, *P.* 47, 166; Deville, *Ph. C.* 1848, 200).

Colloidal sulphur, soluble in water, is prepared by passing  $H_2S$  into  $SO_2Aq$  at a little above  $0^\circ$  till all the  $SO_2$  is decomposed, filtering, and concentrating over  $KOH$  *in vacuo*. The yellow solid so obtained is sol. water, but changes to ordinary  $S$  on keeping (Dobus, *C. J.* 63, 282). According to Engel (*C. R.* 112, 866) this form of  $S$  exists in the solution obtained by adding 1 vol.  $Na_2S_2O_3Aq$ , saturated at the ordinary temperature, to 2 vols.  $HClAq$  saturated at  $25^\circ$ – $30^\circ$  and let cool to c.  $10^\circ$ , and filtering from  $NaCl$  that separates. This form of  $S$  has not been isolated in a state of purity.

Regarding the formation of the varieties of  $S$  one from the other, cf. *Allotropy of sulphur*, p. 609.

*Properties*.— $S$  exists in several modifications. The chief are (1) soluble in  $CS_2$ , (2) insoluble in  $CS_2$ , (3) soluble in water.

1. Soluble sulphur exists in two, perhaps in three, varieties, differing in S.G., crystalline form, &c.

A. *Ordinary rhombic (octahedral) sulphur* is a pale-yellow, tasteless, very brittle solid. By crystallisation from  $CS_2$ , it forms clear, yellow, transparent, lustrous crystals; the colour becomes paler at low temperatures, until at  $-50^\circ$  the crystals are almost colourless (Schönbein, *J. pr.* 55, 161); by immersion in boiling water it becomes easily powdered (Daquin, *C. R.* 20, 1667). The crystals are derived from the fundamental form of a rhombic pyramid; about thirty varieties are known. When held in the hand  $S$  emits a distinct odour, probably because of slight volatilisation; according to Berthelot (*C. R.* 100, 1826)  $S$  is wholly volatilisable at a temperature not much above the ordinary.  $S$  is said to phosphoresce in air or  $O$  at  $200^\circ$  (Heumann, *B.* 16, 139). When  $S$  is rubbed it becomes strongly (negatively) electrified.  $S$  is a bad conductor of heat, and a very bad conductor of electricity; the conductivity varies slightly,

according as the light is or is not allowed to fall on the S (Monckman, *Pr.* 46, 136). Insoluble in water; easily sol.  $\text{CS}_2$  (data at beginning of article); also sol.  $\text{C}_2\text{H}_6$ ,  $\text{CHCl}_3$ , &c. Sol. warm conc. acetic acid (Liebemann, *B.* 10, 866); sol. liquid  $\text{SO}_2$  (Sestini, *Z.* 1868, 718). As octahedral S changes to prismatic S near the m.p. of the former, it is evident that hot solutions of the former, in solvents which boil near to, or above, the m.p. of S must contain some prismatic S. Rhombic S slowly changes to monoclinic S when kept near its m.p. (v. p. 609, *Allotropy of sulphur*); the change is accompanied by absorption of heat (c. 650 g.-units for 32 grams S) and expansion of volume (v. Petersen, *Z. P. C.* 8, 601). According to Gernez (*C. R.* 83, 217), if a fair quantity of rhombic S is heated till melting begins on the surface, the interior portions change to microscopic monoclinic crystals, and the surface parts solidify again; this occurs only if the m.p. of monoclinic S (117.4°) is not exceeded. S melts to a clear yellow liquid; at c. 150° the liquid begins to darken and thicken; between 170° and 200° it is black, and so viscous that it does not pour out when the vessel containing it is inverted; at 330°–340° the liquid becomes thin, but it remains dark coloured until it boils at c. 444°. These changes are accompanied by very considerable changes in the electrical conductivity of S: the conductivity is almost constant from 270°–290°; it increases considerably up to 340°–350°, and then very rapidly up to the b.p. (v. Monckman, *Pr.* 46, 136). The expansion-coefficient, for each interval of 10°, decreases from 110° to 180°, and then increases gradually, but not regularly, to the b.p. (v. Moitessier, *J.* 1866, 27). Melted S may be cooled below 95° without solidifying (cf. Gernez, *C. R.* 97, 1298, 1366, 1433). For S.G., S.H., and other physical properties of S, v. beginning of this article.

B. *Monoclinic sulphur*, obtained by cooling molten S, forms transparent, yellowish brown needles; as obtained by crystallisation from solutions the crystals are nearly colourless. The crystals gradually become pale yellow and opaque, due to change into the rhombic form. The crystals are secondary forms of a monoclinic prism. This form of S is sol.  $\text{CS}_2$ ; rhombic S crystallises from this solution; it also dissolves in alcohol,  $\text{C}_2\text{H}_6$ ,  $\text{CHCl}_3$ , &c. On evaporation, crystals, both of rhombic and monoclinic S, separate (Maquenne, *Bl.* [2] 41, 238); monoclinic S may be recrystallised from alcoholic solution of  $(\text{NH}_4)_2\text{S}$  (for references v. p. 607, *Preparation of monoclinic S*). The change of monoclinic to rhombic S is hastened by scratching with a glass rod, or by covering with  $\text{CS}_2$ ; heated to 95.1° at 760 mm. pressure, monoclinic changes to rhombic S; the change is accompanied by appearance of heat and contraction of volume (v. p. 609, *Allotropy of sulphur*). For S.G. &c. of monoclinic S v. beginning of this article.

C. *Soft soluble sulphur* (v. *Preparation of soft soluble sulphur*, p. 607) is only partly sol.  $\text{CS}_2$ ; it contains both soluble and insoluble amorphous S; it is a very pale yellow, or nearly white, soft, amorphous, magma that gradually hardens; when heated it gives off  $\text{H}_2\text{S}$  (Weber, *A.* 141, 432; Rose, *P.* 47, 166; Deville, *Ph. C.* 1848, 200; Fordos a. Gélis, *Ph. C.* 1854, 294).

2. *Insoluble sulphur*. It is doubtful whether more than one variety of this form of S exists, or whether substances described as varieties are not merely mixtures of ordinary insoluble S with impurities.

D. *Plastic sulphur* is a citron-yellow, soft, caoutchouc-like, amorphous solid, formed by suddenly cooling molten S (v. p. 607, *Preparation of insoluble sulphur*); as prepared from ordinary S it is dark brown, but Mitscherlich (*J. pr.* 67, 369) found that the dark colour is caused by the presence of small quantities of fatty substances (cf. Dietzenbacher, *C. R.* 56, 39). The S.G. of brown, plastic S is c. 1.91 to 1.96; but the substance is not homogeneous; it contains both soluble and insoluble S. Plastic S soon hardens and becomes yellow, more quickly when broken up and rubbed with a glass rod, or when immersed in turpentine, or when heated to c. 100°; heat is given out in this change (v. p. 609, *Allotropy of sulphur*). For determinations of the volumes occupied at different temperatures by plastic S v. Toepler (*W.* 47, 169).

E. *Amorphous yellow sulphur* is prepared from plastic S, or flowers of S, or the S obtained by decomposing thionates by acid, or  $\text{H}_2\text{S}$  by oxidisers &c. (v. p. 607, *Preparation of insoluble sulphur*), by washing with warm  $\text{CS}_2$ , till all soluble S is removed. This variety is an amorphous, buff-yellow powder; kept under  $\text{CS}_2$ , it seems white; when dried and rubbed it forms a loose, flocculent powder. Insol.  $\text{CS}_2$ ; somewhat sol.  $\text{CHCl}_3$ ,  $\text{Et}_2\text{O}$ , and alcohol, according to Deville (*J. pr.* 56, 359). Unchanged at the ordinary temperature, but slowly converted to crystalline soluble S at 100° (v. Berthelot, *J. pr.* 70, 941; 71, 364; Favre, *J. Ph.* [3] 24, 344; F. a. Silbermann, *A. Ch.* [3] 34, 447). S.G. 2.046 (v. data at beginning of this article). H.C.  $[\text{S}, 0] = 71,990$  (Petersen, *Z. P. C.* 8, 601). The accounts of this variety of S vary considerably.

F. *Black sulphur*. When S mixed with a very little oil is thrown into a hot Pt dish, a black substance is obtained which has been looked on as a modification of S (Magnus, *P.* 92, 367; 99, 145; Dietzenbacher, *P.* 124, 644; Gross, *B. B.* 1879, 768; Jones, *C. N.* 41, 244; Keller, *Bl.* [2] 4, 346). Knapp (*J. pr.* [2] 38, 48; 43, 305) has shown 'that the black substance contains c. 55 p.c. S and c. 33 p.c. carbonaceous matter; K. thinks it is probably a modification of S adhering to carbonised products of the oil. This substance is said to be non-volatile above the b.p. of S; it is a lustrous, amorphous, solid, insol.  $\text{CS}_2$ , alcohol,  $\text{Et}_2\text{O}$ , oils,  $\text{H}_2\text{SO}_4$ , &c.

3. *Colloidal sulphur soluble in water*. This form of S is said to exist in *Wackenroder's solution* (the milky liquid formed by passing  $\text{H}_2\text{S}$  into  $\text{SO}_2\text{Aq}$ ), and also in the solution obtained by adding  $\text{HClAq}$  to  $\text{Na}_2\text{S}_2\text{O}_4\text{Aq}$  (v. p. 607, *Preparation of colloidal sulphur*). This form of S has not yet been obtained free from impurities; it is a plastic, gummy, pale-yellow solid; it dissolves in water, forming a turbid liquid. By ppg. by  $\text{NaCl}$ , filtering, drying on bibulous paper, shaking with water, and repeating this treatment, Debus (*C. J.* 53, 284) obtained colloidal S that dissolved in water so as to form an almost clear, opalescent liquid which became quite clear on warming, and turbid

on cooling. This solution yielded ordinary S on addition of several salts; evaporation left a viscous, transparent residue; the S in solution did not diffuse through a porous membrane.

*Other modifications of sulphur.* Various experimenters have described forms of S different from those usually recognised, but there is much doubt as to whether any of these are really distinct varieties, or merely mixtures of known varieties (*v. Maquenne, Bl. (2) 41, 238; Gernez, A. Ch. [6] 8, 266; C. R. 100, 1326; Engel, C. R. 112, 866; Berthelot, C. R. 100, 1328; Braine, C. R. 101, 533, 639*).

*Allotropy of sulphur.* The following table presents the best established allotropic forms of S:—

Insoluble in water.	
<i>Soluble in CS<sub>2</sub></i>	<i>Insoluble in CS<sub>2</sub></i>
Rhombic; S <sub>8</sub>	Plastic; S <sub>8</sub>
Monoclinic; S <sub>8</sub>	Amorphous, yellow
Amorphous, soft	
Soluble in water.	
Colloidal; S <sub>8</sub>	

The amorphous forms of S (soft, soluble; yellow, insoluble; and plastic, insoluble) and colloidal S have not been obtained pure; the soluble amorphous always contains insoluble, and the insoluble forms always contain soluble S; the colloidal contains S insoluble in water (*cf. Magnus, J. pr. 70, 215; 72, 48; Weber, J. pr. 70, 354*). It would probably be more accurate to make only three divisions of amorphous S: soluble in water, insol. water but sol. CS<sub>2</sub>, insol. both water and CS<sub>2</sub>. Berthelot (*J. pr. 71, 364; 78, 241*) holds that there are two main varieties of S: soluble in CS<sub>2</sub>, and insoluble in CS<sub>2</sub>. S separated from compounds wherein it acts as the positive radicle, or part of the positive radicle (*e.g. S<sub>2</sub>Cl<sub>2</sub>, SO<sub>2</sub>Aq*), is insoluble, according to B.; whereas when separated from compounds wherein it forms the negative radicle, or part of the negative radicle (*e.g. H<sub>2</sub>S, K<sub>2</sub>S*), S is soluble in CS<sub>2</sub>. B. distinguishes the two varieties of S as electro-positive and electro-negative. Clotz (*J. pr. 74, 266; 78, 241*) asserts that insoluble S is obtained from S<sub>2</sub>Cl<sub>2</sub> when this compound is rapidly shaken with water, but that soluble (crystalline) S separates from the same compound by the gradual action of moist air; and that insoluble S is obtained by electrolysis H<sub>2</sub>SAq provided the electrolysis is rapid (*cf. Weber, P. 141, 432*).

Any form of S changes gradually to the rhombic crystals (S<sub>8</sub>); this change is hastened by raising the temperature within certain limits. Berthelot (*J. pr. 71, 360*) examined the amount of soluble (crystalline) S changed to insoluble at different temperatures; he found that rhombic S heated to 130°–140° and rapidly cooled was still wholly soluble in CS<sub>2</sub>, that much insoluble S was formed by heating to c. 170°, and not much more at c. 230°. These results can be taken only as very roughly approximate, on account of difficulties in cooling, &c. (*cf. Deville, J. pr. 56, 865; Frankenheim, J. pr. 54, 436*). According to experiments of Gernez (*C. R. 97, 1298, 1366, 1433; 100, 1343, 1382*), Ruys (*R. T. C. 8, 1*), and Reicher (*J. 1885, 247*), monoclinic S (S<sub>8</sub>) changes to rhombic (S<sub>8</sub>) in c. 12 days at –86°

to –15°, and in c. 30 minutes at 40°. Reicher (*R. T. C. 2, 246; Z. K. 8, 593*) says that the temperature of change of S<sub>2</sub> to S<sub>8</sub> is 95° at the ordinary pressure, and rises 0°5 for each increase of 1 atmosphere pressure; at 96°1° S<sub>2</sub> changes to S<sub>8</sub>, and at 95°1° S<sub>2</sub> changes to S<sub>8</sub>. The change of any form of S to rhombic crystals is accompanied by the appearance of heat and contraction of volume; the data for the heats of combination of S<sub>2</sub>, S<sub>8</sub>, and amorphous insoluble S give c. 650 gram-units as the quantity of heat produced when 32 grams S<sub>2</sub> change to S<sub>8</sub>, and c. 900 gram-units for the change of 32 grams insoluble amorphous S to S<sub>8</sub>. (*cf. Berthelot, C. R. 70, 941; and Mitscherlich, P. 88, 828*). By keeping S molten for some time at 100°, and then inducing crystallisation by dropping in a crystal of S, either rhombic or monoclinic crystals can be obtained, according as the crystal dropped in is rhombic or monoclinic. When rhombic S is melted and allowed to cool under ordinary conditions the solid contains both S<sub>2</sub> and S<sub>8</sub>; if the cooling is rapid, some amorphous S (both soluble and insoluble) is also produced; hence ordinary 'flowers of sulphur,' formed by rapidly cooling S vapour, contains both soluble and insoluble S, and generally also, when freshly prepared, both rhombic and monoclinic crystals. The crystals of S that separate from solutions in CS<sub>2</sub> are rhombic; both forms of crystals separate from solutions in alcohol, C<sub>2</sub>H<sub>5</sub>, CHCl<sub>3</sub>, &c.; and monoclinic crystals separate from solutions in alcoholic (NH<sub>4</sub>)<sub>2</sub>S. Light brings about the change of soluble into insoluble S; if bright sunlight, or light from the electric arc, falls on molten S at c. 130°, a film of insoluble S is produced. Similarly, light concentrated by a lens and directed on to a conc. solution of S in CS<sub>2</sub>, quickly causes the formation of a speck of insoluble S, which soon increases in size till the liquid becomes turbid (Berthelot, *J. pr. 31, 396; Lallemand, C. R. 70, 182*). No differences have been observed between the chemical behaviour of the soluble and insoluble varieties of S (*v. Schmitz-Dumont, B. 25, 2659*).

*Atomic weight of sulphur.* The at. w. of S has been determined (1) by converting AgCl into Ag<sub>2</sub>S (Berzelius, *P. 65, 319 [1845]; Svanberg a. Struve, J. pr. 44, 320 [1849]*); (2) by reducing Ag<sub>2</sub>SO<sub>4</sub> to Ag by H (Struve, *A. 80, 203 [1851]; Stas, Stas R. 125 [1860]*); (3) by direct synthesis of Ag<sub>2</sub>S (Dumas, *A. Ch. [3] 55, 147 [1859]; Stas, Stas R. 53 [1860]*); (4) by determining S.H. of S (Kopp, *T. 1865, 71*); (5) by determining V.D. of, and analysing, SH<sub>2</sub>, SO<sub>2</sub>, S<sub>2</sub>Cl<sub>2</sub>, &c.

*Molecular weight of sulphur.* The V.D. determinations of Dumas (*A. Ch. [2] 50, 170*) gave c. 95 at 450°–500°, pointing to the molecular formula S<sub>8</sub>; Bineau (*C. R. 49, 799*) found V.D. 39 from 714° to 743°, and 34 between 840° and 1160°, indicating the molecular weight S<sub>8</sub>. The determinations by Deville a. Troost (*C. R. 56, 891*) at 860°–1040° confirmed the number 32 and the molecular weight S<sub>8</sub>. Troost (*C. R. 95, 30*) got the number 42·5 at 665°, indicating a mol. w. of c. S<sub>8</sub> (V.D. corresponding to S<sub>8</sub> = 48). In 1888 Biltz determined V.D. of S at intervals from 468° to 606°, and got results ranging from 113·2 at the lower temperature to 68·4 at the higher (S<sub>8</sub> = 112; S<sub>8</sub> = 64). The V.D. constantly decreased as temperature rose; the V.D. was constant only between 602° and 524°, but the

values were between those calculated for  $S_8$  and  $S_2$ . Biltz concluded that the only molecules which exist as gas through any considerable range of temperature have the composition  $S_8$ . Ramsay (*Z. P. C.* 3, 67 [1899]) thought that Biltz's results did not negative the existence of gaseous molecules more complex than  $S_8$ . Schall (*B. 23*, 1701 [1890]) got numbers for V.D. varying from 115 to 122, at 573° and pressures from 10-20 mm., in an atmosphere of N or  $CO_2$ ; S. concluded that molecules  $S_8$  probably exist in the vapour of S. Riecke (*Z. P. C.* 6, 430 [1890]) regarded the decrease of V.D. with increasing temperature as a dissociation of  $S_8$  to  $S_4$  and  $S_2$ ; by making certain assumptions, his calculated results agreed well with the experimental numbers of Biltz. In 1888 Paterno a. Nasini (*B. 21*, 2153) determined the depression in the freezing-point of benzene caused by dissolving S therein; their results indicated  $S_8$  as the molecular formula of S in solution in benzene. By determining the increase in the boiling-point of  $CS_2$  produced by dissolving S in that solvent, Beckmann (*Z. P. C.* 5, 76 [1889]) got values for the mol. w. of S varying from 245 to 280 ( $S_8 = 256$ ). Sakurai also used this method in 1892 (*C. J.* 61, 989); his values for mol. w. of S in  $CS_2$  varied from 252.3 to 254.9. From observations of the effect of dissolving S in naphthalene on the f.p. of the solvent, Hertz (*Z. P. C.* 6, 358 [1890]) concluded that the mol. w. of S in solution in naphthalene is 256 =  $S_8$ . Helft (*Z. P. C.* 12, 196) in 1893 also got  $S_8$  for mol. w. of S in  $CS_2$ , and in molten P. These results leave little doubt that molecules  $S_8$  exist in solutions of S in  $CS_2$ , and in naphthalene, and  $S_2$  in solutions in benzene; that molecules of greater complexity than  $S_8$ —probably as complex as  $S_8$ —exist in S vapour, but these are stable only through a small range of temperature, and gradually dissociate as temperature rises until all the molecules existing above c. 700° have the composition  $S_2$ . Biltz a. Meyer (*B. 22*, 725 [1889]) have shown that the V.D. of S corresponds with the mol. w.  $S_8$  up to 1600°-1700°.

**Reactions.**—1. Reacts with water at 100° to form  $H_2S$ . Cross a. Higgin (*C. J.* 35, 249; *B. 16*, 1195) found that the solution contained thionic acids; they supposed that these were produced by reactions between the  $H_2S$  and  $SO_2$  formed by the action of the S on the water (*cf.* Payen, *J. Ph.* 8, 371; Mulder, *J.* 1858, 84; Meyer, *C. R.* 74, 195; Gélis, *C. R.* 56, 1004). Senderens (*Bl.* [3] 6, 800) regarded the production of  $H_2S$  as due to interactions between the S and the glass vessels employed; O. a. H. (*C. J.* 35, 252) found  $H_2S$  was produced when dilute  $H_2SO_4$  was used in place of water, and they concluded that the alkaline constituents of the glass were without influence. Becquerel (*C. R.* 56, 287) says that when water containing S in suspension is electrolysed,  $H_2SO_4$  forms at the positive, and  $H_2S$  at the negative, electrode (*cf.* Colson, *Bl.* [2] 34, 66). When S is moistened with water and let stand in the air,  $H_2SO_4$  is said to be produced (Polacci, *C. C.* 1884, 484; Böhm, *M.* 8, 224).—2. S is oxidised to  $H_2SO_4$  by heating with nitric acid, aqua regia, or potassium chlorate and hydrochloric acid.—3. Conc. hot sulphuric acid is reduced, giving off  $SO_2$ .—4. Conc. hydriodic acid gives  $H_2S$  and I (I de-

composes dilute  $H_2SAq$  to  $HIAq + S$ ).—5. Chlorosulphonic acid when heated with S produces  $S_2Cl_2$ ,  $SO_2$ , and HCl (Heumann a. Köhlin, *B.* 15, 416).—6. S dissolves in boiling alkali solutions, also in molten alkalis and alkaline carbonates, to form mixtures of polysulphides and thiosulphates. Boiling ammonia solution forms polysulphides; heated in a sealed tube above 100° some  $(NH_4)_2S_2O_8$  is produced (v. Brunner, *D. P. J.* 150, 371).—7. Sulphur trioxide dissolves S, forming a blue solution of  $S_2O_3$  (v. SURRUR oxides).—8. Carbon dioxide reacts with boiling S to form COS (Cossa, *B.* 1, 117; Berthelot, *Bl.* [2] 40, 364). The same compound is produced by volatilising S, by an electric current, in carbon monoxide (Chevrier, *C. R.* 69, 56).—9.  $PCl_5$  is formed by the interaction of S and phosphorus trichloride at 130° (Henry, *Bl.* 13, 495). Phosphorus pentachloride forms  $PCl_5$  and  $S_2Cl_2$  (Goldschmidt, *C. C.* 1881, 489).—10. S decomposes many sulphates and carbonates at high temperatures, forming sulphides and  $SO_2$ , or  $CO_2$  (v. Sestini, *Bl.* [2] 34, 490; Berthelot, *Bl.* [2] 40, 364).—11. Solutions of salts are very often reduced by boiling with S, sulphides being generally ppd. (v. Vortmann a. Padberg, *B.* 22, 2642; and, more fully, Senderens, *Bl.* [3] 6, 800; 7, 511).

**Combinations.**—1. Sulphur combines directly with most of the elements. The binary compounds of S—with the exception of those with Br, Cl, F, I, or O, and also compounds of S with more than one other element (except these be some of the five just mentioned)—are described under the least negative of the component elements; e.g. compounds of S with P and Cl are described (as sulphochlorides) under Phosphorus. For the conditions of formation of the binary compounds of S reference must be made to the various elements, except in the cases of bromide, chloride, fluoride, iodides, and oxides of S, which are described in this article in their proper (alphabetical) places.—2. Chlorine monoxide  $Cl_2O$  is said to combine directly with S (suspended in  $S_2Cl_2$ ), at -12°, to form  $SOCl_2$  (Wurtz, *C. R.* 62, 460).

**Sulphur, acids of.** Reference should be made to HYDROGEN SULPHIDE, vol. ii. p. 725; SULPHUR OXYACIDS, this vol. p. 619; SULPHUR OXYACIDS, NITROGEN DERIVATIVES OF, this vol. p. 619; SULPHOXYANIC ACID, vol. ii. p. 303; SULPHONIC ACIDS AND DERIVATIVES, this vol. p. 599; THIOCARBONIC ACID, vol. i. p. 703. For acids, and salts of acids, containing S and F, and S, P, and O, v. PHOSPHORUS SULPHIDES, this vol. p. 145 (beginning of article); also PHOSPHOROUS SULPHIDE, Reactions 7 and 8 (p. 146), PHOSPHORIC SULPHIDE, Reaction 8, and also end of that article (p. 147).

**Sulphur, bromides of.** It is very doubtful whether any definite compound of S and Br exists. Powdered S dissolves in Br with evolution of a little heat; the deep ruby-red liquid begins to distil over at c. 60° and the thermometer rises steadily to c. 190°, when it ascends slowly to c. 200°, after which it steadily rises till S remains; the fraction coming over at 190°-200° agrees fairly in composition with the formula  $S_2Br_2$  (Pattison Muir, *O. J.* 28, 845). M. found that by passing  $CO_2$  through a solution of S in excess of Br for some hours, at 16°, 50°, and 90°, the residual liquid had nearly the com-

position  $S_2Br_2$ ; Hannay, however, by passing air through such a liquid for 400–500 hours found that the whole of the Br was removed and that pure S remained (*C. J.* 33, 284; 35, 16). It is, however, possible that at the temperature of this experiment, c.  $15^\circ$ , dissociation of  $S_2Br_2$  was induced by the stream of air. H. also found that the vapour given off by the supposed  $S_2Br_2$ , even at  $0^\circ$ , showed the absorption-spectrum of Br. Spring a. Lecrenier (*Bil.* [2] 45, 867) examined the reaction of the supposed  $S_2Br_2$  with  $K_2SO_4$ . S. had before shown that  $S_2Cl_2$  and  $K_2SO_4$  produce KCl and  $K_2S_2O_8$ , but Cl and S acting as free elements produce  $K_2SO_4$ , KCl,  $K_2S_2O_8$  and  $SO_2$ .  $S_2Br_2$  ought then to produce KBr and  $K_2S_2O_8$ , whereas S and Br would form  $K_2SO_4$ , KBr,  $K_2S_2O_8$ , and  $SO_2$ ; by determining the quantities of the products S. a. L. calculated that the supposed  $S_2Br_2$  contains c. 27 p.c. of the elements uncombined. Various reactions of the supposed  $S_2Br_2$  are described in the memoirs already referred to (v. also Rose, p. 44, 327; Michaelis, *J. Z.* 6, 297; Ogier, *C. R.* 92, 922).

**Sulphur, chlorides of.** Three compounds of S and Cl are known:  $S_2Cl_2$ ,  $SCl_2$ , and  $SCl_3$ . These compounds are liquids;  $S_2Cl_2$  boils unchanged at c.  $138^\circ$ ,  $SCl_2$  begins to decompose to  $S_2Cl_2$  and Cl at c.  $10^\circ$ , and the decomposition of  $SCl_3$  to  $SCl_2$  and Cl begins at c.  $-20^\circ$ .

**Sulphur monochloride  $S_2Cl_2$ .** (*Sulphur protochloride, Sulphur sulphochloride, Sulphothionyl chloride, Thio-thionyl chloride.*) Mol. w. 134.7. Boils at  $138.12^\circ$ ; S.G.  $\frac{25}{4}$  1.70941, S.G. at b.p. 1.49201 (Thorpe, *C. J.* 37, 356). S.V. 90.23 (*T.*, l.c., p. 372). V.D. 68.4 (Dumas, *A. Ch.* [2] 49, 204; Marchand, *J. pr.* 22, 507).  $\mu_{11}$  = 1.61440 (Haagen, *P.* 131, 117). I.H.F. [ $S_2Cl_2$ ] (from  $S_8$ ) = 14,257 (*Th.* 2, 310); 17,600 (Ogier, *C. R.* 92, 922).

**Formation.**—1. By the interaction of S and Cl.—2. By distilling S with 9 parts  $SnCl_2$  or 8.5 parts  $HgCl_2$ .—3. By reacting on  $PCl_3$  with S (Goldschmidt, *C. C.* 1881, 489).—4. By decomposing  $PSCl_3$  by Cl or by heating to redness.—5. By the interaction of  $P_2S_5$  and  $SOCl_2$ , the other product being  $P_2O_5$  (Carius, *A.* 106, 331).—6. By the action of  $CS_2$  on  $ICl_3$  (Weber, *P.* 128, 459).

**Preparation.**—A stream of dry Cl is passed into a flask, or retort, containing S (flowers or sticks) until most, but not quite all, S is dissolved to a yellowish-red liquid, the vessel being gently warmed. The liquid is repeatedly distilled until it boils constantly at  $138^\circ$ – $139^\circ$ . If the passage of Cl is continued until the S is completely dissolved, the liquid must be distilled from a little S (to decompose  $SCl_3$  quickly).

**Properties.**—A yellowish-red, oily liquid, with a very characteristic, rather disagreeable, odour and an acid taste; the vapour affects the mucous membranes rapidly, causing tears, and affecting the breathing. Does not become viscid at  $-75^\circ$  (Haase, *B.* 26, 1052). Fumes in air. Dissolves in  $CS_2$  and  $C_2H_6$ , also in alcohol and ether with decomposition.  $S_2Cl_2$  dissolves large quantities of S; solution of  $S_2Cl_2$  containing free S, in  $CS_2$ , is used for vulcanising (v. *Dictionary of Applied Chemistry*, vol. iii, p. 706).

**Reactions and Combinations.**—1.  $S_2Cl_2$  sinks in water, and then decomposes, giving  $HCl$  and

$SO_2$ , Ag, and S, with a little  $H_2SAg$ ,  $H_2SO_4$ , Ag, and some of the thionio acids.—2. *Hydrogen sulphide* produces HCl and S; *hydrogen iodide* reacts at the ordinary temperature to form HCl, I,  $S_2I_2$ , and then  $H_2S$  (Hautefeuille, *Bil.* [2] 7, 198).—3. By passing  $S_2Cl_2$  vapour, mixed with *air* or *oxygen*, through a red-hot tube,  $SO_2$ ,  $SO_3$ , and Cl are formed (Donny a. Mareska, *C. R.* 20, 817; Spring a. Lecrenier, *Bil.* [2] 45, 867).—4. Heating with *phosphorus* produces  $PCl_3$ ,  $PSCl_3$ , and S if a little P is used; or  $PCl_3$ , P sulphides, and red P if much P is used (Wöhler a. Hiller, *A.* 93, 274; Chevrier, *C. R.* 63, 1003).—5. Heated with many metals,  $S_2Cl_2$  gives metallic chlorides and S; the more volatile the metallic chloride the more readily does the reaction occur (v. Chevrier, *C. R.* 64, 302).—6.  $S_2Cl_2$  combines with *chlorine*, forming  $SCl_2$  and  $SCl_4$  (*q.v.*, *infra*). Br and I are absorbed by  $S_2Cl_2$ ; according to Evans a. Ramsay (*C. J.* 45, 65) no compound is formed with Br.—7. With *oxides of arsenic and antimony*  $S_2Cl_2$  forms  $AsCl_3$  and  $SbCl_3$ , giving off  $SO_2$  and separating S; *selenium dioxide* produces  $SeCl_4$  and  $SO_2$ ; *oxides of phosphorus, boron, and silicon* do not react (Prinz, *A.* 223, 355).—8.  $S_2Cl_2$  absorbs *sulphur trioxide*, below  $0^\circ$ , forming a brownish-yellow liquid, from which excess of  $SO_3$  crystallises out; a little above  $6^\circ$   $SO_2$  is given off, rapidly at  $10^\circ$ ;  $S_2O_2Cl_2$  is formed on distillation (Rose, *P.* 44, 291).—9. By passing vapour of  $S_2Cl_2$  along with the vapours from *sulphonic acid* through a hot tube,  $SO_2$ ,  $H_2S$ , S, HCl, and Cl are produced (Brault a. Poggiale, *J. Ph.* 21, 140).—10. Heating  $S_2Cl_2$  with *sulphates* generally produces  $SO_2Cl_2$ , chlorides, S, and  $SO_2$ ; heated with *sulphuryl chloride* to  $250^\circ$ ,  $S_2OCl_2$  is formed (v. Schneider, *J. pr.* 104, 83; [2] 32, 18; Demaray, *C. R.* 92, 726).—11.  $S_2Cl_2$  combines with *ammonia* gas to form  $S_2Cl_4NH_3$ , stable in air, sol. alcohol, decomposed by water giving  $NH_4Cl$  and  $(NH_4)_2S_2O_8$ , Ag, and S (Brault a. Poggiale, *J. Ph.* 21, 140).—12. Reacts with *organic compounds containing oxygen*, generally forming Cl compounds and small quantities of S compounds, and also HCl,  $SO_2$ , and S.—13. Combines with *unsaturated hydrocarbons*; e.g. with  $C_2H_4$  forms  $C_2H_4S_2Cl_2$ .

**Sulphur dichloride  $SCl_2$ .** Mol. w. (in solution in benzene or acetic acid) 102.72. S.G. 1.6182 at  $15.4^\circ$  (Costa, *G.* 20, 367).  $\mu_{11}$  = 1.5716 (Costa, l.c.). No constant b.p. (*v. infra*). This compound was prepared by H. Rose in 1831 (*P.* 21, 431; 27, 167); the experiments of Dumas (*A. Ch.* [2] 49, 204) and Marchand (*J. pr.* 22, 507) led to its recognition as a definite compound (v. also Caries, *A.* 106, 291); Häbner a. Guerout (*Z.* 1870, 455) isolated the compound satisfactorily, and their results were confirmed by Thorpe a. Dalzell, in 1871 (*C. N.* 24, 159). Costa, in 1890 (*G.* 20, 367), determined the mol. w. of the compound in solution.

**Preparation.**—Dry Cl is led into  $S_2Cl_2$ , surrounded by a freezing mixture, until the liquid becomes deep red; excess of Cl is removed by a stream of dry  $CO_2$ . The temperature must not rise above  $6^\circ$ ; the vessel containing the  $SCl_2$  should be kept filled with Cl continually, and should not be exposed to direct sunlight (H. a. G., l.c.; C., l.c.; T. a. D., l.c.; also Soubeiran *A. Ch.* [2] 67, 64; Michaelis, *A.* 170, 1).

**Properties.**—A thin, dark, brownish-red, liquid, with smell and taste like  $S_2Cl_2$ ; does not solidify at  $-30^\circ$ ; gives off Cl when exposed to sunlight, and should, therefore, be kept in a sealed tube in the dark. Easily decomposed by heat to  $S_2Cl_2$  and Cl; Michaelis (*B.* 6, 995) gives a table showing amount of dissociation from  $20^\circ$  to  $130^\circ$ ; the temperature whereat 50 p.c. of the  $SCl_2$  is dissociated is c.  $86^\circ$ .  $SCl_2$  reddens dry litmus paper. The depression of the freezing-point of benzene or glacial acetic acid by solution therein of  $SCl_2$  shows that the mol. w. agrees with the formula  $SCl_2$  (Costa, *G.* 20, 367).

**Reactions and Combinations.**—1. Heat, or direct sunlight, causes dissociation to  $S_2Cl_2$  and Cl (*v. supra*, **Properties**).—2. Water produces  $HClAq$  and  $H_2SO_4Aq$ .—3. Oxidised violently by nitric acid to  $HClAq$  and  $H_2SO_4Aq$ .—4. Ammonia solution produces  $NH_4ClAq$ , N, and S; ammonia gas combines to form  $SCl_2 \cdot 2NH_3$  and  $SCl_2 \cdot 4NH_3$ , soluble, unchanged, in absolute alcohol and ether (Soubeiran, *A. Ch.* [2] 67, 74).—5. Thionyl chloride ( $SOCl_2$ ), when heated with  $SCl_2$ , forms  $S_2OCl_2$  (Ogier, *Bl.* [2] 37, 293).—6. Alkali sulphites produce chlorides and trithionates (Spring a. Lecrenier, *Bl.* [2] 45, 867).—7. Some metals, e.g. Cu, Fe, K, react with  $SCl_2$ , with production of heat and light, and formation of chlorides and sulphides.—8. Combines with arsenious chloride, forming  $AsCl_2SCl_2$  according to H. Rose (*P.* 27, 107).—9.  $SCl_2$  reacts with oxygenised carbon compounds similarly to, but more readily than,  $S_2Cl_2$ ; it combines with several unsaturated hydrocarbons (*v. Heintz*, *A.* 100, 370; Guthrie, *C. J.* 12, 109).

**SULPHUR TETRACHLORIDE  $SCl_4$ .** This compound exists only at temperatures under  $-20^\circ$ . The molecular weight is probably 173.46 ( $SCl_4$ ).

**Preparation.**— $S_2Cl_2$  is cooled to below  $-20^\circ$  (c.  $-22^\circ$ ) and a slow stream of dry Cl is passed in until absorption of Cl ceases. Michaelis a. Schifferdecker (*B.* 6, 993) found that 67.5 g.  $S_2Cl_2$ , kept at  $-20^\circ$  to  $-22^\circ$ , absorbed 106 g. Cl in 10 hours, that absorption of Cl then ceased, and that the liquid had the composition  $SCl_4$ .

**Properties.**—A mobile, yellowish-brown liquid; when removed from the freezing mixture used in the preparation, the liquid gives off Cl, and boils with an absorption of much heat. M. a. S. give the following data showing the dissociation of  $SCl_4$  to  $SCl_2$  and Cl:—

Temp.	P.c. $SCl_2$	P.c. $SCl_4$
$-23^\circ$	100.0	0.0
$-15$	41.95	58.05
$-10$	27.62	72.38
$-7$	21.97	78.03
$-2$	11.93	88.07
$+0.7$	8.87	91.13
$+6.2$	2.43	97.57

**Reactions.**—1. Water causes rapid decomposition to  $HClAq$  and  $SO_2Aq$ , with more or less S according to the mass and temperature of the water.—2. With sulphur trioxide, in the ratio  $SCl_4:SO_3$ , the products are  $SOCl_2$  and  $S_2O_3Cl_2$ , in the ratio  $SCl_4:2SO_3$ , the products are  $SOCl_2$ ,  $SO_2$ , and Cl (M. a. S., *L.c.*; also *B.* 5, 924). Sulphur dioxide does not react.—3. Chlorosulphonic acid reacts at a low temperature to form  $S_2O_3Cl_2$  and  $HCl$  (M. a. S., *B.* 6, 996).—4. With some hydroxylic organic compounds, e.g.  $C_2H_5OH$  and

$QH_3CO.OH$ , OH is replaced by Cl and  $SOCl_2$  is formed.

**Combinations.**—1. Compounds of  $SCl_2$  with several metallic chlorides are produced by warming the chlorides with  $S_2Cl_2$ , and passing in Cl; the compounds  $2AlCl_3 \cdot SCl_2$ ,  $AuCl_3 \cdot SCl_2$ , and  $2TiCl_3 \cdot SCl_2$  are formed thus (Weber, *P.* 104, 421; Rose, *P.* 42, 517; Casselmann, *A.* 83, 267). The compound with  $AlCl_3$  may be distilled in a closed  $\wedge$  shaped tube; the other two compounds give off Cl when heated. The compounds  $SbCl_3 \cdot 3SCl_2$  and  $SnCl_4 \cdot 2SCl_2$  are produced by passing Cl over  $SnS$  and  $Sb_2S_3$ , respectively (R., *L.c.*; C., *L.c.*).—2. With iodine trichloride forms  $ICl_3 \cdot SCl_2$  (Weber, *P.* 128, 459; cf. Jaillard, *A. Ch.* [3] 59, 451, who gives the composition  $SCl_2 \cdot 2ICl_3$ ). Prepared by passing Cl into I dissolved in  $CS_2$ , till the liquid is wine-red, cooling, and drying the red-yellow, prismatic, very deliquescent, crystals, in a tube in a stream of dry Cl. Also formed by passing Cl into a mixture of 2 pts. S and 1 pt. I. Melts to a brown liquid when heated in a closed tube; heated in an open tube forms Cl,  $ICl$ , and  $S_2Cl_2$ ; decomposed by water or dilute  $HNO_3Aq$ .

Sulphur, chloro-iodide of,  $SCl_2I$  ( $= SCl_2 \cdot ICl_2$ ); *v. supra*, SULPHUR TETRACHLORIDE, **Combinations**, No. 2.

Sulphur, chloronitride of,  $S_2Cl_2N$ ; *v. NITROGEN SULPHOCHLORIDE*, vol. iii. p. 571.

Sulphur, cyanides of, *v. CYANOGEN, SULPHIDES*, vol. ii. p. 358.

Sulphur, fluoride of. According to Gore (*Pr.* 20, 70 [1871]) the heavy colourless gas produced by fusing  $AgF$  with S is a fluoride of S. This gas is not liquefied at  $0^\circ$ , at the ordinary pressure; it fumes in the air, and attacks glass; no analyses are given by G.

Sulphur, haloid compounds of. The most stable of these compounds belong to the forms  $SX_n$ , where  $X = Cl, Br, \text{ or } I$ . The chloride  $S_2Cl_2$  may be distilled unchanged; the bromide,  $S_2Br_2$ , is exceedingly easily decomposed if, indeed, it has been isolated; the iodide,  $S_2I_2$ , has been very slightly examined. The compounds  $SCl_2$  and  $SCl_4$  also exists; the former at temperatures below c.  $10^\circ$ , and the latter below c.  $-20^\circ$ . The compound  $SI_2$ , perhaps exists; it gives up I at the ordinary temperature. The only haloid compound of S that has been gasified unchanged is  $S_2Cl_2$ .

Sulphur, hydrides of,  $SH_2$  and (?)  $S_2H_2$ ; *v. HYDROGEN SULPHIDES*, vol. ii. p. 725.

Sulphur, nitride of,  $SN$ ; *v. NITROGEN SULPHIDE*, vol. iii. p. 570.

Sulphur, iodides of. S and I probably combine when heated together, but no definite compound has been isolated by this method (*cf.* Gay-Lussac, *G.* 4, 872; H. Rose, *P.* 27, 115; Lamers, *J. pr.* 84, 349; Sestini, *J.* 1863, 153; Wheeler a. Ludeking, *Fr.* 26, 602).

SULPHUR MONO-IODIDE  $SI_2$ . Guthrie (*C. J.* 14, 67) obtained this compound by placing 2½ parts  $EtI$  and 1 part  $S_2Cl_2$  in a sealed tube, opening after 12 hours, evaporating  $EtCl$  by warming with the hand and removing excess of  $EtI$  by gently warming; the  $SI_2$  crystallised out in lustrous crystals resembling I. (One analysis is given, but no full description of properties.)

Ogier (*C. R.* 92, 922) gives H.F. [ $S^2$ , I $^2$ ] (from gases) = 10,800.

**SULPHUR HEXA-IODIDE  $SI_6$ .** This compound is said to be formed by slowly evaporating, at a low temperature, a solution of I with slight excess of S in  $CS_2$ . Grey-black crystals; resembling, and isomorphous with, I; I evaporates on exposure to air and eventually only S remains; Alcohol, conc. KOH, or KIO $_4$ , also withdraws all I (G. vom Rath, *P.* 110, 116; Lamers, *J. pr.* 84, 349). It is very doubtful whether the crystals examined by vom Rath were a compound or only I retaining a little S.

By passing  $H_2S$  into a dilute solution of  $KCl.ICl_3$ , Lamers (*loc.*) obtained an orange-red pp. which dried in an exsiccator to a brown amorphous mass containing S and I in the ratio  $S.I_2$ .

By subliming  $SnS$ , with I, Schneider (*J.* 1860, 186) obtained a compound to which he gave the composition  $SnSI_2.SI_2$ .

**Sulphur, iodochloride of,  $SICl_3$  (=  $SOCl_2.ICl_3$ ).**

**v. SULPHUR TETRACHLORIDE, *Combinations* No. 2.**

**Sulphur, oxides of.** Four compounds have been isolated;  $S_2O_3$ ,  $SO_3$ ,  $SO_2$ , and  $S_2O$ . S and O combine directly to form  $SO_2$  and  $SO_3$ ; S dissolves in  $SO_2$  to form  $S_2O_3$ ;  $S_2O_3$  is formed by the action of an electric discharge on a mixture of  $SO_2$  and O, or  $SO_2$  and O.

**Sulphur sesquioxide  $S_2O_3$  (*Hyposulphurous anhydride*).** The production of a blue substance, on distilling fuming  $H_2SO_4$  and S, was noticed by Buchholz in 1804 (*Gehlen's J.* 3, 7); Vogel, in 1812, obtained the blue body by bringing together S and  $SO_2$  (*S.* 4, 121); the substance was examined by Wach (*S.* 50, 1), Berzelius (*Lehrbuch* [5th edit.] 1, 485), and Stein (*J. pr.* [2] 6, 172). Weber, in 1875, isolated the compound and found its composition to be  $S_2O_3$  (*P.* 156, 531).

$S_2O_3$  is prepared by adding well-dried flowers of sulphur, little by little, to  $SO_2$  quite free from  $H_2SO_4$ , more S being added when the previous quantity has all combined. The process is conveniently conducted in a test tube, covered with a small porcelain crucible to exclude moisture, and plunged into water cooled to c.  $12^\circ$ ; the S disappears in the  $SO_2$ , and blue drops are formed; the tube should be tilted so that the blue drops come into contact with the sides of the tube where they form a thin crust (if the drops solidify as they float in the  $SO_2$ , the solid  $S_2O_3$  retains  $SO_2$ , from which it cannot be freed). When c. 1 g. S has been added, excess of  $SO_2$  (which should be colourless) is poured off, the last traces being removed by gently and carefully warming not above  $35^\circ$ ; the solid  $S_2O_3$  is scraped out of the tube by a glass rod.

$S_2O_3$  is a blue-green solid, consisting of a mass of microscopic crystals. Insoluble pure  $SO_2$ ; if a little  $H_2SO_4$  is present the  $S_2O_3$  dissolves to a deep-blue liquid. Melts with decomposition; decomposes slowly in dry air, quickly on heating, to  $SO_2$  and S; deliquesces in moist air to a brown liquid from which S soon separates; reacts violently with water, giving  $H_2SO_4$ ,  $SO_2$ ,  $SO_3$ ,  $H_2S_2O_4$ , polythionic acids, and S; decomposed also by alcohol and ether, with separation of S, also by ordinary  $H_2SO_4$ .

$S_2O_3$  may be regarded as the anhydride of  $H_2S_2O_3$ ; although the acid has not been ob-

tained from the oxide, nor the oxide from the acid.

For the compounds  $SSeO_3$  and  $STeO_3$ , v. *Selenion thio-oxide* (p. 441) and *Tellurium thio-oxide* (under TELLURIUM OXIDES).

**SULPHUR DIOXIDE  $SO_2$  (*Sulphurous oxide*).**

**Sulphurous anhydride. Thionyl oxide.** Mol. w. 63.9. Melts at c.  $-76^\circ$  (Faraday, *T.* 1845, 155); c.  $-80^\circ$  (Mitchell, *A.* 37, 356). Boils at c.  $-10^\circ$  (Bunsen, *P.* 46, 97; Andr eff, *J.* 1859; Pictet, *C. C.* 1877, 81). S.G. (liquid) 1.4911 at  $-20.5^\circ$ , 1.4384 at  $-2.08^\circ$ , 1.4252 at  $+2.8^\circ$ , 1.3769 at  $20^\circ$ , 1.3258 at  $38.65^\circ$  (Andr eff, *A. Ch.* [3] 56, 317); 1.4338 at  $0^\circ$ , 1.2872 at  $52^\circ$ , 1.1845 at  $82.4^\circ$ , 1.1041 at  $102.4^\circ$ , .956 at  $130.3^\circ$ , .7317 at  $151.75^\circ$ , .52 at  $156^\circ$  (Caillietet a. Mathias, *C. R.* 104, 1563). S.G. (gas at  $0^\circ$  and 760 mm.) 2.2639 (Leduc, *C. R.* 117, 219). V.D. 32.23 (Gay-Lussac, Berzelius, Buff; Biltz, *B.* 21, 2769). S.H. (equal wt. water = 1) .1544; (equal volume air = 1) .3414 (Regnault, *J.* 1863, 84). Ratio of S.H. constant pressure to S.H. constant volume = 1.2562 (Miller, *W.* 18, 94). C.E. .00423 for  $1^\circ$  between  $0^\circ$  and  $10^\circ$ , .004005  $10^\circ$  to  $20^\circ$ , .003816 at  $50^\circ$ , .003757 at  $100^\circ$ , .003718 at  $150^\circ$ , .003695 at  $200^\circ$ , .003685 at  $250^\circ$  (Amagat, *C. R.* 73, 183; cf. *C. R.* 68, 1170). Leduc (*C. R.* 117, 219) gives C.E. between  $0^\circ$  and  $20^\circ$  as .00396. For C.E. of liquid  $SO_2$ , v. Drion (*A. Ch.* [3] 56, 5) and Andr eff (*A.* 110, 1). The

ratio  $\frac{PV}{P_1V_1} > 1$ ; Amagat (*loc.*) gives these values,

1.0185 at  $15^\circ$ , 1.0110 at  $50^\circ$ , 1.0054 at  $100^\circ$ , 1.0032 at  $150^\circ$ , 1.0021 at  $200^\circ$ , 1.0016 at  $250^\circ$ . H.F. [ $S_2O_3$ ] = 71,070 from solid rhombic S; 71,720 from solid monoclinic S (*Th.* 2, 247). Heat of liquefaction of gaseous  $SO_2$  = 5644 (Favre, *A. Ch.* [5] 1, 209). Critical temperature =  $156^\circ$  (Caillietet a. Mathias, *C. R.* 104, 1563);  $155.4^\circ$  (Sajotscheffski, *P. B.* 1879, 741);  $157^\circ$  (Ladenburg, *B.* 11, 821). Heat of vaporisation of liquid  $SO_2$  at  $0^\circ$  = 91.2, at  $60^\circ$  = 69 (C. a. M., *loc.*; cf. Chappuis, *C. R.* 104, 897). Regnault (*C. R.* 50, 1063) gives vapour pressures as follows:

Temp.	Vap. pressure	Temp.	Vap. pressure
$-25^\circ$	373.79 mm. Hg	$30^\circ$	3131.80 mm. Hg
$-20^\circ$	479.46 "	40	4670.23 "
$-10^\circ$	762.49 "	50	6220.01 "
0	1165.06 "	60	8123.80 "
$+10^\circ$	1719.55 "	65	9221.40 "
20	2462.05 "		

Vapour-pressure at critical temp. =  $78.9$  atmos. (Sajotscheffski, *P. B.* 1879, 741). \*S. in water between  $0^\circ$  and  $20^\circ$  (gaseous  $SO_2$ ) = 79.789 -  $2.6077t + .029349t^2$ ; 1 vol. of the saturated  $SO_2$ .Aq contains 68.861 -  $1.87025t + .01225t^2$  vols.  $SO_2$ ; S. (water) between  $21^\circ$  and  $40^\circ$  = 75.182 -  $2.1716t + .01903t^2$ ; 1 vol. of the saturated  $SO_2$ .Aq contains 60.952 -  $1.38898t + .00726t^2$  vols.  $SO_2$  (Bunsen a. Sch nfeldt, *A.* 95, 2). S. in alcohol, at 760 mm. = 328.62 -  $16.95t + .3119t^2$ ; S.G. of solution =  $1.11937 - .014091t + .000257t^2$  (Carius, *A.* 94, 148). Sims (*C. J.* 14, 1) gives the table on the next page, which presents both the weight of  $SO_2$  in grams and the volume of gaseous  $SO_2$  in c.c. dissolved by unit weight of water at the normal pressure and different temperatures:—

Temp.	Grams SO <sub>2</sub> absorbed by 1 g. water at 760 mm.	
	c.c. SO <sub>2</sub>	
8°	.168	58.7
12	.142	49.9
16	.121	42.2
20	.104	36.4
24	.092	32.3
28	.083	28.9
32	.073	25.7
36	.065	22.8
40	.058	20.4
44	.053	18.4
48	.047	16.4
50	.045	15.6

The quantity of SO<sub>2</sub> dissolved by a given weight of water varies with pressure, and only at c. 40° and upwards is the quantity proportional to the partial pressure of the gas (v. Sims, *C. J.* 14, 1). For S.G. and composition from .5 to 10 p.c. of SO<sub>2</sub> Aq v. Anthon (*C. C.* 1860, 744); also Giles & Schearer (*S. C. I.* 4, 303), [SO<sub>2</sub> Aq] = 7.700 (gaseous SO<sub>2</sub>) (*Th.* 2, 249); 1500 (liquid SO<sub>2</sub>) (Berthelot, *C. R.* 96, 142, 208; Chappuis, *A. Ch.* [2] 19, 21). H<sub>2</sub>SO<sub>4</sub> Aq absorbs the following quantities of gaseous SO<sub>2</sub> (Kolb, *D. P. J.* 209, 270; cf. Dunn, *C. N.* 43, 121; 45, 270):—

S.G. H <sub>2</sub> SO <sub>4</sub> Aq	Kilos. SO <sub>2</sub> per kilo. acid	Litres SO <sub>2</sub> per litre acid
1.841	.009	5.8
1.839	.014	8.9
1.540	.021	11.2
1.407	.032	15.9
1.227	.068	29.7

SO<sub>2</sub> is absorbed by charcoal; 1 c.c. charcoal = 1.57 g. was found by Favre (*A. Ch.* [5] 1, 209) to absorb 165 c.c. SO<sub>2</sub>. Camphor absorbs c. 308 times its vol., glacial acetic acid c. 318 times, SO<sub>2</sub>Cl<sub>2</sub> c. 187 times, its volume of SO<sub>2</sub> (Schulze, *J. pr.* [2] 24, 168; Bineau, *A. Ch.* [3] 34, 326).  $\mu_{Na}$  = 1.35 at 15° (Bleekrode, *Pr.* 37, 359). For surface tension of liquid SO<sub>2</sub> v. Clark (*C. N.* 38, 294; 40, 8). For absorption-spectrum v. Liveing & Dewar (*C. N.* 47, 121).

**Occurrence.**—In volcanic gases, and in river and spring water near volcanoes (v. Nicciardi, *G.* 18, 38).

**Formation.**—1. By burning S in O. Baker (*Pr.* 45, 1; *C. J.* 47, 349) found that the combustion of S in O is retarded the drier the O is; using very carefully dried O there was no flame. According to Henipel (*B.* 23, 1456) c. 2 p.c. of the gas formed when S is burnt in O at the ordinary pressure is SO<sub>2</sub>, 98 p.c. being SO<sub>3</sub>; at a pressure of 40°–50° atmos. c. half the S is burnt to SO<sub>2</sub> and half to SO<sub>3</sub>; at higher pressures c. 70 atmos. the proportion of SO<sub>2</sub> increases.—2. By heating S with oxide of Pb, Mn, Hg, Zn, &c.—3. By heating various sulphates with S, also SO<sub>2</sub> with S, or conc. H<sub>2</sub>SO<sub>4</sub> with C, Cu, Hg, or S; by heating Na<sub>2</sub>SO<sub>3</sub> with charcoal and SiO<sub>2</sub>.—4. By the decomposition, by acids, of alkali thiosulphate or polythionate solutions.—5. By burning H<sub>2</sub>S, CS<sub>2</sub>, and various organic compounds containing S.—6. By decomposing conc. H<sub>2</sub>SO<sub>4</sub> by heat.—7. By the action of electric sparks on a mixture of sulphur with CO<sub>2</sub>, NO, or N<sub>2</sub>O (Chevrier, *C. R.* 69, 136).

**Preparation.**—1. Pure H<sub>2</sub>SO<sub>4</sub>, mixed with half to two-fifths its volume of water, is heated with pure Cu; the SO<sub>2</sub> that comes off is passed through water in a large flask, and then through a couple of bottles filled with pumice, broken into small pieces and moistened; the pumice should be twice moistened with pure H<sub>2</sub>SO<sub>4</sub> and heated to redness before being used, to remove chlorides and fluorides (Stas, *Chem. Propriétés*, 115). The SO<sub>2</sub> may be dried by passing it through pure conc. H<sub>2</sub>SO<sub>4</sub>, and then over CaCl<sub>2</sub>.—2. A mixture of 3 parts pure CuO and 1 part S in powder is heated in a tube of hard glass; the anterior part of the tube contains CuO only, to oxidise S that may sublime (Marchand, *P.* 42, 144).—3. Neumann (*B.* 20, 1584) obtains a regular stream of approximately pure SO<sub>2</sub> by placing a mixture of three parts CaSO<sub>3</sub> and 1 part CaSO<sub>4</sub>, made into small cubes, in a Kipp's apparatus, and decomposing by ordinary oil of vitriol. The acid should be allowed to come into contact with sufficient cubes, and no more, to give the stream of gas that is required. Using c. 500 g. of the cubes, N. obtained a constant stream of SO<sub>2</sub> for 30 hours. The cubes are made by mixing the CaSO<sub>3</sub> and CaSO<sub>4</sub>, moistening with water so that a semi-solid mass is obtained that can be worked with the fingers with some difficulty, pressing this in an iron mortar, hammering it into an iron frame c. 10–12 mm. in height, covering with oilcloth and pressing strongly, cutting into cubes while still in the frame, removing and drying at c. 20° (v. Winkler, *B.* 20, 184).

**Properties.**—A colourless gas, at ordinary temperatures and pressures, with the strong penetrating, choking odour of burning S; causes coughing and blood-spitting if inhaled in any quantity. Incombustible in air, and extinguishes flame; when mixed with O and passed over heated spongy Pt it is oxidised to SO<sub>3</sub>. Dry SO<sub>2</sub> is said not to reddens litmus paper (Wilson, *C. J.* 1, 332). Bleaches many vegetable colours; the colours are generally restored by alkalis. Bad conductor of electricity (v. Bleekrode, *P. M.* [5] 5, 375, 439). Is not decomposed by passing through a red-hot tube. Condensed at c. –10° under the ordinary pressure—by passing the dry gas into a tube surrounded by a mixture of snow and salt; may also be condensed at the ordinary temperature by evolving the gas (by warming charcoal saturated with SO<sub>2</sub>, or a mixture of 1 part S and 5 parts SO<sub>2</sub>) in one limb of a closed tube, the other limb being placed in cold water. Convenient apparatus for liquefying SO<sub>2</sub> is described by Wöhler (*A.* 137; 371) and Hofmann (*B.* 2, 262).

Liquid SO<sub>2</sub> is a colourless, mobile liquid. Exposed to air it evaporates very rapidly, with disappearance of much heat; an air thermometer placed in liquid SO<sub>2</sub> at 10°, in an open vessel, falls to –57°. Liquid SO<sub>2</sub> dissolves P, S, I, Br, and many gums. It is miscible in all proportions with liquid SO<sub>3</sub>, partially miscible with CS<sub>2</sub>, Et<sub>2</sub>O, CHCl<sub>3</sub>, and C<sub>2</sub>H<sub>5</sub>Br on warming; but immiscible with conc. H<sub>2</sub>SO<sub>4</sub> (Sestini, *Bl.* [2] 10, 226). Liquid SO<sub>2</sub> is a non-conductor of electricity (Magnus, *P.* 104, 532).

By evaporating liquid SO<sub>2</sub> rapidly in an air-pump, part of it solidifies to a white, woolly

mass; the liquid may also be solidified by placing it in a mixture of solid CO<sub>2</sub> and ether.

**Reactions and Combinations.**—1. SO<sub>2</sub> is not decomposed by passing through a red-hot tube. But by heating to c. 1200° it is changed to SO<sub>3</sub> and S (8SO<sub>2</sub> = 2SO<sub>3</sub> + S); the action stops when the SO<sub>3</sub> attains a certain vapour pressure, but if the SO<sub>3</sub> is removed (by conc. H<sub>2</sub>SO<sub>4</sub>) the whole of the SO<sub>2</sub> is decomposed (Deville, *C. R.* 60, 317). Induction sparks effect the decomposition of SO<sub>2</sub> to SO<sub>3</sub> and S (v. Buff a. Hofmann, *A.* 113, 129); light acts similarly (Morron, *C. R.* 69, 397).—2. H<sub>2</sub>O and S are produced by passing SO<sub>2</sub> mixed with hydrogen through a red-hot tube.—3. Chlorine combines with SO<sub>2</sub>, in sunlight, to form SO<sub>2</sub>Cl<sub>2</sub> (v. SULPHURYL CHLORIDE). SO<sub>2</sub>Cl<sub>2</sub> is also formed by passing SO<sub>2</sub> and Cl into glacial acetic acid, even in the dark; also by passing SO<sub>2</sub> over charcoal saturated with Cl (Melsens, *C. R.* 76, 92).—4. Ozone produces SO<sub>3</sub>; the same compound is formed by passing SO<sub>2</sub> mixed with oxygen over heated spongy Pt, or by burning SO<sub>2</sub> in O under a pressure of several atmos. (v. *supra*, Formation, No. 1). According to Berthelot (*A. Ch.* [5] 12, 463), S<sub>2</sub>O<sub>3</sub> is formed by the action of the silent discharge on SO<sub>2</sub> mixed with oxygen. The compound S<sub>2</sub>O<sub>3</sub>N<sub>2</sub> is said to be formed by passing electric sparks through a mixture of SO<sub>2</sub> and air. This compound is probably S<sub>2</sub>O<sub>3</sub>(NO<sub>2</sub>)<sub>2</sub> (v. NITROSULPHONIC ANHYDRIDE, p. 601).—5. Passed over red-hot carbon the products are CO, CO<sub>2</sub>, and S; COS and CS<sub>2</sub> are also sometimes formed, probably by secondary reactions (Scheurer-Kestner, *C. R.* 114, 296; cf. Berthelot, *Bl.* [2] 40, 362; Eilsart, *J.* 1885, 457).—6. Potassium burns when heated in SO<sub>2</sub>, giving K<sub>2</sub>SO<sub>3</sub>, K<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, and polysulphides.—7. Many other metals, especially when in fine powder, burn in SO<sub>2</sub>; Sb and Sn form oxides and sulphides; Fe, sulphide and sulphate; Pd and Pt, sulphides and SO<sub>3</sub>; Au, S and SO<sub>3</sub>; Mg, sulphate, sulphite, and sulphide; Al, Co, Ni, and Zn also burn; Bi and Hg do not react (Schiff, *A.* 67, 94; 117, 92; Uhl, *B.* 23, 2151).—8. Water dissolves SO<sub>2</sub>, forming H<sub>2</sub>SO<sub>3</sub>Aq (v. SULPHUROUS ACID, p. 614). 9. Several metallic peroxides combine readily with SO<sub>2</sub> forming sulphates; e.g. PbO<sub>2</sub> + SO<sub>2</sub> = PbSO<sub>4</sub>; in this reaction much heat is produced.—10. Nitrogen dioxide is said to react with liquid SO<sub>2</sub> to form nitrosulphonic anhydride S<sub>2</sub>O<sub>3</sub>(NO<sub>2</sub>)<sub>2</sub> (v. p. 601). With nitric oxide or dioxide, in presence of water, nitrosulphonic acid NO<sub>2</sub>(SO<sub>2</sub>OH) (q.v., p. 601) is formed. Nitric oxide in presence of alkali produces salts of SO<sub>2</sub>OH(NO)<sub>2</sub>H (v. NITROSULPHATES, p. 581).—11. Selenium dioxide does not react with SO<sub>2</sub> (Schulze, *J. pr.* [2] 32, 890).—12. Dry hydrogen sulphide does not react; moist H<sub>2</sub>S, at the ordinary temperature, produces H<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, S, and H<sub>2</sub>O (Cluzel a. Schmid, *Chem. Zeitung*, 11, 50); there is said to be no reaction in presence of water above 400° (Mulder, *J.* 1858, 84).—13. Phosphoretted hydrogen reacts at the ordinary temperature to form H<sub>2</sub>O and P<sub>2</sub>S<sub>3</sub> (C. a. S., l.c.).—14. Ammonia combines with SO<sub>2</sub>, probably producing SO<sub>2</sub>NH<sub>2</sub> (= SO<sub>2</sub>OH.NH<sub>2</sub>) and SO<sub>2</sub>2NH<sub>2</sub> (= SO<sub>2</sub>ONH<sub>2</sub>.NH<sub>2</sub>) (v. THIONAMIC ACID).—15. Hydrochloric or hydriodic acid produces H<sub>2</sub>O, S, and Cl or I.—16. Many oxy-salts, e.g. nitrates and chlorates, react with

SO<sub>2</sub>, when heated, to form sulphates and N oxides; at higher temperatures SO<sub>2</sub> is sometimes produced (v. Hodgkinson a. Young, *C. N.* 66, 199).—17. Alkali nitrites yield salts of nitrosulphonic acid N(SO<sub>2</sub>OH)<sub>2</sub> (q.v., p. 601), and salts of oxy-imidosulphonic acid N(OH)(SO<sub>2</sub>OH)<sub>2</sub> (q.v., p. 602).—18. Combines with aluminium chloride at 50°–60°, forming AlCl<sub>3</sub>.SO<sub>2</sub>, which gives off SO<sub>2</sub> at a higher temperature (Adrianoffski, *B.* 12, 638).—19. Phosphorus pentachloride produces POCl<sub>3</sub> and SOCl<sub>2</sub> (Kremers, *A.* 70, 297; Schiff, *A.* 102, 111).

**SULPHUR DIOXIDE SO<sub>2</sub>.** (*Sulphuric oxide. Sulphuric anhydride.*) Mol. w. 79.86. Melts at 14.8° (Weber, *B.* 19, 3189; Rebs, *A.* 246, 356). Some other observers have given m.p. as high as 29.5° (v. Buff, *A. Suppl.* 4, 129; Bussy, *A. Ch.* [2] 26, 411; Fischer, *P.* 16, 119; Marignac, *A.* 88, 230). Boils at 46.2° (Weber, l.c.; v. also Buff, l.c.; Fischer, l.c.; Schultze-Sellack, *P.* 139, 480). S.G. 1.94 at 16° (Weber, l.c.); 1.97 at 20° (Bussy, l.c.); 1.9086 at 25° (Buff, l.c.). V.D. 39.78 (Schultze-Sellack, *P.* 139, 480; Perman, *Pr.* 48, 45). I.F. [S<sub>2</sub>O<sup>2</sup>] = 103,240 (liquid SO<sub>2</sub> from solid S; *Th.* 2, 254); [SO<sup>2</sup>, O] = 32,160 (liquid SO<sub>2</sub> from gaseous SO<sub>2</sub>; *Th.*, l.c.); [SO<sup>2</sup>, Aq] = 39,170 (liquid SO<sub>2</sub>; *Th.*, l.c.). For heat of vaporisation v. Berthelot (*C. R.* 90, 1510). Schultze-Sellack gives vapour-pressure at 20° as 152 mm. Hg (*P.* 139, 480).

**Formation.**—1. By the interaction of ozone and SO<sub>2</sub>. Also by the action of an induction current on a mixture of SO<sub>2</sub> and O<sub>2</sub> (Buff a. Hofmann, *A.* 113, 129; Deville, *Bl.* [2] 3, 366); Berthelot (*C. R.* 86, 20) says that the product is S<sub>2</sub>O<sub>3</sub>.—2. By burning S in O under a pressure of several atmos. (v. SULPHUR DIOXIDE, Formation No. 1). Also by heating pyrites (Scheurer-Kestner, *C. R.* 99, 917; Lunge, *B.* 10, 1824).—3. By passing a mixture of SO<sub>2</sub> and O over heated Pt (Phillips a. Magnus, *P.* 24, 610), spongy Pt (Hodgkinson a. Lowndes, *C. N.* 67, 193), or certain oxides, e.g. Fe<sub>2</sub>O<sub>3</sub>, CuO, Cr<sub>2</sub>O<sub>3</sub> (Mahla a. Wöhler, *A.* 81, 255).—4. By heating certain sulphates or bisulphates, e.g. Fe<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>, Bi<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>, Ag<sub>2</sub>SO<sub>4</sub>, or NaHSO<sub>4</sub>.—5. By distilling Nordhausen sulphuric acid (v. Osann, *D. P. J.* 151, 159) also by heating conc. H<sub>2</sub>SO<sub>4</sub> with P<sub>2</sub>O<sub>5</sub> (Barreswil, *C. R.* 25, 30; Evans, *Ph.* 8, 127).

**Preparation.**—1. Fuming sulphuric acid is heated at as low a temperature as possible; the impure SO<sub>2</sub> is collected in a dry retort and redistilled once or twice, the most volatile portion being collected each time. The partially purified SO<sub>2</sub> is then distilled into a small tube, c. 8–10 mm. wide and about the length of a finger, containing some dry P<sub>2</sub>O<sub>5</sub>; this tube is narrowed at one end and fused on to a thick-walled tube c. 1–1.5 mm. wide, which is bent round and fused to a receiving tube c. 12–15 mm. wide and 300 mm. long; the tube containing the SO<sub>2</sub> and P<sub>2</sub>O<sub>5</sub> is heated in a water-bath to 90°–100° for 6 or 8 hours, the receiving tube projecting upwards, so that the distillate flows back again into the distilling-tube. The position of the apparatus is then changed, so that the receiving tube is lower than the distilling tube, and the SO<sub>2</sub> is distilled from the P<sub>2</sub>O<sub>5</sub> on a water-bath. When sufficient SO<sub>2</sub> has been collected, the narrow connecting tube is fused off, and the SO<sub>2</sub> is kept in the sealed receiving tube (Weber, *B.* 19, 3189).—

2. A mixture of  $\text{SO}_2$  and O, in the ratio  $\text{SO}_2:\text{O}$ , is passed over platinised asbestos heated nearly to redness; the  $\text{SO}_2$  is condensed in a small dry tube, in which it is sealed up. The mixture of  $\text{SO}_2$  and O is obtained by strongly heating conc.  $\text{H}_2\text{SO}_4$  and removing  $\text{H}_2\text{O}$  ( $\text{H}_2\text{SO}_4 = \text{H}_2\text{O} + \text{SO}_3 + \text{O}$ ) by cooling and passing through coke moistened with 60 p.c.  $\text{H}_2\text{SO}_4$  (Winkler, *D. P. J.* 218, 128). The asbestos is platinised by soaking in  $\text{PtCl}_4$  made alkaline by soda, and mixed with sufficient  $\text{HCO}_2\text{Na}$  to reduce the Pt, drying at  $100^\circ$ , carefully washing out the salts with water, and drying (Thomsen, *B. 3*, 496). The  $\text{SO}_3$  thus obtained is not quite pure. It may be purified by distillation with  $\text{P}_2\text{O}_5$  (v. *supra*).

**Properties.**—A colourless, mobile liquid, solidifying at  $c. 15^\circ$  to long, prismatic, transparent crystals, which melt at  $14.8^\circ$ . According to some observers (v. Marignac, *Ar. Ph.* 22, 225; 58, 228; Schultz-Sellack, *P.* 139, 480) the crystals of  $\text{SO}_3$  slowly change to a mass of tough, opaque, lustrous needles, which melt above  $50^\circ$ , and constitute a distinct modification of  $\text{SO}_3$ ; but the experiments of Weber (*P.* 139, 480; *B.* 19, 3187; cf. Rebs, *A.* 246, 356) have shown that pure  $\text{SO}_3$  exists only in one form, and that the substance with higher m.p. is formed by the action of traces of  $\text{H}_2\text{SO}_4$  in the  $\text{SO}_3$ ; a small trace of moisture suffices to cause the gradual change.  $\text{SO}_3$  is very acrid and poisonous; it chars paper, wood, and organic matter generally.  $\text{SO}_3$  is extremely hygroscopic; it dissolves in water with a hissing sound and production of much heat ( $[\text{SO}_3:\text{Aq}] = 39, 170$ ), forming  $\text{H}_2\text{SO}_4$ . Non-conductor of electricity (Magnus, *P.* 104, 553); not decomposed by electric sparks, but by passing through a red-hot tube gives  $\text{SO}_2$  and O.  $\text{SO}_3$  does not redden dry litmus. It is a strongly acid-forming oxide (v. SULPHURIC ACID).

**Reactions and Combinations.**—1. Heated to redness (by passing through red-hot tube) gives  $\text{SO}_2 + \text{O}$ .—2. Not decomposed by electric sparks (Magnus, *P.* 104, 553); electrolysis of  $\text{SO}_3$  in  $\text{H}_2\text{SO}_4$  causes separation of S and O, and the solution becomes blue (Geuther, *A.* 109, 129).—3. Water reacts violently with  $\text{SO}_3$  forming  $\text{H}_2\text{SO}_4$  (v. SULPHURIC ACID).—4. Hydrogen sulphide produces  $\text{H}_2\text{SO}_4$  and S.—5. A mixture of  $\text{SO}_2$  and oxygen, in the ratio  $2\text{SO}_2:\text{O}$ , forms  $\text{S}_2\text{O}_3$ , when submitted to the silent electric discharge (Berthelot, *A. Ch.* [5] 14, 345).—6. Sulphur dissolves in  $\text{SO}_3$  forming  $\text{S}_2\text{O}_3$ ; selenium and tellurium react similarly (v. SULPHUR THIO-OXIDE, SELENIUM THIO-OXIDE, and TELLURIUM THIO-OXIDE).—7. Phosphorus ignites in vapour of  $\text{SO}_3$ , forming  $\text{P}_2\text{O}_5$  and S.—8. Iodine dissolves in  $\text{SO}_3$ , apparently forming several compounds (v. Wach, *S.* 50, 37; Schultz-Sellack, *B.* 4, 109); Weber (*J. pr.* [2] 25, 224) describes the compounds  $\text{I}(\text{SO}_3)_2$ ,  $\text{I}(\text{SO}_3)_3$ , and  $\text{I}_2(\text{SO}_3)_4$ .—9. Iron and zinc react at red heat to give sulphides and oxides; mercury produces sulphate and  $\text{SO}_2$  (*d'Heureuse*, *P.* 75, 255).—10. Several metallic sulphides—e.g. of Sb, Pb, K—form sulphates and  $\text{SO}_2$  when heated with  $\text{SO}_2$  (Weber, *P.* 139, 480).—11. Dry sulphur dioxide is absorbed by  $\text{SO}_3$  at  $0^\circ$ , forming a thin, fuming liquid, approximately  $\text{SO}_2 \cdot 2\text{SO}_3$  (H. Rose, *P.* 89, 173). According to Schultz-Sellack, liquid  $\text{SO}_2$  and  $\text{SO}_3$  are miscible in all proportions (*P.* 139, 480).—12. Selenium dioxide combines to form  $\text{SO}_2 \cdot \text{SeO}_2$ ,

(v. SELENIUM DIOXIDE, Combinations, No. 4, p. 441).—13. Nitric oxide, in absence of moisture and O, forms  $\text{S}_2\text{O}_3\text{N}_2$ , which is generally called nitrosulphonic anhydride (q. v., p. 601) and written  $\text{S}_2\text{O}_3(\text{NO})_2$ . Nitrogen dioxide (made by heating  $\text{Pb}(\text{NO}_3)_2$ ) seems to form  $\text{SO}_2 \cdot \text{NO}_2$ , and on heating this and passing in more  $\text{NO}_2$ , O is given off and the compound  $\text{S}_2\text{O}_3\text{N}_2$  remains (v. Weber, *P.* 123, 337; Brüning, *A.* 98, 377). The formula of the first of these compounds is generally doubled, and the compound regarded as  $\text{S}_2\text{O}_3 \cdot \text{O}(\text{NO}_2)_2 = \text{oxynitrosulphonic anhydride}$  (q. v., p. 601); the second is described in some books as  $\text{S}_2\text{O}_3(\text{NO})_2$ , and is called nitrosyl pyrosulphate, but from the descriptions of Weber and Brüning it is evidently the same as the compound  $\text{S}_2\text{O}_3\text{N}_2$  formed from NO and  $\text{SO}_2$ , i.e. it is nitrosulphonic anhydride.—14.  $\text{SO}_3$  combines with iodine pentoxide to form  $3\text{SO}_3 \cdot \text{I}_2\text{O}_5$  and  $\text{SO}_3 \cdot 5\text{I}_2\text{O}_5$  (Weber, *B.* 20, 86; Kämmerer, *J. pr.* 83, 72). With phosphorus pentoxide  $3\text{SO}_3 \cdot \text{P}_2\text{O}_5$ , decomposing at  $30^\circ$ , is formed (Weber, *B.* 19, 3185; 20, 86). Arsenious oxide forms various unstable compounds (Adie, *C. J.* 55, 157; cf. Weber, *B.* 19, 3185; Schultz-Sellack, *B.* 4, 109; Reich, *J. pr.* 90, 176; Schafhäütl, *B. J.* 22, 113; and Pearce, *Z. K.* 20, 632). According to Baker (*C. J. Proc.* 1893, 130), dry  $\text{SO}_3$  does not react with dry oxides of barium, calcium, or copper.—15. The compound  $\text{SO}_2 \cdot \text{N}_2\text{O} \cdot 5\text{H}_2\text{SO}_4$  is said to be formed by passing  $\text{SO}_2$  into pure, well-cooled, nitric acid (Weber, *P.* 123, 233; 142, 602).—16. Boric acid forms  $\text{BH}_3\text{O}_3 \cdot 3\text{SO}_3$ , [ $= \text{B}(\text{HSO}_3)_3$ ] (*D'Arcy*, *C. J.* 55, 155; cf. Merz, *J. pr.* 90, 81; Schultz-Sellack, *B.* 4, 15).—17. Hydrobromic and hydriodic acids separate Br and I, and form  $\text{H}_2\text{SO}_4$  and  $\text{SO}_2$ .—18. Hydrochloric and hydrofluoric acids form  $\text{Cl}(\text{SO}_3\text{OH})$  and  $\text{F}(\text{SO}_3\text{OH})$  (v. CHLOROSULPHONIC ACID, p. 599; and FLUOSULPHONIC ACID, p. 600).—19. Conc. sulphuric acid forms  $\text{H}_2\text{S}_2\text{O}_7$  (v. PYROSULPHURIC ACID, p. 625).—20. Ammonia produces  $\text{NH}_4(\text{SO}_3\text{OH})$  and salts of this acid (v. SULPHAMIC ACID AND SALTS, p. 567); and also salts of  $\text{NH}(\text{SO}_3\text{OH})_2$  (v. IMIDOSULPHONIC ACID AND SALTS, p. 600).—21. Phosphoretted hydrogen produces  $\text{SO}_2$  and red P (H. Rose, *P.* 24, 140; Aimé, *J. pr.* 6, 79).—22. Phosphorus trichloride reacts violently, forming  $\text{POCl}_3$  and  $\text{SO}_2$  (Armstrong, *B.* 3, 732; Michaelis, *J. Z.* 6, 239). Phosphorus pentachloride produces pyrosulphuryl chloride  $\text{S}_2\text{O}_3\text{Cl}_2$  (q. v. under SULPHUR OXYCHLORIDES, p. 617).—23. Boron chloride reacts at  $c. 120^\circ$  to form  $\text{S}_2\text{O}_3\text{Cl}_2$  (Prudhomme, *Bl.* [2] 14, 385).—24. Nitrosyl chloride (produced by heating aqua regia) produces  $\text{SO}_2 \cdot \text{NOCl}$ — $\text{NO}_2(\text{SO}_2\text{Cl})$  (v. NITROSULPHONIC CHLORIDE, p. 601).—25. Pyrosulphuryl bromide  $\text{S}_2\text{O}_3\text{Br}_2$  (q. v., p. 617) is perhaps formed by the reaction of bromoform with  $\text{SO}_2$ .—26. Selenium tetrachloride produces  $\text{SSeO}_3\text{Cl}_4$  (v. SELENIUM THIOXYCHLORIDE, p. 441).

SULPHURIC PEROXIDE  $\text{S}_2\text{O}_8$ . (Sulphur heptoxide. Persulphuric anhydride.) Mol. w. not known with certainty but probably 176.68 ( $\text{S}_2\text{O}_8$ ). This oxide was prepared by Berthelot in 1877 (*A. Ch.* [5] 14, 345) by passing the 'silent' electric discharge, for several hours, through a mixture of  $\text{SO}_2$  and O in the ratio  $2\text{SO}_2:\text{O}$ , or of  $\text{SO}_2$  and O in the ratio  $2\text{SO}_2:3\text{O}$ . (For apparatus used v. B., *A. Ch.* [5] 12, 463.) Oily drops

formed on the sides of the tube, and on reducing the temperature nearly to  $0^{\circ}$  they solidified to long, white, crystalline, needles.  $S_2O_3$  resembles solid  $SO_2$  in appearance; it remains unchanged in a sealed tube for some days at  $0^{\circ}$ ; when heated it gives  $SO_2$  and  $O$ ; dissolves in conc.  $H_2SO_4$  forming a fairly stable solution; fumes in the air; in water it rapidly decomposes forming  $H_2SO_4$  and giving off a brisk stream of  $O$ ; with  $BaO$  forms  $BaSO_4$  and  $O$ ; and also some  $Ba$  persulphate, according to Berthelot (*l.c.*; no analyses given). By electrolysis  $H_2SO_4$  containing water and acid in the ratio  $10H_2O:H_2SO_4$ , B. (*C. R.* 90, 269) obtained a quantity of persulphuric acid ( $H_2S_2O_8$ ; v. under SULPHURIC ACID, p. 625) equal to from 88 to 123 g.  $S_2O_3$  per litre; using an acid of the concentration  $H_2SO_4:2H_2O$  to  $H_2SO_4:3H_2O$ , B. (*l.c.*) says that a compound  $S_2O_3 \cdot 2H_2O$  is formed, which is decomposed by excess of conc.  $H_2SO_4$  chiefly to  $H_2S_2O_8$ , and by dilution with water to  $H_2S_2O_8$  and  $H_2O$ , which after a time decompose to  $H_2SO_4$ ,  $H_2O$ , and  $O$ .

$S_2O_3$  is the anhydride of persulphuric acid  $H_2S_2O_8$  (*q. v.*, p. 625). Mendeléeff (*B.* 15, 242) regards  $S_2O_3$  as analogous in constitution to

$H_2O_3$ , and writes the formula  $\begin{matrix} & OSO_2 \\ & | \\ OSO_2 & \backslash \\ & O \end{matrix}$ ; he

looks on the corresponding acid as derived from  $H_2O_3$  by replacing  $2H$  by  $2SO_2OH$ , thus:  $O(SO_2OH)_2$ .

$O(SO_2OH)_2$ .

According to Traube (*B.* 22, 1518; 24, 1764; 25, 95), the liquid obtained by electrolysis 40 p.c.  $H_2SO_4$  contains an oxide to which he gives the formula  $SO_2$ , and calls *sulphuryl hyperoxide* (or *holoxide*),  $SO_2 \cdot O_2$ . Traube did not isolate this compound; his argument for its existence is based on the results of indirect analyses. In the light of the criticisms of Carnegie (*C. N.* 64, 158) it may be concluded that the existence of  $SO_2$  is extremely improbable. In a later communication (*B.* 26, 1481) Traube thinks it is probable that  $SO_2$  does not exist.

**Sulphur, oxyacids of.** For compositions of these acids, and references to articles where they are described, v. SULPHUR, OXYACIDS OF (p. 619).

**Sulphur, oxyacids of, nitrogen derivatives of.** For a general statement regarding these compounds, and references to the articles where they are described, v. SULPHUR OXYACIDS, NITROGEN DERIVATIVES OF (p. 619).

**Sulphur, oxybromides of.** There is very little definite knowledge regarding the compounds of  $S$ ,  $O$ , and  $Br$ . According to Michaelis (*J. Z.* 6, 239, 296)  $PBr_3$  does not react with  $SO_2$ , and a mixture of  $PCl_5$  and  $Br$  (in the ratio  $PCl_5:Br_2$ ) produces  $POCl_3$  and  $S$  bromides. Rose (*P.* 44, 327) and Clausnizer (*B.* 11, 2012) could not obtain an oxybromide by the reaction of  $SO_2$  and  $S$  bromide, nor by the action of  $SO_2$  and  $HBr$ .

In his memoir on  $S_2O_3Cl_2$  prepared by the reaction of  $SO_2$  with  $CHCl_3$ , Armstrong (*B.* 2, 712) states that  $CHBr_3$  reacts with  $SO_2$  similarly to  $CHCl_3$ , but he does not describe the product. If the reaction of  $CHBr_3$  with  $SO_2$  is strictly similar

to that of  $CHCl_3$ , the product would be *pyrosulphuryl bromide*  $S_2O_3Br_2$ .

Odling (*C. J.* 7, 2) supposed that *sulphuryl oxy-bromide*  $SO_2Br_2$  was formed by the action of sunlight on  $SO_2$  and  $Br$ , but Sestini (*Bl.* [3] 10, 226) and Melsens (*C. R.* 76, 92) failed to obtain an oxybromide by this method.

**Thionyl bromide  $SOBr_2$ .** This compound was obtained, but not quite free from  $S$  bromides, by Hartog a. Sims (*C. J. Proc.* No. 118, 1893, 10) by the interaction of  $SOCl_2$  and  $NaBr$ ; it is described as a very hygroscopic, crimson liquid, S.G. 2.68 at  $18^{\circ}$ , decomposing at  $150^{\circ}$  to  $Br$ ,  $S$  bromides, &c.

**Sulphur, oxychlorides of.** Five compounds have been isolated,  $SOCl_2$ ,  $SO_2Cl_2$ ,  $S_2O_3Cl_2$ ,  $S_2O_4Cl_2$ , and  $S_2O_5Cl_2$ .

**Thionyl chloride  $SOCl_2$  (Sulphurous oxychloride).** Mol. w. 118.62. Boils at  $78.8^{\circ}$ ; S.G.  $d_4^{20}$  1.67673, S.G. at b.p. 1.52143 (Thorpe, *C. J.* 37, 354; for other data v. Carius, *A.* 106, 303; 111, 93; Wurtz, *C. R.* 62, 460). V.D. at  $c. 150^{\circ} = 56$ , at  $c. 440^{\circ} = 39$  (Heumann a. Köchlin, *B.* 10, 1625). H.P.  $[S_2O_3Cl_2] = 40,800$ ; heat of vaporisation = 6,480 (Ogier, *C. R.* 94, 82). S.V. 78.01 (Thorpe, *l.c.*).

**Formation.**—1. By the reaction of  $PCl_5$  with  $SO_2$  (Kremers, *A.* 70, 297; Schiff, *A.* 102, 111),  $SO_2Cl_2$ ,  $C_6H_5SO_2Cl$ , and several other organic compounds containing  $S$  (v. Kekulé a. Barbaglia, *B.* 5, 875; Carius, *J. pr.* [3] 2, 262), sulphites, or thiosulphates; also by the reaction of  $POCl_3$  with sulphates.—2. By the action of  $Cl_2O$  on  $CS_2$ , or on  $S$  in  $S_2Cl_2$  at  $-12^{\circ}$  (Wurtz, *C. R.* 62, 460).—3. By the interaction of  $SO_2$  and  $SCl_2$  (Michaelis a. Schifferdecker, *B.* 5, 924; 6, 993).—4. Along with  $SO_2Cl_2$  by the gradual decomposition of  $S_2O_5Cl_2$  (*q. v.*, p. 619).

**Preparation.**—1. About 100 g. dry  $PCl_5$  are placed in a retort connected with a reversed condenser, and a stream of dry  $SO_2$  is led in till the  $PCl_5$  has liquefied; another 100 g.  $PCl_5$  is added and the stream of  $SO_2$  is continued; when sufficient  $PCl_5$  has thus been decomposed ( $PCl_5 + SO_2 = SOCl_2 + POCl_3$ ) the liquid is heated for some time (the reversed condenser being still attached) to get rid of  $SO_2$ , and then fractionated repeatedly ( $SOCl_2$  boils at  $78.8^{\circ}$  and  $POCl_3$  at  $107.2^{\circ}$ ) (Carius, *A.* 106, 303; 111, 98; Wurtz, *A.* 139, 375; Michaelis, *A.* 170, 1; Thorpe, *C. J.* 37, 354).—2.  $S_2Cl_2$  is placed in a small flask, cooled to  $c. -20^{\circ}$ , a stream of dry  $Cl_2$  is led in till the liquid is saturated, and then  $SO_2$  is distilled into the flask from a solution in conc.  $H_2SO_4$ ; the weights of  $S_2Cl_2$  and  $SO_2$  used should be in the ratio  $S_2Cl_2:4SO_2$  ( $=1:2.37$ ); convenient quantities to use are 22 g.  $S_2Cl_2$  and 50 g.  $SO_2$  ( $SCl_2 + 2SO_2 = SOCl_2 + S_2O_4Cl_2$ ). The liquid is fractionated finally from a small quantity of  $SO_2$  (Michaelis a. Schifferdecker, *B.* 5, 924; 6, 993).

**Properties.**—A colourless, very refractive liquid, fuming in the air, with a very penetrating odour; vapour attacks the eyes and respiratory organs. V.D. 56 at  $c. 150^{\circ}$ , but 89 at  $c. 440^{\circ}$ ; the smaller value corresponds with the decomposition  $4SOCl_2 = S_2Cl_2 + 2SO_2 + S_2Cl_2$ ; these products are obtained by passing vapour of  $SOCl_2$  through a red-hot tube (Heumann a. Köchlin, *B.* 10, 1625).

**Reactions and Combinations.**—1. *Moist air* produces  $\text{HCl}$  and  $\text{SO}_2$ .—2. *Water* also forms  $\text{HClAq}$  and  $\text{SO}_2$ , warm water forming in addition  $\text{H}_2\text{SO}_4\text{Aq}$  and  $\text{S}$  (Carius, *l.c.*).—3. *Hydrogen sulphide* produces  $\text{SO}_2$ ,  $\text{HCl}$ , and  $\text{S}$  (Prinz, *A.* 228, 371).—4. *Phosphorus pentasulphide* reacts to form  $\text{SO}_2$ ,  $\text{PSCl}_2$ , and  $\text{S}$ , and some  $\text{S}_2\text{Cl}_2$  (Prinz, *l.c.*).—5. With *antimony trisulphide* the products are  $\text{SbCl}_3$ ,  $\text{SO}_2$ , and  $\text{S}$ .—6. *Sulphur*, heated to  $180^\circ$  with  $\text{SOCl}_2$ , forms  $\text{S}_2\text{Cl}_2$  and  $\text{SO}_2$ ; *selenium* forms  $\text{S}_2\text{Cl}_2$  and  $\text{SSeCl}_2$  (Prinz, *l.c.*).—7. Powdered *antimony* reacts without heating, forming  $\text{SbCl}_3$ ,  $\text{Sb}_2\text{S}_3$ , and  $\text{SO}_2$ .—8.  $\text{POCl}_3$ ,  $\text{PSCl}_2$ , and  $\text{PCl}_5$  are formed by heating  $\text{SOCl}_2$  with *phosphorus trichloride* (Michaelis, *J. Z.* 6, 239).—9. Heating with *sulphur dichloride* produces  $\text{S}_2\text{OCl}_2$  (*q. v.*, p. 619) (Ogier, *Bl.* [2] 37, 293).—10. *Ammonia* does not produce thionylamide  $\text{SO}(\text{NH}_2)_2$ , but forms  $\text{NS}$ ,  $\text{NH}_4\text{Cl}$ ,  $(\text{NH}_4)_2\text{SO}_4$ , and  $\text{NH}_3$  polythionates (*M., l.c.*).—11. Reacts rapidly with *silver nitrate*, forming  $\text{NO}_2$ ,  $(\text{SO}_2\text{Cl})$  (Thorpe, *C. J.* 41, 297).—12.  $\text{SOCl}_2$  absorbs *sulphur dioxide* and *chlorine* freely (*M., l.c.*).—13. For reactions with various *organic compounds* v. Michaelis (*l.c.*); Heumann a. Köchlin (*B.* 16, 1625); Böttfiger (*B.* 11, 1407).

**SULPHURYL CHLORIDE**  $\text{SO}_2\text{Cl}_2$  (*Sulphuric oxychloride*). Mol. w. 134.58. Boils at  $69-95^\circ$  (Thorpe, *C. J.* 37, 359; for other determinations v. Regnault, *J. pr.* 19, 243; Clausnizer, *B.* 11, 2010; Ogier, *C. R.* 94, 82). S.G.  $_{20}^{20}$  1.70814; at b.p. 1.56025 (Thorpe, *l.c.*). V.D. 65 at  $184^\circ$ ; 84 at  $440^\circ$  (Heumann a. Köchlin, *B.* 16, 602; cf. Regnault, *J. pr.* 18, 97; Behrend, *J. pr.* [2] 15, 23). S.V. 85.29 (Thorpe, *l.c.*, p. 372). H.F.  $[\text{S}_2\text{O}_4\text{Cl}_2] = 89,780$ ;  $[\text{SO}_2\text{Cl}_2] = 18,700$  (*Th.* 2, 810; cf. Ogier, *C. R.* 94, 82). S.H. ( $15^\circ-63^\circ$ ) .233 (Ogier, *l.c.*). Heat of vaporisation 7,060 (*O., l.c.*).

**Formation.**—1. By the direct combination of  $\text{SO}_2$  and  $\text{Cl}$  in sunlight, or by reacting on a mixture of  $\text{C}_2\text{H}_4$  and  $\text{SO}_2$  by  $\text{Cl}$  in sunlight (Regnault, *J. pr.* 18, 93; 19, 243). Schulze (*J. pr.* [2] 23, 351; 24, 168) recommends to allow  $\text{SO}_2$  and  $\text{Cl}$  to react in presence of camphor. Melsens (*C. R.* 76, 92) passes  $\text{SO}_2$  and  $\text{Cl}$  into glacial acetic acid.—2. By passing  $\text{SO}_2$  over charcoal saturated with  $\text{Cl}$  (*M., l.c.*).—3. By the interaction of  $\text{PCl}_5$  with  $\text{H}_2\text{SO}_4$  or  $\text{SO}_3$  (Williamson, *P. M.* [4] 7, 865; Schiff, *A.* 102, 111); according to Michaelis (*J. Z.* 6, 233, 292),  $\text{SO}_2$  and  $\text{PCl}_5$  form  $\text{S}_2\text{O}_4\text{Cl}_2$ .—4. By heating  $\text{SO}_2$  and  $\text{BCl}_3$  in the ratio  $2\text{SO}_2:\text{BCl}_3$  to  $120^\circ$  in a closed tube (Gustavson, *B.* 6, 9).—5. By heating  $\text{Cl}(\text{SO}_2\text{OH})$  to a  $200^\circ$  for some time (Behrend, *B.* 8, 1004; cf. Otto a. Beckurts, *B.* 11, 2058).

**Preparation.**—1.  $\text{Cl}$  and  $\text{SO}_2$  are passed into camphor, and the colourless liquid is fractionated (Schulze, *l.c.*).—2.  $\text{Cl}(\text{SO}_2\text{OH})$  (*v. Chlorosulphonic acid*, p. 509) is heated to a  $200^\circ$ , in a closed tube, for some hours, when it decomposes thus,  $2[\text{Cl}(\text{SO}_2\text{OH})] = \text{SO}_2\text{Cl}_2 + \text{H}_2\text{SO}_4$ ; the liquid is distilled, the portion coming over at  $67^\circ-71^\circ$  being collected separately and then repeatedly fractionated (Behrend, *l.c.*; cf. Thorpe, *l.c.*).

**Properties and Reactions.**—A colourless liquid, fuming slightly in air. 1. Decomposed by heating to dull redness into  $\text{SO}_2$  and  $\text{Cl}$ ; decomposition is complete at  $440^\circ$  (Heumann a. Köchlin, *B.* 16, 602); but does not begin at  $250^\circ$

(Beckurts a. Otto, *B.* 11, 2060).—2. *Water* produces  $\text{HClAq}$  and  $\text{H}_2\text{SO}_4\text{Aq}$ ; a small quantity of water is said to form  $\text{Cl}(\text{SO}_2\text{OH})\text{Aq}$ .—3. Excess of  $\text{SO}_2\text{Cl}_2$  added to a little alcohol forms  $\text{Cl}(\text{SO}_2\text{OEt})$ ; with excess of alcohol  $\text{SO}_2(\text{OEt})_2$  is produced (Behrend, *B.* 9, 1834).—4. *Phosphorus pentachloride* reacts to form  $\text{POCl}_3$ ,  $\text{SOCl}_2$ , and  $\text{Cl}$  (*H. a. K., B.* 15, 1736).—5. *Phosphorus, arsenic, and antimony* produce  $\text{PCl}_3$ ,  $\text{AsCl}_3$ , and  $\text{SbCl}_3$  respectively, and  $\text{SO}_2$  (*H. a. K., l.c.*).—6. *Ammonia* forms  $\text{NH}_4\text{Cl}$  and  $\text{SO}_2\text{NH}_4\text{ONH}_2$ .—7. With many *organic compounds*  $\text{SO}_2\text{Cl}_2$  reacts like  $\text{PCl}_5$  or  $\text{POCl}_3$ , substituting  $\text{Cl}$  for  $\text{H}$  (*v. Dubois, Z.* [2] 2, 705; Michaelis, *A.* 170, 1).

#### PYROSULPHURYL CHLORIDE

$\text{S}_2\text{O}_4\text{Cl}_2 = \text{Cl.SO}_2\text{O.SO}_2\text{Cl}$ . (*Disulphuryl chloride. Pyrosulphuric oxychloride. Chlorosulphonic anhydride*). Mol. w. 214.38. Boils at  $139-59^\circ$  (Thorpe, *C. J.* 37, 360; for other determinations v. Rose, *P.* 44, 291; Michaelis, *J. Z.* 6, 235, 240, 292; Rosenstiehl, *C. R.* 53, 658; Schützenberger, *C. R.* 69, 352). S.G.  $_{20}^{20}$  1.85846, at b.p. 1.60610 (Thorpe, *l.c.*). V.D. at slightly above b.p. = 104; between  $160^\circ$  and  $240^\circ = 54.8$  (Heumann a. Köchlin, *B.* 16, 470; Kanowaloff, *B.* 16, 1127; cf. Rosenstiehl, *C. R.* 53, 658; Rose, *P.* 44, 291; Ogier, *C. R.* 94, 82, 217; 96, 648). H.F.  $[\text{S}_2\text{O}_4\text{Cl}_2] = 180,600$  (Kanowaloff, *l.c.*); Ogier (*l.c.*) gives 159,400. Heat of vaporisation 7,570 (*K., l.c.*); 13,160 (*O., l.c.*). S.H. .258 (*K., l.c.*).

**Formation.**—1. By the interaction of  $\text{PCl}_5$  and  $\text{SO}_2$  or  $\text{Cl}(\text{SO}_2\text{OH})$ .—2. By heating  $\text{P}_2\text{O}_5$  and  $\text{Cl}(\text{SO}_2\text{OH})$  (Billitz a. Heumann, *B.* 16, 483).—3. By heating  $\text{SO}_2$  with  $\text{NaCl}$  (*R., l.c.*), with  $\text{S}_2\text{Cl}_2$  (Rose, *P.* 44, 291), with  $\text{CCl}_4$  (Schützenberger, *C. R.* 69, 352; Kanowaloff, *C. R.* 95, 1284), with  $\text{C}_2\text{Cl}_6$  (Frudhomme, *C. R.* 70, 1137), with  $\text{CHCl}_3$  (Armstrong, *C. J.* [2] 1, 244), or with  $\text{SiCl}_4$  (Gustavson, *B.* 5, 332).—4. By the interaction of  $\text{POCl}_3$  and  $\text{SOCl}_2$  (Michaelis, *J. Z.* 6, 235, 240, 292).

**Preparation.**—1.  $\text{P}_2\text{O}_5$  and  $\text{Cl}(\text{SO}_2\text{OH})$  are heated in a flask with a reversed condenser, using rather more  $\text{Cl}(\text{SO}_2\text{OH})$  than  $\text{P}_2\text{O}_5$ ; when  $\text{HCl}$  and  $\text{SO}_2$  cease to be given off, the liquid is distilled, and the portion coming over between  $135^\circ$  and  $145^\circ$  is fractionated (*B. a. H., l.c.*).—2.  $\text{S}_2\text{Cl}_2$  in a flask is surrounded by a freezing mixture, and saturated with  $\text{SO}_2$ ; the product is fractionated;  $5\text{SO}_2 + \text{S}_2\text{Cl}_2 = 5\text{SO}_2 + \text{S}_2\text{O}_4\text{Cl}_2$  (Rose, *P.* 44, 291). Thorpe (*C. J.* 37, 360) found that the product of this reaction boiled almost wholly between  $135^\circ$  and  $138^\circ$ .

**Properties and Reactions.**—A colourless, mobile, very refractive liquid, fuming in the air with formation of  $\text{Cl}(\text{SO}_2\text{OH})$ .—1. Decomposed by heat to  $\text{SO}_2$ ,  $\text{SO}_3$ , and  $\text{Cl}$  (Rose, *P.* 44, 291); the V.D. determinations of Heumann a. Köchlin (*B.* 16, 479) show that at  $440^\circ$  the decomposition is  $\text{S}_2\text{O}_4\text{Cl}_2 = \text{SO}_2 + \text{SO}_3 + \text{Cl}_2$ .—2. Sinks in water, and is slowly decomposed to  $\text{HClAq}$  and  $\text{H}_2\text{SO}_4\text{Aq}$ ; if a very little water is used  $\text{Cl}(\text{SO}_2\text{OH})$  is formed, thus  $\text{S}_2\text{O}_4\text{Cl}_2 + \text{H}_2\text{O} = 2\text{Cl}(\text{SO}_2\text{OH})$  (*v. B. a. H., l.c.*).—3. Reacts with *phosphorus, sulphur, antimony, copper, iron, zinc*, and some other metals, to produce chlorides,  $\text{SO}_2$  and  $\text{SO}_3$  (Heumann a. Köchlin, *B.* 16, 479).—4. *Phosphorus trichloride* produces

$\text{POCl}_3$ ,  $\text{POCl}_2$ , and  $\text{SO}_2$ ; *phosphorus pentachloride* forms  $\text{POCl}_2$ ,  $\text{Cl}$ , and  $\text{SO}_2$  (Geuther, *B.* 5, 925). *Selenium tetrachloride* gives  $\text{SSeO}_4\text{Cl}$  (Clausenizer, *B.* 11, 2010).—6. *Chromates* react to form  $\text{CrO}_4\text{Cl}_2$  (Rosenstiehl, *C. R.* 58, 558).—7. *Ammonia* forms a white solid, which dissolves in water, producing  $\text{NH}_4\text{Cl}$  and a sulphamate of  $\text{NH}_3$  (Rose, *l.c.*).

**SULPHUR MONOXYTETRACHLORIDE**  $\text{S}_2\text{OCl}_4$ . By heating equal weights of  $\text{S}_2\text{Cl}_2$  and  $\text{SO}_2\text{Cl}_2$  to  $250^\circ$  in a sealed tube, Ogier (*Bl.* [2] 37, 293) obtained a deep-red liquid resembling  $\text{S}_2\text{Cl}_4$ , S.G. 1.656 at  $0^\circ$ , decomposing under  $100^\circ$  to  $\text{S}_2\text{Cl}_4$ ,  $\text{SO}_2$ , and  $\text{S}$ , to which he gave the composition  $\text{S}_2\text{OCl}_4$ . Decomposed by water to  $\text{H}_2\text{SO}_4\text{Aq}$ ,  $\text{SO}_2\text{Aq}$ ,  $\text{HClAq}$ , thionic acids, and  $\text{S}$ .

**SULPHUR TRI-OXYTETRACHLORIDE**  $\text{S}_3\text{O}_4\text{Cl}_4$ . Mol. w. not determined. This compound was obtained by Millon (*A. Ch.* [3] 29, 327) by the action of moist  $\text{Cl}$  on  $\text{S}_2\text{Cl}_4$  (cf. Marchand, *J. pr.* 22, 507; Carius, *A.* 106, 295). It is conveniently prepared by the reaction  $\text{SOCl}_2 + \text{Cl}(\text{SO}_2\text{OH}) = \text{HCl} + \text{S}_3\text{O}_4\text{Cl}_4$ ; a stream of dry  $\text{Cl}$  is led into a mixture, in the ratio of equal numbers of molecules, of  $\text{S}_2\text{Cl}_4$  and  $\text{Cl}(\text{SO}_2\text{OH})$ , kept at  $c. -20^\circ$ , until a semi-solid mass is obtained (a very wide tube must be used to lead in  $\text{Cl}$ ); the temperature is then kept at  $c. -13^\circ$  and the  $\text{Cl}$  is continued till the mass gets quite solid; the freezing mixture is then removed, and the  $\text{Cl}$  is continued till the mass is white, when the excess of  $\text{Cl}$  is removed by a stream of dry  $\text{CO}_2$  (Michaelis a. Schifferdecker, *B.* 6, 996).

$\text{S}_3\text{O}_4\text{Cl}_4$  is a white, crystalline solid, with a most disagreeable odour; the vapour acts on the eyes. Melts at  $57^\circ$ , giving off  $\text{SO}_2$  and  $\text{Cl}$ , and leaving a liquid that solidifies chiefly to  $\text{SOCl}_2$  and  $\text{S}_2\text{O}_3\text{Cl}_2$ ; a portion sublimates in fine white needles. Ice-cold water produces  $\text{SO}_2\text{Aq}$ ,  $\text{H}_2\text{SO}_4\text{Aq}$ , and  $\text{HClAq}$ ; water at the ordinary temperature also separates  $\text{S}$ . Deliquesces in a partially closed vessel, giving off  $\text{HCl}$ ,  $\text{Cl}$ , and  $\text{SO}_2$ , and leaving a liquid that gives  $\text{SOCl}_2$  and  $\text{S}_2\text{O}_3\text{Cl}_2$  on distillation. Conc.  $\text{H}_2\text{SO}_4$  reacts violently, forming  $\text{HCl}$ ,  $\text{SO}_2$ , and  $\text{Cl}(\text{SO}_2\text{OH})$ ;  $\text{CS}_2$  produces very rapid decomposition to  $\text{COCl}_2$ ,  $\text{CO}$ ,  $\text{SO}_2$ ,  $\text{S}_2\text{Cl}_2$ , and  $\text{SOCl}_2$ . On long standing in a closed tube  $\text{S}_3\text{O}_4\text{Cl}_4$  separates into equal numbers of molecules of  $\text{SOCl}_2$  and  $\text{SO}_2\text{Cl}_2$  (M. a. Mathias, *B.* 6, 1452).

**SULPHUR, OXYACIDS OF.** M. M. P. M. Several acids have been isolated, and salts of some others are known. The following list gives the names and compositions of the oxyacids of sulphur and their salts, with references to the articles where these compounds are described:—

**HYPOSULPHUROUS ACID AND SALTS**  $\text{H}_2\text{S}_2\text{O}_3$ , and  $\text{M}_2\text{S}_2\text{O}_3$ ; v. *Hyposulphurous acid* under SULPHUROUS ACID (p. 627), and *hyposulphites* under SULPHITES (p. 592).

**SULPHUROUS ACID AND SALTS**  $\text{H}_2\text{SO}_3$ ,  $\text{MHSO}_3$ , and  $\text{M}_2\text{SO}_3$ ; v. *Sulphurous acid* (p. 628), and *Sulphites* (p. 587).

**SULPHURIC ACID AND SALTS**  $\text{H}_2\text{SO}_4$ ,  $\text{MHSO}_4$ , and  $\text{M}_2\text{SO}_4$ ; v. *Sulphuric acid* (p. 620) and *Sulphates* (p. 567).

**THIOSULPHURIC ACID AND SALTS**  $\text{H}_2\text{S}_2\text{O}_3$ ,  $\text{MHS}_2\text{O}_3$ , and  $\text{M}_2\text{S}_2\text{O}_3$ ; v. *Thiosulphuric acid* (p. 708) and *thiosulphates* (p. 705).

**THIONIC ACIDS AND SALTS**  $\text{H}_2\text{S}_2\text{O}_4$ ,  $\text{H}_2\text{S}_3\text{O}_4$ ,  $\text{H}_2\text{S}_4\text{O}_4$  (and salts); v. *Thionic acids* (p. 698) and *thionates* (p. 695).

**PYROSULPHURIC ACID AND SALTS**  $\text{H}_2\text{S}_2\text{O}_7$ ,  $\text{MHS}_2\text{O}_7$ , and  $\text{M}_2\text{S}_2\text{O}_7$ ; v. *Pyrosulphuric acid* under SULPHURIC ACID (p. 625), and *Pyrosulphates* under SULPHATES (p. 583).

**PERSULPHURIC ACID AND SALTS**  $\text{H}_2\text{S}_2\text{O}_8\text{Aq}$ ,  $\text{M}_2\text{S}_2\text{O}_8$ , and  $\text{MS}_2\text{O}_8$ ; v. *Persulphuric acid* under SULPHURIC ACID (p. 625), and *Persulphates* under SULPHATES (p. 582). M. M. P. M.

**SULPHUR OXYACIDS, NITROGEN DERIVATIVES OF.** In 1845 Fremy (*A. Ch.* [3] 15, 408) described the K salts of a number of acids obtained by the interaction of  $\text{KNO}_3\text{Aq}$  and  $\text{K}_2\text{SO}_4\text{Aq}$ , and by boiling the products of this interaction with slightly acidified water; he called the compounds *salts of sulphazotised acids*. The examination of these salts was prosecuted by Claus a. Koch (*A.* 152, 336 [1874]), and by Claus (*A.* 158, 52, 194 [1876]); Berglund (*Bl.* [2] 25, 455; *B.* 9, 252, 1896 [1875]); and Raschig (*A.* 241, 161; *B.* 20, 584 [1887]) also investigated the sulphazotised acids of Fremy; and the researches of Divers and Haga (*C. J. Trans.* 1885, 1886, 1889, 1892) have thrown much light on many classes of these compounds. The more recent investigations noted above have shown many of the formulae given by Fremy to be inaccurate, and they have also led to a considerable revision of Claus's results. As the compounds that have been fairly thoroughly examined are noticed under the heading *Sulphonic acids and derivatives* (p. 509), it does not seem necessary to give an account of the other *salts of sulphazotised acids*, especially as it is very probable that the formulae assigned to these compounds will require modification, and that some of the compounds will be found not to exist.

The chief *sulphazotised compounds* that have been investigated sufficiently to establish their composition satisfactorily are the following:—

*Amidosulphonic acid and salts*  $\text{NH}_2(\text{SO}_2\text{OH})$ ; described as *Sulphamic acid* (p. 567).

*Imidosulphonic acid and salts*  $\text{NH}(\text{SO}_2\text{OH})$ , (p. 600).

*Nitrosulphonates*  $\text{N}(\text{SO}_2\text{OM})_2$ , (p. 601).

*Nitrosulphonic acid and salts*  $\text{NO}_2(\text{SO}_2\text{OH})$  (p. 601).

*Nitrosulphonic anhydride*  $(\text{NO}_2)_2\text{S}_2\text{O}_3$ , (p. 601).

*Nitrosulphonic chloride*  $\text{NO}_2(\text{SO}_2\text{Cl})$ , (p. 601).

*Nitroso-oxy-amidosulphonates*  $\text{N}(\text{NO.OH})(\text{SO}_2\text{OM})$ ; described as *nitroso-sulphates* under SULPHATES (p. 581).

*Oxy-amidosulphoric acid and salts (and salts derived therefrom)*  $\text{NH}(\text{OH})(\text{SO}_2\text{OH})$  (p. 602).

*Oxy-imidosulphonates (and salts derived therefrom)*  $\text{N}(\text{OH})(\text{SO}_2\text{OM})_2$ , (p. 602).

*Oxy-nitrosulphonic anhydride*  $(\text{NO}_2)_2\text{O.S}_2\text{O}_3$ , (p. 601).

*Sulphamides*  $(\text{NH}_2)_2\text{SO}_2$ , (p. 587).

*Sulphimides*  $\text{NH.SO}_2$ , (p. 587).

*Sulphimido-amide*  $\text{NH}(\text{SO}_2\text{NH}_2)_2$  (p. 687).  
*Thionamic acid and salts*  $\text{NH}_2(\text{SO}_2\text{OH})$  (p. 695). M. M. P. M.

**SULPHURETTED HYDROGEN** v. **HYDROGEN SULPHIDE**, vol. ii. p. 725.

**SULPHURIC ACID**; also **PERSULPHURIC ACID** and **PYROSULPHURIC ACID**.

**SULPHURIC ACID**  $\text{H}_2\text{SO}_4$  (*Oil of vitriol*). Mol. w. probably 97.76. Melts at  $10.35^\circ$  (Pickering, *C. J.* 57, 331);  $10.5^\circ$  (Thilo, *Chem. Zeitung*, 16, 1688). Boiling begins at  $c. 290^\circ$ ,  $\text{SO}_2$  and  $\text{H}_2\text{O}$  with some  $\text{H}_2\text{SO}_4 \cdot x\text{H}_2\text{O}$  passing off; b.p. rises till  $338^\circ$  is reached, when it becomes constant and complete dissociation to  $\text{SO}_2$  and  $\text{H}_2\text{O}$  occurs; for b.p. of  $\text{H}_2\text{SO}_4$  from 95 to 5 p.c.  $\text{H}_2\text{SO}_4$  v. Lunge (*B. J.* 11, 370). S.G.  $1.8884$  (Perkin, *C. J.* 63, 59; cf. Pickering, *C. J.* 57, 73, note; Kohlrausch, *W.* 17, 69; Schertel, *J. pr.* [2] 26, 246; Mondeloeff, *B.* 17, 80, 2536; Lunge a. Isler, *Zeit. für anorg. Chemie*, 1890, 129). V.D. 25 at  $440^\circ$ , corresponding with dissociation to  $\text{SO}_2 + \text{H}_2\text{O}$  (Deville a. Troost, *C. R.* 56, 891; Wanklyn a. Robinson, *Pr.* 12, 507). S.H. ( $22^\circ$  to  $80^\circ$ ) .355; ( $22^\circ$  to  $170^\circ$ ) .37 (Pfaundler, *B.* 3, 798); ( $16^\circ$  to  $20^\circ$ ) .3315 (Marignac, *Ar. Sc.* 39, 217, 273). C.E. .0005585 at  $20^\circ$  (Marignac, *l.c.*). H.F.  $[\text{H}^2, \text{SO}^2] = 192,320$ ;  $[\text{H}^2\text{O}, \text{SO}^2] = 21,320$  (formation of liquid  $\text{H}_2\text{SO}_4$ ) (*Th.* 2, 255). Heat of fusion = 860 g. units (for 98 g.  $\text{H}_2\text{SO}_4$ ) (Berthelot, *C. R.* 78, 716). T. C. v. Beetz (*W.* 7, 435; Weber (*J.* 1885, 121).  $\frac{\mu-1}{d}$ . Mol. w. = 32.45 (Gladstone, *P. M.* [4] 36, 311). For further data v. *infra*.

**Occurrence.**—Small quantities of  $\text{H}_2\text{SO}_4$ , from 1 to .5 p.c., are found in some rivers and springs in volcanic districts; in a pool in Texas, Mallet (*C. N.* 26, 147) found 5.29 g.  $\text{H}_2\text{SO}_4$  per litre of water. The acid is also found in certain animal secretions; the salivary glands of some molluscs are said to contain c. 2 p.c. (Bödeker a. Troschel, *B. B.* 1854, 486; De Luca a. Panceri, *BZ.* [2] 9, 400; Maly, *M.* 1, 205). The salts of sulphuric acid occur in large quantities (v. **SULPHATES**, p. 667).

**Formation.**—The formation of an oily liquid by heating alum is spoken of by Geber in the eighth century; a similar liquid was formed in the fifteenth century by burning sulphur with saltpetre. These liquids were shown to be identical towards the end of the sixteenth century. Oil of vitriol seems to have been manufactured in fair quantities by heating ferrous sulphate from about the early part of the eighteenth century; the first manufactory for making the acid from sulphur was started at Richmond by Ward about 1740. The composition of sulphuric acid was determined by Lavoisier.

1. By long exposure of flowers of sulphur in the air (John, *S.* 14, 417; Wagenmann, *P.* 24, 601).—2. By heating S with  $\text{H}_2\text{O}$  to  $c. 200^\circ$ ; by electrolysing  $\text{H}_2\text{O}$  using Pt electrodes with pieces of S attached, the  $\text{H}_2\text{SO}_4$  forms at the positive pole (Bequerel, *C. R.* 56, 237).—3. By the oxidation of S in presence of  $\text{H}_2\text{O}$  by  $\text{Cl}$ ,  $\text{HNO}_3$ ,  $\text{HCl}$  and  $\text{KClO}_4$ , *aqua regia*, &c.; also by certain metallic salts (v. Wicke, *A.* 82, 146; Parkmann, *Am. S.* [2] 38, 328).—4. By oxidising  $\text{SO}_2$  or  $\text{SO}$ , in presence of water, by  $\text{Cl}$ ,  $\text{Br}$ ,  $\text{H}_2\text{O}_2$ ,  $\text{Ag}$ ,

$\text{NO}$ ,  $\text{HNO}_3$ , &c.; by passing moist  $\text{SO}_2$  and air over hot Pt black (Phillips, *A.* 4, 171), through a red-hot tube containing pieces of glass (Magnus, *P.* 24, 610), or over red-hot sand (Blondeau, *C. R.* 29, 405).—5. By the oxidation of  $\text{H}_2\text{S}$  and polythionic acids (v. Cloëz a. Guignet, *C. R.* 46, 1110).—6. By the interaction of water and  $\text{SO}_2$ ,  $\text{SO}_2\text{Cl}_2$ ,  $\text{SO}_2\text{Cl.OH}$ , &c.

**Preparation.**—Commercial oil of vitriol is diluted until the S.G. is 1.53 (=  $50^\circ$  Beaumé, or  $106^\circ$  Twaddell, = 62.5 p.c.  $\text{H}_2\text{SO}_4$  by weight); the acid is heated to  $70^\circ$ – $80^\circ$ , and  $\text{Na}_2\text{S}_2\text{O}_3$  is added in quantity sufficient to decompose the  $\text{As}_2\text{O}_3$  present (which should be estimated beforehand), according to the equation  $3\text{Na}_2\text{S}_2\text{O}_3 + \text{As}_2\text{O}_3 = 3\text{Na}_2\text{SO}_4 + \text{As}_2\text{S}_3$ ; the acid is stirred until the  $\text{As}_2\text{S}_3$  separates in flocks (Thorn, *D. P. J.* 217, 495); the acid is filtered from  $\text{As}_2\text{S}_3$  through asbestos or glass-wool, and is then concentrated by evaporation in a Pt dish till it begins to fume, and then in a retort of Pt or hard glass. The conc. acid is now heated with a little pure  $(\text{NH}_4)_2\text{SO}_4$ , whereby  $\text{HNO}_3$  and  $\text{HNO}_2$  are decomposed ( $\text{NH}_4\text{NO}_2$  and  $\text{NH}_4\text{NO}_3$  are formed, and then decomposed to  $\text{N}$  and  $\text{H}_2\text{O}$ , and  $\text{N}_2\text{O}$  and  $\text{H}_2\text{O}$ ). The acid is then distilled from a glass retort, heated by a ring-burner placed around the retort at about two-thirds of the distance from the level of the acid to the bottom of the retort. The distillate is re-distilled in small quantities from a Pt retort into a Pt receiver; the condenser being formed of Pt tubes, soldered with gold and fitting closely one into the other, and the temperature being such that the acid does not boil during the distillation (cf. Stas, *Chem. Propriétés*, 112). Various other methods for removing As have been proposed; for the preparation of  $\text{H}_2\text{SO}_4$  free from As for chemico-medical use v. Bloxam (*C. J.* 15, 52), also Buignet a. Bussy (*J. Ph.* [3] 44, 177; 46, 252).

Commercial oil of vitriol is prepared by passing  $\text{SO}_2$ , mixed with a little  $\text{HNO}_3$ , into large leaden chambers into which jets of steam are also sent. The  $\text{SO}_2$  is prepared by burning S or pyrites in a stream of air; the hot gas is passed over  $\text{HNO}_3$ , or over pots containing  $\text{KNO}_3$  and  $\text{H}_2\text{SO}_4$ , so that it sweeps into the leaden chambers a certain quantity of  $\text{HNO}_3$ . The interactions between the hot  $\text{SO}_2$  and  $\text{HNO}_3$  probably produce  $\text{NO}$  and  $\text{N}_2\text{O}_3$  ( $3\text{SO}_2 + 2\text{HNO}_3 + 2\text{H}_2\text{O} = 3\text{H}_2\text{SO}_4 + 2\text{NO}$ ; and also  $2\text{SO}_2 + 2\text{HNO}_3 + \text{H}_2\text{O} = 2\text{H}_2\text{SO}_4 + \text{N}_2\text{O}_3$ ); the  $\text{NO}$  then combines with O in the air of the chambers to form  $\text{N}_2\text{O}_3$  ( $4\text{NO} + \text{O}_2 = 2\text{N}_2\text{O}_3$ ), which interacts with  $\text{SO}_2$  and  $\text{H}_2\text{O}$  to produce  $\text{H}_2\text{SO}_4$  and  $\text{NO}(\text{N}_2\text{O}_3 + \text{SO}_2 + \text{H}_2\text{O} = \text{H}_2\text{SO}_4 + 2\text{NO})$ ;—if  $\text{N}_2\text{O}_3$  is produced in the primary reaction of  $\text{SO}_2$  with  $\text{HNO}_3$ , this  $\text{N}_2\text{O}_3$  may take up O to form  $\text{N}_2\text{O}_5$ , which in turn may react with  $\text{SO}_2$  and  $\text{H}_2\text{O}$  to produce  $\text{H}_2\text{SO}_4$  and  $\text{NO}(\text{N}_2\text{O}_5 + 2\text{SO}_2 + 2\text{H}_2\text{O} = 2\text{H}_2\text{SO}_4 + 2\text{NO})$ . These cycles of changes proceed as long as  $\text{SO}_2$  is sent into the chambers, and there is present a sufficiency of O,  $\text{H}_2\text{O}$ , and oxides of N. If there is not sufficient  $\text{H}_2\text{O}$  present to complete the decomposition of  $\text{N}_2\text{O}_5$  and  $\text{SO}_2$  (or  $\text{N}_2\text{O}_3$  and  $\text{SO}_2$ ) to  $\text{H}_2\text{SO}_4$  and  $\text{NO}$ , nitrosulphonic acid— $\text{NO}_2(\text{SO}_2\text{OH})$ —is formed as a solid on the sides of the chamber ( $3\text{N}_2\text{O}_5 + 2\text{SO}_2 + \text{H}_2\text{O} = 2\text{NO}_2(\text{SO}_2\text{OH}) + 4\text{NO}$ ; or  $3\text{N}_2\text{O}_5 + 4\text{SO}_2 + 2\text{H}_2\text{O} = 4\text{NO}_2(\text{SO}_2\text{OH}) + 2\text{NO}$ );

when steam is now sent into the chamber the nitrosulphonic acid is decomposed to  $\text{H}_2\text{SO}_4$  and  $\text{N}_2\text{O}_5$  ( $2\text{NO}_2(\text{SO}_2\cdot\text{OH}) + \text{H}_2\text{O} = 2\text{H}_2\text{SO}_4 + \text{N}_2\text{O}_5$ ). It is possible that the formation of  $\text{NO}_2(\text{SO}_2\cdot\text{OH})$  and the interaction of this with water may form normal stages in the series of reactions that occur in the chambers. Lunge (*C. J.* 47, 465) regards  $\text{N}_2\text{O}_5$  as the chief carrier of O from the air to the  $\text{SO}_2$ ; he formulates the two main interactions as

moreover, he insists that the interactions take place for the most part between gases in contact with the surface of the vesicles of liquid water formed by the condensation of the steam sent into the chamber. (A fuller discussion of the reactions that occur in the leaden chambers will be found in the *DICTIONARY OF APPLIED CHEMISTRY*, vol. iii. p. 726.)

Some portion of the oxides of N is swept through the chambers and so lost (part of this is recovered in the Gay-Lussac towers); some is lost by leakage, solution in the acid formed in the chambers, and in other mechanical ways; but some portion of the available oxides of N is also destroyed by secondary reactions that occur in the chambers, and result in the formation of  $\text{N}_2\text{O}$  and sometimes of N or  $\text{NH}_3$  (v. Weber, *P.* 130, 329; Pelouze, *A. Ch.* [2] 60, 162; Lunge, *B.* 14, 2196; cf. *DICTIONARY OF APPLIED CHEMISTRY*, vol. iii. p. 729).

**Properties.**—A clear, colourless, oily, hygroscopic liquid; solidifying at c.  $10\cdot5^\circ$ . The liquid may be cooled much below its freezing-point without solidifying, but addition of a crystal of  $\text{H}_2\text{SO}_4$  or a small quantity of  $\text{SO}_2$  causes crystallisation; the presence of a trace of water lowers the freezing-point to c.  $0^\circ$ .  $\text{H}_2\text{SO}_4$  is exceedingly acid and burning, and is a violent poison.  $\text{H}_2\text{SO}_4$  fumes very slightly in air at the ordinary temperature; at  $30^\circ\text{--}40^\circ$  it fumes much, giving off  $\text{SO}_3$ ; according to Colefax (*C. N.* 63, 179),  $\text{H}_2\text{SO}_4$  is probably slightly volatilised at ordinary temperatures. The mol. w. of  $\text{H}_2\text{SO}_4$  has not been determined directly, but from the mol. weights of such derivatives as  $\text{SO}_2\text{Cl}_2$ ,  $\text{SO}_2(\text{OMe})_2$ , etc., the formula  $\text{H}_2\text{SO}_4$  is most probably molecular.  $\text{H}_2\text{SO}_4$  is decomposed when heated, and does not show a definite b.p.; boiling begins at c.  $290^\circ$ , and the temperature gradually rises to  $338^\circ$ , at which temperature dissociation to  $\text{H}_2\text{O}$  and  $\text{SO}_3$  is complete. The residue has the composition  $\text{H}_2\text{SO}_4\cdot\frac{1}{2}\text{H}_2\text{O}$ ; acid with this composition is obtained by boiling down either  $\text{H}_2\text{SO}_4\cdot x\text{H}_2\text{O}$  or  $\text{H}_2\text{SO}_4\cdot x\text{SO}_3$  (Marignac, *A. Ch.* [3] 89, 184; Dittmar, *C. J.* [2] 7, 446). The sp.gr. of the vapour given off at c.  $440^\circ$  corresponds with that calculated for the dissociation of  $\text{H}_2\text{SO}_4$  into  $\text{SO}_3 + \text{H}_2\text{O}$  (Deville a. Troost, *C. R.* 56, 891; Wanklyn a. Robinson, *Pr.* 12, 507). The b.p. of  $\text{H}_2\text{SO}_4\text{Aq}$  containing from 95 p.c.  $\text{H}_2\text{SO}_4$  (b.p. =  $295^\circ$ ), to 5 p.c.  $\text{H}_2\text{SO}_4$  (b.p.  $101^\circ$ ) is given by Lunge (*B.* 11, 370).  $\text{H}_2\text{SO}_4$  freezes at  $10\cdot352^\circ$  (v. Pickering, *C. J.* 57, 331; where a long series of determinations is given of t.p. of  $\text{H}_2\text{SO}_4\text{Aq}$  containing from  $\cdot005$  to 100 p.c.  $\text{H}_2\text{SO}_4$ ). The S.H. and mol. heat (= S.H.  $\times 98$ ) are given by Pfander (*B.* 3, 798) as follows:

Temp. interval from $22^\circ$ to	S.H.	Mol. heat
$80^\circ$	$\cdot855$	84-790
90	$\cdot856$	84-888
100	$\cdot858$	85-084
110	$\cdot859$	85-182
120	$\cdot860$	85-280
130	$\cdot862$	85-476
140	$\cdot864$	85-672
150	$\cdot865$	85-770
160	$\cdot867$	85-966
170	$\cdot870$	86-260

For S.H. of  $\text{H}_2\text{SO}_4\cdot x\text{H}_2\text{O}$  from  $16^\circ$  to  $20^\circ$ , varying from 0 to 400, v. Marignac (*Ar. Sc.* 81, 217, 273); Bode (*Zeit. für anorg. Chemie*, 1886, 244) gives S.H. of  $\text{H}_2\text{SO}_4\text{Aq}$  from S.G. 1-842 to 1-037; Pickering (*C. J.* 57, 160) gives S.H. of  $\text{H}_2\text{SO}_4\text{Aq}$  from c.  $\cdot2$  to c.  $12$  p.c.  $\text{H}_2\text{SO}_4$  dissolves in water in all proportions; much heat is produced, and contraction occurs; for thermal measurements v. Thomsen (*Th.* 3, 44), Favre a. Silbermann (*C. R.* 24, 1081), P. a. Quailard (*C. R.* 50, 1150), Pfander (*J.* 1869, 122), and, especially, Pickering (*C. J.* 57, 164). According to Pickering (*C. N.* 64, 14), the maximum contraction, calculated for unit weight of solution, changes from 67 p.c. at  $8^\circ$  to  $70\cdot1$  p.c. at  $38^\circ$ ; but the maximum is constant at 76 p.c., from  $8^\circ$  to  $38^\circ$ , if calculated for unit volume; for fuller data v. P. (*C. J.* 57, 148). The expansion of  $\text{H}_2\text{SO}_4\cdot x\text{H}_2\text{O}$  at  $20^\circ$ , when  $x$  varies from 0 to 400, is given by Marignac (*Ar. Sc.* 39, 217, 273). The refractive indices and dispersion of  $\text{H}_2\text{SO}_4\text{Aq}$  containing from 98-87 to  $\cdot088$  p.c.  $\text{H}_2\text{SO}_4$  are given by Pickering (*C. J.* 63, 99; cf. van der Willigen, *Ar. N.* 3, 122). Perkin (*C. J.* 63, 57) gives Mol. R. for  $\text{H}_2\text{SO}_4\text{Aq}$  from 99-92 to 9-18 p.c.  $\text{H}_2\text{SO}_4$  (= from  $\text{H}_2\text{SO}_4 + 53\cdot87$   $\text{H}_2\text{O}$  to  $\text{H}_2\text{SO}_4 + \cdot004$   $\text{H}_2\text{O}$ ).

The electrical conductivities of  $\text{H}_2\text{SO}_4\text{Aq}$  of different concentrations have been measured by Kohlrausch (*P.* 154, 215; 159; 233; *W.* 6, 1; 17, 69), also by Pickering (*C. J.* 57, 158), who gives determinations for  $\text{H}_2\text{SO}_4\text{Aq}$  containing from 1 to 100 p.c.  $\text{H}_2\text{SO}_4$  (v. also Bouty, *C. R.* 108, 393; also Grotrian, *P.* 151, 378).

The S.G. and composition of  $\text{H}_2\text{SO}_4\text{Aq}$  of varying concentrations have been determined by many observers. Pickering (*C. J.* 57, 152) gives S.G. and composition of  $\text{H}_2\text{SO}_4\text{Aq}$  containing from  $\cdot5$  to 100 p.c.  $\text{H}_2\text{SO}_4$  at  $0^\circ$ ,  $2^\circ$ ,  $4^\circ$ , and each  $2^\circ$  up to  $40^\circ$ . Lunge a. Isler (*Zeit. für anorg. Chemie*, 1890, 129) give the following tables (cf. Mendeleeff, *Z.P.C.* 1887, 273; Pickering, *C. N.* 64, 311; Lunge, *C. N.* 65, 13):—

For the properties of fuming H<sub>2</sub>SO<sub>4</sub>, v. *Præparatio Sulphurici Acid*, p. 625.

For a test for small quantities of free H<sub>2</sub>SO<sub>4</sub>, v. Carey Lea (*Am. S.* [5] 45, 478; abstract in *C. J.* 64 (II.), 566).

*Reactions.*—1. Conc. H<sub>2</sub>SO<sub>4</sub> is decomposed

by heat; at c. 440° the products are SO<sub>2</sub> and H<sub>2</sub>O, and by passing through a red-hot tube SO<sub>2</sub>, O<sub>2</sub> and H<sub>2</sub>O are formed (Dewille a. Troost, *C. R.* 56, 891; Wanklyn a. Robinson, *Pr.* 12, 507; Redwood, *Ph.* [2] 5, 601; Dewille a. Debray, *A. Ch.* [3] 61, 125).—2. Decomposed by the electric current; with conc. H<sub>2</sub>SO<sub>4</sub> and a raised temperature O separates at the positive pole, and H and S at the negative; at 0° only H and O are given off (Faraday, *T.* 1834; Warburg, *P.* 135, 114; Luckow, *Fr.* 1880. 1; Berthelot, *C. R.* 86, 71; 90, 269). Gladstone a. Tribe (*C. J.* 86, 176; 43, 345) found that a little SO<sub>2</sub> was formed when the electrolysis of 98.2 p.c. H<sub>2</sub>SO<sub>4</sub> was very slow. According to the concentration of the H<sub>2</sub>SO<sub>4</sub> electrolysed, the strength of the current, and the current density, ozone, H<sub>2</sub>O<sub>2</sub>, and S<sub>2</sub>O<sub>2</sub> are formed, besides H and O. For an examination of the conditions favourable to the production of ozone v. McLeod (*C. J.* 49, 591, where references are given to earlier memoirs). According to Bouty (*C. R.* 108, 393), acid of the concentration H<sub>2</sub>SO<sub>4</sub> + H<sub>2</sub>O always gives H<sub>2</sub>O<sub>2</sub> on electrolysis; Richarz (*A. Ch.* [2] 24, 189) says that the maximum production of H<sub>2</sub>O<sub>2</sub> is obtained with acid of the concentration H<sub>2</sub>SO<sub>4</sub> + 1.347H<sub>2</sub>O; with acid more dilute than 60 p.c. H<sub>2</sub>SO<sub>4</sub> very little H<sub>2</sub>O<sub>2</sub> is obtained, but considerable quantities of S<sub>2</sub>O<sub>2</sub> and ozone (Bouty, *l.c.*; cf. Kuriloff, *J. R.* 23, 235). In connection with the electrolysis of H<sub>2</sub>SO<sub>4</sub> and the conditions of production of H and O only, or of H<sub>2</sub>O<sub>2</sub>, ozone, and S<sub>2</sub>O<sub>2</sub>, also, v. Armstrong (*C. J.* Proc. 1893-4, 188 (No. 127)).—3. By passing a mixture of the vapour of H<sub>2</sub>SO<sub>4</sub> mixed with hydrogen through a red-hot tube, H<sub>2</sub>O is obtained along with SO<sub>2</sub>, S, or H<sub>2</sub>S, according to the quantity of H (v. Warner, *C. N.* 28, 18). Hydrogen occluded by palladium or platinum partially reduces 98.2 p.c. H<sub>2</sub>SO<sub>4</sub>, giving SO<sub>2</sub> (G. a. T., *l.c.* p. 177).—4. SO<sub>2</sub>, CO<sub>2</sub>, and H<sub>2</sub>O are formed by heating conc. H<sub>2</sub>SO<sub>4</sub> with carbon; and SO<sub>2</sub> and H<sub>2</sub>O by heating with sulphur.—5. Phosphorus takes fire in boiling H<sub>2</sub>SO<sub>4</sub>, with separation of S; red phosphorus reacts with the conc. acid when hot, forming SO<sub>2</sub> and H<sub>2</sub>PO<sub>4</sub>.—6. Chlorine reacts with conc. H<sub>2</sub>SO<sub>4</sub> to form Cl(SO<sub>3</sub>OH) (v. Chlorosulphonic acid, p. 509).—7. Most metals interact; K and Na give off H, Zn and Fe and several other metals also give off H with more or less dilute H<sub>2</sub>SO<sub>4</sub> at ordinary temperatures; on raising the temperature SO<sub>2</sub> and H<sub>2</sub>S are generally evolved and S is often separated. Some metals, such as Sb, Bi, Cu, Hg, react only with warm fairly conc. H<sub>2</sub>SO<sub>4</sub>, giving off SO<sub>2</sub>, and often also H<sub>2</sub>S. Au, Ir, Pt, Rh, and W do not interact with H<sub>2</sub>SO<sub>4</sub>. Regarding the conditions of the interaction of H<sub>2</sub>SO<sub>4</sub> with metals—concentration, temperature, and products—v. Ditté (*A. Ch.* [6] 19, 58). Pattison Muir a. Adie (*C. J.* 53, 47) found that the only products of the interaction of approximately pure zinc and dilute H<sub>2</sub>SO<sub>4</sub> (c. H<sub>2</sub>SO<sub>4</sub>.12H<sub>2</sub>O to c. H<sub>2</sub>SO<sub>4</sub>.15H<sub>2</sub>O) were ZnSO<sub>4</sub> and H<sub>2</sub>; that with conc. acid (c. H<sub>2</sub>SO<sub>4</sub>.H<sub>2</sub>O to c. H<sub>2</sub>SO<sub>4</sub>) SO<sub>2</sub> was the chief gaseous product, and that H<sub>2</sub>S was also produced at higher temperatures; and that with acid of intermediate concentration (c. H<sub>2</sub>SO<sub>4</sub>.2H<sub>2</sub>O) both SO<sub>2</sub> and H<sub>2</sub>S were formed in considerable quantities at c. 160°. For experiments on the rate of action of H<sub>2</sub>SO<sub>4</sub> on

different specimens of zinc v. Divers a. Shimidzu (C. J. 47, 598), who have also examined the production of  $\text{NH}_4\text{OH}$  by the interaction of zinc with  $\text{H}_2\text{SO}_4\text{Aq}$  and  $\text{HNO}_3\text{Aq}$  together (cf. *HYDROXYLAMINE*, vol. ii. p. 734). For qualitative experiments on the interaction of  $\text{H}_2\text{SO}_4$  and *tin*, v. Pattison Muir a. Robbs (C. N. 46, 69, where references to other memoirs are given). Pullinger (C. J. 59, 815) found that pure zinc was not acted on by  $\text{H}_2\text{SO}_4\text{Aq}$  (1 part conc. acid + 3 parts water by weight) provided the acid had been boiled for a long time before use and the surface of the zinc was quite smooth; if the surface was rough some of the zinc was dissolved. P. also found that oxidisers increased the rate of solution of zinc, and reducers, if not containing S, almost stopped the solution. P. concluded that when the surface of the zinc was rough  $\text{S}_2\text{O}$ , was probably formed, and then the action proceeded. Weeren (B. 24, 1785) noticed that there was scarcely any reaction between pure zinc and  $\text{H}_2\text{SO}_4\text{Aq}$  (c. 20 parts water); he supposed that a layer of H was condensed on the surface of the metal. W. thought that with impure zinc the H is given off from the surface of the more negative metal present, and so the surface of the zinc is left exposed to the action of the acid. W. found that the evolution of H proceeded more rapidly *in vacuo*, and that it was hastened by brushing the surface of the metal. The weight of pure zinc dissolved in 30 mins. was 2.1 mgm. at  $0^\circ$ , 9.3 mgm. at  $98^\circ$ , and 122.1 mgm. at the b.p. of the acid used. W. obtained similar results with Al, Cd, Co, and Fe. Sodium amalgam or zinc amalgam, with conc.  $\text{H}_2\text{SO}_4$ , gives off H, then quantities of  $\text{H}_2\text{S}$ , then  $\text{SO}_2$ , and S, and finally only  $\text{SO}_2$  (Walz, C. N. 23, 245). The interaction of  $\text{H}_2\text{SO}_4$  and copper has been fully examined by Pickering (C. J. [2] 18, 112; cf. *COPPER*, vol. ii. p. 253).—8.  $\text{H}_2\text{SO}_4$  reacts with the oxides of nitrogen (not with  $\text{N}_2\text{O}$ ) to form  $\text{NO}(\text{SO}_2\text{OH})$  (v. *NIROSULPHURIC ACID*, p. 601).—9. *Phosphoretted hydrogen* reacts slowly with  $\text{H}_2\text{SO}_4$  at the ordinary temperature, giving  $\text{SO}_2$ , S, and  $\text{H}_3\text{PO}_3$  (Rose, P. 24, 139).—10. With *sulphuretted hydrogen*,  $\text{H}_2\text{O}$ , S, and  $\text{SO}_2$  are formed.—11. *Phosphorus pentoxide* withdraws  $\text{H}_2\text{O}$  from hot conc.  $\text{H}_2\text{SO}_4$ , producing  $\text{P}_2\text{O}_5\text{H}_2\text{O}$  and  $\text{SO}_2$  (Barreswil, C. R. 25, 30; Evans, Ph. 8, 127); *phosphorus pentachloride* or *trichloride* forms  $\text{SO}_2$  and  $\text{POCl}_3$ , also  $\text{SO}_2\text{Cl}_2$  when  $\text{PCl}_5$  is used (Williamson, P. M. [4] 7, 365; Schiff, A. 202, 111; cf. Michaelis, J. Z. 6, 233, 292), and also  $\text{Cl}(\text{SO}_2\text{OH})$  (Müller, B. 6, 277; Geuther, B. 5, 925; Thorpe, C. J. 37, 358).—12.  $\text{H}_2\text{SO}_4$  reacts with most salts to form sulphates, and set free the acid of the salt if that acid is more volatile than  $\text{H}_2\text{SO}_4$ . In several cases secondary reactions occur between the acid set free and the  $\text{H}_2\text{SO}_4$ ; thus, with bromides and iodides, Br and I, and  $\text{SO}_2$  or  $\text{H}_2\text{S}$ , are produced. The interaction of  $\text{H}_2\text{SO}_4\text{Aq}$  and KBr has been examined by Addyman (C. J. 61, 94), who found that the percentage of HBr decomposed varied almost directly with the quantity of  $\text{H}_2\text{SO}_4$  used, and that when so much  $\text{H}_2\text{SO}_4$  was present that the water produced in the reaction  $2\text{HBr} + \text{H}_2\text{SO}_4 = 2\text{H}_2\text{O} + \text{SO}_2 + \text{Br}_2$  caused no sensible dilution of the  $\text{H}_2\text{SO}_4$ , all the HBr was decomposed; with dilute acid, c. 80 p.c.  $\text{H}_2\text{SO}_4$ , using excess of acid, scarcely a trace of HBr was decomposed (cf. Feit a. Kubierschki,

J. Ph. [5] 24, 159). Jackson (C. J. 48, 839) finds that the interaction of conc.  $\text{H}_2\text{SO}_4$  and KI varies according as the acid is present in large excess, or in quantity just sufficient for the KI used. In the first case all the I of the KI is set free along with an equivalent quantity of  $\text{SO}_2$ ; in the second case all the I is liberated with the equivalent quantity of  $\text{H}_2\text{S}$ . Many salts of acids containing much oxygen, e.g. dichromates and permanganates, are decomposed by hot conc.  $\text{H}_2\text{SO}_4$  with evolution of O. The reaction of  $\text{H}_2\text{SO}_4\text{Aq}$  with  $\text{KMnO}_4\text{Aq}$  has been examined by Gooch a. Danner (Am. S. [3] 44, 301), who found that the quantity of O given off increased with (1) concentration of  $\text{H}_2\text{SO}_4\text{Aq}$ , (2) time, (3) temperature; no O was given off after a few hours with 20 p.c. acid at the ordinary temperature, but a considerable quantity of O was produced after five days' action, and c. the same result was obtained by heating to  $80^\circ$  for one and a half hours (cf. Jones, C. J. 33, 95).—13. Conc.  $\text{H}_2\text{SO}_4$  reacts with many oxygenated organic compounds, withdrawing  $\text{H}_2\text{O}$ ; with benzenoid hydrocarbons it forms sulpho-acids; many organic compounds, such as sugar, starch, &c., are charred by warm  $\text{H}_2\text{SO}_4$ .—14. Pictet (C. R. 115, 708, 814) has examined the reactions of sulphuric acid at low temperatures, using acid of 89 p.c.  $\text{H}_2\text{SO}_4$ ; no action occurred below  $-125^\circ$  with such bodies as  $\text{NaOH}$ ,  $\text{NaCl}$ ,  $\text{NH}_3$ ,  $\text{Na}_2\text{CO}_3$ , Na, K; in most cases action began suddenly at temperatures varying from  $-120^\circ$  to  $-60^\circ$ .—15.  $\text{H}_2\text{SO}_4$  combines with water; the hydrates  $\text{H}_2\text{SO}_4\text{H}_2\text{O}$ ,  $\text{H}_2\text{SO}_4\text{2H}_2\text{O}$ , and  $\text{H}_2\text{SO}_4\text{3H}_2\text{O}$  have been isolated as solids (v. *infra*).—16. Conc.  $\text{H}_2\text{SO}_4$  combines with sulphur trioxide to form  $\text{H}_2\text{SO}_4\text{SO}_3$ , and other compounds (v. *PYROSULPHURIC ACID*).

For the reactions of fuming  $\text{H}_2\text{SO}_4$ , v. *PYROSULPHURIC ACID* (p. 625). The salts of  $\text{H}_2\text{SO}_4$  are described under *SULPHATES* (p. 667). Both amides of  $\text{H}_2\text{SO}_4$ , viz.  $\text{SO}_2\text{OH.NH}_2$  and  $\text{SO}_2(\text{NH}_2)_2$ , have been isolated (v. *SULPHAMIC ACID*, p. 567, and *SULPHAMIDE*, p. 567); the imide  $\text{SO}_2\text{NH}$  is also known, v. *SULPHIMIDE*, p. 587; cf. also *SULPHIMIDO-AMIDE*  $\text{NH}(\text{SO}_2\text{NH}_2)_2$ , p. 587, and *IMIDO-SULPHONIC ACID*  $\text{NH}(\text{SO}_2\text{OH})_2$ , p. 600.

*Constitution of sulphuric acid*.—The reactions of  $\text{H}_2\text{SO}_4$  with Cl and with  $\text{PCl}_5$ , and the reactions of the products with water, also the formation of  $\text{SO}_2\text{OH.NH}_2$ ,  $\text{SO}_2(\text{NH}_2)_2$ , and  $\text{SO}_2\text{NH}$ , show that  $\text{H}_2\text{SO}_4$  contains two OH groups. The fact that only one compound,  $\text{SO}_2\text{OEt.OMe}$ , can be formed from  $\text{H}_2\text{SO}_4$ , shows that the two OH groups in  $\text{SO}_2(\text{OH})_2$  are related to the rest of the molecule in the same way; hence the formula for the acid is to be written  $\text{S} \begin{smallmatrix} \text{O.OH} \\ \text{O.OH} \end{smallmatrix}$  or  $\text{O}_2\text{S} \begin{smallmatrix} \text{OH} \\ \text{OH} \end{smallmatrix}$ . Inasmuch as  $\text{SO}_2\text{Cl}_2$

is formed from  $\text{SO}_2(\text{OH})_2$  by the reaction of  $\text{PCl}_5$ , as certain hydrocarbons interact with  $\text{SO}_2\text{Cl}_2$  to form  $\text{SO}_2\text{R}_2$  (where R = Me, Ph, &c.), and as these compounds  $\text{SO}_2\text{R}_2$  are reduced to  $\text{SR}_2$ , where the radicles R are certainly in direct union with S, it is extremely probable that the OH groups in  $\text{SO}_2(\text{OH})_2$  are in direct union with S, and hence the formula  $\text{O}_2\text{S} \begin{smallmatrix} \text{OH} \\ \text{OH} \end{smallmatrix}$  is to be preferred to  $\text{S} \begin{smallmatrix} \text{O.OH} \\ \text{O.OH} \end{smallmatrix}$  for sulphuric acid. It is

undecided whether the group  $\text{SO}_2$  in  $\text{O}_2\text{S.OH.OH}$

has the constitution  $\text{O.S.O}$  or  $\text{S} \begin{array}{c} \diagup \text{O} \\ \diagdown \text{O} \end{array}$ .

**HYDRATES OF SULPHURIC ACID.** Two solid hydrates have been isolated; a liquid hydrate has probably also been isolated.

**Monohydrate**  $\text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}$  (*Tetrahydroxy-sulphuric acid*  $\text{SO}(\text{OH})_2$ ). Large, colourless, six-sided tablets; formed by mixing 1 part conc.  $\text{H}_2\text{SO}_4$  with rather less than one-fifth part water (by weight), and surrounding with a freezing mixture. The crystals melt at  $7.5^\circ$  (Pierre a. Puchot, *A. Ch.* [5] 2, 164). The hydrate readily remains liquid considerably below its m. p. S.G.  $d_4^{20} = 1.7943$  (for the liquid) (Mendeleff, *B.* 19, 880);  $1.77806$  at  $15^\circ$ ,  $1.77423$  at  $20^\circ$ ,  $1.77071$  at  $25^\circ$  (Perkin, *C. J.* 49, 777; determinations made with liquid, and referred to water at same temperatures). Thomsen gives H.F. from liquid  $\text{H}_2\text{SO}_4$  and  $\text{H}_2\text{O}$   $[\text{H}^+\text{SO}_4^-\text{H}^+\text{O}] = 6.379$  (*Th.* 3, 54); Berthelot gives 6.120 (*C. R.* 78, 716). Heat of fusion = 3680 g. units (for 116 g.)  $\text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}$  (Berthelot, *C. R.* 78, 716). For vapour pressures from  $143^\circ$  to  $204^\circ$  v. Tate (*P. M.* [4] 26, 602).

**Dihydrate**  $\text{H}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$  (*Perhydroxysulphuric acid*  $\text{SO}(\text{OH})_2$ ). Formed by adding 368 parts  $\text{H}_2\text{O}$  to 1 part pure  $\text{H}_2\text{SO}_4$  by weight. This hydrate has not been obtained as a solid; the S.G. of the liquid at  $0^\circ$  is given by Mendeleff (*B.* 19, 380) as 1.6655 (cf. Perkin, *C. J.* 49, 777).

It is stated (v. Mendeleff, *B.* 19, 388) that the maximum contraction when  $\text{H}_2\text{SO}_4$  and  $\text{H}_2\text{O}$  are mixed occurs when the compounds are present in the ratio  $\text{H}_2\text{SO}_4 : 2\text{H}_2\text{O}$ , but Pickering (*C. J.* 57, 84) says that the maximum does not correspond with the composition of any hydrate the existence of which is indicated in other ways.

**Tetrahydrate**  $\text{H}_2\text{SO}_4 \cdot 4\text{H}_2\text{O}$ . Obtained by Pickering (*C. J.* 57, 339) as a crystalline solid, melting at  $-25^\circ$ , by cooling  $\text{H}_2\text{SO}_4$  aq containing 57.6 p.c.  $\text{H}_2\text{SO}_4$  ( $\text{H}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$  corresponds with 57.66 p.c.  $\text{H}_2\text{SO}_4$ ). The crystals are large and well defined, and resemble  $\text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}$ ; the compound may be kept liquid at  $20^\circ$  to  $25^\circ$  below its freezing point.

**Hydrates of sulphuric acid in aqueous solution.**—According to Mendeleff (*B.* 19, 380; cf. his *Principles of Chemistry*, vol. ii. p. 234), an examination of the connections between the concentration of  $\text{H}_2\text{SO}_4$  aq and the S.G. indicates the existence of hydrates that have not yet been isolated. Pickering (*C. J.* 57, 64) comes to the same general conclusion from an extended examination of the connections between the changes of composition of  $\text{H}_2\text{SO}_4$  aq and the changes of S.G., heat capacity, electrical conductivity, heat of solution, and expansion by heat of the solution. Pickering's reasoning is a special case of that explained in the article *SOLUTIONS* (part ii. p. 492); for the detailed argument, and criticisms of it, v. Pickering, *C. J.* 57, 64; Rücker, *P. M.* [5] 82, 304; 83, 204; P. F. M. [5] 83, 132, 463; cf. Mendeleff, *Z. P. C.* 1, 275; and Crompton, *C. J.* 53, 116.

**PERSULPHURIC ACID**  $\text{H}_2\text{S}_2\text{O}_8$  aq. This acid is present in the solution obtained by electrolysis.

**trolysing  $\text{H}_2\text{SO}_4$  aq of certain concentrations;** Berthelot (*C. R.* 90, 269; 112, 1481) obtained a quantity of the acid equal to from 88 to 123 g.  $\text{S}_2\text{O}_8$  per litre by electrolysis  $\text{H}_2\text{SO}_4$  aq containing water and acid in the ratio  $10\text{H}_2\text{O}:\text{H}_2\text{SO}_4$  (cf. *SULPHURIC PEROXIDE*, p. 616; and *SULPHURIC ACID, Reactions*, No. 2, p. 623). According to Traube (*B.* 22, 1518, 1528) a solution of  $\text{H}_2\text{S}_2\text{O}_8$  in  $\text{H}_2\text{SO}_4$  does not oxidise  $\text{H}_2\text{C}_2\text{O}_4$ ,  $\text{HNO}_2$ ,  $\text{CO}$ , or  $\text{Cr}_2(\text{SO}_4)_3$ ; Richarz, however (*B.* 21, 1670), says that oxalic and nitrous acids are oxidised. The acid has not been isolated; by electrolysis at temperatures below  $0^\circ$ , and then adding  $\text{BaO}$  aq or  $\text{KOH}$  aq, the Ba or K salt is obtained. The formula  $\text{H}_2\text{S}_2\text{O}_8$  is given rather than  $\text{HSO}_5$ , because of the results of Bredig's measurements of the conductivities of solutions of the K salt. For salts of this acid v. *PERSULPHATES*, p. 582.

**PYROSULPHURIC ACID**  $\text{H}_2\text{S}_2\text{O}_7$  (*Disulphuric acid*). A solution of this acid in  $\text{H}_2\text{SO}_4$  is known as *fuming sulphuric acid*, or *Nordhausen acid*. This acid is obtained by adding rather more  $\text{SO}_3$  to  $\text{H}_2\text{SO}_4$  than the proportion  $\text{SO}_3:\text{H}_2\text{SO}_4$  cooling, and spreading out the crystals that form over nearly conc.  $\text{H}_2\text{SO}_4$  under a bell-jar till the excess of  $\text{SO}_3$  is removed (Schultz-Sellack, *B.* 4, 109). Forms large crystals, melting at  $35^\circ$ . Easily decomposed by heat to  $\text{H}_2\text{SO}_4$  and  $\text{SO}_3$ .  $\text{H}_2\text{S}_2\text{O}_7$  is dibasic, forming salts  $\text{MHSO}_4$  and  $\text{M}_2\text{S}_2\text{O}_7$  (v. *PERSULPHATES*, p. 683). *Fuming sulphuric acid* is a solution of  $\text{H}_2\text{S}_2\text{O}_7$  in  $\text{H}_2\text{SO}_4$ ; it is prepared by heating dry  $\text{FeSO}_4$  in fireclay vessels and collecting the oily, fuming liquid that distils over. The acid fumes strongly in the air, and gives off  $\text{SO}_3$  when warmed. But few of the reactions described for *pyrosulphuric acid*, or for *fuming sulphuric acid*, can be set down as belonging to a definite compound, but rather to solutions of  $\text{H}_2\text{S}_2\text{O}_7$  (and perhaps other compounds of  $\text{H}_2\text{SO}_4$  and  $\text{SO}_3$ ) in  $\text{H}_2\text{SO}_4$ . Finely-divided silver dissolves easily; the solution poured into water gives  $\text{Ag}_2\text{SO}_4$  and  $\text{SO}_3$ ; mercury reacts similarly; spongy copper has a slight reaction, giving  $\text{Cu}_2\text{S}$  and  $\text{CuSO}_4$  (Divers a. Shimidzu, *C. J.* 47, 636). Distilled with phosphorus pentoxide in a stream of hydrogen chloride,  $\text{Cl}(\text{SO}_3\text{OH})$  is formed; the same acid is formed by heating with  $\text{PCl}_5$ , and also by heating 'crystallised fuming sulphuric acid' with  $\text{HCl}$  (v. *CHLOROSULPHONIC ACID*, p. 509). Nitrogen dioxide passed into well-cooled pyrosulphuric acid gives  $\text{NO}_2(\text{SO}_3\text{OH})$  (v. *NITROSULPHONIC ACID*, p. 601). By saturating ordinary conc.  $\text{H}_2\text{SO}_4$  with  $\text{SO}_3$  (Jacquelin, *A. Ch.* [3] 80, 848), or by cooling fuming  $\text{H}_2\text{SO}_4$  to  $-10^\circ$  (Wackendorfer, *Ar. Ph.* [2] 87, 267), the compound  $\text{H}_2\text{S}_2\text{O}_7 \cdot 2\text{H}_2\text{SO}_4$  ( $= 3\text{H}_2\text{SO}_4 \cdot \text{SO}_3$ ) is said to be obtained in transparent crystals. Schultz-Sellack (*B.* 4, 109) failed to obtain any compound of  $\text{H}_2\text{SO}_4$  and  $\text{SO}_3$ , except  $\text{H}_2\text{S}_2\text{O}_7$ . Crystals of the composition  $\text{H}_2\text{SO}_4 \cdot 3\text{SO}_3$  ( $= \text{H}_2\text{S}_2\text{O}_7 \cdot \text{SO}_3$ ) melting at  $8^\circ$ – $10^\circ$  are said by Weber (*P.* 159, 313) to be formed by adding cooled conc.  $\text{H}_2\text{SO}_4$ , little by little, to  $\text{SO}_3$ . M. M. P. M.

**SULPHURIC ANHYDRIDE**  $\text{SO}_3$ , v. *SULPHUR TRIOXIDE*, p. 615.

**Persulphuric anhydride**  $\text{S}_2\text{O}_7$ , v. *SULPHURIC PEROXIDE*, p. 616.

**SULPHURIC-NITROSYL CHLORIDE**  
 $\text{SO}_2\text{NOCl}$  v. NITROSULPHONIC CHLORIDE, p. 601.  
**SULPHURIC OXIDE**  $\text{SO}_2$ , v. SULPHUR TRIOXIDE, p. 615.  
**SULPHURIC PEROXIDE**  $\text{S}_2\text{O}_8$ , v. p. 616.  
**SULPHUROSAMIC ACID**  $\text{SO}_2\text{OH.NH}_2$ , v. THIONAMIC ACID, p. 695.  
**SULPHUROUS ACID** and **HYPOSULPHUROUS ACID**.

**SULPHUROUS ACID**  $\text{H}_2\text{SO}_3\text{Aq}$ . The acid has not been isolated; a solution of  $\text{SO}_2$  in water reacts as a weak dibasic acid, forming salts of the types  $\text{M}^+\text{HSO}_3$ ,  $\text{M}^+\text{SO}_3$ , and  $\text{M}^+\text{SO}_3^-$  (v. SULPHITES, p. 587). H.F.  $[\text{H}^+\text{S}_2\text{O}_3\text{Aq}] = 147,130$ ;  $[\text{H}^+\text{O}_3\text{S}_2\text{O}_3\text{Aq}] = 78,780$  (from rhombic S; *Th.* 2, 251).

The methods of formation and preparation of  $\text{H}_2\text{SO}_3\text{Aq}$  are sufficiently detailed under SULPHUR DIOXIDE (p. 618); it is only necessary to add water to the  $\text{SO}_2$  obtained.

**Properties.**—An aqueous solution of  $\text{H}_2\text{SO}_3$  readily decomposes, giving off  $\text{SO}_2$ ; on standing for some time in the air, and more quickly by warming,  $\text{H}_2\text{SO}_3\text{Aq}$  is formed with production of much heat;  $[\text{H}^+\text{SO}_3\text{AqO}] = 63,634$  (*Th.* 2, 253).  $\text{H}_2\text{SO}_3\text{Aq}$  is altered by the action of light, so that after exposure to light for some time the solution ppt.  $\text{Ag}_2\text{S}$  from  $\text{AgNO}_3\text{Aq}$ , and reduces silver haloid compounds, forming some  $\text{Ag}_2\text{S}$ ; the solution after exposure to light behaves like a dilute solution of a polythionous acid (Stas, *Chem. Proport.* 64). Löw (*L'Institut*, 1873, 67) says that dilute  $\text{H}_2\text{SO}_3\text{Aq}$  is changed to  $\text{H}_2\text{SO}_4\text{Aq}$  and S by long exposure to light.

**Reactions.**—1. Heated in a closed tube to  $170^\circ$ – $180^\circ$ ,  $\text{H}_2\text{SO}_3\text{Aq}$  and S are formed, and after a time also  $\text{H}_2\text{S}$  (Geitner, *A.* 129, 350).—2. Decomposed by an electric current, giving  $\text{H}_2\text{SO}_3\text{Aq}$  at the positive pole and S at the negative; with a weak current  $\text{H}_2\text{SO}_3\text{Aq}$  is probably formed at first at the negative pole (Guérout, *C. R.* 85, 226).—3. Phosphorus pentachloride produces  $\text{SOCl}_2$  and  $\text{POCl}_3$  (Kremers, *A.* 70, 297; Schiff, *A.* 102, 111).—4. Sulphurous chloride with  $\text{H}_2\text{SO}_3\text{Aq}$  produces polythionous acids (v. Debus, *C. J.* 53, 345).—5. Vapour obtained by heating  $\text{H}_2\text{SO}_3\text{Aq}$  reacts with chlorine, when passed over red-hot Pt, to form  $\text{Cl}(\text{SO}_2\text{OH})$  (v. CHLOROSULPHONIC ACID, p. 599).—6.  $\text{NO}_2(\text{SO}_2\text{OH})$  (v. NITROSULPHONIC ACID, p. 601) is formed by the interaction of moist  $\text{SO}_2$ , i.e.  $\text{H}_2\text{SO}_3\text{Aq}$ , with nitric oxide or nitrogen dioxide.—7.  $\text{H}_2\text{SO}_3\text{Aq}$  is oxidised to  $\text{H}_2\text{SO}_4\text{Aq}$  by oxygen, the halogens, and many other oxidisers.—8. Heated with phosphorus in a closed tube to  $200^\circ$ ,  $\text{H}_2\text{S}$  is produced (Oppenheim, *Bl.* [2] 1, 163).—9. Reduced by *sine* and dilute sulphuric acid to  $\text{H}_2\text{S}$  (v. Reinsch, *D. P. J.* 163, 286; 181, 332); with *sine* alone,  $\text{H}_2\text{SO}_3\text{Aq}$  is partly reduced, probably giving  $\text{H}_2\text{S}_2\text{O}_3\text{Aq}$  (v. HYPOSULPHUROUS ACID, p. 627).—10. Many metals which evolve H from  $\text{H}_2\text{SO}_4\text{Aq}$  or  $\text{HClAq}$  react with  $\text{H}_2\text{SO}_3\text{Aq}$  to form sulphites and sulphides, with evolution of little or no H (v. Federoff, *Chem. Zeitung*, 5, 15). For a fairly full qualitative examination of the interaction of Al, Cd, Mg, Ni, and Zn with  $\text{H}_2\text{SO}_3\text{Aq}$ , v. Schweitzer (*C. N.* 23, 293).—11. Many of the oxyacids of the halogens are reduced to hydrides by  $\text{H}_2\text{SO}_3\text{Aq}$ .—12. Phosphorous acid gives  $\text{H}_3\text{PO}_3\text{Aq}$  and  $\text{H}_2\text{S}$ ; then S, and thionous acids (Wöhler, *A.* 39, 252; Maquenne, *Chem. Zeitung*,

1890 [1] 511).—13. Phosphoretted hydrogen produces  $\text{H}_3\text{PO}_3\text{Aq}$ , and S (Cavazzi, *G.* 16, 169).—14. Hydrogen sulphide passed into  $\text{H}_2\text{SO}_3\text{Aq}$  forms a solution containing  $\text{H}_2\text{SO}_3$ ,  $\text{H}_2\text{S}_2\text{O}_3$ ,  $\text{H}_2\text{S}_3\text{O}_3$ ,  $\text{H}_2\text{S}_4\text{O}_3$ , probably  $\text{H}_2\text{S}_5\text{O}_3$ , S in suspension, and a colloidal form of S in solution; if the passage of  $\text{H}_2\text{S}$  is continued until reaction ceases the final products are S and  $\text{H}_2\text{O}$  (Debus, *C. J.* 53, 282; cf. THIONIC ACIDS, p. 698).—15. Many metallic salts are reduced, in aqueous solutions, by  $\text{H}_2\text{SO}_3\text{Aq}$ ; salts of Ag and Hg to the metals, ferric to ferrous salts, &c. According to Divers a. Shimidzu (*C. J.* 49, 575), the reduction does not consist in the withdrawal of O by  $\text{H}_2\text{SO}_3\text{Aq}$  and the oxidation of that acid thereby to  $\text{H}_2\text{SO}_4\text{Aq}$ . The first step is looked on by D. a. S. as probably the formation of a sulphite of the metal of the salt, and this is followed by either the decomposition of this sulphite by water to metal and  $\text{H}_2\text{SO}_4\text{Aq}$ , or the reaction of the sulphite with some of the original, unchanged, salt to form metal and a persulphite (or -ie sulphite) of the metal.—16. With potassium thiosulphate  $\text{H}_2\text{SO}_3\text{Aq}$  forms K tri- tetra- and penta-thionates, and S (Debus, *C. J.* 53, 343).—17.  $\text{H}_2\text{SO}_3\text{Aq}$  dissolves many freshly ppd. metallic sulphides, e.g.  $\text{MnS}$ ,  $\text{FeS}$ ,  $\text{ZnS}$ , forming thiosulphates (Schönbein, *P.* 104, 300; Heldt, *J. pr.* 83, 20).—18. Alkali nitrites give salts of nitrosulphonic acid  $\text{N}(\text{SO}_2\text{OH})$ , (q. v., p. 601), and also salts of oxy-imidosulphonic acid  $\text{N}(\text{OH})(\text{SO}_2\text{OH})_2$  (q. v., p. 602). Using a dilute, ice-cold solution of  $\text{H}_2\text{SO}_3$  (= 5 p.c.  $\text{SO}_2$ ), and adding 40 g.  $\text{KNO}_2$  in 1,000 c.c. water to 3 litres of this  $\text{H}_2\text{SO}_3\text{Aq}$ , Raschig (*A.* 211, 234) obtained  $\text{NH}_4(\text{SO}_2\text{OK})$  (cf. SULPHAMIC ACID, p. 567). Under certain conditions of concentration and temperature NO and  $\text{N}_2\text{O}$ , also  $\text{NH}_3$  and sometimes  $\text{NH}_4\text{OH}$ , are produced. With nitrous acid the final products are  $\text{NH}_3$ , NO,  $\text{N}_2\text{O}$ , and  $\text{H}_2\text{SO}_4\text{Aq}$ ; according to Raschig (*loc.*),  $\text{NH}_4(\text{SO}_2\text{OH})$  is always formed, and the gaseous products are to be looked on as resulting from secondary reactions between nitrous acid and  $\text{NH}_4(\text{SO}_2\text{OH})$  or other nitrogenised sulphonic acids formed in the primary reaction between the nitrous and sulphurous acids. With silver and mercurous nitrites Divers a. Haga (*C. J.* 51, 659) found that sulphites were produced, along with some NO and  $\text{H}_2\text{SO}_3$ , and more or less  $\text{NH}_4\text{OH}$ .—19. For the reaction of  $\text{H}_2\text{SO}_3\text{Aq}$  with potassium platinochloride v. PLATINO-SULPHONATES, this vol., p. 285.

Neither the amide  $\text{SO}(\text{NH}_2)_2$  (v. the heading THIONAMIDE), nor the imide  $\text{SO.NH}$ , of  $\text{H}_2\text{SO}_3$  has been isolated; and it is doubtful whether the acid  $\text{SO}_2\text{OH.NH}_2$  or  $\text{SO}_2\text{NH}_2\text{H}$  is known, v. THIONAMIC ACID.

**Constitution of sulphurous acid.** The fact that many haloid derivatives of hydrocarbons interact with  $\text{NaHSO}_3$  to form sulphonic acids—e.g.  $\text{EtI} + \text{NaHSO}_3 = \text{EtSO}_3\text{H} + \text{NaI}$ —makes it probable that the Na in  $\text{NaHSO}_3$  is in direct union with the S, because the S in sulphonic acids is almost certainly in direct union with the hydrocarbon radiolo; hence it is likely that one H atom in  $\text{H}_2\text{SO}_3$  is directly combined with the S atom, and hence the formula for  $\text{H}_2\text{SO}_3$  is probably  $\text{H}_2\text{SO}_2\text{OH}$ . This view of the constitution of  $\text{H}_2\text{SO}_3$  is insisted on, and illustrated, by Divers (*C. J.* 47, 205).

**Hydrates of sulphurous acid.** Colourless, ice-like crystals are obtained by passing  $\text{SO}_2$  into water surrounded by ice, by cooling saturated  $\text{SO}_2$  aq. or by passing moist  $\text{SO}_2$  through a tube kept at a low temperature. After filtering quickly in a covered filter, and pressing between filter paper at  $8^\circ$ , the crystals have the composition  $\text{H}_2\text{SO}_3 \cdot x\text{H}_2\text{O}$ ; Dopping (*Petersburg Acad. Bull.*, 7, 100) found  $x=10$ , Pierre (*A. Ch.* [3] 23, 416) found  $x=8$ , Schönfeld (*A.* 95, 22) found  $x=14$ , Roozeboom (*R. T. C.* 3, 29, 59, 75, 84; 4, 65) found  $x=6$ , and this was confirmed by Geuther (*A.* 224, 218). Roozeboom (*L.c.*) gives S.G. of the crystals as 1.21 (referred to water at  $4^\circ$ ); Geuther (*L.c.*) gives 1.147 as the S.G. after melting at  $14^\circ$ , and  $14^\circ$  as the m.p. with separation of some liquid  $\text{SO}_2$  under the layer of  $\text{SO}_2$  aq. *It. (L.c.)* gives the following dissociation-pressures, which are independent of the quantity of the hydrate: 803 mm. at  $0^\circ$ , 754 mm. at  $7.05^\circ$ , 1177 mm. at  $10^\circ$ , 1773 mm. at  $12.1^\circ$ . According to R. the critical temperature of decomposition is  $7.1^\circ$  in an open vessel and  $12.1^\circ$  in a closed vessel.

**HYPOSULPHUROUS ACID**  $\text{H}_2\text{S}_2\text{O}_4$  aq. This acid has not been isolated. An aqueous solution is probably formed by decomposing the Na salt by dilute  $\text{H}_2\text{SO}_4$  aq or  $\text{H}_2\text{C}_2\text{O}_4$  aq, and also perhaps by dissolving  $\text{H}_2\text{SO}_4$  aq with zinc clippings till the liquid is brownish red; but neither the aqueous solution of the acid, nor any of its salts, has been obtained free from impurities. For preparation of the sodium salt, and for references, v. **HYPOSULPHITES** (p. 592).

**SULPHUVINURIC ACID**  $\text{C}_8\text{H}_7\text{N}_2\text{SO}_2$ , i.e.  $\text{S}-\text{C}(\text{NH}_2)-\text{CH}_2\text{C}(\text{CO}_2\text{H})-\text{N}$  (Strende, *A.* 261, 26). Formed from di-bromo-pyruvic acid and a conc. solution of thio-urea (Nencki a. Sieber, *J. pr.* [2] 25, 74). Crystals (containing 2aq), sl. sol. cold water. Reduces Fehling's solution in the cold.  $\text{FeCl}_3$  gives a deep violet colour.—Salts:  $\text{MgA}'_2$ —

$\text{ZnA}'_2$ : minute needles.— $\text{HA}'\text{HCl}$ .— $\text{HA}'\text{HBr}$ .— $\text{HA}'\text{HNO}_3$  aq: needles, sl. sol. water.

**SULPHYDRO-ACETIC ACID** v. **THIOGLYCOLLIC ACID**.

**SULPHYDRO-ACETONE**  $\text{CH}_3\text{CO.CH}_2\text{SH}$ . *Ethyl derivative*  $\text{EtS.CH}_2\text{Ac}$ . [171°].

Formed from chloro-acetone and  $\text{NaSEt}$  (Autenrieth, *B.* 24, 165). Yields a phenyl hydrazide [57°].

*Phenyl derivative*  $\text{PhS.CH}_2\text{Ac}$ . [36°]. (266°). Formed from  $\text{CH}_3\text{CO.CH}_2\text{Cl}$  and  $\text{NaSPh}$  in alcohol in the cold. Crystals. Yields a phenyl-hydrazide [87°] (*A.*, cf. Delisle, *A.* 260, 250). Combines with  $\text{KHSO}_4$  and  $\text{NaHSO}_4$ .

**SULPHYDRO-ACETOPHENONE**. *Phenyl derivative*  $\text{C}_6\text{H}_5\text{SO}$ , i.e.  $\text{C}_6\text{H}_5\text{S.CH}_2\text{CO.C}_6\text{H}_5$ . [53°]. Formed from  $\omega$ -bromo-acetophenone and  $\text{NaOPh}$  (Delisle, *B.* 22, 309). Needles (from alcohol), v. sol. ether and acetone.

**SULPHYDRO-ACETYL-PROPIONIC ETHER**.

*Phenyl derivative*  $\text{C}_6\text{H}_5\text{SO}$ , i.e.  $\text{C}_6\text{H}_5\text{S.CH}_2\text{CO.CH}_2\text{CO.Et}$ . (197° at 15 mm.). Formed from bromo-acetyl-propionic ether and  $\text{NaSPh}$  (Delisle, *B.* 22, 309).

**SULPHYDRO-ALLYL-QUINAZOLINE**. *Dihydride*  $\text{C}_8\text{H}_7\text{N}_2\text{S}$ . [91°]. Formed

from  $\omega$ -oxy-tolyl-allyl-thio-urea and  $\text{HClAq}$  at  $100^\circ$  (Söderbaum a. Widman, *B.* 22, 1670). Needles, v. c. sol. alcohol and benzene.

*Reference.*—**OXY-SULPHYDRO-ALLYL-QUINAZOLINE**.

**DISULPHYDRO-DI-ALLYL-TRIAZOLE**

$\text{NH}<\text{CS.N.C}_6\text{H}_5$ . Formed from allyl-thio-urea and  $\text{HNO}_2$  (Hector, *J. pr.* [2] 41, 605). Oil.— $\text{B}'\text{H}_2\text{P}(\text{Cl})_2$ : crystalline pp.

**o-SULPHYDRO-BENZOIC ACID**

$\text{C}_6\text{H}_4(\text{SH}).\text{CO}_2\text{H}$ . *Thio-salicylic acid*. Formed by reducing *o*-sulpho-benzoic chloride with zinc-dust and  $\text{H}_2\text{SO}_4$  (Delisle, *B.* 22, 2306). Amorphous powder, sl. sol. hot water, v. sol. alcohol. Not volatile with steam.— $\text{AgA}'$ .

*Thio-amide*  $\text{C}_6\text{H}_4(\text{SH}).\text{CS.NH}_2$ . Formed by heating *o*-oxy-benzamide with  $\text{P}_2\text{S}_5$  (Spilker, *B.* 22, 2771). Minute dark-red crystals.

*Phenyl derivative*  $\text{C}_6\text{H}_5\text{S.C}_6\text{H}_4\text{CO}_2\text{H}$ . [166°]. Formed from *o*-diazobenzonic acid, phenyl mercaptan, and  $\text{NaOHAq}$  at  $50^\circ$  (Graebe a. Schultze, *A.* 263, 4). Plates (from alcohol) or needles (from  $\text{HOAc}$ ); sl. sol. water.— $\text{NH}_4\text{A}'$ .— $\text{KA}'$ : needles, v. sol. water.— $\text{EtA}'$ . [151°].

*m*-Sulphydro-benzoic acid  $\text{C}_6\text{H}_4(\text{SH}).\text{CO}_2\text{H}$ . [147°]. Formed by the action of tin and  $\text{HClAq}$  on  $\text{C}_6\text{H}_4(\text{SO}_2\text{Cl}).\text{COCl}$  (Frerichs, *B.* 7, 793). Colourless plates, m. sol. water.— $\text{BaA}'$ , 2;  $\text{AgA}'$ , 2.— $\text{PbC}_6\text{H}_4\text{SO}_3$  3aq.— $\text{Cu}(\text{OH})\text{A}'$ .— $\text{AgA}'$ .

**o-SULPHYDRO-BUTYRIC ACID**

$\text{CHEt}(\text{SH}).\text{CO}_2\text{H}$ . Formed from  $\alpha$ -bromo-butyric acid and alcoholic  $\text{KSH}$  (Duvillier, *Bl.* [2] 80, 507). Sol. water, alcohol, and ether.

**Sulphhydro-isobutyric acid**  $\text{HS.CMe}_2\text{CO}_2\text{H}$ . Formed from  $\alpha$ -bromo isobutyric ether by successive treatment with alcoholic  $\text{KSH}$  and alcoholic  $\text{KOH}$  (Lovén, *J. pr.* [2] 33, 109). Oil.

**o-SULPHYDRO-CINNAMIC ACID**

$\text{C}_6\text{H}_5\text{CH}=\text{C}(\text{SH}).\text{CO}_2\text{H}$ . [119°]. Formed, together with sulphocyanic acid, by heating benzylidene-rhodanic acid  $\text{C}_6\text{H}_5\text{CH}=\text{C}(\text{SH}).\text{COS.CN}$  with baryta-water (Ginsburg a. Bondzynski, *B.* 19, 128; *M.* 8, 850). Yellowish crystals. V. sol.

alcohol, ether, benzene, and  $\text{CS}_2$ , nearly insol. water. By treatment with iodine in alcoholic solution it is oxidised to di-sulphido-di-cinnamic acid  $\text{S}_2(\text{C}_6\text{H}_5\text{CH}(\text{CO}_2\text{H}))_2$ .

*Reference.*—NITRO-SULPHYDRO-CINNAMIC ACID.

**$\beta$ -SULPHYDRO-CROTONIC ACID.** *Ethyl derivative*  $\text{CH}_3\text{C}(\text{SEt})\text{CH}(\text{CO}_2\text{H})$ . [113°]. Formed from  $\beta$ -chloro-crotonic acid [94.5°], mercaptan, and Na (Autenrieth, A. 254, 235; B. 20, 3189). Crystals, insol. water, v. sol. ether and alcohol. Gives a dark-green colour on warming with isatin and  $\text{H}_2\text{SO}_4$ . Yields  $\text{CH}_3\text{C}(\text{SEt})\text{CH}_2$  (110°) on heating above its melting-point.— $\text{BaA}'$ , aq.— $\text{AgA}'$ : silky needles, not decomposed by hot water.  $\text{Ac}_2\text{O}$  forms the compound  $\text{CH}_3\text{C}(\text{SEt})\text{CH}(\text{CO}_2\text{OAc})$ , a brownish oil.

*Isomeride of the ethyl derivative*  $\text{CH}_3\text{C}(\text{SEt})\text{CH}(\text{CO}_2\text{H})$ . [92°]. S. (alcohol) 20. Formed in like manner from the isomeric  $\beta$ -chloro-crotonic acid (A.). Crystals, nearly insol. water. Forms a dark-green liquid on warming with isatin and  $\text{H}_2\text{SO}_4$ . When heated alone it yields the same ethyl-sulphydro-propylene (110°) as its isomeride.— $\text{BaA}'$ , aq.: thin plates (from Ag).

*Phenyl derivative v. PHENYL-SULPHYDRO-CROTONIC ACID.*

#### SULPHYDRO-ETHYL ALCOHOL

$\text{HO}(\text{C}_2\text{H}_4)_2\text{SH}$ . Formed from glycolic chlorhydrin and alcoholic KSH (Carius, A. 124, 258). Oil, v. e. sol. alcohol. Oxidised by  $\text{HNO}_3$  to isethionic acid.— $\text{Hg}(\text{C}_2\text{H}_3\text{OS})_2$ . Needles (from warm alcohol).

#### SULPHYDRO-ETHYL-QUINAZOLINE.

*Dihydrate*  $\text{C}_6\text{H}_4\text{CH}_2\text{NH}(\text{CS})\text{NH}_2$ . [103°]. Formed by warming  $\omega$ -tolyl-ethyl-thio-urea with HCl (Söderbaum & Widman, B. 22, 2936). Needles.— $\text{B}'\text{H}(\text{AuCl}_4)$ . [118°].— $\text{B}'\text{H}(\text{PtCl}_6)$ . [208°].

**SULPHYDRO-METHANE DISULPHONIC ACID**  $\text{HS}(\text{CH}(\text{SO}_3\text{H}))_2$ . Formed by boiling the trisulphonic acid with  $\text{HOAc}$  (Albrecht, A. 161, 134). Gives a blue colour with  $\text{FeCl}_3$ .— $\text{K}_2\text{A}''$  2aq.— $\text{Ph}_2(\text{CHSO}_3)_2$  2aq. Small needles.

*Sulphydro-methane trisulphonic acid*  $\text{HS}(\text{CH}(\text{SO}_3\text{H}))_3$ . Formed by boiling  $\text{CS}_2$  or  $\text{CSCl}_2$  with  $\text{K}_2\text{SO}_4$  aq.— $\text{K}_2\text{A}'''$  2aq.: tridinic crystals. S. 2 at 12°. Gives a blue colour with  $\text{FeCl}_3$ .— $(\text{NH}_4)_2\text{A}'''$  aq. Thin plates.

#### SULPHYDRO-METHENYL-AMIDO-CRESOL

$\left[ \begin{smallmatrix} 1 \\ 2 \end{smallmatrix} \right] \text{C}_6\text{H}_4\text{Me} \langle \text{N} \rangle \text{C.SH}$ . [217°]. Formed by heating benzene-azo-*p*-cresol with  $\text{CS}_2$  at 200° (Jacobsen & Schenke, B. 22, 3235). Needles.

#### SULPHYDRO-METHENYL-AMIDO-( $\alpha$ )-

**NAPHTHOL**  $\text{C}_{10}\text{H}_7 \langle \text{N} \rangle \text{C.SH}$ . [above 220°]. Formed by heating an alcoholic solution of  $\text{S}_2(\text{C}_6\text{H}_4\text{NH}_2[1:2])_2$  with  $\text{CS}_2$  (Jacobson, B. 21, 2624). Needles. Oxidised by  $\text{K}_2\text{FeCy}_6$  to a crystalline disulphide.

*Sulphydro-methenyl-amido-( $\beta$ )-naphthol*. [249°]. Formed by heating benzene-azo-( $\beta$ )-naphthol with  $\text{CS}_2$  at 250° (Jacobson, B. 21, 414). Needles, sl. sol. benzene.  $\text{HClAq}$  at 170° yields amido-( $\beta$ )-naphthol. An alcoholic solution of iodine forms crystalline  $(\text{C}_{10}\text{H}_7 \langle \text{N} \rangle \text{O})_2\text{S}_2$ .

#### SULPHYDRO-METHENYL- $\alpha$ -AMIDO-

**NAPHTHYL MERCAPTAN**  $\text{C}_{10}\text{H}_7 \langle \text{N} \rangle \text{C.SH}$ . [above 240°]. Formed by heating  $\alpha$ -naphthyl

thiocarbimide with S at 225°, and got also by the action of  $\text{CS}_2$  on di-amido-di-naphthyl disulphide (Jacobson, B. 21, 2625; 24, 1406). Minute rosettes, sol. alcohol. Oxidised by  $\text{K}_2\text{FeCy}_6$  to  $(\text{C}_{10}\text{H}_7 \langle \text{N} \rangle \text{C})_2\text{S}_2$ .— $\text{B}'\text{HgCl}_4$ . [210°].

*Sulphydro-methenyl-amido-( $\beta$ )-naphthyl mercaptan* [232°]. Formed by heating ( $\beta$ )-naphthyl thiocarbimide with S. Minute needles. Yields a methyl ether [74°], crystallising in needles.

#### SULPHYDRO-METHENYL-o-AMIDO-

**PHENOL**  $\text{C}_6\text{H}_5 \langle \text{N} \rangle \text{C.SH}$ . *Thiocarbamido-*

*phenol*. [196°]. Formed by boiling an alcoholic solution of *o*-amido-phenol for several days with  $\text{CS}_2$  in a current of H as long as  $\text{H}_2\text{S}$  is given off (Dünner, B. 9, 465). Formed also by heating oxy-phenyl-thio-urea, and by heating *o*-oxy-phenyl-allyl-thio-urea with HCl at 130° (Von Chelmicki, J. pr. [2] 42, 442; B. 20, 177). Obtained also by adding dilute alcohol to a mixture of potassium xanthogenate and amido-phenol hydrochloride (Kalkhoff, B. 16, 1825). Needles (from water), sl. sol. cold water. Sol.  $\text{NH}_4\text{Aq}$ , crystallising therefrom unaltered.

*Reactions.*—1. Converted in *o*-amido-phenol by  $\text{HClAq}$  at 170°, and by  $\text{NH}_4\text{Aq}$  at 200°.—

2.  $\text{Ac}_2\text{O}$  yields  $\text{C}_6\text{H}_4 \langle \text{N} \rangle \text{C.SAc}$  [120°].—3.  $\text{BzCl}$

forms benzenyl-amido-phenol and  $\text{C}_6\text{H}_4(\text{NHBz})\text{OBz}$ .—4. An alcoholic solution of iodine, added to its solution in  $\text{NaOHAq}$ ,

forms  $(\text{C}_6\text{H}_4 \langle \text{N} \rangle \text{C})_2\text{S}_2$  [110°], which is reconverted by hot dilute  $\text{NaOHAq}$  into sulphydro-methenyl-amido-phenol.—5. Boiling methyl-aniline forms a base  $(\text{C}_6\text{H}_4 \langle \text{N} \rangle \text{C.NPhMe})$  which yields  $\text{B}'\text{H}(\text{PtCl}_6)$ .

*Salt.*— $\text{AgC}_6\text{H}_4\text{NSO}$ . Amorphous.

*Ethyl ether*  $\text{EtC}_6\text{H}_4\text{NSO}$ . (c. 267°). Solid, melting below 35°; volatile with steam.

#### SULPHYDRO-METHENYL-AMIDO-PHENYL-

**MERCAPTAN**  $\text{C}_6\text{H}_5 \langle \text{N} \rangle \text{C.SH}$ . [179°] (H.); [174°] (J. a. F.).

*Formation.*—1. By digesting *o*-amido-phenol with  $\text{CS}_2$  (Hofmann, B. 20, 1789).—2. By heating  $\text{C}_6\text{H}_5\text{N}_2\text{C}_6\text{H}_5$  with  $\text{CS}_2$  at 265° (Jacobson & Frankenbacher, B. 24, 1403).—3. By heating phenyl thiocarbimide with sulphur.

*Properties.*—Needles or plates, v. sol. alcohol and ether. Forms  $\text{B}'\text{HgCl}_4$ . Oxidised by  $\text{K}_2\text{Cr}_2\text{O}_7$  to  $(\text{C}_6\text{H}_5 \langle \text{N} \rangle \text{C})_2\text{S}_2$ , which yields  $\text{B}'\text{K}_2\text{Cr}_2\text{O}_7$ , [180°].  $\text{MeI}$  yields  $\text{C}_6\text{H}_5 \langle \text{N} \rangle \text{C.SMe}$  [52°], which forms  $\text{B}'\text{H}(\text{PtCl}_6)$ , crystallising in plates.

#### SULPHYDRO-METHENYL-BENZENYL-

**THIO-AMIDOXIM**  $\text{C}_6\text{H}_5 \langle \text{N} \rangle \text{C.SH}$ . [162°].

Formed by the action of  $\text{CS}_2$  on an alkaline alcoholic solution of benzenyl-amidoxim (Crayen, B. 24, 888). Needles, nearly insol. water and cold alcohol. Conc.  $\text{HClAq}$  at 150° decomposes it into benzoic acid,  $\text{CO}$ ,  $\text{NH}_3$ ,  $\text{H}_2\text{S}$ , and S.  $\text{NaOEt}$  and  $\text{EtI}$  yield  $\text{C}_6\text{H}_5 \langle \text{N} \rangle \text{CEt}$  [49°].

while benzyl chloride forms, in like manner,  $C_6H_5C \begin{smallmatrix} N \\ \text{---} \end{smallmatrix} \begin{smallmatrix} N \\ \text{---} \end{smallmatrix} C \cdot CH_2Ph$  [79°].

**SULPHYDRO - METHENYL - p - TOLYL - METHENYL-THIO-AMIDOXIM**  $C_8H_8N_2S$ , *i.e.*  $C_6H_4Me.C \begin{smallmatrix} N \\ \text{---} \end{smallmatrix} \begin{smallmatrix} N \\ \text{---} \end{smallmatrix} C.SH$ . [166°]. Formed from  $CS_2$  and tolyl-methenyl-amidoxim (Crayen, *B.* 24, 391). Crystals (from alcohol acidulated with  $HOAc$ ), insol. water, sl. sol. ether. Forms salts with bases. *p*-Tolyl-methenyl-amidine forms the salt  $C_6H_4Me.C(NH_2).NHHA'$  [172°]. Boiling  $EtI$  and  $NaOEt$  yield  $C_6H_4Me.C \begin{smallmatrix} N \\ \text{---} \end{smallmatrix} \begin{smallmatrix} N \\ \text{---} \end{smallmatrix} C.SEt$  [37°].

**SULPHYDRO - METHYL - GLYOXALINE**  $C_6H_5SN_2$ , *i.e.*  $CH.NMe \begin{smallmatrix} N \\ \text{---} \end{smallmatrix} \begin{smallmatrix} N \\ \text{---} \end{smallmatrix} C.SH$ . [142°]. (c. 280°). Formed by boiling  $CH(OEt).CH_2NH_2$  with methyl thiocarbimide, alcohol, and dilute (30 p.c.)  $H_2SO_4$  (Wohl a. Marckwald, *B.* 22, 1354). Plates, v. sol. water, sol. alcohol. —  $B^+PtCl_6^-$  —  $B^+AuCl_4^-$  —  $C_6H_5AgSN_2$  —  $B^+MeI^-$  [148°]. Needles.

*Methyl derivative*  $CH.NMe \begin{smallmatrix} N \\ \text{---} \end{smallmatrix} \begin{smallmatrix} N \\ \text{---} \end{smallmatrix} C.SMe$ . *Methylimidazolyl methyl sulphide*. (225° uncor.). Formed by treatment with  $MeI$  and alkalis. Liquid, miscible with water, alcohol, and ether. Boiling dilute  $HNO_3$  forms  $C_6H_5(NO_2)SN_2$  [85°], which yields  $B^+H_2PtCl_6^-$  [197°],  $C_6H_5SN_2.MeI$  [173°]. Needles, v. sol.  $Aq$ . *Reference.* — Oxy-sulphydro-di-methyl-glyoxaline.

**SULPHYDRO-DI-METHYL-PYRIDINE**  $CS \begin{smallmatrix} CH:CMc \\ CH:CMc \end{smallmatrix} NH$ . [210°–215°]. Formed by heating oxy-di-methyl-pyridine with  $P_2S_5$  at about 160° (Guthzeit a. Epstein, *B.* 20, 2113). Needles, v. sol. hot water and alcohol.

**SULPHYDRO - METHYL - QUINAZOLINE**. *Dihydride*  $C_8H_8 \begin{smallmatrix} CH_2.NMe \\ NH.CS \end{smallmatrix}$ . [189°]. Formed by warming  $\omega$ -oxy-tolyl-methyl-thio-urea with  $HClAq$  (Söderbaum a. Widman, *B.* 22, 2335). Needles. —  $B^+H_2PtCl_6^-$  [195°]. —  $B^+HAuCl_4^-$  [153°]. Minute needles.

**SULPHYDRO-METHYL-QUINOLINE**  $C_{10}H_8NS$  *i.e.*  $C_6H_4 \begin{smallmatrix} CMc:CH \\ N=CSH \end{smallmatrix}$ . [253°]. Formed by heating (*Py.* 3,1)-oxy-methyl-quinoline with  $P_2S_5$  (Roos, *B.* 21, 625). Small brown needles (from alcohol). Tastes bitter. Insol. cold water. Does not react with hydroxylamine and phenylhydrazine.  $H_2O_2$  forms  $C_{10}H_8N_2S_2$  [167°] crystallising from benzene in plates.  $EtI$  and alcohol at 100° form  $C_6H_4 \begin{smallmatrix} CMc:CH \\ N=CSH \end{smallmatrix}$ , which is oily and yields  $B^+HI$  [240°] and  $B^+H_2PtCl_6^-$   $\frac{1}{2}aq$  crystallising in reddish prisms.

*Sulphydro-methyl-quinoline*  $C_6H_4 \begin{smallmatrix} C(SH):CH \\ N=CMc \end{smallmatrix}$ . [187°]. Got by heating (*Py.* 1,3)-oxy-methyl-quinoline with  $P_2S_5$  at 160° (Roos, *B.* 21, 629). Yellow prisms (from water).  $EtI$  and  $NaOEt$  yield  $C_6H_4EtNS$  [58°]. —  $B^+HCl$  [205°–210°] (Conrad a. Limpach, *B.* 21, 1972).

**SULPHYDRO-METHYL-THIAZOLE**. *Dihydride*  $CHMe.S \begin{smallmatrix} N \\ \text{---} \end{smallmatrix} \begin{smallmatrix} N \\ \text{---} \end{smallmatrix} C.SH$ . [82°]. Formed from  $\beta$ -bromo-propyl-amine hydrobromide,  $NaOHAq$ , and  $CS_2$  (Hirsch, *B.* 23, 968). White needles, v. sol. hot water. Yields  $C_6H_5MeNS(SMe)$

(217°),  $C_6H_5MeNS(SeEt)$  (229°), and the propyl ether  $C_6H_5MeNS(SC_2H_5)$  (247°).

$\psi$ -**SULPHYDRO-(a)-NAPHTHYL-METHYL-BIAZOLE**  $O \begin{smallmatrix} CMc:N \\ CS=NC_6H_4 \end{smallmatrix}$ . [86°]. Formed from acetyl (a)-naphthyl-hydrazine and  $CSCl_2$  in  $CHCl_3$  (Preund, *B.* 24, 4184). Yellow needles, v. c. sol. alcohol. The isomeride from (b)-naphthyl-hydrazine melts at 109°.

**SULPHYDRO-PENTHIAZOLE Dihydride**  $CH \begin{smallmatrix} CH_2.S \\ CH_2.N \end{smallmatrix} \begin{smallmatrix} N \\ \text{---} \end{smallmatrix} \begin{smallmatrix} N \\ \text{---} \end{smallmatrix} C.SH$ . [132°]. Formed by shaking  $\gamma$ -bromo-ethylamine hydrobromide with  $NaOHAq$  and  $CS_2$  in the cold (Gabriel a. Lauer, *B.* 23, 92). Crystals, v. sol. hot water and alcohol, insol. acids, sol.  $NaOHAq$ . Bromine-water at 100° produces  $CH_2(NH_2).CH_2.CH_2.SO_2H$ .

$\psi$ -**SULPHYDRO-PHENYL-AMIDO-(a)-NAPHTHYL-THIOBIAZOLE**  $C_{18}H_{11}N_3S_2$  *i.e.*  $S \begin{smallmatrix} C(NHPh):N \\ CS.N(C_6H_5) \end{smallmatrix}$ . [255°]. Formed by mixing  $NHPh.CS.NH.NHCO_2H$  with  $OSCl_2$  in benzene (Preund, *B.* 24, 4192). Colourless crystals, v. sol. acetone, sl. sol. alcohol.

$\psi$ -**SULPHYDRO-PHENYL-METHYL-BIAZOLE**  $O \begin{smallmatrix} CS.NPh \\ CMc:N \end{smallmatrix}$ . [72°]. Formed from dichloro-phenyl-methyl-biazole dihydride and alcoholic ammonium sulphide (Preund a. Kuh, *B.* 23, 2837). Formed also from  $NHAc.NHPh$  and  $OSCl_2$  (Preund a. Goldschmidt, *B.* 21, 2456). Prisms (from alcohol). Yields phenyl thiocarbimide on distilling with  $P_2S_5$ .

**SULPHYDRO-PHENYL-GLYOXALINE**  $C_6H_5N_2S$  *i.e.*  $CH:CH \begin{smallmatrix} N:C(SH) \\ N:C(SH) \end{smallmatrix} NPh$ . [181°]. Formed by boiling  $NHPh.CS.NH.CH_2.CH(OEt)_2$  with dilute  $H_2SO_4$  (Wohl a. Marckwald, *B.* 22, 569, 1353). Needles (from hot water), v. sol.  $NaOHAq$ , insol.  $NH_4aq$ . — Salts:  $C_6H_5AgN_2S$  —  $B^+H_2PtCl_6^-$ : deep-red crystals. —  $B^+MeI^-$  [152°].

*Methyl derivative*  $CH:CH \begin{smallmatrix} N=C(SMe) \\ N=C(SMe) \end{smallmatrix} NPh$ . [54°]. Formed by treatment with alcoholic  $NaOH$  and  $MeI$ . White needles (from alcohol), insol. water. —  $B^+C_6H_5N_3O_2^-$  —  $B^+HNO_3^-$ . Needles, v. c. sol. water. —  $B^+MeI^-$  [177°]. Crystalline rosettes (from water). Oxidised by dilute  $HNO_3$  to a nitro-compound [116°].

$\psi$ -**SULPHYDRO-PHENYL-DI-METHYL-PYRIDINE DICARBOXYLIC ETHER**

$CS \begin{smallmatrix} CMc:C(CO_2Et) \\ CMc:C(CO_2Et) \end{smallmatrix} NPh$ . [245°]. Formed by heating  $CS \begin{smallmatrix} CMc:C(CO_2Et) \\ CMc:C(CO_2Et) \end{smallmatrix} O$  with aniline and  $HOAc$  (Guthzeit a. Epstein, *B.* 20, 2112). Sulphur-yellow crystals (from alcohol).

$\psi$ -**SULPHYDRO-PHENYL-NAPHTHYL-BIAZOLE**  $O \begin{smallmatrix} CS.NC_{10}H_7 \\ CPh:N \end{smallmatrix}$ . [164°]. Formed from  $NHPh.NHCO_2H$  and  $OSCl_2$  in  $CHCl_3$  (Preund, *B.* 24, 4186). Needles, v. sol. alcohol.

**SULPHYDRO-PHENYL-QUINAZOLINE**. *Dihydride*  $C_8H_8 \begin{smallmatrix} CH_2.NPh \\ NH.OS \end{smallmatrix}$ . [197°]. Formed by warming  $\omega$ -oxy-tolyl-phenyl-thio-urea with conc.  $HClAq$  (Söderbaum a. Widman, *B.* 22, 1671). Needles. —  $B^+H_2PtCl_6^-$  [319°]. —  $B^+HAuCl_4^-$  [197°]. Needles.

*Reference.* — Oxy-sulphydro-phenyl-quinazoline.

**DI-SULPHYDRO-DI-PHENYL-THIO-UREA.**

*Di-methyl derivative*  $\text{CS}(\text{NH.C}_6\text{H}_5.\text{SMe})_2$ . [162°]. Formed by boiling [1:2]  $\text{NH}_2\text{C}_6\text{H}_4.\text{SMe}$  with  $\text{CS}_2$  and solid KOH (Hofmann, B. 20, 1794). Prisms, v. sl. sol. alcohol. Forms, when heated,  $\text{SCN.C}_6\text{H}_4.\text{SMe}$  (c. 270°).

 **$\beta$ -SULPHYDRO-PROPIONIC ACID**

$\text{CH}_3(\text{SH}).\text{CH}_2.\text{CO}_2\text{H}$ . Formed from  $\beta$ -iodopropionic acid and KSH. Got also by reducing sulphido-dipropionic acid (Lövén, J. pr. [2] 29, 376). Liquid, miscible with water, alcohol, and ether. Easily oxidised by air.  $\text{CuSO}_4$  gives a pale-violet pp., but if not in excess it forms a yellow pp. of  $\text{CH}_2(\text{SCu}).\text{CH}_2.\text{CO}_2\text{H}$  while  $\text{S}(\text{C}_2\text{H}_5.\text{CO}_2\text{H})_2$  remains dissolved.  $-\text{Hg}(\text{S.C}_2\text{H}_5.\text{CO}_2\text{H})_2$ . Scales.  $-\text{Bi}(\text{S.C}_2\text{H}_5.\text{CO}_2\text{H})_2$ .

*Isomericide.*—THIOACTIC ACID.

**SULPHYDRO - PROPYL - PHTHALIMIDE**

$\text{C}_6\text{H}_5\text{O}_2\text{N.CH}_2.\text{CH}_2.\text{CH}_2.\text{SH}$ . [48°]. Formed by heating  $\gamma$ -bromo-propyl-phthalimide with KSHAq at 100° (Gabriel & Thier, B. 23, 88). Needles (from hot ligroin). Fuming HClAq at 180° forms phthalic acid and  $\gamma$ -amido-propyl mercaptan.

**(Py. 3)-SULPHYDRO-QUINOLINE**

$\text{C}_8\text{H}_7\text{N} \begin{smallmatrix} \text{CH:CH} \\ \text{N:C.SH} \end{smallmatrix}$  [174°]. Formed by heating (Py. 3)-oxy-quinoline with  $\text{P}_2\text{S}_5$  at 140° (Roos, B. 21, 620). Yellow plates (from dilute alcohol), insol. cold water, sol. acids and alkalis. Oxidised by  $\text{H}_2\text{O}_2$  to  $\text{C}_8\text{H}_7\text{N}_2\text{S}_2$  [137°]. EtI and alcohol at 100° form  $\text{C}_8\text{H}_7(\text{SEt})\text{NHI}$  [154°], which yields  $(\text{C}_8\text{H}_7(\text{SEt})\text{N})_2\text{H}_2\text{PtCl}_4$  aq. melting, when anhydrous, at 190°.

**SULPHYDRO - THIAZOLE. Dihydride**

$\text{CH}_2\text{S} \begin{smallmatrix} \text{CH}_2\text{N} \\ \text{CH}_2\text{N} \end{smallmatrix} > \text{C.SH}$ . [107°]. Formed from bromoethyl-amine, NaOH,  $\text{CS}_2$ , and alcohol (Gabriel, B. 22, 1162). Needles, sol. alcohol and hot water. Sol. alkalis. Bromine-water yields taurine. Alcohol, KOH and MeI form oily

$\text{C}_2\text{H}_5 \begin{smallmatrix} \text{S} \\ \text{N} \end{smallmatrix} > \text{C.SMe}$  (217°), insol. alkalis but sol. acids.

*Reference.*—OXY-SULPHYDRO-THIAZOLE.

**SULPHYDRO-ACETONE.** The compound  $\text{CH}_3\text{O}(\text{SEt}).\text{CH}_2\text{SEt}$  (170°) is formed by passing gaseous HCl into  $\text{CH}_3\text{CO.CH}_2\text{SEt}$  mixed with mercaptan (Autenrieth, B. 24, 167).

**$\alpha$ -SULPHYDRO- $\alpha$ -TOLUIC ACID.** *Methyl derivative*  $\text{CH}_3(\text{SMe}).\text{C}_6\text{H}_4.\text{CO}_2\text{H}$ . [138°]. Formed by the action of conc. HClAq at 100° on the nitrile  $\text{CH}_3(\text{SMe}).\text{C}_6\text{H}_4.\text{CN}$  (278°), which is got by dissolving thio-phthalimidine in alcoholic KOH and adding MeI (Day & Gabriel, B. 23, 2484). Light oil.

**SULPHYDRO-ISOVALERIC ACID**

$\text{CHPr}(\text{SH}).\text{CO}_2\text{H}$ . Formed from  $\alpha$ -bromo-isovaleric acid and alcoholic KSH (Duvillier, B. [2] 80, 507).

**SUPER.** Use of this prefix applied to inorganic compounds. The prefix *super* is sometimes employed to denote the presence in compounds of relatively more of the characteristic negative element, or elements, than is found in the normal compounds of the same form. The prefix *per* is, however, much oftener used than *super*. It has been proposed by Mendeleeff to designate the oxides that belong to the same type as  $\text{H}_2\text{O}_2$ ,

*superoxides*, to distinguish them from other peroxides (v. OXIDES, vol. iii. p. 660).

M. M. P. M.

**SUPERBIN.** A poisonous substance contained in the root of *Gloriosa superba* (Warden, Ph. [3] 11, 496).

**SYGOCERYL ALCOHOL**  $\text{C}_{22}\text{H}_{44}\text{O}$ . [114°].

Occurs as acetyl derivative in the resin of *Ficus rubiginosa* (De la Rue & Müller, C. J. 5, 62; Rennie & Goyder, C. J. 61, 916). Thin crystals (from alcohol), insol. water and alkalis.  $\text{BzCl}$  yields a crystalline benzoyl derivative.

*Acetyl derivative*  $\text{C}_{22}\text{H}_{42}\text{O}_2$ . [121°]. Flat six-sided tablets, v. sol. hot alcohol, ether, and chloroform.

**SYLVANE**  $\text{C}_8\text{H}_8\text{O}$ . (63°). S.G. .887. Got by distilling pine-wood (Atterberg, B. 13, 879). Liquid, readily resinified. Oxidised by  $\text{KMnO}_4$  to acetic acid. Not attacked by Na, alkalis, or  $\text{Ac}_2\text{O}$ . HCl passed into its ethereal solution forms a small quantity of  $\text{C}_{11}\text{H}_{22}\text{O}$ , a liquid boiling at 240°.

**SYLVANE-ACETIC ACID** v. METHYL-FURFURYL-ACETIC ACID.

**SYLVANE-CARBOXY-ACETIC ACID** v. METHYL-CARBOXY-FURFURYL-ACETIC ACID and METHRONIC ACID.

**SYLVESTRENE** v. TERPENES.

**SYLVIC ACID**  $\text{C} = 78.7$  p.c.  $\text{H} = 9.7$  p.c. [c. 162°].  $[\alpha]_D = -53^\circ$ . This acid is obtained from colophony by repeated crystallisation from dilute alcohol, and is perhaps identical with abietic acid (Liebermann, B. 17, 1884; Haller, B. 18, 2166). By heating with HI and P it is converted into a terpene  $\text{C}_{10}\text{H}_{16}$ . Sylvic acid appears also to be formed by the action of gaseous HCl on an ethereal solution of dextropimaric acid (Yesterberg, B. 19, 2173). A sylvic acid  $\text{C}_{20}\text{H}_{30}\text{O}_2$  is described by Maly (Sitz. W. 44, 121) as formed by adding dilute  $\text{H}_2\text{SO}_4$  or gaseous HCl to a solution of abietic acid. Duvernoy (A. 148, 147) obtained a sylvic acid [129°] by distilling pimaric acid *in vacuo*.

Isosylvic anhydride  $\text{C}_{10}\text{H}_{16}\text{O}_3$ . (250° at 30 mm.).  $\alpha_D = +63^\circ$ . Got by distilling rosin *in vacuo* (Bischoff, B. 23, 1921). Colourless, brittle, microcrystalline substance, insol. water, v. sol. alcohol and ether. Isosylvic acid [62°] is ppd. on adding dilute HOAc to its solution in potash.

**SYLVINOLIC ACID**  $\text{C}_{20}\text{H}_{30}\text{O}_4$ ? [130°]. Formed, together with sylvic acid, by saturating an alcoholic solution of abietic acid with HCl (Maly, Sitz. W. [2] 44, 121). Amorphous powder, v. sol. alcohol and ether.  $-\text{CaA}''$ .  $-\text{Ag}_2\text{A}''$ : pulverulent pp., insol.  $\text{NH}_4\text{Aq}$ .

**SYMBOLS.** Symbols are employed to express the composition, and, as far as possible, the interactions, of compounds; v. EQUATIONS, CHEMICAL (vol. ii. p. 433), FORMULÆ (vol. ii. p. 572), ISOMERISM (vol. iii. p. 79), and cf. ORBITAL METHODS (this vol. p. 253). M. M. P. M.

**SYNANTHRENE**  $\text{C}_{14}\text{H}_{10}$ . *Phosene*. Occurs in crude anthracene (Zeidler, A. 191, 298; cf. Barbier, A. Oh. [5] 1, 526). Yellowish-white plates. Yields a di-bromo-derivative  $\text{C}_{14}\text{H}_8\text{Br}_2$  [175°], crystallising in minute yellow needles, sol. alcohol (difference from di-bromo-anthracene). Di-bromo-synanthrene is oxidised by  $\text{CrO}_3$  and HOAc to a quinone (?) [240°-250°].

**SYNANTHRIN** v. LUTULIN.

**SYNTHESIS.** The building up of compounds from their elements, or from groups of elements.

**SYNTONIN v. FROZIDS.**

**SYNINGIN**  $C_{11}H_{16}O_4$ . [191°]. *Dimethoxy-coniferin*. Occurs in the bark of the lilac (*Syringa vulgaris*) and of the privet (*Ligustrum vulgare*) (Bernays, *J. pr.* 25, 121; Kromayer, *Ar. Ph.* [2] 108, 7; 109, 18, 216; 113, 19; Körner, *G.* 18, 215). White needles (containing aq.), v. sl. sol. cold water, v. sol. alcohol, insol. ether. Its aqueous solution is slightly bitter, is levorotatory, and does not ppt. metallic salts. Conc.  $HNO_3$  gives a blood-red solution. Conc.  $HClAq$  forms a colourless solution, turning blue, and finally giving a blue pp. Conc.  $H_2SO_4$  gives a yellowish-green colour, changing to violet-brown and, on pouring into water, giving a bright-blue solution, which soon deposits an azure powder. Does not reduce Fehling's solution. Decomposed by emulsin into glucose and syringenin.  $KMnO_4$  yields glucosyrringic acid.  $CrO_3$  forms glucosyrringic aldehyde.

**Syringenin**  $C_{11}H_{16}O_4$ , i.e. [5:3:4:1]?  $C_6H_3(OMe)_2(OH).C_5H_9OH$ . Formed as above. Resembles coniferyl alcohol.

**Glucosyrringic acid**  $C_{12}H_{18}O_6$ . [208°]. Formed as above. Needles or prisms (containing 2aq), sl. sol. cold water. Decomposed by dilute  $H_2SO_4$  into syringic acid and glucose.

**Syringic acid**  $C_8H_8(OH)(OMe).CO_2H$ . *Dimethyl derivative of gallic acid*. [202°]. Decomposes at 230° into  $CO_2$  and the dimethyl derivative of pyrogallol. —  $BaA'$ , 3aq: four-sided tables. —  $MeA'$  aq. [83-5°]. Crystals, sol.  $Aq$ .

**Methyl derivative**  $C_8H_8(OMe).CO_2H$ . [168°]. Needles. Yields  $C_8H_8(OMe)_2$  when distilled with lime. Identical with the tri-methyl derivative of gallic acid. —  $MeA'$ . [82-5°]. Needles.

**Glycosyrringic aldehyde**  $C_{11}H_{16}O_5$ . [162°]. Colourless, silky needles. Decomposed by emulsin or dilute  $H_2SO_4$  into glucose and syringic aldehyde. Yields a phenyl-hydrazide [156°] and a crystalline oxim.

**Syringic aldehyde**  $C_8H_8O_3$ , i.e.  $C_6H_3(OH)(OMe).CHO$ . [111-5°]. Small needles, smell like vanilla. Turns brown in air. Reacts with phenyl-hydrazine, and combines with  $NaHSO_4$ .

## T

**TAIGUIC ACID v. LAPACUIC ACID.**

**TALOMUCIC ACID**  $C_{11}H_{16}O_6$ . [158°].  $[a]_D^{20} = +29.4^\circ$  at 20°. Formed from talonic acid and  $HNO_3$  (S.G. 1-15) (Fischer, *B.* 24, 3625). Minute plates, v. e. sol. cold water and warm alcohol; v. sl. sol. ether. Converted by  $HCl$  and  $HBr$  at 150° into dehydromucic acid. Yields a phenyl-hydrazide [185-190°]. Pyridine at 150° forms mucic acid. —  $CaA''$ : crystalline powder.

**TALONIC ACID**  $C_8H_{10}O_7$ . Formed by heating galactonic acid with pyridine at 150° (Fischer, *B.* 24, 3622). Purified by means of its brucine salt. Syrup, very soluble hot alcohol. Levorotatory. Yields a phenyl-hydrazide  $C_8H_{11}O_6(N_2H_4Ph)$  (c. 155°). —  $CaA'$ , aq. Needles (from alcohol), v. e. sol. water. — Brucine salt. [130°-133°]. Crystals, v. sol. water.

**TAMPICIN**  $C_{11}H_{16}O_{11}$ . [130°]. A neutral substance resembling convolvulin, occurring in *Tampica Jalap* (Spirigatis, *N. R. P.* 19, 452). Resin, v. sol. alcohol and ether. Converted by hot baryta-water into amorphous tampicic acid  $C_{11}H_{16}O_{11}$ . Boiling dilute acids resolve tampicin into glucose (3 mols.) and tampicolic acid  $C_{11}H_{16}O_{10}$ , which crystallises from dilute alcohol in minute needles and forms  $NaA'$  and  $EtA'$ , both being crystalline.

**TANACETIN**  $C_{11}H_{16}O_4$ . A bitter substance obtained from the leaves and flowers of the tansy (*Tanacetum vulgare*) (Leroy, *J. Chim. Med.* 21, 357; Leppig, *J.* 1882, 1175). Amorphous, sol. water and alcohol.

**TANACETOGENIC ACID**  $C_8H_8O_4$ . (114° at 15 mm.). Formed by the action of  $Br$  and (4 p.c.)  $NaOHAq$  on tanacetone (Sefnmler, *B.* 25, 3846). Oil, solidified below 0° —  $AgA'$ .

**TANACETONE**  $C_8H_8O$ . (84-5° at 13 mm.). Occurs in oil of absinth, thuja, and sage, con-

stituting the chief part of absinthol, sahyol, and (8)-thujol (Semmler, *B.* 25, 3843, 3850). Got from etheral oil of *Tanacetum vulgare* by shaking with  $NaHSO_4$ , decomposing the crystalline product with  $Na_2CO_3$ , and distilling with steam. Oil, v. sol. alcohol and ether. Does not reduce ammoniacal  $AgNO_3$ . Dextrorotatory;  $\alpha = 38.1^\circ$  in a 20 c.m. tube. S.G.  $22^\circ$  913.  $\mu_D = 1.450$ .

**Reactions.**—1.  $Br$  and  $KOHAq$  yield bromoform, hence it probably contains  $CO.CH_3$ .—2. Reduced in alcoholic solution by  $Na$  to tanacetyl alcohol  $C_8H_{10}O$ , (93° at 13 mm.), S.G.  $22^\circ$  925,  $\mu_D = 1.4635$ . This body does not combine with  $Br$ . With  $PCl_5$  it yields tanacetyl chloride (72° at 10 mm.).—3. Oxidised by  $KMnO_4$  to Tanacetketocarboxylic acid  $C_{10}H_{12}O_6$ . Needles [78°] (from ligroin) or plates [74-5°] (from water). Yields  $AgA'$ . Hydroxylamine yields  $C_{10}H_{14}O_6(NO_2H)$  [103] when prepared from the needles and [169°] when got from the plates. The ketonic acid is oxidised by  $Br$  and  $NaOH$  to tanacetogew dicarboxylic acid  $C_{10}H_{12}O_8$ , [142°]. Plates (from water). This acid yields  $Ag_2A''$  while  $Ac_2O$  yields the anhydride  $C_{10}H_{10}O_7$ , [55°], which gives isopropyl succinic acid [114°] when fused with potash.

**Oxim**  $C_8H_{10}O.NOH$ . [52°]. (136° at 20 mm.). Reduced in alcoholic solution by  $Na$  to tanacetylamine  $C_8H_{11}NH_2$  (80-5° at 14 mm.), S.G.  $22^\circ$  874,  $\mu_D$  1.462, which yields  $B/ECl$ , which when heated gives tanacetene  $C_8H_8$ , (69° at 14 mm.), S.G.  $22^\circ$  841,  $\mu_D$  1.476. Tanacetone oxim may be converted by warming with alcohol and dilute sulphuric acid into the cyminide  $C_8H_8(C_2H_5)(NH_2)Me$  [1:3:4], whence nitrous acid forms carvacrol.

**TANACETOPHORONE**  $C_8H_8O$ . (90° at 13 mm.). S.G.  $22^\circ$  938,  $\mu_D$  1.462. Got by distilling tanacetogen dicarboxylic acid with soda-lime

(Semmler, *B.* 25, 3350). An oil, smelling like camphor-phorone. Reacts with hydroxyl-amine. [182°].

**TANGHININ**  $C_{27}H_{30}O_8$ , 2aq. [182°].  $[\alpha]_D = -67^\circ$ . Obtained from the kernels of *Tanghinia venenifera* of Madagascar (Arnaud, *C. R.* 108, 1255; 109, 701). Crystals (from alcohol), v. sl. sol. water, sl. sol. ether. Cardiac poison. Resinified by dilute acids. Baryta-water at  $180^\circ$  forms  $C_{27}H_{30}O_{10}$ .

**TANNIN. TANNIC ACIDS.** Under the above names are included a large series of compounds, occurring in the vegetable kingdom, of different constitutions, many of which have been very imperfectly studied. Their chief characteristics are their astringent taste and property of giving a dark-blue or green colouration with iron salts and a precipitate with a solution of gelatin. They all reduce solutions of the noble metals, and absorb oxygen in presence of alkalis. They are all aromatic derivatives, and yield on fusion with potash either pyrogallol or pyrocatechin. In some cases they have been synthetically prepared from these phenols and their derivatives, but in many cases the tannin appears to exist in the plant as a glucoside and attempts at a synthetical production have proved futile. Schiff (*B.* 15, 2590) prepared some of the tannins synthetically, and concluded that they were anhydro-compounds of gallic and protocatechuic acids respectively. Etti (*A.* 186, 332) and others have also, for example, synthetically prepared catechutannic acid by heating pyrocatechin with water or alkalis. Gallo-tannic acid was formerly believed to be a glucoside, but subsequent investigation showed that the amount of sugar present was variable, and Schiff (*A.* 170, 43) finally proved that, although existing in the plant as a very unstable glucoside, when it was isolated it had the constitution of an anhydro-acid formed by the removal of one molecule of water from two molecules of a tri-oxy-benzoic acid. He considered that in gallo-tannic acid the anhydride was formed thus:— $C_6H_3(OH)_2CO.O.C_6H_3(OH)_2COOH$ , whilst C. Etti, who has similarly investigated the tannins of the formulæ  $C_{11}H_{14}O_6$  and  $C_{22}H_{28}O_{12}$ , has proved that they also are not glucosides, and regards them as derivatives of a ketonic acid of the formula  $C_6H_3(OH)_2CO.C_6H_3(OH)_2COOH$ . It would appear, then, possible to define the tannic acids as mono-carboxylic acids formed by condensation from two molecules of poly-oxy-benzoic acids and which exist as unstable glucosides in plants. The ease with which gallo-tannic acid is hydrolysed renders it probable that the difference in constitution between Schiff's and Etti's formulæ does not actually exist, and renders it possible to subdivide the tannins into these two groups so soon as the different tannins have been re-examined from this point of view. The ketonic character of the tannins was established by Etti through noting that they reacted with phenyl-hydrazine and hydroxylamine.

The origin of tannin in plants has given rise to much debate. According to Waage (*Ph.* 1890; *Phar. Centr.* 1891, 247) its formation is similar to that of the conversion of glucose into starch. The plant removes one molecule  $H_2O$  from glucose for reserve purposes, and if under favourable circumstances three molecules  $H_2O$  can be removed, a body having the composition

of a triketohexamethylene would be produced

$CH_2COCH_2COCH_2CO$ . This constitution corresponds to the secondary form of phloroglucin. It is probable that the phloroglucin combines with the  $CO_2$  in the nascent state produced by the respiration of the plant, and is thus converted into a carboxylic acid (gallic acid); two molecules of this acid by the removal of another molecule of water would then form tannin. Light and chlorophyll are necessary for the production of tannin.

Westermaier (*B.* 1887, 127-143) showed that with experiments made with *Quercus pedunculata* the tannin migrates downwards through the bark and the pith. Starch is always present, and it is probable that the starch only migrates in the form of tannin. The leaves of *Rumex patens* and *Rheum raphaniticum* give both the starch and the tannin reactions. Schultze (*A. a.* 14, 525-526; *B. C.* 18, 137), by microchemical observations, also supports the view of Sachs and Heberland that the leaves of evergreens contain tannin as a winter reserve material. Tannin and starch only rarely occur simultaneously in the same cells. When the cells are rich in starch they contain a smaller amount of tannin, and *vice versa*.

In the case of leaves containing fatty oils and tannin, the cells which contain the oil are free from tannin, and cells containing no oil are free from starch. Kraus (*B. C.* 330-334) also notes that the formation of tannin in leaves depends on the presence of light and  $CO_2$ , but believes that it acts more as a protecting agent either to prevent the plant from being eaten or rotting than as a reserve material. He points out that as fallen leaves contain as much tannin as they did during their best time of growth, the leaf tannin is of no value to the plant. Heckel a. Schlagenhauffen (*Ph.* July 1892) note that the protecting leaf buds of certain species of gardenia contain a resinous substance which on analysis gives figures resembling cinchotannic acid. Both the gardenias and the cinchonas belong to the same order of plants (*cf.* Cross a. Bevan, *C. J.* 41, 106; Gardiner, *Ph.* [3] 14, 588; Braemer, *Les Tannins*, Toulouse, 1890; Büsgen, *C. C.* 1890, 397).

**Classification.**—No satisfactory classification of these bodies exists. Wagner (*Fr.* 5, 1) divides them into pathological and physiological tannins. The former are chiefly glucosides, and precipitate gelatin, yield gallic acid when hydrolysed with dense sulphuric acid, and when heated alone form pyrogallol. The physiological tannins, on the other hand, form leather, and on distillation yield pyrocatechin. The old classification into iron-blueing and iron-greening tannins is found now to be untenable, as the presence of acids and salts modifies the colour which the tannins produce with  $FeCl_3$ , and the purity of many of the tannins examined by the earlier investigators cannot be guaranteed.

**Reactions.**—The oxidation of gallic and tannin acids by nitric acid of moderate dilution yields oxalic acid and two acids, probably tri-oxy-glutaric and tri-oxy-butyric. The acetyl-o-querictannic acid yields the same acids on oxidation (Böttiger, *A.* 257, 248-252). Metallic Na does not reduce gallic acid in absolute alcohol,

but tannic acid similarly treated undergoes simple hydrolysis, the yield of gallic acid amounting to 80 p.c. of the weight of tannin. No reduction products could be prepared (Böttiger, *A.* 258, 252-260). Ammonia and zinc dust at 60° convert both acids into benzoic acid. Dilute  $H_2SO_4$  and Zn also form benzoic acid from gallic acid (Guignet, *C. R.* 113, 200-201).

**The action of heat.** Most tannins begin to blacken at 120°, and at 160° decomposition into metagallic acid, and either pyrogallol or pyrocatechin, takes place. Those which yield pyrogallol usually also form a 'bloom' on leather, and give a blue colour with  $FeCl_3$ . This class includes galls, sumac, chestnut, and oak bark. The pyrocatechin-yielding tannins do not form a 'bloom' on leather, give green compounds with  $FeCl_3$ , and include hemlock, catechu, rhatany, and mangrove (Trimble, *The Tannins*, 1892).

The products of the action of heat on the tannins are best obtained by allowing the heating to take place on the material suspended in glycerin (1 g. in 5 c.c. glycerin). After heating to 200° for 80 minutes, dilute with water, and extract with ether. The ethereal extract contains either pyrogallol or pyrocatechin. The tannin must be freed from gallic acid and catechin before subjecting it to this test by previous ether extraction of the aqueous solution.

**The action of dilute acids.** 2 p.c. absolute HCl at 100° in sealed tubes decomposes the tannins; insoluble ellagic acid, anhydrides, or phlobaphenes separate, and the filtrate contains gallic acid, glucose, and unaltered tannin. Glucose should be removed from the tannin by repeated lead acetate precipitation before this treatment, or the amount of glucose before and after hydrolysis may be determined by Fehling's solution (Wehmer & Tollens, *A.* 243, 327).

**The action of alkalis.** The pyrocatechin-yielding tannins on heating with alkali yield protocatechuic acid, and either phloroglucin or acetic acid. The pyrogallol-yielding tannins form gallic and ellagic acids (20 g. with 150 c.c. of KHO solution, sp.gr. 1.2 for 3 hours are convenient quantities (Trimble, *The Tannins*).

The tannins in the bark of oak, chestnut, horsechestnut, fir, &c., are precipitated in brominated condition by bromine water; tannin, sumach tannin, and oak wood tannin are not so precipitated (Böttiger, *A.* 240, 330). From oak tannin, Böttiger, by treating with acetic anhydride, has formed an acetyl-o-compound of the formula  $C_{12}H_{14}BrAcO_6$ , and from it two bromoderivatives  $C_{12}H_{14}BrAcO_6$  and  $C_{12}H_{14}Br_2AcO_6$  (*B.* 20, 761-766). A benzoyl-o-derivative has also been obtained from tannin by treatment with conc.  $NaOH$  and benzoyl chloride (Böttiger, *A.* 254, 370). The same author has attempted to prepare cyanhydrins, but without success. Well-dried tannic acid heated with anhydrous HCN in sealed tubes yielded only an amide of gallic acid. Treated with hydroxylamine no oxim was formed, but only gallic acid (*A.* 259, 182-186). With pure tannin phenyl-hydrazine, however, forms derivatives which do not crystallise,  $CO_2$  and N being evolved at the same time. The tannins experimented upon were extracts of sumach, divi divi, oak wood, oak bark and pine bark; the dry precipitates contained phenyl-hydrazine derivatives of tannic

and gallic acids, osazones of dextrose and levulose, and caramel (*A.* 259, 126-182; *A.* 256, 342).

Tannin solutions are very unstable, undergoing hydrolysis into gallic acid on standing. The hydrolysis into gallic acid is almost quantitative when the acid is dissolved in conc.  $H_2SO_4$ , and then water added (Böttiger, *A.* 254, 378). When heated with  $KHSO_4$  and glycerin to 119°-200° and the melt extracted with water, a residue is left soluble in absolute alcohol which contains two new acids of the composition  $C_{12}H_{10}O_6$  and called hydrotannic and isotannic acids respectively. The former, which is the less soluble in alcohol, forms with  $Ac_2O$  a tetra-acetyl-compound while the iso- acid forms a brown tri-acetyl-compound (*C. J.* 1892, 181).

**Preparation of tannic acid for pharmaceutical purposes.** Pelouze in 1834 first suggested the extraction of tannic acid from galls by percolation with ether, and this method is still in use. The powdered galls are placed in a closed percolator with commercial ether containing alcohol and water. The ethereal layer contains gallic and ellagic acids, together with resins and fats and a small portion of the tannic acid; the lower aqueous solution contains nearly pure tannic acid. The percolation is stopped when the lower layer ceases to increase in volume. The B. P. method consists in taking the damp galls, macerating with commercial ether, and expressing through muslin (Lecomet & Dominé). The purest acid is obtained when 10 pts. powdered galls are allowed to stand two days covered in a percolator with a mixture of 12 pts. ether and 3 pts. alcohol. At the end of this time the percolation is commenced until 10 pts. are obtained. One-third its volume of water is then added, and the mixture well agitated. The aqueous layer contains nearly pure tannic acid, and is evaporated rapidly in *vacuo*. The commercial acid is known under the names of ether-tannin, alcohol-tannin, or water-tannin, according to the method of extraction adopted on a large scale.

**Purification.**—Petroleum ether percolation removes fat, wax, and some of the colouring matter. Solution in water removes resin, and, after decantation, sodium chloride precipitates the acid. Trimble adds lead acetate to the aqueous solution to precipitate colouring matter, filters, and extracts with acetic ether. The acid is re-dissolved in water, and extracted with ether to remove the last traces of gallic acid, and the aqueous solution finally dried in *vacuo*.

**Detection.**—1. Dilute  $H_2SO_4$  or HCl precipitates conc. solutions.—2.  $FeCl_3$ , a blue or green precipitate destroyed by long boiling, sol. weak mineral acids.—3. Lime-water precipitates the Ca salt. 4. Cinchonine sulphate precipitates white cinchonine tannate.—5. Gelatin forms leather and albumen also gives a precipitate. Alum and  $NH_4Cl$  render the precipitation more complete. 6. An alcoholic solution of thymol, followed by conc.  $H_2SO_4$ , yields a rose-coloured turbid solution (pyrogallol violet; gallic acid gives no colour; Saul, *Ph.* [3] 17, 887).—7. Iodine in presence of neutral salts gives a purple colouration (Nasser). 8. Acetate of lead acidulated with acetic acid ppt. tannic and not gallic acid (Guyard, *Bl.* 2, 41, 838).—9.  $NH_4Cl$  and  $NH_3$  give a white precipitate rapidly becoming red, gallic acid a red colour.

tion only.—10. Cl water and  $\text{NH}_3$  give a red colouration both with gallic and tannic acids.—11.  $\text{K}_2\text{FeO}_4$  gives a similar reaction (Rawson, *O. N.* 59, 52-53).—12. In plants, Moll (*A. a.* 12, 496) detects tannins micro-chemically by treatment with 7 p.c. copper acetate for some days, then cuts sections, treats with a drop of 0.05 p.c. ferric acetate, washes with water and then alcohol to remove chlorophyll, and mounts in glycerin and looks for blue or green stain.—13. KCN gives a green colouration with tannin and none with gallic acid.—14.  $\text{K}_2\text{Cr}_2\text{O}_7$  gives a brown pp. with most tannins.—15. Saturated solutions of NaCl,  $\text{CaCl}_2$ , KOAc, and a number of other salts ppt. tannins from solution.—16. Conc.  $\text{H}_2\text{SO}_4$  dissolves the dry tannins with a yellow colour, and on heating forms dark-red rufigallic acid and then black metagallic acid.—17.  $\text{HNO}_3$  forms a yellow colour, and finally oxidises them to oxalic acid.—18.  $\text{As}_2\text{O}_3$  heated with the dry tannins converts most into ellagic acid.—19. Most tannins are pptd. by the alkalis.

**Estimation of tannic acid.** The methods devised for the estimation of tannic acid in vegetable extracts are very numerous, and may be grouped under the following heads:—

1. Gelatin or hide-powder absorption.
2. Titration with permanganate.
3. Precipitation with metallic salts.
4. Methods not included in the above.

For details of these various processes, vide Proctor, *Textbook of Tanning*; Trimble, *The Tannins*; Thorpe's *DICTIONARY OF APPLIED CHEMISTRY*, and Rideal, *Chemical Notes on Modern Tanning*; *The Assay of Tanning Materials*; *Industries*, vol. xi. pp. 19, 139, 451. The two methods most generally employed are the hide-powder method and Löwenthal's permanganate process.

The hide-powder method is conducted as follows. A weighed quantity of the material is extracted with water and made up to a known volume. 100 c.c. of this solution is then evaporated, dried, and weighed to give the total solids present in the extract. Another portion of the same solution is agitated with, aspirated, or filtered through hide powder, and the total solids left in 100 c.c. of the solution again determined. The difference gives the quantity of tannic acid or matter which combines with gelatin per 100 c.c. of the solution (*Fr.* 24, 271).

The modified Löwenthal's process, which is now official in Germany, requires a standard solution of permanganate whose indigo value is known. A measured volume of the tannin solution, together with a known volume of indigo solution, is then titrated with the permanganate solution. Another equal volume of the tannin solution is then agitated with hide powder or shaken with a gelatin and alum solution and filtered, and the filtrate, after indigo solution of known amount has been added, is titrated with the permanganate solution. The difference in the quantity of permanganate consumed is a measure of the tannic acid present. The various tannins of commerce have different permanganate values; it is, therefore, necessary to standardise the permanganate for different tannin materials (Löwenthal, *Fr.* 16, 33; Kathreiner, *Fr.* 18, 118; Simaud, *Fr.* 22, 595; Schroeder, *Fr.* 25, 121).

**Gallotannic acid**  $\text{C}_{14}\text{H}_{10}\text{O}_8$ . Occurs in gall nuts and sumach.

**Constitution.**

$\text{C}_6\text{H}_3(\text{OH})_2\text{CO.O.C}_6\text{H}_3(\text{OH})_2\text{COOH}$  (Schiff, *A.* 170, 43; Paul a. Kingzett, *C. J.* 33, 217).

**Solubility.**—Sol. acetone, glycerin, and oils; insol.  $\text{CS}_2$ ,  $\text{CHCl}_3$ , petroleum, and  $\text{C}_6\text{H}_6$ .

**Compounds.**—With gelatin contains 16.5 p.c. nitrogen = 34 p.c. tannin (Böttlinger, *A.* 244, 227). (For other nitrogen values of gelatin-tannin compounds in leather, v. Rideal a. Trotter, *S. C. I.* 1891.) Penta-acetyl-compound  $\text{C}_{30}\text{H}_{18}(\text{OAc})_5\text{CO.O.C}_6\text{H}_3(\text{OAc})_2\text{COOH}$  [137°] (Böttlinger, *B.* 17, 1504).

**Action of heat.**—At 215° it forms pyrogallol,  $\text{CO}_2$ , and a trace of metagallic acid  $\text{C}_6\text{H}_3\text{O}_8$ . Strong heating at 240°-250° forms chiefly metagallic acid (Pelouze, *A.* 10, 159). Cold  $\text{HNO}_3$  forms oxalic, trioxylglutaric, and trioxylbutyric acids (Böttlinger, *A.* 257, 248). Boiling with KHO forms tannouclanic acid  $\text{C}_8\text{H}_6\text{O}_5$ ; cold KHO and air form tannoxyllic acid  $\text{C}_8\text{H}_6\text{O}_5$  (Büchner, *A.* 53, 373). Hydrolysed by dil.  $\text{H}_2\text{SO}_4$  to gallic acid. Ferments also form gallic acid (van Tieghem, *C. R.* 65, 1092).

**Oak bark.** Tannic acid  $\text{C}_{14}\text{H}_{10}\text{O}_8$ .

**Preparation.**—The bark is extracted with alcohol, and the extract agitated with acetic ether and ether. Evaporate off ether, separate the precipitate of ellagic acid, and from residue separate gallic acid from the tannic acid by acetic ether and ether.

**Properties.**—Reddish-white powder. Sol. alcohol and acetic ether. Sl. sol. ether and water. Heated to 130°-140°C. it forms an anhydride  $\text{C}_{28}\text{H}_{20}\text{O}_{11}$ , which is sl. sol. water; sol. alcohol and alkalis, and with conc.  $\text{H}_2\text{SO}_4$  gives a second anhydride  $\text{C}_{28}\text{H}_{20}\text{O}_{10}$ . Heated with conc. HCl it evolves  $\text{CH}_2\text{Cl}$ , gives also the iodoform reaction. On dry distillation it forms pyrocatechin. Fused with KOH yields protocatechuic acid, pyrocatechol, and traces of phloroglucin (Etti, *M.* 1880, 262-278). When boiled with ether the above anhydrides form a third anhydride  $\text{C}_{28}\text{H}_{20}\text{O}_{13}$  (*M.* 1883, 512). Other anhydrides analysed by Etti are  $\text{C}_{16}\text{H}_{12}\text{O}_{11}$ ,  $\text{C}_{16}\text{H}_{12}\text{O}_{12}$ ,  $\text{C}_{16}\text{H}_{12}\text{O}_{13}$ , and  $\text{C}_{16}\text{H}_{12}\text{O}_{14}$ . Forms two hydrates (Löwe, *C. J.* 40, 901).

**Salts.** With Ca, Ba, and Pb; analysed by Etti and Löwe (*l.c.*).

**Derivatives.**—Oak-red  $\text{C}_{14}\text{H}_{10}\text{O}_8\frac{1}{2}\text{aq}$  (Grabowski, *A.* 145, 2);  $\text{C}_{28}\text{H}_{20}\text{O}_{11}$  (Böttlinger, *A.* 240, 341). Böttlinger has prepared various bromo-, acetyl-, and benzoyl-derivatives (*l.c.*) (Rochleder, *A.* 63, 205; Böttlinger, *A.* 202, 270; *B.* 14, 1598; Löwe, *Fr.* 20, 210; Etti, *M.* 4, 514; Grabowski, *A.* 145, 2).

**Fraxitannic acid**  $\text{C}_{26}\text{H}_{20}\text{O}_{12}$ . In ash-leaves. Forms an anhydride  $\text{C}_{26}\text{H}_{20}\text{O}_{13}$ , a benzoyl-compound  $\text{C}_{26}\text{H}_{20}\text{O}_{13}(\text{OBz})_2$ , an acetyl-compound  $\text{C}_{26}\text{H}_{20}(\text{OAc})_2\text{O}_{12}$ , a bromoacetyl-compound  $\text{C}_{26}\text{H}_{20}(\text{OAc})\text{Br}_2\text{O}_{12}\text{aq}$ , and a similar nitro-compound. On heating with  $\text{Ba}(\text{OH})_2$  it forms protocatechuic acid and other products. On heating to 100° it loses 1 mol.  $\text{H}_2\text{O}$ , forming an anhydride  $\text{C}_{26}\text{H}_{20}\text{O}_{13}$  (Gintl a. Reinitzer, *M.* 3, 745 *et seq.*).

The following table gives the source of the principal tannins which have been investigated, and references to the papers in which a description will be found.

Plant	Part	Name	Formula	Per cent.	References
<i>Æsculus Hippocastanum</i>	Nearly all parts	Horsechestnut tannin	$C_{22}H_{34}O_{12}$	—	Rochleder, <i>Sitz. B.</i> 53 [2] 478; 54 [2] 609
<i>Æsculus Hippocastanum</i>	Juice of berries	Rhamnotannic acid	$C_{22}H_{34}O_{13} \cdot H_2O$	—	Rochleder, <i>Z.</i> 1867, 84
<i>Algarobilla</i>	Pods	Ellagotannic acid	$C_{11}H_{16}O_{10} \cdot 1\frac{1}{2} C_2H_3(OH) \cdot CO_2O \cdot C_6H_4(OH)_2 \cdot COOH?$	68.38	Godefroy, <i>C. N.</i> 40, 144; Lowe, <i>Fr.</i> 14, 35; Zäffel, <i>Ar. Ph.</i> 229, 123; Hurst, <i>D. P. J.</i> 262, 288; Eitner, <i>D. P. J.</i> 244, 80
<i>Alnus glutinosa</i>	Wood	Alder tannin	$C_{22}H_{34}O_{11}$	—	Dreykorn a. Reichard, <i>D. P. J.</i> 195, 157
<i>Anacaulis</i>	Wood and bark	Aspertannic acid	$C_1H_{16}O_6$	—	Buchner, <i>J.</i> 1861, 771
<i>Asperula odorata</i>	—	Filittannic acid	$C_1H_{16}O_6$	—	Schwartz, <i>Sitz. B.</i> 6, 446
<i>Aspidium Filix-mas</i>	Root	Atherosperma tannin	$C_{10}H_{16}O_6$	—	Malin, <i>A. Ch.</i> 63, 276
<i>Atherosperma Moschatum</i>	Bark	Beech tannin	$C_{22}H_{34}O_6$	10.0	Zeyer, <i>J.</i> 1861, 769
<i>Bablak (acacia)</i>	Fruit	Caffeianic acid	$C_{11}H_{16}O_6$	—	Wagner, <i>Fr.</i> 5, 10
<i>Betula rubra</i>	Bark	—	—	—	Hofstetter, <i>A.</i> 51, 78; Etti, <i>M.</i> 10, 650
<i>Caffea arabica</i>	Berry	Fracticornitannin	$C_1H_{16}O_6$	—	Rochleder, <i>A.</i> 59, 300; <i>A.</i> 66, 39; Rochleder a. Hlasi- wetz, <i>Sitz. B.</i> 9, 286
<i>Calandra granaria</i> (corn weevil)	Plant without root	Callutannic acid	$C_1H_{16}O_6$	—	Villon, <i>C. N.</i> 56, 175
<i>Calluna vulgaris</i>	Bark	Canagie tannin	$C_1H_{16}O_6$	—	Rochleder, <i>A.</i> 84, 354; <i>Sitz. B.</i> 9, 286
<i>Canagie</i>	—	—	$C$ 58-10 per cent. $H$ 5.33 $O$ 36.57 (same group as mangrove tannin)	—	<i>D. P. J.</i> July 1893
<i>Castanea vesca</i>	Bark	Chestnut bark tannin or galloannic acid?	$C_2H_4(OH) \cdot COOC_6H_4(OH) \cdot COOH$	—	Trimble, <i>C. N.</i> Jan. 6, 1893
<i>Catechu</i>	—	Catechutannic acid	$C_{12}H_{18}O_6?$	—	Guignet, <i>C. R.</i> 113, 200
<i>Cephalis Ipecacuanha</i>	Root	Ipecacuanhic acid	$C_1H_{16}O_6$	—	Willigt, <i>A.</i> 76, 342
<i>Cerasus acida</i>	Bark	Cherry bark tannin	$C_2H_4O_2 \cdot H_2O$	—	Rochleder, <i>Sitz. B.</i> 59, 819
<i>Chirococca racemosa</i>	Root	Caffeianic acid	$C_{12}H_{18}O_6$	—	Rochleder, <i>A.</i> 84, 354; <i>Sitz. B.</i> 9, 286

S. R.

**TANSY OIL.** The essential oil, obtained by distillation of the tansy (*Tanacetum vulgare*), contains 1 p.c. of a terpene  $C_{10}H_{16}$ , (155°-160°), 26 p.c. of an alcohol  $C_{15}H_{26}O$ , and 70 p.c. of 'tanacetyl hydride'  $C_{15}H_{24}O$  (Braylants, *J. Ph.* [4] 26, 898; B. 11, 449; cf. Persoz, *C. R.* 8, 483). Tanacetyl hydride  $C_{15}H_{24}O$  (195°-196°), S.G. 4.918, V.D. 5.1, is converted by  $H_2SO_4$  into cymene. It reduces ammoniacal  $AgNO_3$ , forming a mirror.  $NaHSO_4$  forms crystalline  $C_{15}H_{24}NaSO_4$ . Split up by water into the parent substances.

**TANTALATES v. TANTALUM, ACIDS OF, AND THEIR SALTS,** p. 639.

**TANTALUM.** Ta. At. w. c. 182 (exact value not known). Mol. w. not known. Ta has not been isolated.

**Occurrence.**—Tantalates occur in a few rare minerals, generally associated with niobates; *tantalite* contains from 35 to 75 p.c.  $Ta_2O_5$ , *columbite* from 13 to 86 p.c., *ytrotantalite* from 6 to 47 p.c., and a mineral from Western Australia, recently analysed and called *stibio-tantalite*, c. 52 p.c.,  $Ta_2O_5$  (Goyder, *C. J.* 63, 1076).

**History.**—A short account of the researches that led to the identification of two distinct oxides in *tantalite* is given in the article Niobium (vol. iii. p. 505). Marignac (*C. R.* 60, 234, 1365) gave the formula  $Ta_2O_5$  to oxide of Ta, which had been represented by Rose as  $TaO_2$ . Deville determined the V.D. of the chloride, and deduced the molecular formula  $TaCl_5$  (*C. R.* 56, 891). By heating  $Na_2TaF_6$  with Na, H. Rose (*P.* 99, 69) obtained a black powder, probably a mixture of Ta and oxides of Ta. Berzelius (*P.* 4, 6) also obtained very impure Ta; Marignac (*Ar. Sc.* 1868) failed to isolate approximately pure metal.

**Preparation of impure Ta.**—Very finely powdered *tantalite* is fused with three times its weight of  $KHSO_4$  in an iron or platinum crucible, until completely dissolved. After cooling, the fused substance is powdered and treated with boiling water, whereby sulphates of K, Fe, and Mn are dissolved out; the insoluble portion is washed, and then digested with yellow ammonium sulphide, whereby sulphides of Sn and W are dissolved, and FeS remains mixed with  $Ta_2O_5$  and  $Nb_2O_5$ . The residue is washed thoroughly, and digested with  $HClAq$  to remove FeS, and the portion insoluble in  $HClAq$  is thoroughly washed with boiling water until it is white. The mixture of  $Ta_2O_5$  and  $Nb_2O_5$  thus obtained is dissolved in  $HFAq$  in a platinum dish, the solution is heated to boiling, and a quantity of  $KHF_4$  is added equal to one-fourth of the weight of mixed  $Ta_2O_5$  and  $Nb_2O_5$  used; the liquid is evaporated until 1 g. of the mixed oxides is present in about 7 c.c. and allowed to cool; the prismatic crystals of  $K_2TaF_6$  that separate are washed with cold water until the washings give a yellow pp., without any shade of red, after standing for two hours with tincture of galls. The  $K_2TaF_6$  thus obtained is heated, in a platinum dish, with rather more than its weight of pure conc.  $H_2SO_4$ , whereby  $KHSO_4$ , HF, and  $Ta_2O_5$  are formed; the HF is removed by heat, and the  $KHSO_4$  by repeated washing with water (Berzelius, *P.* 4, 6; cf. H. Rose, *P.* 144, 64, 72).

Lawrence Smith (*Am. S.* 44) recommends to warm 5 g. of very finely powdered *tantalite*, dried at 150°, in a platinum basin with a little water and 8 to 10 c.c. very conc.  $HFAq$ , to filter when reaction is completed, add a little water to the filtrate and evaporate nearly to dryness, to warm with excess of conc. pure  $H_2SO_4$ , and, after the acid has been almost wholly removed by heating, to place the residue in c. 500 c.c. dilute  $HNO_3Aq$  (L. M., *C. N.* 61, 289, 304), and boil until  $Ta_2O_5$  and  $Nb_2O_5$  are ppd. By dissolving in  $HFAq$ , adding  $KHF_4$ , and proceeding as described above,  $Ta_2O_5$  is obtained free from  $Nb_2O_5$ .

The pure  $Ta_2O_5$  obtained by one of the preceding methods is dissolved in  $HFAq$ , in a platinum vessel, the solution is heated to boiling, and 70.8 pts. by weight of  $KHF_4$  are added for 100 pts.  $Ta_2O_5$  used. The solution is evaporated and allowed to cool; the crystals of  $K_2TaF_6$  are washed with a little cold water, dried, mixed with c. half their weight of potassium, and heated in an iron crucible, the mixture of  $K_2TaF_6$  and K being covered with KCl. The contents of the crucible, after cooling, are added, little by little, to water; the black powder that separates is washed with water, and then with dilute alcohol and dried (Berzelius, *P.* 4, 6). The black powder is probably a mixture of Ta and oxides of the metal. Berzelius found that 100 pts. took up 17 pts. O when heated in air, 100 pts. pure Ta require 22 pts. O to form  $Ta_2O_5$ . H. Rose (*P.* 99, 69) obtained a black powder—probably Ta mixed with oxides—by reducing  $Na_2TaF_6$ , by heating with sodium.

**Properties and Reactions.**—The black powder obtained by Rose was a good conductor of electricity; it glowed when heated in the air, and slowly formed  $Ta_2O_5$ ; it was insoluble in acids, except in  $HFAq$ , by which it was slowly dissolved; heated in a stream of Cl it burnt to  $TaCl_5$ . Oxidation was effected by molten alkalis or alkali carbonates. The S.G. of a specimen containing c. 40 p.c. acid sodium tantalate was c. 10.8.

The at. w. of Ta was determined by Marignac (*A.* 140, 153; *Suppl.* 4, 351 [1865]) by decomposing  $K_2TaF_6$  and  $(NH_4)_2TaF_6$  by  $H_2SO_4$ , and determining the quantities of  $Ta_2O_5$  and  $K_2SO_4$  produced. The values obtained varied from 180.1 to 185.2. H. Rose in 1856 (*P.* 99, 80) analysed  $TaCl_5$  by decomposing by water, ppg.  $Ta_2O_5 \cdot xH_2O$  by  $NH_4Aq$ , and estimating Cl in the filtrate. His results showed marked discrepancies.

Ta is metallic in its physical properties, so far as may be judged from the impure specimens that have been prepared.  $Ta_2O_5$  dissolves in  $HFAq$ , probably forming  $TaF_5$ . No salts are known to be formed by replacing the H of an oxyacid by Ta. In all the salts of Ta that have been isolated, other than the haloid compounds, Ta forms part of the negative radicle. Ta is the fifth member of the even-series family of Group V.; it is closely related to Nb, and less closely to N, P, V, As, Sb, Bi, Er, and Bi. The only compound of Ta whose V.D. has been determined is  $TaCl_5$ ; in this molecule the atom of Ta is pentavalent (v. NITROGEN GROUP OF ELEMENTS, vol. iii. p. 571).

**Detection and Estimation.**—Tantalum comp-

pounds form potassium tantalate when fused with KOH, and the fused mass dissolves in water. The product obtained by fusion with NaOH dissolves in water to a clear liquid only after NaOH has been removed by washing, as sodium tantalate is insoluble in much NaOH aq. Addition of acid to an aqueous solution of an alkali tantalate, followed by boiling, ppt's  $Ta_2O_5 \cdot xH_2O$  more or less completely. By adding HCl aq to a solution of an alkali tantalate, and placing zinc in the solution, no blue colour is produced (cf. NIOBIUM, DETECTION OF, vol. iii, p. 506). According to Levy (C. R. 103, 1074), an amethyst colour is produced by adding a very small quantity of  $Ta_2O_5$  to a solution of resorcin in  $H_2SO_4$  aq. Ta is estimated as  $Ta_2O_5$ ; the process is sufficiently indicated under *Preparation*.

**Tantalum, acids of, and their Salts.**  $Ta_2O_5$  reacts with molten alkalis, and alkali carbonates, to form salts which may be regarded as derived from various hydrates of  $Ta_2O_5$ . Two hydrates are obtained,  $Ta_2O_5 \cdot 2H_2O$  and  $2Ta_2O_5 \cdot 3H_2O$ , by decomposing  $TaCl_5$  by a little water, and by fusing  $Ta_2O_5$  with  $KHSO_4$  and washing with water (v. TANTALUM, OXIDES AND HYDRATED OXIDES OF, p. 640). The first of these hydrates may be called *pyrotantallic acid*  $H_2Ta_2O_7$ , corresponding with  $H_2F_2O_7$ ; and the second may be formulated  $H_4Ta_2O_9$ . The tantalates that have been examined do not seem to be derived from either of these compounds, but from the hypothetical acids  $HTaO_3$ , corresponding with  $HPO_3$  and  $HNO_3$ , and  $H_2Ta_2O_7$  ( $= 3Ta_2O_5 \cdot 4H_2O$ ). Tantalates are not produced by neutralising  $Ta_2O_5 \cdot xH_2O$ , but by fusing  $Ta_2O_5$  with alkalis, or by double decomposition from alkali salts.

**TANTALATES.** The tantalates belong to the form  $xTa_2O_5 \cdot yMO$ , where  $M = (NH_4)_2, Mg, Hg, K, Ag, or Na$ ; of those that have been fairly fully examined, some correspond with the metaphosphates and meta-niobates  $MXO_3$ , and others belong to the more complex form  $M_2Ta_2O_9$ . Some of the alkali tantalates dissolve slightly in water, the other tantalates are insoluble. *Fluotantalates* and *fluoxytantalates* are also known (v. *infra*). The tantalates have been investigated chiefly by H. Rose (P. 100, 417) and Marignac (Bl. [2] 6, 111, 118).

**Ammonium tantalate.** A pp. is obtained by adding  $NH_4Cl$  to solution of  $Na_2Ta_2O_7 \cdot xH_2O$ , but the composition of the pp. is not known with certainty.

**Magnesium tantalate.** By adding  $MgSO_4$  aq to solution of  $Na_2Ta_2O_7 \cdot xH_2O$  a crystalline pp. was obtained which, after drying at  $100^\circ$ , had the composition  $MgTa_2O_7 \cdot 3H_2O$ . A crystalline Mg tantalate was obtained by Joly (C. R. 81, 266, 1266) by fusing  $Ta_2O_5$  with  $MgCl_2$ .

**Mercurous tantalate.** A brown, amorphous compound, perhaps  $HgTa_2O_7 \cdot xH_2O$ , is formed by adding  $HgNO_3$  aq to solution in water of  $Na_2Ta_2O_7 \cdot xH_2O$ .

**Potassium tantalates.** (1)  $K_2Ta_2O_7 \cdot 16H_2O$ ; this salt is obtained by fusing  $Ta_2O_5$  with KOH, dissolving in water, and crystallising. (2)  $KTaO_3$ ; this salt, *potassium metatantalate*, is formed by heating the other tantalate, alone or with  $(NH_4)_2CO_3$ , and then treating with water.

**Silver tantalate.** The yellowish white pp.

obtained by adding solution of a salt of Ag to solution of  $Na_2Ta_2O_7 \cdot xH_2O$ , and drying at  $100^\circ$ , has the composition  $AgTa_2O_7 \cdot 8H_2O$ .

**Sodium tantalates.** The *meta-salt*  $NaTaO_3$  is obtained by fusing  $Ta_2O_5$  with  $Na_2CO_3$ , and washing with water. A salt of the composition  $Na_2Ta_2O_7 \cdot xH_2O$  ( $x = 25$  and  $30$ ) is prepared by fusing  $Ta_2O_5$  with NaOH, dissolving in water, and crystallising.

**FLUOTANTALATES. (Tantalifluorides.)** These salts may be regarded as compounds of  $TaF_5$  with metallic fluorides, or as metallic derivatives of the hypothetical acid  $H_2TaF_7$ ; they are prepared by dissolving  $Ta_2O_5$  in  $HFAq$ , adding metallic fluorides, and crystallising; some of them are formed by dissolving  $Ta_2O_5$  and a metallic oxide in  $HFAq$  (Marignac, A. Ch. [4] 9, 276; Berzelius, P. 4, 6).

**Ammonium fluotantalate**  $(NH_4)_2TaF_7$  is obtained by evaporating a solution of  $NH_4F$  in solution of  $TaF_5$  in  $HFAq$ , and evaporating; the salt is crystalline and easily soluble in water.

**Copper fluotantalate**  $CuTaF_6$  forms blue, deliquescent, rhombic prisms; it is prepared by dissolving  $CuO$  and  $Ta_2O_5$  in excess of  $HFAq$ , and evaporating.

**Potassium fluotantalate**  $KTaF_6$  forms white needles by dissolving  $KHF_4$  in solution of  $Ta_2O_5$  in  $HFAq$ , evaporating, and crystallising from hot water. The salt is very slightly soluble in cold water, but dissolves easily in hot water. On long boiling,  $KTaF_6$  aq gives a white pp., probably having the composition  $K_2Ta_2O_7 \cdot F_4$  ( $= 2TaF_5 \cdot Ta_2O_5 \cdot 4KF$ ). By dissolving  $KTaF_6$  in warm 4 p.c.  $H_2O_2$  aq with a little  $HFAq$  and allowing to cool, Piccini (Zcit. für anorg. Chemie, 2, 21) obtained crystals of the *fluoxytantalate*  $KTaO_3 \cdot F_3 \cdot H_2O$  ( $= TaO_3 \cdot F_3 \cdot 2KF \cdot H_2O$ ).

**Sodium fluotantalate**  $NaTaF_6 \cdot H_2O$  is obtained, as white crystals, by dissolving  $Na_2Ta_2O_7$  in  $HFAq$ , evaporating, and drying at  $100^\circ$  the salt that separates.

**Zinc fluotantalate**  $ZnTaF_6 \cdot 7H_2O$ ; a deliquescent salt, obtained by dissolving  $ZnO$  and  $Ta_2O_5$  in excess of  $HFAq$  and crystallising.

**Tantalum alloys of.** By heating  $KTaF_6$  with Al and washing with HCl aq, Marignac (P. 100, 145) obtained a grey powder, S.G. 7.02. By heating to whiteness, in a carbon crucible, a mixture of  $Ta_2O_5$  and iron filings, an alloy of Ta and Fe was obtained resembling pig iron (Gahn, Berzelius a. Eggertz, S. 16, 437).

**Tantalumf, bromide of,  $TaBr_5$ .** A yellowish, crystalline compound, obtained by heating a mixture of dry  $Ta_2O_5$  and Cl in vapour of Br, and removing excess of Br by a long-continued stream of dry  $CO_2$ ; decomposed by water to  $HBr$  aq and  $Ta_2O_5 \cdot xH_2O$  (H. Rose, P. 90, 456; 99, 75). The conditions of preparation are similar to those in making  $TaCl_5$  (q. v.).

**Tantalum, carbide of.** By heating  $TaN$  (v. TANTALUM NITRIDE) with C to the melting-point of steel, N is given off and the nitride is partly converted into brass-yellow coloured  $TaC_2$  (Joly, Bl. [2] 25, 206).

**Tantalum, carbonitride of.** Joly (Bl. [2] 25, 206) obtained a substance, to which he gave the formula  $10TaC.TaN$ , by very strongly heating a mixture of  $Ta_2O_5$  with C and soda.

**Tantalum, chloride of,  $TaCl_5$ .** Mol. w. c. 359 (not determined with great accuracy, as at. w. of Ta is doubtful). V.D. 185 at  $860^\circ$  (Deville a. Troost, *C. R.* 64, 294). Melts at  $211^\circ$ , and boils at  $242^\circ$  at 753 mm. pressure (D. a. T., *l.c.*). Only one chloride of Ta has been isolated.

**Preparation.**—About 5 g. pure dry  $Ta_2O_5$  is mixed with a considerable excess of dry sugar or starch, and the mixture is completely charred by heating in a closed crucible; the charred mass is broken into small pieces, which are heated to redness and placed, while red hot, in a rather wide tube of hard glass that is quickly heated to redness while a stream of thoroughly dried  $CO_2$  is passed through it as long as any trace of moisture is given off from the contents of the tube; the tube is then allowed to cool, the current of dry  $CO_2$  being maintained; when the tube is cold a stream of dry Cl is passed through it, and when every part of the apparatus is filled with Cl (but not until then) the contents of the tube are heated.  $TaCl_5$  forms immediately behind the carbonaceous matter, as a pale-yellow solid; when the reaction has entirely ceased and CO is no longer evolved, the  $TaCl_5$  may be sublimed into another part of the tube, a plentiful stream of dry Cl being maintained during the process. If sublimation is attempted before the whole of the  $Ta_2O_5$  has been chlorinated, a part of the  $TaCl_5$  is decomposed by the CO, with re-formation of  $Ta_2O_5$ . If there should be any air in the tube during the process a white sublimate is formed which is probably an oxychloride (H. Rose, *P.* 90, 456; 99, 75). Should the  $Ta_2O_5$  used contain any  $WO_3$ , the sublimate obtained is reddish; by gently heating, the greater part of the red  $WOCl_3$  may be removed, as it is more volatile than  $TaCl_5$ .

Demarcay obtained  $TaCl_5$  by passing vapour of  $CCl_4$  over  $Ta_2O_5$  heated to redness (*C. R.* 104, 11).

**Properties and Reactions.**—Pale-yellow prismatic needles, melting at  $211^\circ$ , and boiling at  $242^\circ$  under the pressure of 753 mm.; begins to vaporise at  $144^\circ$ ; V.D. 185 at  $860^\circ$  (Deville a. Troost, *C. R.* 64, 294). Decomposes in ordinary air, giving off HCl and becoming covered with a crust of crystalline  $Ta_2O_5$ . Decomposed entirely by water to  $HClAq$  and  $Ta_2O_5 \cdot xH_2O$ . Conc.  $H_2SO_4$  causes evolution of HCl, and forms a somewhat turbid solution from which  $Ta_2O_5 \cdot xH_2O$  separates on boiling; by adding water to this solution, and boiling, the whole of the Ta is precipitated as  $Ta_2O_5 \cdot xH_2O$ . Conc.  $HClAq$  reacts similarly to  $H_2SO_4$ , but only a portion of the  $Ta_2O_5 \cdot xH_2O$  is pptd. on adding water and boiling.  $TaCl_5$  is partly dissolved by heating with  $KOHAq$ .  $TaCl_5$  is soluble in absolute alcohol;  $H_2SO_4Aq$  does not ppt.  $Ta_2O_5 \cdot xH_2O$  from this solution.

No double compounds of  $TaCl_5$  with KCl or NaCl—similar to those of  $TaF_5$ —have been obtained.

**Tantalum, fluoride of.**  $Ta_2O_5 \cdot xH_2O$  dissolves in  $HFAq$ ; neither boiling, nor adding  $H_2SO_4Aq$  to the solution, ppts.  $Ta_2O_5$ . The solution in  $HFAq$  gives off vapours on evaporation that probably contain  $TaF_5$ ; by evaporating at a low temperature, Rose obtained crystals that dissolved easily in water, and were partly vaporised when heated, leaving some  $Ta_2O_5$  (*P.* 90, 456;

99, 75). By evaporating *in vacuo* a solution of  $Ta_2O_5 \cdot xH_2O$  in  $HFAq$ , Marignac obtained a white amorphous mass—probably an oxyfluoride—and then small crystals that were likely  $TaF_5$ .

$TaF_5$  combines with some metallic fluorides, forming *fluotantalates* (*q.v.*, p. 639).

**Tantalum, haloid compounds of.** The only haloid compounds of Ta that have been isolated are  $TaCl_5$  and  $TaBr_5$ . The former has been gasified, and the formula is molecular.  $TaF_5$  also probably exists in solution of  $Ta_2O_5 \cdot xH_2O$  in  $HFAq$ . There is no reaction between I and  $Ta_2O_5$  mixed with C even at a very high temperature.  $TaCl_5$  and  $TaBr_5$  are readily decomposed by water, with formation of  $Ta_2O_5 \cdot xH_2O$  and  $HXAq$ . Double compounds of  $TaF_5$  with some metallic fluorides are known; they belong to the form  $M^1TaF_5$  (*v.* FLUOTANTALATES). Oxyhaloid compounds probably exist, but none has been isolated with certainty.

**Tantalum, nitrides of.**  $TaCl_5$  absorbs  $NH_3$  at the ordinary temperature; by heating the product in  $NH_3$ , Joly (*Bl.* [2] 25, 206) obtained an amorphous, yellow solid, to which he gave the formula  $Ta_2N_5$ . By heating this yellow solid to redness in very dry  $NH_3$ , a black solid was obtained which, after washing with water and drying, had the composition  $TaN$ . This black solid conducts electricity; heated in air it burns to  $Ta_2O_5$ ;  $NH_3$  is given off by the action of molten KOH; it is insoluble in acids, except in a mixture of  $HFAq$  and  $HNO_3Aq$  (Joly, *l.c.*; cf. H. Rose, *P.* 100, 166).

**Tantalum, nitrocarbide of; v. TANTALUM CARBONITRIDE, p. 639.**

**Tantalum, oxides and hydrated oxides of.** The oxide  $Ta_2O_5$  has been isolated, and also a hydrate of this oxide  $Ta_2O_5 \cdot 2H_2O$ , and probably also another hydrate  $2Ta_2O_5 \cdot 3H_2O$ . The existence of another oxide,  $TaO_3$ , is doubtful.

**TANTALUM PENTOXIDE  $Ta_2O_5$ .** (*Tantalio anhydride. Tantalio oxide.*) The preparation of this compound from *tantalite* is described at the beginning of this article under *Preparation of tantalum* (p. 638).  $Ta_2O_5$  is also obtained by decomposing  $TaCl_5$  by water, or by adding  $H_2SO_4Aq$  to solution of a tantalate and boiling, and then heating the  $Ta_2O_5 \cdot xH_2O$  thus pptd.  $Ta_2O_5$  is a white powder; it has not been fused; by heating with boric acid or microcosmic salt in a porcelain oven it is obtained in rhombic prisms (Ebelmen, *A. Ch.* [3] 33, 34; Nordenskjöld a. Chydenius, *J.* 1860, 145). S.G. c. 7.6 (Marignac, *Ar. Sc.* 1868; Deville, *C. R.* 66, 894).  $Ta_2O_5$  is insoluble in acids except  $HFAq$ ; after being very strongly heated, it is insoluble in  $HFAq$ .  $Ta_2O_5$  dissolves in molten alkalis, also in molten  $KHSO_4$  (*v.* TANTALATES, p. 639).

**HYDRATES OF TANTALUM PENTOXIDE.** By decomposing  $TaCl_5$  by water,  $Ta_2O_5 \cdot xH_2O$  is obtained, which, after very thorough washing with water, then with  $NH_3Aq$  to remove adhering HCl, and finally with water, and drying at  $100^\circ$ , gives off from 6 to 7.8 p.c. water when heated to redness. The formula  $2Ta_2O_5 \cdot 3H_2O$  requires 5.7 p.c.  $H_2O$ , and the formula  $Ta_2O_5 \cdot H_2O$  requires 7.5 p.c.  $H_2O$ . It is doubtful whether one or more than one definite hydrate exists in this pp. When  $SO_3$  is passed into a solution of  $Na_2Ta_2O_7$ , a pp. of  $Ta_2O_5 \cdot xH_2O$  is obtained, which, when

thoroughly washed and dried at 100°, is said to be  $\text{Ta}_2\text{O}_5 \cdot 2\text{H}_2\text{O} = \text{H}_2\text{Ta}_2\text{O}_7$  (H. Rose, *P.* 100, 417). Strong acids, such as  $\text{H}_2\text{SO}_4$ ,  $\text{HNO}_3$ , and  $\text{HCl}$ , ppt.  $\text{Ta}_2\text{O}_5 \cdot x\text{H}_2\text{O}$  apparently in combination with the acid used as precipitant from solutions of alkali tantalates; weak acids ppt. insoluble alkali tantalates.

**TANTALUM DIOXIDE  $\text{Ta}_2\text{O}_5$ .** (*Tantalum tetroxide* [ $\text{Ta}_2\text{O}_7$ ].) The isolation of this oxide is doubtful. Berzelius obtained a brown powder by heating  $\text{Ta}_2\text{O}_5$  to redness in a carbon crucible; it was not dissolved by any acids, not even by a mixture of  $\text{HNO}_3$  and  $\text{HFAc}$ ; when strongly heated in air it gave  $\text{Ta}_2\text{O}_5$  (*P.* 4, 20).

**Tantalum, oxyfluoride of.** The white powder formed by decomposing  $\text{K}_2\text{TaF}_7$  by boiling water may be an oxyfluoride, according to Marignac (*A. Ch.* [4] 9, 276).

**Tantalum, salts of.** No salt has been isolated by replacing the H of acids, except  $\text{HCl}$  and  $\text{HIF}$ , by Ta. When alkali tantalates are decomposed by strong acids such as  $\text{HCl}$ ,  $\text{HNO}_3$ , or  $\text{H}_2\text{SO}_4$ , the ppt.  $\text{Ta}_2\text{O}_5 \cdot x\text{H}_2\text{O}$  retains some of the acid used as precipitant; compounds of  $\text{Ta}_2\text{O}_5$  with these acids are perhaps formed.

**Tantalum, sulphide of.** By strongly heating  $\text{Ta}_2\text{O}_5$  in  $\text{CS}_2$  vapour, also by heating to redness a mixture of vapour of  $\text{TaCl}_5$  and  $\text{H}_2\text{S}$ , a yellowish black solid is obtained, which has the composition  $\text{TaS}_2$ , according to Berzelius (*P.* 4, 6; v. also H. Rose, *P.* 99, 575). Roasted in air, this solid gives  $\text{Ta}_2\text{O}_5$ ; heated in  $\text{Cl}_2$  it produces  $\text{TaCl}_5$  and  $\text{S}_2\text{Cl}_2$ ; conc.  $\text{HNO}_3$  oxidises it to  $\text{Ta}_2\text{O}_5 \cdot x\text{H}_2\text{O}$  and  $\text{H}_2\text{SO}_4$  aq.  $\text{TaS}_2$  does not combine with alkali sulphides (*R. L.*); fused with  $\text{KOH}$ , it forms  $\text{K}_2\text{S}$  and potassium tantalates. M. M. P. M.

**TARCHONYL ALCOHOL  $\text{C}_{20}\text{H}_{42}\text{O}$  (?)** Obtained from the leaves of *Tarchonanthus camphoratus* by extracting with alcohol (Canzonieri & Spica, *O.* 12, 227). Silvery scales, insol. water and ether. Converted by  $\text{PCl}_5$  into a chloride [70°] crystallising in small plates (from alcohol).

**TARCONINE** v. vol. iii. p. 496.

**TARNINE** v. vol. iii. p. 497.

**TARTARIO ACID  $\text{C}_4\text{H}_4\text{O}_6$ , i.e.**

**$\text{CO}_2\text{H} \cdot \text{CH}(\text{OH}) \cdot \text{CH}(\text{OH}) \cdot \text{CO}_2\text{H}$ .** *Dextro-tartaric acid. Di-oxy-succinic acid.* [135°]. S.G. 1.764 (Schiff, *A.* 113, 189); 1.74 (Buignet, *J.* 1861, 15); 1.7594 (Perkin). S. 115 at 0°; 132 at 15°; 313 at 100° (Leidie, *Fr.* 22, 269; *C. R.* 95, 87; cf. Schiff, *J.* 1859, 41; Maisch, *J.* 1865, 392). S. (alcohol) 25.6 at 15°. S. (ether) 4 at 15° (Bourgoin, *Bl.* [2], 29, 214; *A. Ch.* [5] 13, 400).  $[\alpha]_D^{20} = +15.06 - +13.19$  in a p per cent. solution (Landolt, *B.* 6, 1075; Lippmann, *B.* 24, 3300). H.F. 372,000 (Von Rechenberg). *Heat of solution*: -3454 at 9° (Pickering, *C. J.* 51, 376).

Occurs free or as K or Ca salt in grape-juice, tamarinds, unripe mountain-ash berries, madder-root, potatoes, Jerusalem artichokes, sorrel, gherkins, mulberries, pine-apples, black pepper, the leaves of *Chelidonium majus*, the bulbs of *Scilla maritima*, in beet-juice, and in many other plants.

**Formation.**—1. Mostly together with racemic acid, by oxidation of saccharic acid, dextrose, cane-sugar, milk-sugar, starch, gum arabic, and sorbin by nitric acid (Dessaigues, *A. Suppl.* 2, 242; Hornemann, *J.* 1863, 381; Kiliani, *A.* 205, 175).—2. By the action of sodium-amalgam on

an alcoholic solution of oxalic ether (Debus, *A.* 166, 124; *C. J.* 24, 376). The product is probably inactive tartaric acid.

**Preparation.**—Powdered chalk is added to a boiling solution of cream of tartar; the filtrate is ppt. by calcium chloride, and both pps. decomposed by the proper quantity of boiling dilute  $\text{H}_2\text{SO}_4$ . The filtrate from  $\text{CaSO}_4$  is evaporated to crystallisation. It may be purified by saturating with  $\text{CaCO}_3$ , digesting with  $\text{ZnCl}_2$ , and decomposing the zinc salt by  $\text{H}_2\text{S}$  (Ficinus, *Ar. Ph.* [3] 14, 310).

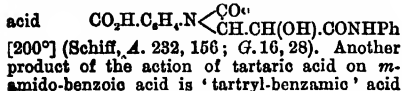

**Properties.**—Monoclinic prisms, with hemihedral facets;  $a:b:c = .785:1:.805$ ;  $\beta = 79^\circ 43'$ . Dextrorotatory, the rotation being dependent on the concentration of the solution, and being also greatly affected by the presence of alcohols, acids, and other substances in the solution (Landolt, *B.* 13, 2329; Biot, *J.* 1850, 169; Fribrah, *M.* 9, 485; *D.* 22, 6; Loug, *Ann. S.* 36, 351; Thomson, *J. pr.* [2] 35, 145). Sodium molybdate in the proportion of Na MoO<sub>4</sub> to  $2\text{C}_4\text{H}_4\text{O}_6$  increases the rotation 37 times, while ammonium molybdate (1 mol.) increases the rotation of tartaric acid (3 mols.) 56 times (Gernez, *C. R.* 104, 733; 105, 803). Lithium and magnesium molybdate also increase the rotation. Sodium tungstate also increases the rotation, the maximum effect being 22 times (Gernez, *O. R.* 106, 1527; 108, 942). Crystals of tartaric acid are strongly pyro-electric. An aqueous solution of tartaric acid is ppt. by baryta, lime, and lead acetate. Potassium salts, when the solution is not too dilute, form a crystalline pp. of  $\text{K}_2\text{H}_2\text{O}_4$ ; the formation of the pp. being promoted by rubbing the sides of the vessel with a glass rod and by the addition of alcohol.  $\text{CaCl}_2$  ppts.  $\text{CaA}'$  from neutral solutions of tartrates; the ppn. is hindered by ammonium salts. Calcium tartrate dissolves in  $\text{KOH}$  aq and is re-ppt. in gelatinous form on boiling. Reduces ammoniacal  $\text{AgNO}_3$  forming a mirror; the solution then contains oxalic acid (Claus, *B.* 8, 550). Tartaric acid prevents the ppn. by alkalis of the oxides of Al, Bi, Ni, Co, Cr, Cu, Fe, Pb, Pt, and Zn, even on boiling (Aubel & Ramdohr, *A.* 103, 33; Groth, *J. pr.* 92, 175). 1 mol. acid prevents the ppn. of 1 mol.  $\text{Cu}(\text{OH})_2$ . A solution of tartaric acid, coloured by a drop of  $\text{K}_2\text{CrO}_7$ , gradually becomes colourless (difference from citric acid) (Salzer, *B.* 21, 1910). A saturated solution of potassium bichromate is slowly turned coffee-brown by tartaric (but not by citric) acid (Caillaud, *C. C.* 1879, 14). Boiling alkaline  $\text{KMnO}_4$  is turned green, and finally brown, by tartaric acid, but only green by citric acid. Decolourises  $\text{KMnO}_4$  in acid solution. When  $\text{H}_2\text{SO}_4$  is present, twice as much  $\text{KMnO}_4$  must be added to produce a permanent red colour as when it is absent, for in the latter case  $\text{MnO} \cdot \text{C}_4\text{H}_4\text{O}_6$  is formed (Fleischer, *B.* 5, 350). Tartaric acid gives an odour of burnt sugar when heated till carbonised. A crystal added to conc.  $\text{H}_2\text{SO}_4$  containing 1 p.p. resorcin gives a red colour on warming (difference from citric and maleic acids) (Mohler, *Bl.* [3] 4, 728).

To detect small quantities of tartaric acid in presence of citric acid. Add about 1 g. citric acid to a 20 p.c. solution of molybdate of ammonia (1 c.c.), then two or three drops of a dilute solution of  $\text{H}_2\text{O}_2$ , and heat for three minutes on the water-bath. If the citric acid is pure the

solution remains yellow. If 0.1 p.c. or more of tartaric acid is present, the liquid become blue (Crismer, *Bl.* [3] 6, 23).

**Redctions.**—1. Melts at 185°, changing to the isomeric metatartaric acid. The metatartaric acid may be reconverted into tartaric acid by boiling with water (Grosjean, *C. J.* 43, 334).—2. At 140°–150° water is eliminated and ditartrylic acid  $C_4H_4O_6$  is formed. On further heating soluble tartaric anhydride (tartrelic acid), and then insoluble tartaric anhydride, are formed. On further heating the products of distillation (from 250 g.) are pyruvic acid (9 g.), pyrotartaric acid (2 g.), formic acid (4 g.), resins, aldehydes and volatile acids (2 g.), and tarry bodies (3 g.) (P. Liebermann, *B.* 15, 428). 'Dipyrrotartaric acid'  $C_4H_4O_6$  (230°), a colourless liquid, with aromatic odour, is among the products of the distillation of tartaric acid. It combines with bromine (Bourgois, *C. R.* 86, 674).—3. By heating tartaric acid (10 pts.) with water (1 pt.) at 175° it is converted into racemic acid and inactive tartaric acid. 'At 165° there is a greater yield of the inactive acid (Jungfleisch, *J.* 1872, 515). Heated with more water at 150° it yields  $CO_2$  and pyrotartaric acid (Wedard, *C. C.* 1888, 889).—4. *Potash-fusion* yields acetic and oxalic acids.—5. *Oxidation* by  $CrO_3$ ,  $KMnO_4$ ,  $PbO_2$  or  $MnO_2$ , and  $H_2SO_4$  yields  $CO_2$  and formic acid. The rate of oxidation has been studied by Kruhwig (*Z. P. C.* 2, 787). By slow oxidation by  $HNO_3$  tartaric acid may be obtained.—6. Reduced by HI and P to malic and succinic acids.—7.  $PCl_5$  forms chloro-fumaric chloride.—8.  $FeSO_4$  at 100° yields iso-arabic acid  $C_4H_4O_6$ , a thick dextrorotatory syrup,  $[\alpha]_D^{20} = 20^\circ$ , yielding the salts  $CaA' \cdot 9aq$ ,  $Ca_2OA' \cdot 8aq$ ,  $PbA' \cdot 4$ , and  $Pb_2A' \cdot O_2$  (Ballo, *B.* 22, 750).—9. *Chloral* forms  $C_4H_4Cl_2O_6$  [124°], crystallising from chloroform in small needles, insol. water, sol. warm alcohol and ether (Wallach, *A.* 193, 46).—10. On submitting tartaric acid to *electrolysis* and treating the syrupy mass with phenyl-hydrazine, glyoxal-oxazone [160°] and glyoxal-carboxylic oxazone [218°] are obtained (Friedel, *A. Combes*, *Bl.* [3] 8, 770).—11. On adding powdered tartaric acid to fused glucose tartaric glucoside is obtained (Guyard, *Bl.* [2] 41, 291; cf. Berthelot, *A. Ch.* [3] 54, 78).—12. *m-Amido-benzoic acid* at 160° forms 'tartril-dibenzamio' acid  $C_{10}H_{10}N_2O_6$ , i.e.  $(CO_2H \cdot C_6H_4 \cdot NH \cdot CO)_2C_2H_2(OH)_2$ , a colourless powder, insol. water, sol. hot alcohol. Its alkaline salts form yellow solutions in which  $Cu(OAc)_2$  ppts.  $C_{10}H_{10}(CuOH)_2N_2O_6$ . On heating to 190° it yields the anhydride  $C_{10}H_{10}N_2O_5$ , a greenish-yellow powder, converted by an alcoholic solution of aniline into tartranil dibenzamio acid

$CO_2H \cdot CH(OH) \cdot CH(OH) \cdot CO \cdot NH \cdot C_6H_4 \cdot CO_2H$ , which crystallises from water in pale-yellow aggregates, yields an acetyl derivative and an anhydride 'tartranbenzamio' acid  $C_{10}H_{10}NO_6$ , crystallising from water in green plates, forming  $C_4H_8BaNO_6$  and  $C_4H_8CuNO_6$ , and converted at 210° in 'benzamtartridio' acid by dehydration. A warm alcoholic solution of aniline converts 'tartranbenzamio' acid into 'tartranilbenzamio'

acid [245°], which yields an acetyl derivative [198°]. 'Tartril-benzamio' acid heated with dry amido-benzamide at 140° forms the compound  $C_4H_4(OH)_2(CO \cdot NH \cdot C_6H_4 \cdot CONH)_2$ , a white powder, insol. water, sl. sol. alcohol, and yielding  $C_{10}H_{10}CuN_2O_6$ , aq.—13. *Glycerin* at 100° yields the compounds  $C_4H_4(OH)_2 \cdot O \cdot C_2H_4 \cdot O_2$  and  $C_4H_4(OH)(OC_2H_4O_2)_2$  (Desplats, *J.* 1859, 500). Glycerin at 140° gives  $C_{11}H_{14}O_{12}$  and  $C_{11}H_{12}O_{12}$ .—14. *Erythrite* at 100° forms  $C_{11}H_{14}O_{14}$ , which gives  $Ca_3(C_{12}H_{14}O_{14})_2 \cdot 3aq$  (Berthelot, *A. Ch.* [3] 54, 84).—15. *Quercite* at 120° forms  $C_{22}H_{32}O_{11}$ , which gives  $Ca_3C_{22}H_{32}O_{11} \cdot 2aq$ .—16. *Pinite* at 120° forms  $C_{30}H_{40}O_{16}$ , which gives  $Ca_3C_{30}H_{40}O_{16} \cdot 3aq$ .—17. *Mannite* at 120° forms  $C_{30}H_{40}O_{16}$ , which yields  $Mg_3O(C_{30}H_{40}O_{16})_3 \cdot 30aq$  and  $Ca_3C_{30}H_{40}O_{16} \cdot 6aq$ .—18. *Dulcite* forms  $C_{11}H_{14}O_{12}$ , which gives  $Ca(C_{11}H_{14}O_{12})_2 \cdot 4aq$ .—19. *Phenyl hydrazine* (2 mols.) at 140° forms  $C_{16}H_{18}N_4O_4$ , i.e.  $C_6H_5O_2(CO \cdot N \cdot H \cdot Ph)_2$  [226°] (Bülow, *A.* 236, 196); [c. 240°] (Fischer, *A. Passmore*, *B.* 22, 2734), crystallising from alcohol in plates.

**Estimation.**—Methods for estimating tartaric acid have been described by Scheurer-Kestner, *C. R.* 86, 1024; Berthelot, *Fr.* 3, 216; Vogel, *A. Braun*, *Fr.* 7, 149; Kissel, *Fr.* 8, 409; Fleischer, *Fr.* 12, 328; Oliveri, *G.* 14, 453; Piccard, *Fr.* 21, 424; C. Schmitt, *A. Hiepe*, *Fr.* 21, 539; Amthor, *Fr.* 21, 195; Nessler, *A. Barth*, *Fr.* 21, 60; 22, 159; Kayser, *Fr.* 22, 123; 23, 29; Musset, *Fr.* 24, 279; Ferrari, *Fr.* 24, 279; Warington, *C. J.* 28, 25; Grosjean, *C. J.* 35, 341; Klein, *Fr.* 24, 379; Bornträger, *Fr.* 25, 327; 26, 699; Gantter, *Fr.* 26, 714; Von Lorenz, *Fr.* 27, 8; Phillips, *Fr.* 29, 577; Goldenberg, *Fr.* 22, 270; Heidenhain, *Fr.* 27, 681; Weigert, *Fr.* 23, 357; Haas, *C. C.* 1888, 1045; Ward, *Ph.* [3] 19, 380.

**Salts** (Berzelius, *P.* 19, 305; 36, 4; *A. Ch.* [2] 67, 303; Werther, *J. pr.* 32, 383; Dumas, *A. Piria*, *A. Ch.* [3] 5, 353; De la Provostaye, *A. Ch.* [3] 3, 129).— $(NH_4)_2A''$ .  $[\alpha]_D = 33.7^\circ$  in a 1.2 p.c. solution (Sonnenthal, *M.* 12, 603). Efflorescent monoclinic prisms, v. sol. water;  $a:b:c = .868:1:1.244$ ;  $\alpha = 88^\circ 9'$ . Give off  $NH_3$  in air. Yield succinic acid on fermentation (Koenig, *G.* 11, 180).— $(NH_4)HA''$ .  $[\alpha]_D = 25.7^\circ$  (Landolt). Minute laminae, sl. sol. cold water. Forms with ammonium malate  $(NH_4)HA''(NH_4)C_4H_4O_6$ , crystallising in prisms, *S.* 9 (Pasteur, *J.* 1853, 415).— $KA'' \cdot \frac{1}{2}aq$ .  $[\alpha]_D = 25.5^\circ$  in a 2 p.c. solution. *S.* 135 at 2°; 158 at 28° (Osann). V. sl. sol. hot alcohol. Monoclinic crystals;  $a:b:c = .402:1:1.109$ ;  $\alpha = 75^\circ 12'$ .— $KHA''$ . *Cream of tartar*.  $[\alpha]_D = 22^\circ$  in a .4 p.c. solution. 100 g. solution contain .369 + .000569 g. grammes at  $t^\circ$  (Blarez, *C. R.* 112, 434, 808). *S.* .25 at 0°; .4 at 10°; .55 at 20°; 1.13 at 40° (Chancel, *C. R.* 60, 408; cf. Alluard, *C. R.* 59, 500). Obtained by crystallisation of argol, which is deposited during vinous fermentation. Trimetric crystals;  $a:b:c = .712:1:1.787$ . Insol. alcohol.— $Na_2A'' \cdot 2aq$ .  $[\alpha]_D = 81^\circ$  in a 1 p.c. solution (Sonnenthal; cf. Thomsen, *J. pr.* [2] 34, 80; 35, 145). *S.* 29 at 6°; 44 at 24°; 66 at 42.5° (Osann). Trimetric prisms;  $a:b:c = .770:1:1.387$ . V. sol. Hot water, insol. alcohol.— $NaHA''$ .  $[\alpha]_D = 24.8^\circ$  in a 1.3 p.c. solution (*S.*).— $NaHA'' \cdot aq$  (Dumas, *A. Piria*, *A.* 44, 80). *S.* 11 in the cold; 55 at 100°. Minute crystals, with hemihedral facets. Insol. alcohol.— $Li_2A''$ .  $[\alpha]_D = 87.5^\circ$  in a .7 p.c. solution (*S.*). Deliques.

cent.—LiHA'' 1 $\frac{1}{2}$ aq. Small crystals, v. sol. water (Dulk, *Schw. J.* 64, 180, 193; *A.* 2, 47).—LiHA'' aq.—Li<sub>2</sub>H<sub>2</sub>A''TeO 2aq. Needles (Klein, *A. Ch.* [6] 10, 118; *C. R.* 102, 47).—Hydroxylamine salt (NH<sub>2</sub>O)<sub>2</sub>A''. Very thin plates (Lossen, *A. Suppl.* 6, 233).—NH<sub>4</sub>NaA'' 4aq. Trimetric crystals, with hemihedral facets, isomorphous with KNaA'' 4aq; *a:b:c* = 823:1:420. [ $\alpha$ ]<sub>D</sub> = 26°. [ $\alpha$ ]<sub>D</sub> = 32.7° (Landolt). *S.* 26 at 0° (Pasteur, *J.* 1849, 309).—LiNaA'' 2aq.—Na<sub>2</sub>A''TeO 2aq.—K<sub>2</sub>A''TeO aq.—(NH<sub>4</sub>)KA''. Monoclinic crystals, isomorphous with K<sub>2</sub>A''. Give off NH<sub>3</sub> in air. V. sol. water. [ $\alpha$ ]<sub>D</sub> = 31° (L.).—KLiA'' aq.—KNaA'' 4aq. *Rochelle salt*. *S.* 30 at 3°, 66 at 26° (Osann). Heat of solution —6290 at 15°. The heat of solution of KNaA'' is —2989 (Pickering, *C. J.* 51, 351). Large trimetric prisms, with hemihedral facets. Melts at 70°–80° in its water of crystallisation, and becomes anhydrous at 215° (Fresenius, *A.* 53, 234). [ $\alpha$ ]<sub>D</sub> = 29.7° (L.). *Molecular rotation*: Long, *Am. S.* 86, 351.—K<sub>2</sub>A''TeO (dried at 100°).—RbHA''. Trimetric prisms, isomorphous with the cesium salt; *a:b:c* = 726:1:695 (*J. P. Cooke, Am. S.* [2] 37, 70). *S.* 1–18 at 25°; 11.7 at 100° (Allen, *Am. S.* [2] 34, 367).—NaRbA'' 4aq. Isomorphous with Rochelle salt (Piccard, *J.* 1862, 125).—Cs<sub>2</sub>A''. Trimetric prisms. *S.* 10 at 25°; 100 at 100°.—Tl<sub>2</sub>A'' 1 $\frac{1}{2}$ aq. [ $\alpha$ ] = 4.8° in a 5 p.c. solution at 20°. Sl. sol. water and alcohol.—THA''. [ $\alpha$ ] = 12° in a 1 p.c. solution at 20°. Small flat prisms (De la Provostaye, *A. Ch.* [3] 3, 129; Kuhlmann, *J.* 1862, 188).—TlNaA'' 4aq. At 20° [ $\alpha$ ] = 0° in a 5 p.c. solution and 6.5° in a 20 p.c. solution.—TlLiA'' aq. [ $\alpha$ ] = 9.5° in a 5 p.c. solution at 20°.—TlKA''. [ $\alpha$ ] = 10° in a 5 p.c. solution at 20°.—Tl(NH<sub>4</sub>)A''. [ $\alpha$ ] = 10° in a 5 p.c. solution at 20°.—BaA''. White amorphous pp., becoming crystalline. *S.G.*  $\frac{21}{4}$  2.973 (Clarke, *Am. S.* 2, 174).—BaA'' aq (Dulk). *S.* (amorphous) 1.2; (crystalline) .077 (Vogel & Reischauer, *J.* 1859, 288).—K<sub>2</sub>BaA'' 2aq. Powder, sl. sol. water.—Na<sub>2</sub>BaA'' 2aq. Needles, sl. sol. water, more soluble in a solution of Rochelle salt. Ppd. on mixing a solution of Rochelle salt with BaCl<sub>2</sub>.—BaA''TeO (dried at 100°).—SrA'' 4aq. Monoclinic prisms. *S.* .7 at 16°. *S.G.*  $\frac{19}{4}$  1.966 (Clarke).—SrA'' 3aq (Marignac, *Ann. M.* [5] 15, 280).—(NH<sub>4</sub>)<sub>2</sub>SrA'', 12aq. Thin plates.—K<sub>2</sub>SrA'' 2aq.—Na<sub>2</sub>SrA'' 2aq.—CaH<sub>2</sub>A''. *S.* .71 at 15.6°. Trimetric crystals.—CaA'' 4aq. Occurs in grapes. Ppd. as white crystalline powder on adding CaCl<sub>2</sub> to a solution of K<sub>2</sub>A''. Small trimetric prisms. *a:b:c* = 872:1:908 (Anschütz, *A.* 226, 191). *S.* .016 at 15°; .3 at 100° (Mohr, *J.* 1865, 893). Forms, with calcium malate, the double salt CaA''CaC<sub>2</sub>H<sub>3</sub>O<sub>6</sub> 6aq, crystallising in needles. *S.* 1.25 at 17° (Ordonneau, *Bl.* [3] 6, 262).—MgA'' 4aq. *S.* .8 at 16°. [ $\alpha$ ]<sub>D</sub> = 36°.—Mg<sub>2</sub>C<sub>2</sub>H<sub>3</sub>O<sub>6</sub> 3aq. *S.* .024. Ppd. by adding NH<sub>3</sub> to a solution of MgA'' (Mayer, *A.* 101, 166).—MgNa<sub>2</sub>A'' 10aq.—MgK<sub>2</sub>A'' 8aq.—MgH<sub>2</sub>A''. *S.* 2 at 16°.—BaA'' 3aq (Atterberg, *Bl.* [2] 21, 162).—BeK<sub>2</sub>C<sub>2</sub>H<sub>3</sub>O<sub>6</sub> 8aq. Prism (Toczynski, *Z.* 1871, 277).—K(SbO)<sub>2</sub>A'' 1 $\frac{1}{2}$ aq. *Tartar emetic*. Prepared by boiling Sb<sub>2</sub>O<sub>3</sub> (3 pts.) with cream of tartar (4 pts.) and water. Octahedra; *a:b:c* = .956:1:1.054. [ $\alpha$ ] = 141° in a 4 p.c. solution at 20°. *S.G.* 2.6. Efflorescent. At 200° it becomes K(SbO)<sub>2</sub>C<sub>2</sub>H<sub>3</sub>O<sub>6</sub>. *S.* 5 at 8°; 8 at 21°; 52

at 100°. .05 to .1g. produce vomiting. Its solution reddens litmus, and gives a crystalline pp. of K(SbO)<sub>2</sub>A'' with alcohol. Its solution is ppd. by mineral acids, by alkalis, and by H<sub>2</sub>S. HgCl<sub>2</sub> is reduced by it to calomel. Heat of formation: Guntz, *C. R.* 104, 699. Volumetric estimation of Sb in tartar emetic (Dunstan & Boole, *Ph.* [8] 19, 385).—K(SbO)<sub>2</sub>A''H<sub>2</sub>A'' 2 $\frac{1}{2}$ aq. Efflorescent prisms. Alcohol added to its aqueous solution ppt. tartar-emetic, leaving tartaric acid in solution (Knapp, *A.* 32, 76).—K(SbO)<sub>2</sub>A''3KHA''. Mammellated groups of needles, v. sol. water.—(K(SbO)<sub>2</sub>A'')<sub>2</sub>NaNO<sub>3</sub> (Martenson, *J.* 1869, 539).—Na(SbO)<sub>2</sub>A'' 1 $\frac{1}{2}$ aq. Trimetric, hygroscopic prisms; *a:b:c* = .922:1:1.03. —(Na<sub>2</sub>A'')<sub>2</sub>Sb(OH)<sub>2</sub> 3aq. Amorphous, v. sol. water (Clarke & Evans, *B.* 16, 2385).—NH<sub>4</sub>(SbO)<sub>2</sub>A'' 1 $\frac{1}{2}$ aq. —NH<sub>4</sub>(SbO)<sub>2</sub>A'' 2 $\frac{1}{2}$ aq (Berlin, *A.* 64, 359).—Rb(SbO)<sub>2</sub>A'' 1 $\frac{1}{2}$ aq. Isomorphous with tartar-emetic (Grandea, *A. Ch.* [3] 67, 165).—Tl(SbO)<sub>2</sub>C<sub>2</sub>H<sub>3</sub>O<sub>6</sub> aq. [ $\alpha$ ] = 100° in a 2 p.c. solution at 20° (Long, *Am. S.* [3] 38, 264).—Ag(SbO)<sub>2</sub>A'' 1 $\frac{1}{2}$ aq. Crystals (*J. P. Cooke, Am. S.* [3] 19, 393).—Ba(SbO<sub>2</sub>A'')<sub>2</sub> 2 $\frac{1}{2}$ aq.—Cd(SbO<sub>2</sub>A'')<sub>2</sub> 2aq. Converted at 200° into Cd(SbOC<sub>2</sub>H<sub>3</sub>O<sub>6</sub>)<sub>2</sub> (Schiff, *A.* 104, 328).—(Ca(SbO<sub>2</sub>A''))<sub>2</sub>Ca(NO<sub>3</sub>)<sub>2</sub> 24aq. Crystallises from a solution of tartar-emetic mixed with calcium nitrate in trimetric forms (Marignac, *Ann. M.* [5] 15, 280).—Sr(SbO<sub>2</sub>A'')<sub>2</sub> Hexagonal crystals. —Sr<sub>2</sub>(SbO<sub>2</sub>A'')<sub>2</sub>(NO<sub>3</sub>)<sub>2</sub> 12aq. Very soluble crystals (Kossler, *P.* 75, 410).—Pb(SbO<sub>2</sub>A'')<sub>2</sub> 4aq. —Be<sub>2</sub>Sb<sub>2</sub>(C<sub>2</sub>H<sub>3</sub>O<sub>6</sub>)<sub>2</sub>. —Sb(HA'')<sub>2</sub> 4aq. Needles, v. sol. water (O. A. E.).—Sb<sub>2</sub>A'' 6aq.—(SbO)<sub>2</sub>HA'' aq (Clarke & Stallo, *B.* 13, 1788).—(SbO)<sub>2</sub>HA'' (Guntz, *C. R.* 104, 850).—O<sub>2</sub>H<sub>2</sub>O<sub>2</sub>Sb<sub>2</sub>O<sub>6</sub> aq. White granular pp., formed by adding alcohol to a solution of Sb<sub>2</sub>O<sub>3</sub> in aqueous tartaric acid (Berzelius). Converted by heat into SbOC<sub>2</sub>H<sub>3</sub>O<sub>6</sub>.—(C<sub>2</sub>H<sub>3</sub>O<sub>6</sub>)<sub>2</sub>Sb<sub>2</sub>O<sub>6</sub> 6aq (Pelouze, *A. Ch.* [3] 20, 289).—(C<sub>2</sub>H<sub>3</sub>O<sub>6</sub>)<sub>2</sub>Sb<sub>2</sub>O<sub>6</sub> (dried) (P.).—(C<sub>2</sub>H<sub>3</sub>O<sub>6</sub>)<sub>2</sub>Sb<sub>2</sub>O<sub>6</sub>H<sub>2</sub>O. Crystals (Guntz, *A. Ch.* [6] 13, 396).—Berberine salt C<sub>20</sub>H<sub>15</sub>NO<sub>4</sub>(SbO)<sub>2</sub>A'' (Stenhouse, *J.* 1863, 452).—Bruceine salt C<sub>20</sub>H<sub>15</sub>N<sub>2</sub>O<sub>4</sub>(SbO)<sub>2</sub>A''.—Quinine salt C<sub>20</sub>H<sub>23</sub>N<sub>2</sub>O<sub>4</sub>(SbO)<sub>2</sub>A'' (Clarke, *B.* 15, 1540).—Atropine salt C<sub>17</sub>H<sub>23</sub>NO<sub>4</sub>(SbO)<sub>2</sub>A'' 2aq.—Aniline salt C<sub>6</sub>H<sub>5</sub>N(SbO)<sub>2</sub>A''. Long white prisms. *S.G.* 1.89 at 11°.—NH<sub>4</sub>(AsO)<sub>2</sub>A'' 1 $\frac{1}{2}$ aq. Large efflorescent trimetric crystals; *a:b:c* = .876:1: .694. Got by dissolving As<sub>2</sub>O<sub>3</sub> in NH<sub>4</sub>HA'' (Mitscherlich; Werther, *J. pr.* 32, 409).—K(AsO)<sub>2</sub>A'' 2 $\frac{1}{2}$ aq. Got by dissolving arsenic acid in a solution of cream of tartar (Pelouze, *A. Ch.* [3] 6, 68).—(Sr(AsO<sub>2</sub>A''))<sub>2</sub>NH<sub>4</sub>NO<sub>3</sub> 12aq. Large trimetric crystals (Marignac).—Bi<sub>2</sub>A'' 6aq. Small crystals, decomposed by water (Schneider, *P.* 88, 55).—K(BiO)<sub>2</sub>C<sub>2</sub>H<sub>3</sub>O<sub>6</sub> (Schwarzenberg, *A.* 61, 244).—Bi<sub>2</sub>K(BiO)(C<sub>2</sub>H<sub>3</sub>O<sub>6</sub>)<sub>2</sub> (Frisch, *J.* 1866, 401).—K(BO)<sub>2</sub>A'' (dried at 100°). *Potassium borotartate*. Amorphous mass, v. sol. water, insol. alcohol. At 100° it becomes K(BO)<sub>2</sub>C<sub>2</sub>H<sub>3</sub>O<sub>6</sub>. Purgative. [ $\alpha$ ] = 58° in a 20 p.c. solution at 20°.—K<sub>2</sub>(BO)<sub>2</sub>C<sub>2</sub>H<sub>3</sub>O<sub>6</sub>.—K<sub>2</sub>(BO)<sub>2</sub>C<sub>2</sub>H<sub>3</sub>O<sub>6</sub>.—Na(BO)<sub>2</sub>A''.—Na<sub>2</sub>(BO)<sub>2</sub>C<sub>2</sub>H<sub>3</sub>O<sub>6</sub>.—Na<sub>2</sub>(BO)<sub>2</sub>C<sub>2</sub>H<sub>3</sub>O<sub>6</sub> (Duve, *J.* 1869, 540).—K<sub>2</sub>(BO)<sub>2</sub>C<sub>2</sub>H<sub>3</sub>O<sub>6</sub>Na(BO)<sub>2</sub>A''.—Ba(BO)<sub>2</sub>C<sub>2</sub>H<sub>3</sub>O<sub>6</sub>.—Ba(BO)<sub>2</sub>C<sub>2</sub>H<sub>3</sub>O<sub>6</sub>.—PbA''. *S.G.*  $\frac{11}{4}$  4.012 (Clarke, *Am. S.* 2, 174). White crystalline pp., v. sol. HNO<sub>3</sub>.—Pb<sub>2</sub>C<sub>2</sub>H<sub>3</sub>O<sub>6</sub> aq (Erdmann, *A.* 21, 14). Insol. water, v. sol. KOHAq. —Pb<sub>2</sub>(C<sub>2</sub>H<sub>3</sub>O<sub>6</sub>)<sub>2</sub>.—CaA'' 9aq (?).—Th<sub>2</sub>K<sub>2</sub>A''.—CuA'' 3aq. *S.* .06 in the cold; .8 at 100°. Light

green powder.— $\text{CuA}''4\text{NH}_3$  (Schiff, *A.* 123, 46).— $(\text{H}(\text{NH}_4)\text{A}')_2(\text{HgO})_3\text{H}_2\text{O}$  (Harff, *Brandes' Arch.* 5, 259; Burekhardt, *ibid.* [2] 11, 257).— $(\text{KHA}')_2\text{HgCl}_2$  6aq.— $\text{K}_2\text{NiA}''$  (dried at  $110^\circ$ ). Efflorescent, apple-green crystalline powder (Fabian, *A.* 103, 248).— $\text{CoCl}(\text{HA}'')_2\cdot 5\text{NH}_3\cdot 2\frac{1}{2}\text{aq}$  (Jørgensen, *J. pr.* [2] 18, 239).— $\text{ZnA}''2\text{aq}$  (Schiff, *A.* 125, 146).— $\text{Zn}_2\text{C}_2\text{H}_2\text{O}_4$  4aq. Powder, insol. water.— $\text{Cr}(\text{OH})\text{A}''$ . Violet flakes, turning dark-blue over  $\text{H}_2\text{SO}_4$  (Schiff, *A.* 125, 145). At  $220^\circ$  it yields  $\text{CrC}_2\text{H}_2\text{O}_4$ .— $\text{K}(\text{CrO})\text{A}''3\frac{1}{2}\text{aq}$  (Malaguti, *C. R.* 16, 457).— $(\text{Uro})\text{A}''3\text{aq}$  (Péligot, *A.* 56, 231).— $\text{K}_2(\text{Uro})\text{A}''_2$  (dried at  $200^\circ$ ).— $(\text{SbO})_2(\text{Uro})\text{A}''_28\text{aq}$ .— $\text{SnA}''$ . Minute crystals.— $\text{K}(\text{FeO})\text{A}''4$  or  $5\text{aq}$ . Prepared by digesting cream of tartar with water and  $\text{Fe}(\text{OH})_3$ . Brown scales, red by transmitted light. Acids ppt. from its solutions a basic salt, sol. excess.— $\text{NH}_4(\text{FeO})\text{A}''4$  (or 5) aq.— $\text{FeA}''_3$ .— $\text{FeA}''$ . Formed by boiling tartaric acid with water and iron wire (Métu, *N. J. P.* 40, 257). Minute crystalline powder. S.  $877$  at  $45.6^\circ$  (Dulk, *A.* 2, 62).— $\text{K}(\text{MnO})\text{A}''4\text{aq}$  (Descamps, *Z.* 1870, 317).— $\text{AgA}''$ . Amorphous curdy pp. got by adding  $\text{AgNO}_3$  to a cold solution of Rochelle salt. Crystallises from a warm solution in white scales. Nearly insol. water. Its ammoniacal solution deposits Ag on warming (Liebig, *A. Redtenbacher*, *A.* 38, 132; Erdmann, *J. pr.* 25, 504).— $\text{AgHA}''$  (Perkin, *C. J.* 51, 369). Monoclinic tables.

**Ethylene-diamine salt**  
 $\text{C}_2\text{H}_4\text{O}_4(\text{N}_2\text{H}_4\text{C}_2\text{H}_4)$ . Dextrorotatory. Leaflets, v. sol. water. The acid salt is sl. sol. water, S. 3 at  $15^\circ$ , and the solution is dextrorotatory (Colson, *Bil.* [3] 7, 808).

**Mono-methyl ether MeHA''**. Formed by boiling tartaric acid with MeOH (Guérin, *A.* 22, 248). Prisms.— $\text{KMeA}''$ .— $\text{BaMeA}''_2$  aq (Dumas a. Péligot, *A. Ch.* [2] 61, 200; [3] 5, 373).

**Di-methyl ether Me<sub>2</sub>A''**. [48°]. (280° i.v.). S.G. (liquid)  $1.340$ .  $[\alpha]_D = 2.454$  at  $18^\circ$  (Anschütz a. Pictet, *B.* 13, 1176; 18, 1399);  $= 2.14$  (Phillips a. Guye, *C. R.* 110, 714). Yields an acetyl derivative [103°]  $[\alpha]_D = -14^\circ$  and a dibenzoyl derivative  $[\alpha]_D = -88.8^\circ$ .

**Mono-ethyl ether EtHA''**. [90°]. Formed by dissolving tartaric acid in boiling alcohol (G.; Marian, *N. J. T.* 13, 2, 43; Trommsdorff, *N. J. T.* 24, 1, 11; Guérin, *A. Ch.* [2] 62, 57). Very deliquescent prisms.— $\text{NaEtA}''$ . Powder, sl. sol. alcohol (Mulder, *B.* 8, 370).— $\text{KEtA}''$ . S.  $106^\circ$  at  $23.5^\circ$ . Colourless trimetric prisms;  $a:b:c = 288.1:417$ .— $\text{Cr}(\text{EtA}'')_3$  5aq.— $\text{Ba}(\text{EtA}'')_2$  2aq. S. 38 at  $23^\circ$ ; 128 at  $100^\circ$ .— $\text{Pb}(\text{EtA}'')_2$ .— $\text{Cu}(\text{EtA}'')_2$  6aq. Blue silky efflorescent needles.— $\text{AgHA}''$ . Prisms.

**Di-ethyl ether Et<sub>2</sub>A''**. (280° i.v.). (233° cor. at  $197\text{ mm.}$ ). S.G.  $\frac{15}{15} 1.2097$ ;  $\frac{25}{25} 1.2019$ .  $[\alpha]_D = 9$  at  $18^\circ$  (Anschütz a. Pictet, *B.* 13, 1176);  $7.23$  at  $12^\circ$ ;  $8.02$  at  $20^\circ$  (Perkin, *C. J.* 51, 868). M.M.  $8.766$  at  $14.8^\circ$ . Liquid miscible with water (Demondèsir, *A.* 80, 301). Sodium forms  $\text{CO}_2\text{Et.CH}(\text{ONa}).\text{CH}(\text{OH}).\text{CO}_2\text{Et}$  and  $\text{CO}_2\text{Et.CH}(\text{ONa}).\text{CH}(\text{ONa}).\text{CO}_2\text{Et}$ , the latter being converted by  $\text{EtCl}$  into a deposit and a liquid, part of which is soluble in alcohol and ether and part insoluble in alcohol and ether (Mulder, *R. T. C.* 8, 375; 9, 238; 10, 171; cf. Cohn, *B.* 20, 2003). The soluble product mixed with alcoholic  $\text{CuCl}_2$  and poured into water forms

a pp. crystallising in light-green needles, sol. alcohol and ether, insol. water and  $\text{CuCl}_2\cdot\text{H}_2\text{O}$ . Tartaric ether is converted by treatment with gaseous  $\text{HCyO}$  into allophanyl-tartaric ether  $\text{NH}_2\cdot\text{CO.NH.CO.O}(\text{C}_2\text{H}_4\text{EtO})_2$  [188°], which is m. sol. hot water and alcohol.

**Acetyl derivative of the ether**  
 $\text{CO}_2\text{Et.CH}(\text{OAc}).\text{CH}(\text{OH}).\text{CO}_2\text{Et}$ . Formed from the ether and  $\text{AcCl}$ , the mixture becoming hot (Perkin, *C. J.* 20, 145). Heavy oil, sl. sol. water, insol. saline solutions. Neutral to litmus.

**Di-acetyl derivative of the ether**  
 $\text{CO}_2\text{Et.CH}(\text{OAc}).\text{CH}(\text{OAc}).\text{CO}_2\text{Et}$ . [67°]. (298°) (Pictet, *B.* 14, 2790); (230° at  $100\text{ mm.}$ ). Formed by heating tartaric ether with  $\text{AcCl}$  at  $100^\circ$  (Perkin; Wislicenus, *A.* 129, 187). Prisms (from water), v. sl. sol. water. Slowly saponified by  $\text{KOH}$  aq.

**Acetyl-benzoyl derivative of the ether**  
 $\text{CO}_2\text{Et.CH}(\text{OAc}).\text{CH}(\text{OBz}).\text{CO}_2\text{Et}$ . Formed by heating the mono-benzoyl derivative of the ether with  $\text{AcCl}$  at  $150^\circ$  (Perkin). Heavy oil.

**Mono-benzoyl derivative of the ether**  
 $\text{CO}_2\text{Et.CH}(\text{OH}).\text{CH}(\text{OBz}).\text{CO}_2\text{Et}$ . [64°]. Formed by heating the ether with  $\text{BzCl}$  at  $100^\circ$ . Prisms, sl. sol. hot aq. Saponified by alcoholic potash yielding  $\text{C}_2\text{H}_4(\text{OH})(\text{OBz})(\text{CO}_2\text{Et}).\text{CO}_2\text{K}$ ,  $\text{C}_2\text{H}_4(\text{OH})(\text{OBz})(\text{CO}_2\text{K})_2$ , and finally, potassium tartrate.  $\text{C}_2\text{H}_4(\text{OH})(\text{OBz})(\text{CO}_2\text{Et}).\text{CO}_2\text{H}$  forms tufts of needles, sl. sol. water.

**Di-benzoyl derivative of the ether**  
 $[\alpha]_D = -60^\circ$  (Phillips a. Guye, *C. R.* 110, 716).

**Di-n-propyl ether Pr<sub>2</sub>A''**. (303° i.v.). S.G.  $1.1392$ .  $[\alpha]_D = 13.77$  at  $18^\circ$  (A. a. P.);  $= 12.44$  (P. a. G.).

**Di-isopropyl ether Pr<sub>2</sub>A''**. (275°). S.G.  $1.130$ .  $[\alpha]_D = 14.89$  at  $20^\circ$  (Pictet, *J.* 1882, 856). Liquid.

**Di-isobutyl ether (Pr.CH<sub>3</sub>)<sub>2</sub>A''**. [68°]. (324°). S.G.  $1.015$ .  $[\alpha]_D = 19.9^\circ$  (P.). Yields a dibenzoyl derivative  $[\alpha]_D = -42^\circ$ .

**Isoamyl ether (C<sub>4</sub>H<sub>9</sub>)<sub>2</sub>A''**. Formed by digesting tartaric acid (150 pts.) with isoamyl alcohol (88 pts.) at  $130^\circ$  (Balard, *A. Ch.* [3] 12, 309; Breunlin, *A.* 91, 314). Nodular mass, with very bitter taste.— $\text{KC}_2\text{H}_4\text{A}''$  aq. Crystalline.— $\text{NaC}_2\text{H}_4\text{A}''$ . Nodules.— $\text{Ba}(\text{C}_2\text{H}_4\text{A}'')_2$  2aq: pearly plates (from water).— $\text{Pb}(\text{C}_2\text{H}_4\text{A}'')_2$ .— $\text{Ca}(\text{C}_2\text{H}_4\text{A}'')_2$ .— $\text{AgC}_2\text{H}_4\text{A}''$ . Tufts of needles.

**Di-acetyl derivative C<sub>2</sub>H<sub>4</sub>O<sub>4</sub> i.e.**  
 $\text{CO}_2\text{H.CH}(\text{OAc}).\text{CH}(\text{OAc}).\text{CO}_2\text{H}$ .  $[\alpha]_D = -23.14$  (Phillips a. Guye, *C. R.* 110, 716). Formed slowly from the anhydride by the action of water. Hard deliquescent crystals (containing 8aq), melting at  $58^\circ$ . V. sol. water, alcohol, and ether, sl. sol. benzene. Levorotatory. Its salts form levorotatory solutions (Colson, *Bil.* [3] 7, 806; *C. R.* 114, 417). Converted into tartaric acid by hot  $\text{KOH}$  aq.— $\text{KHA}''$ : crystalline powder.— $\text{BaA}''$ : slender deliquescent needles.— $\text{CaA}''$ .— $\text{CuA}''$ .— $\text{AgA}''$ : white crystalline mass.—Ethylene-diamine salt  $\text{C}_2\text{H}_4\text{O}_4(\text{N}_2\text{H}_4\text{C}_2\text{H}_4)$ . Levorotatory. V. sol. water.

**Anhydride of the di-acetyl derivative C<sub>2</sub>H<sub>4</sub>O<sub>4</sub>**. [127°]. Formed by heating tartaric acid with  $\text{AcCl}$  (Ballik, *Sitz.* W. 29, 26; Pilz, *Sitz. W.* 44 [2] 7; Perkin, *C. J.* 20, 149). Slender needles (from benzene). Dextrorotatory.

**Benzoyl derivative C<sub>2</sub>H<sub>4</sub>O<sub>4</sub> i.e.**  
 $\text{CO}_2\text{H.CH}(\text{OH}).\text{CH}(\text{OBz}).\text{CO}_2\text{H}$ . Formed by heating tartaric acid with benzoic acid at  $150^\circ$ .

(Dessaignes, *J. Ph.* [3] 82, 47). Minute crystals, v. sol. water, sl. sol. alcohol.— $\text{Ag}_2\text{A}'$ : white pp.

*Di-benzoyl derivative*  $\text{C}_{10}\text{H}_8\text{O}_6$  i.e.  $\text{CO}_2\text{H}.\text{CH}(\text{OBz})_2.\text{CH}(\text{OBz})_2.\text{CO}_2\text{H}$ . [90°].

$[\alpha]_D = -116^\circ$  in alcohol. Formed by dissolving its anhydride in hot water. Needles (containing aq). Converted by heat into a crystalline substance melting at  $132^\circ$ .

*Anhydride*  $\text{C}_4\text{H}_2\text{O}_5$ . [174°].  $[\alpha]_D = 143^\circ$  in acetone at  $18^\circ$ . Formed by heating tartaric acid with  $\text{BzCl}$ . Small needles, insol. cold water, sol. alcohol, benzene, and alkalis. Dextrorotatory.

*Di-nitroxy-derivative*  $\text{CO}_2\text{H}.\text{CH}(\text{NO}_2).\text{CH}(\text{NO}_2).\text{CO}_2\text{H}$ . *Nitrotartaric acid*. Formed by dissolving tartaric acid (1 pt.) in  $\text{HNO}_3$  (4½ pts.) and stirring with an equal volume of  $\text{H}_2\text{SO}_4$  (Dessaignes, *A.* 82, 362; 89, 339). The crystals are dried and crystallised from ether (Kukulic, *A.* 221, 245). Silky prisms, decomposed by hot water, forming oxalic and tartronic acids,  $\text{CO}_2$ , and  $\text{NO}$ . Alcohol containing  $\text{HNO}_3$  forms di-oxy-tartaric acid. Ammonium sulphide reduces it to tartaric acid.— $(\text{NH}_4)\text{HA}'$ .— $\text{Ag}_2\text{A}'$  aq. V. sol. water.— $\text{Et}_2\text{A}'$ . [46°]. S.G. 1.278. Formed by dissolving tartaric ether in a mixture of  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$ , and ppg. with water.

*Amide*  $\text{C}_4\text{H}_5\text{O}_5(\text{CC NH}_2)_2$ . Formed by passing  $\text{NH}_3$  into an alcoholic solution of the ether, or of its di-acetyl derivative (Demondésir, *A.* 80, 303; Pasteur, *C. R.* 35, 176; Grote, *C.* 130, 202; Ruhemann, *B.* 20, 3366). Trimetric crystals (from water), v. c. sol. water. Dextrorotatory.

*Amic acid*  $\text{C}_4\text{H}_5\text{NO}_5$  i.e.  $\text{CO}_2\text{H}.\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CO.NH}_2$ . Formed by passing  $\text{NH}_3$  over tartaric anhydride moistened with alcohol (Laurent, *Compt. Chim.* 1845, 153). Formed also, together with tartaric acid, by heating tartaric ether with  $\text{NH}_4\text{Aq}$  at  $100^\circ$  (Grote). Syrup.— $\text{CaA}'$ ,  $\text{Caq}$ : tetrahedra, v. sol. water.— $\text{Pb}(\text{C}_4\text{H}_5\text{NO}_5)_2$ — $\text{BaA}'$ ,  $\text{Baq}$ .— $\text{EtA}'$ .

*Anilide*  $\text{C}_9\text{H}_7\text{O}_5(\text{CO.NHPh})_2$ . [250°]. Formed by boiling aniline with tartaric acid (Polikier, *B.* 24, 2959). Pearly scales, insol. water, sl. sol. other solvents. Yields mono-, di-, and tri-acetyl derivatives, melting at  $227^\circ$ ,  $216^\circ$ , and  $137^\circ$  respectively.

*Phenyl-amic acid*  $\text{C}_{10}\text{H}_9\text{NO}_5$  i.e.  $\text{CO}_2\text{H}.\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CO.NHPh}$ . [180°]. Formed by boiling the phenylimide with  $\text{NH}_4\text{Aq}$  (Arrpe, *A.* 93, 352). Plates, v. sol. water and alcohol.— $\text{BaA}'$ : spangles, m. sol. hot water.— $\text{AgA}'$ : white powder, v. sl. sol. water.

*Phenylimide*  $\text{C}_{10}\text{H}_9\text{NO}_4$  i.e.  $\text{CH}(\text{OH}).\text{CO} > \text{NPh}$ . [230°]. Formed, together with the anilide, by heating tartaric acid with aniline at  $150^\circ$ . Pearly plates, v. sol. water.

*Di-o-toluide*  $\text{C}_{12}\text{H}_9\text{O}_5(\text{CO.NH.C}_6\text{H}_4\text{Me})_2$ . [183°]. White plates, insol. water (Bischoff, *B.* 23, 2049).  $\text{Ac}_2\text{O}$  at  $140^\circ$  yields a di-acetyl compound [222°].

*Di-p-toluide*  $\text{C}_{12}\text{H}_9\text{O}_5(\text{CO.NH.C}_6\text{H}_4\text{Me})_2$ . [264°]. Got by heating *p*-toluidine with tartaric acid at  $185^\circ$ . Silky needles (from alcohol). Converted by  $\text{Ac}_2\text{O}$  into a di-acetyl derivative [202°].

*Hydrazide*  $\text{C}_4\text{H}_5(\text{OH})_2(\text{CO.NH.NH}_2)_2$ . [133°]. Formed from tartaric ether and hydra-

zine hydrate (Von Rothenburg, *B.* 26, 2057). Needles, sl. sol. alcohol. Converted by benzoic aldehyde into  $\text{C}_6\text{H}_5(\text{OH})_2(\text{CO.NH.CHPh})_2$  [225°], crystallising in yellowish plates (from alcohol).

*Levo-tartaric acid*

$\text{CO}_2\text{H}.\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CO}_2\text{H}$ . *Anti-tartaric acid*. [170°]. When a solution of racemic acid is divided into two equal parts and one is neutralised by ammonia and the other by soda, and the solutions mixed and allowed to evaporate, hemihedral crystals of  $\text{Na}(\text{NH}_4)\text{C}_4\text{H}_4\text{O}_6$  are obtained. Half of these crystals have the hemihedral faces oppositely situated to those of the other half; and on carefully selecting the two kinds of crystals (the solutions of which exhibit equal and opposite action on polarised light), ppg. their solutions by lead nitrate, and decomposing the lead salts by  $\text{H}_2\text{S}$  or  $\text{H}_2\text{SO}_4$ , solutions are obtained which on evaporation yield crystals, the one of dextro- and the other of levo-tartaric acid (Pasteur, *A. Ch.* [3] 28, 66). If in a solution of sodium ammonium racemate of S.G. 1.226 a crystal of the dextro- salt be put on one side and one of the levo- salt be put on the other side of the vessel, the two salts will crystallise separately (Jungfleisch, *J. Ph.* [5] 5, 346). The separation of sodium ammonium racemate into the dextro- and levo-tartrates does not take place if the solution is heated to  $118^\circ$  in a sealed tube and allowed to crystallise without access of air (Bichat, *B.* [2] 46, 64). According to Wyruboff (*C. R.* 102, 637), the splitting up of the sodium ammonium racemate depends upon strength of solution and temperature only.

Levo-tartaric acid is exactly like dextro-tartaric acid in solubility and S.G. Its crystals are like the reflection of those of the dextro-acid. The two acids are oppositely pyro-electric. Solutions of the levo- acid exhibit an effect on light equal and opposite to that produced by solutions of the dextro- acid of like strength. When conc. solutions of equal quantities of the dextro- and levo- acids are mixed, heat is given out and racemic acid separates. The salts of the levo-tartaric acid have the same amount of water of crystallisation, and the same crystalline form as the salts of dextro-tartaric acid. They exhibit opposite hemihedry, opposite rotation, and are oppositely pyro-electric. Differences are observed between the compounds of the two acids with optically active substances. Acid ammonium (active) malate combines with acid ammonium dextro- (but not levo-) tartrate. Cinchonine levo-tartrate  $\text{C}_{19}\text{H}_{22}\text{N}_2\text{O}_6\text{H}_2\text{O}_4$  contains aq, while the dextro-tartrate contains 4aq.

*Di-methyl-ether*  $\text{Me}_2\text{A}'$ . [48°]. (160° at 16 mm.). Levorotatory (Anschütz, *B.* 18, 1398; *A.* 247, 112).

*Di-acetyl derivative of the di-methyl ether*

$\text{CO}_2\text{Me}.\text{CH}(\text{OAc}).\text{CH}(\text{OAc}).\text{CO}_2\text{Me}$ . [103°].  $[\alpha]_D = -1.3$  (in a 3.6 p.c. solution in alcohol of S.G. 826). Formed by heating  $\text{Me}_2\text{A}'$  with  $\text{AcCl}$ . Monoclinic plates (from benzene);  $a:b:c = 1.052:1:0.07$ ;  $\beta = 87^\circ 54'$ . On mixing with the corresponding dextro-compound it forms the isomeric racemic compound [86°].

*Amide*  $\text{C}_4\text{H}_5\text{O}_5(\text{NH}_2)_2$ . Combines with the amide of active malic acid, forming needles, S. more than 33.

**Racemic acid**  $C_4H_4O_6$ . *Paratartaric acid*. [206°] (Blaschhoff, B. 22, 1812). S.G. (of  $H_2A''$ ) 1.778; (of  $H_2A''$  aq) 1.687 (Parker, C. J. 51, 366). S. (of  $H_2A''$ ) 8.16 at 0°; 18 at 20°; 187.8 at 100°. S. (of  $H_2A''$  aq) 9.23 at 0°; 20.6 at 20°; 184.9 at 100° (Liedie, C. R. 95, 87). Heat of solution at 9°: -5675 (for  $H_2A''$ ); -7065 (for  $H_2A''$  aq) (Pickering, C. J. 51, 367). H.C. (for  $H_2A''$ ) 1,851,190 (Ossipoff, C. R. 108, 1105). H.F. (for  $H_2A''$  aq) 278,400. Acid potassium racemate either occurs sometimes in crude argol, or is produced therefrom in the purification processes (Kestner; Jungfleisch, C. R. 85, 805). On crystallisation of cream of tartar, acid potassium racemate remains in the mother-liquor.

**Constitution.**—Assuming racemic acid to be a compound of the dextro- and lævo-tartaric acids, its formula must be at least  $(C_4H_4O_6)_2$ .

**Formation.**—1. By mixing solutions of dextro- and lævo-tartaric acids.—2. By heating tartaric acid (30 g.) with water (4 c.c.) for 30 hours at 175° (Jungfleisch, B. [2], 18, 203).—3. By heating the dextro- or lævo-tartrate of quinine or cinchonine at 170° (Pasteur, A. 72, 164; 84, 157; 88, 211).—4. By heating tartaric ether.—5. By heating inactive tartaric acid at 200° or by boiling it with  $HCl$  aq (Dessaignes, B. 1865, i. 34).—6. By oxidation of fumaric acid by aqueous  $KMnO_4$  (Kekulé a. Anschütz, B. 18, 2150; A. 226, 191; cf. Tanatar, B. 12, 2293). 7. By the action of  $HNO_3$  on levulose, mucic acid, and inulin; and, together with tartaric acid, by the action of  $HNO_3$  on milk sugar, cane sugar, saccharic acid, dulcitol, and mannite (Carlet, *Rép. Chim. pure*, 2, 345; 4, 17; Hornemann, J. pr. 89, 283).—8. Together with inactive tartaric acid by boiling silver di-bromo-succinate with water (Perkin a. Duppa, C. J. 13, 102; Pasteur, A. *Suppl.* 2, 242; Jungfleisch, B. [2] 19, 198).—9. By boiling silver iso-di-bromo-succinate with water (Demuth a. Meyer, B. 21, 268). 10. By boiling glyoxal with dilute  $HCl$  and  $HCl$  (Schöyen, A. 132, 168; Strecker, Z. [2] 4, 216).—11. By the action of zinc-dust (2 mols.) and dilute  $HOAc$  (3 mols.) on glyoxylic acid (1 mol.) at 100° (Genyviessé, B. [3] 7, 225; C. R. 114, 555).—12. From piperic acid, sorbic acid, and  $CHO.CH:CH.CH:CH.CO_2H$  by careful oxidation with dilute  $KMnO_4$  below 4° (Doeberner, B. 28, 2374).—13. By heating a solution of desoxalic acid (Löwig, J. 1861, 605; Klein, J. pr. [2] 20, 157).

**Preparation.**—Sodium ammonium racemate, got from the mother-liquor from which cream of tartar has separated, is treated exactly in the same way as cream of tartar in the preparation of tartaric acid. The small opaque needles of racemic acid can be separated by handpicking from the large, transparent crystals of tartaric acid.

**Properties.**—Triclinic crystals (containing aq);  $a:b:c = 484:1:806$ ;  $\alpha = 120^\circ$ ;  $\beta = 96^\circ 15'$ ;  $\gamma = 78^\circ 5'$  (De la Provostaye, A. Ch. [3] 8, 131). Slightly efflorescent. Gives off aq at 100°. Less soluble than tartaric acid. In dilute solutions of racemic acid the lowering of the freezing-point is the same as with an equal weight of tartaric acid (Raoult, Z. Ph. 2, 186). Absorption of a solution of racemic acid by filter paper does not separate the dextro- and lævo-acids (March-

lewski, B. 26, 988). A solution of racemic acid is pptd. by  $CaSO_4$  (unlike tartaric acid). Calcium racemate is insol. acetic acid (unlike calcium tartrate).  $NH_4Cl$  does not hinder the pptn. of calcium racemate. When heated above 200° racemic acid yields the same products as tartaric acid. By various ferments (e.g. *Penicillium glaucum*) racemic acid, when free or as acid ammonium salt, is converted into tartaric acid (Pasteur; cf. E. Mulder, R. T. C. 1, 231). A solution in  $HNO_3$  (S.G. 1.52) poured into half its volume of  $H_2SO_4$  deposits the crystalline  $C_4H_4(O.NO_2)_2(CO_2H)_2$  (Dessaignes, J. Ph. [3] 32, 46).  $AcCl$  converts racemic acid into di-acetyl-racemic anhydride  $C_4H_2(OAc)_2C_2O_2$  [123°]. Racemic acid and its salts are inactive to light.

**Salts** (Fresenius, A. 41, 1; 53, 230).— $(NH_4)_2A''$ . Trimetric prisms;  $a:b:c = 509:1:847$ . V. sol. water, nearly insol. alcohol. Give off  $NH_3$  in air.— $(NH_4)HA''$ . S. 1 at 20°; less sol. boiling water. Monoclinic prisms. Reddens litmus.— $KA''$  2aq. Six-sided tables. S. 103 at 25°. Nearly insol. alcohol.— $KHA''$ . S. 55 at 19°; 7 at 100°. Insol. alcohol.— $K(NH_4)A''$ . Striated prisms.— $Na_2A''$ . S. 38 at 25°. Trimetric prisms. Insol. alcohol.— $NaHA''$  aq. S. 9 at 19°. Monoclinic prisms (from water). Ppd. from aqueous solution by addition of alcohol.— $Na(NH_4)A''$  aq. S.G. 1.746 (Wyruboff, A. Ch. [6] 9, 229).— $NaKA''$  4aq. S. 47 at 6° (Fresenius, A. 53, 230).— $NaKA''$  3aq. Monoclinic crystals (Wyruboff, A. Ch. [6] 9, 232).— $RbA''$ .— $CaA''$  4aq. Acicular prisms (Anschütz, A. 226, 191).— $BaA''$  2aq. S. 0.5. Crystalline pp.— $SrA''$  4aq.— $TlA''$  (De la Provostaye, A. 126, 79).— $LiTlA''$  2aq (Wyruboff).— $NaTlA''$  2aq. S. 25 at 25°.— $MgA''$  5aq. S. 85 at 19°.— $CdA''$  (Schiff, A. 104, 326).— $PbA''$  (dried at 100°).— $Pb_2C_4H_4O_6$  (Krug, J. 1861, 367).— $CuA''$  2aq. Pale-blue needles, sol. alkalis and solution of  $Na_2CO_3$ .— $Na_2CuC_4H_4O_6$  4aq.— $MnA''$  aq.— $NiA''$  5aq.— $NH_4(AsO_4)A''$  4aq. S. 9.4 at 15°. Efflorescent crystals.— $K(AsO_4)A''$  1aq. S. 18 at 16°. Decomposed by hot water with liberation of  $As_2O_3$ .— $Na(AsO_4)A''$  2aq. S. 7 at 19°. Non-efflorescent white crystals (Werther, J. pr. 32, 385).— $K(SbO_4)A''$  1aq. Monoclinic prisms.— $AgA''$ . Shining scales, less sol. aq. than silver tartrate.

**Mono-methyl ether**  $MeHA''$ . Formed by evaporating racemic acid with  $MeOH$  (Guérin-Varry, A. Ch. [2] 62, 77; A. 22, 252). Rectangular prisms, v. a. sol. cold water. Decomposed by hot water into the parent substances.— $KMeA''$  3aq. Prisms.— $Ba(MeA'')$  4aq. Monoclinic prisms.— $AgMeA''$ . Pp.

**Di-methyl ether**  $Me_2A''$ . [85°]. (282° i.v.). Formed by methylation of racemic acid, and also by mixing equal weights of the di-methyl ethers of the lævo- and dextro-tartaric acids (Anschütz a. Pictet, B. 13, 1178; 18, 1397; A. 247, 116). Monoclinic crystals; optically inactive. Yields a di-acetyl derivative  $C_4H_2(OAc)_2(CO_2Me)_2$  [86°] in trimetric crystals;  $a:b:c = 809.5:1:6728$ . This compound, examined by Raoult's method, has the same molecular weight as the di-acetyl derivative of di-methyl tartrate.

**Mono-ethyl ether**  $EtHA''$ . Deliquescent prisms, v. sol. alcohol. Inactive to light.— $KEtA''$  aq.— $Ba(EtA'')$  2aq.— $AgEtA''$ . Prisms.

**Di-ethyl ether Et.A.** (238° cor. at 197 mm.) S.G.  $\frac{1}{4}$  1.2098;  $\frac{3}{4}$  1.2021. M.M. 8.759 at 15.5° (Perkin, C. J. 61, 364). Yields an oily acetyl derivative and a di-acetyl derivative  $C_4H_4(OAc)_2(CO_2Et)_2$ , [51°] (230° at 100 mm.). BzCl forms  $C_4H_4(OH)(OBz)(CO_2Et)_2$ , [57°]. The compound  $C_4H_4(OEt)_2(CO_2Et)_2$ , (147° at 15 mm.) is formed from di-bromo-succinic ether [58°] and NaOEt (Michael, J. pr. [2] 46, 234).—Ag.A.—AgHA". Monoclinic, *a:b:c* = 721:1:869;  $\beta$  = 70° 10'.

**Inactive tartaric acid**  
 $GO_2H.CH(OH).CH(OH).CO_2H$ . *Mesotartaric acid*. [140°–143°]. S. 125° at 15°.

**Formation.**—1. By heating cinchonine tartrate or racemate for several hours at 170° (Pasteur, A. 88, 212). The product is mixed with  $CaCl_2$ , which ppts. calcium racemate, and the filtrate slowly deposits calcium inactive tartrate.—2. By boiling tartaric acid or racemic acid for 400 hours with HClAq (Dessaignes; Pasteur, Bl. 1862, 107).—3. By heating tartaric acid (30 g.) or racemic acid with water (4 c.c.) for 2 days at 165°. Separated by means of its very soluble acid K salt (Jungfleisch, Bl. [2] 19, 101).—4. A product of the action of  $HNO_3$  on sorbin (Dessaignes, C. R. 55, 769), erythrite (Przybytek, B. 17, 1412; Bl. [2] 43, 126) and glycerin.—5. By oxidation of levulose, (Kiliani, B. 14, 2530).—6. By oxidation of phenol by alkaline  $KMnO_4$  at 0° (Doeberner, B. 24, 1755).—7. A product of the action of moist  $Ag_2O$  on di-bromo-succinic acid. 8. By the action of nitrous acid on di-amido-succinic acid (Lehrfeld, B. 14, 1819).—9. By oxidation of malic acid by alkaline  $KMnO_4$ , (Kekulé a. Anschütz, B. 14, 713).

**Properties.**—Prisms (containing aq). Loses its aq at 100°; at 200° it yields pyrotartaric and racemic acids. Prolonged boiling with HCl aq converts it into racemic acid (Dessaignes). The conversion is also effected by heating the acid with a little water at 175°. The ether is converted by  $AcCl$  into  $C_4H_4(OAc)_2(CO_2Et)_2$ , [48°], crystallising in silky needles.

**Salts KHA".** Needles. S. 12.5° at 19°.—RbHA" ¼aq. —Rb.A" aq. —RbNaA" 2¼aq. —CaA" 3aq. S. 17° at 100°. S. (HOAc) .028 at 18°; .085 at 100°.—PbA" aq: amorphous pp.—ZnA" 2aq (dried at 110°).—THA".—TlA".—NaTlA" 2¼aq.—AgA" aq: white pp.

**Metatartaric acid**  $C_4H_4O_8$ . A deliquescent, glassy mass, v. sol. water, obtained by melting tartaric acid (Braconnot, A. Ch. [2] 68, 239; Erdmann, A. 21, 9; Laurent a. Gerhardt, A. 70, 848). It is sometimes formed when a solution of tartaric acid is evaporated over a water-bath (Grosjean, C. J. 43, 334). Converted by boiling water into tartaric acid.

**Salts.**— $(NH_4)HA"$ . Minute needles. More soluble than the acid ammonium tartrate. Its solution is ppd. by  $CaCl_2$  and  $NH_3$  aq only when highly concentrated. CaA" 4aq. Minute lenticular grains, sol. dil. HClAq, converted by boiling water into calcium tartrate.

**Ditartaric acid**  $C_4H_4O_{11}$ . An anhydride of tartaric acid, got by heating tartaric acid at 170° till it is no longer ppd. by lime-water (Fromy, A. 19, 197; 29, 142; 78, 297). Amorphous and very deliquescent. Sol. alcohol, insol. ether. Its salts are amorphous, v. sol. water, and ppd.

by alcohol. They are converted into metatartarates, and finally into tartrates, by boiling water.—CaA".—BaA".—PbA".—CuA".—AgA". V. sol. water (Schiff, A. 126, 129).

**Ethyl ether Et.A.** Fat-like solid.

**Tartrellic acid**  $C_4H_4O_6$ . **Soluble tartaric anhydride.** Formed by quickly heating small quantities of tartaric acid till the fused mass swells up. Yellowish deliquescent mass, sol. water, forming an acid solution, from which  $CaCl_2$  ppts. CaA", as an amorphous mass, which becomes crystalline on adding alcohol. Tartrellic acid is converted into tartaric acid by boiling water.

**Insoluble tartaric anhydride**  $C_4H_4O_6$ . Formed by heating tartaric acid for some time at 150° and exhausting the product with cold water. Powder, insol. water, alcohol, and ether. Converted by hot water into tartaric acid.

**TARTRONIC ACID**  $C_4H_4O_6$ , i.e.

$CH(OH)(CO_2H)_2$ . **Oxy-malonic acid.** Mol. w. 120. [187°]. Heat of solution -4331 (Gal a. Werner, Bl. [2] 46, 803).

**Formation.**—1. By spontaneous decomposition of nitro-tartaric acid in aqueous solution (Dessaignes, C. R. 34, 731; 38, 44).—2. By the reduction of mesoxalic acid by sodium-amalgam (Bayer, J. 1864, 611).—3. By the action of  $Ag_2O$  on bromo-malonic acid (Petrieff, B. 11, 414).—4. By boiling chloro-malonic ether with KOHAq, the yield being 25 p.c. of the theoretical amount (Conrad a. Bisehoff, A. 209, 222).—5. From di-bromo-pyruvic acid and baryta-water at 40° (Grimaux, B. 10, 903).—6. From glyoxylic acid by treatment with  $KCO_3$ , the resulting nitrile being saponified (Böttlinger, B. 14, 729).—7. A product of the action of alkaline cupric solution on glucose (Claus, Z. [2] 5, 152; A. 147, 114).—8. By slow oxidation of glycerin (Sadler, B. 8, 1456; Campani a. Bizzari, G. 12, 1).—9. By heating sodium carboxy-tartronate (Gruber, B. 12, 514).

**Preparation.**—1. By boiling the di-nitrate of tartaric acid (20 g.) with alcohol (60 g. of S.G. .925) (Demole, B. 10, 1778).—2. By warming tri-chloro-lactic ether  $CCl_3CH(OH).CO_2Et$  with a 10 p.c. solution of NaOHAq (5 mols.), neutralising with HOAc and ppg. with  $BaCl_2$  (Pinner B. 18, 752, 2852).

**Properties.**—Prisms (containing ¼aq), v. sol. water and alcohol, sl. sol. ether. After drying at 100° it loses its water of crystallisation and becomes v. sol. ether. Massol (C. R. 114, 422) obtained anhydrous crystals [155°]. Decomposed by fusion, yielding  $CO_2$  and glycolide  $C_4H_4O_4$ . Reduced by HIAq to malonic acid.

**Salts.**— $Na_2A"$  (dried at 100°). V. sol. water. — $K_2A"$  aq. — $(NH_4)_2A"$ . Needles. — $(NH_4)HA"$ . Yields glycollic amide on heating. —BaA" 2aq. Micro-crystalline powder, v. sl. sol. water (Pinner). —BaA" aq (G.). —CaA" 2¼aq (P.). —CuA" aq (C. a. B.). —CdA". —PbA" (dried at 120°). —MnA". —AgA". Needles (from hot Ag).

**Ethyl ether Et.A.** (c. 224°). Heavy oil (Freund, B. 17, 786; Pinner).

The acetyl derivative  $CH(OAc)(CO_2Et)_2$ , (c. 161° at 60 mm.), S.G.  $\frac{1}{10}$  1.131, is formed from bromo-malonic ether and KOAc in EtOH at 50° (Conrad a. Brückner, B. 24, 2997). Br converts it into mesoxalic ether  $C(OH)_2(CO_2Et)_2$ , [57°].

**Amide**  $\text{CH}(\text{OH})(\text{CO.NH}_2)_2$ . [196°]. Six-sided plates, m. sol. hot water.

**Amic acid**  $\text{CO}_2\text{H.CH}(\text{OH}).\text{CO.NH}_2$ . [160°]. Formed by boiling sodium dialurate with water (Menschutkin, A. 182, 82). Needles, sl. sol. cold water. Converted by nitrous acid into glycollic acid.— $\text{KA}'\text{aq.}$ — $\text{BaA}'\text{aq.}$ — $\text{PbA}'\text{aq.}$  Needles, v. sol. hot water.— $\text{AgA}'$ . Needles.

**Phenyl derivative**  $\text{CH}(\text{OPh})(\text{CO}_2\text{H})_2$ . Formed by saponification of its ether  $\text{CH}(\text{OPh})(\text{CO}_2\text{Et})_2$ , (230°–240° at 60 mm.), which is got from bromo-malonic ether, phenol, and  $\text{NaOEt}$  (C. a. B.). At 196° it forms  $\text{CH}_2(\text{OPh}).\text{CO}_2\text{H}$ .

**TARTRONYL-UREA** v. **DIALURIC ACID**.

**TAURINE**  $\text{C}_2\text{H}_5\text{NSO}_3$ , i.e.

$\text{CH}_2(\text{NH}_2).\text{CH}_2.\text{SO}_3\text{H}$ . **Amido-ethane sulphonic acid**. Mol. w. 125. S. 6.5 at 12°. I.P. 185,700 (Berthelot a. Matignon, A. Ch. [6] 22, 182). Obtained by the action of acids and alkalis on taurocholic acid (Gmelin, *Tiedemann a. Gmelin's Die Verdauung*, 1, 43; Domarçay, A. 27, 286; Dumas a. Polouze, A. 27, 292; Reitenbacher, A. 57, 170; Strecker, A. 65, 132; 67, 34; 91, 101). Occurs in the free state in putrid bile and in the muscles of the oyster, in shark's blood, in the liver, spleen, and kidneys of the ray, and in the lungs of oxen (Valenciennes a. Frey, C. R. 41, 735; Städeler a. Frerichs; Clöetta, A. 99, 289). Formed also by heating  $\beta$ -chloro-ethane sulphonic acid with  $\text{NH}_4\text{Aq}$  at 100° (Kolbe, A. 122, 33), and by the action of  $\text{SO}_3$  on vinylamine (Gabriel, B. 21, 2667). Prepared by evaporating ox-bile with dilute  $\text{HCl}$  at 100°, decanting from a resin, allowing to crystallise, and re-crystallising from water. It may be purified by means of the lead salt.

**Properties**.—Transparent crystals, m. sol. water, insol. alcohol. Neutral to litmus. Not melted below 240°. Converted by nitrous acid into isethionic acid (Gibbs, Am. S. [2] 25, 80). Decomposed by potash-fusion.

**Salts**.— $\text{NaA}'$ . Very deliquescent (Lang, *BZ* [2] 25, 180).— $\text{CaA}'_2$ . Slender needles, v. c. sol. water.— $\text{PbA}'_2$ . Needles, v. c. sol. water.— $\text{Pb}_2\text{A}'_3(\text{OH})_2$ .— $\text{CdA}'_2$ .— $\text{Hg}_2\text{A}'_2$ .— $\text{Hg}_2\text{A}'_2\text{O}$  (Engel, *BZ* [2] 23, 532).— $\text{AgA}'$ .

**Benzoyl derivative**  $\text{NHBz.C}_2\text{H}_4.\text{SO}_3\text{H}$ . Formed by heating  $\mu$ -phenyl-thiazole tetrahydride with  $\text{HCl}$  and bromine-water (Gabriel a. Heymann, B. 23, 159). Syrup.— $\text{AgA}'$ . Spherical groups of plates.

**Phthalyl derivative**  $(\text{C}_6\text{H}_4\text{O}_2):\text{N.CH}_2.\text{CH}_2.\text{SO}_3\text{H}$ . Got by oxidising di-phthalimido-di-ethyl-disulphide with  $\text{HNO}_3$  (S.G. 1.25) (Gabriel, B. 24, 1116). Crystals (containing  $\frac{1}{2}\text{aq}$ ), sol.  $\text{EtOAc}$ . Tastes bitter.

**Imide**  $\text{C}_2\text{H}_4\text{SO}_2$ . [45°–50°]. Prepared from  $\beta$ -chloro-ethane-sulphonic chloride  $\text{CH}_2\text{ClOCH}_2.\text{SO}_2\text{Cl}$  by treatment with ammonia (James, C. J. 49, 491). Solid, resembling gum arabic; bitter in taste. V. sl. sol. cold, v. sol. hot, water, insol. alcohol and ether. Ppd.  $\text{HgO}$  appears to form the compound  $(\text{C}_2\text{H}_4\text{SO}_2\text{N})_2\text{Hg}$ .

**Ethyl-taurine** v. **ETHYL-AMIDO-ETHANE SULPHONIC ACID**.

**Methyl-taurine** v. **METHYL-AMIDO-ETHANE SULPHONIC ACID**.

**TAUROCHENOCHOLIC ACID**  $\text{C}_{26}\text{H}_{45}\text{NSO}_6$ . Occurs as K and Na salts in goose-bile (Heintz

a. Wislicenus, P. 108, 547; Otto, A. 149, 192). Amorphous, sol. water and alcohol. Decomposed by boiling with baryta or potash into taurine and chenochoic acid.— $\text{NaA}'\text{aq}$  (dried at 110°). Small tables. Its aqueous solution gives pps. with  $\text{CaCl}_2$ ,  $\text{AgNO}_3$ , and lead subacetate, but not with lead acetate.

**TAUROCHOLIC ACID**  $\text{C}_{26}\text{H}_{45}\text{NSO}_6$ . Occurs as Na salt in the bile of most animals (Strecker, A. 67, 30; 70, 169; Hüfner, J. pr. [2] 19, 302; Copeman a. Winston, J. Physiol. 10, 213). Obtained by ppg. with lead acetate, filtering from lead glycocholate, and ppg. lead taurocholate by lead subacetate. Deliquescent silky needles, v. sol. water and alcohol, m. sol. ether. Dextrorotatory,  $[\alpha]_D^{25} = 25^\circ$  (Hoppe-Seyler, *Arch. Path. Anal.* 15, 126). Boiling water splits it up into taurine and cholic acid. Antiseptic, and ppts. albumen completely from its solutions (Maly, M. 4, 89).

**Salts**.— $\text{NaA}'$  (dried at 120°). Ppd. by alcohol in an amorphous state, rendered crystalline by ether.— $\text{KA}'$ . Needles, resembling wavelite.

**TAUROCYAMINE**  $\text{C}_2\text{H}_5\text{NSO}_3$ , i.e.  $\text{NH}_2\text{C}(\text{NH}_2).\text{NH}.\text{CH}_2.\text{CH}_2.\text{SO}_3\text{H}$ . [226°]. S. 4 at 21°. Formed by heating taurine with cyanamide (1 mol.) and water at 110° (Engel, B. 8, 1597; Dittrich, J. pr. [2] 18, 63). Small white prisms, v. sol. water, insol. alcohol and ether. From cold water it crystallises with  $\text{aq}$ .

**TAXINE**  $\text{C}_{22}\text{H}_{35}\text{NO}_{10}$ . [82°]. Obtained from the leaves, twigs, and fruit of the yew (*Taxus baccata*) by extracting with ether (Lucas, *Ar. Ph.* [2] 85, 145; Van der Harst, R. T. C. 3, 279; Marmé, *Bl.* [2] 26, 417; Hilger a. Brande, B. 23, 464). The ethereal solution is quickly shaken with acidulated water, and the solution ppd. by  $\text{NH}_4\text{Aq}$ . Crystalline. Gives off aromatic fumes on melting. V. sl. sol. water, v. sol. alcohol and ether, insol. benzene. Conc.  $\text{H}_2\text{SO}_4$  gives a deep purple; Fröhde's reagent a reddish-violet colour. Gives yellow pps. with sodium phosphomolybdate, I in KI, and potassium bismuth iodide. Insol. alkalis. The salts crystallise with difficulty.—**Salts**:  $\text{B}'\text{HCl}$ .— $\text{B}'_2\text{H}_2\text{SO}_4$ .— $\text{B}'_3\text{H}_2\text{PtCl}_6$ .— $\text{B}'_2\text{H}_2\text{AuCl}_4$ .— $\text{B}'\text{EtH}$ .

**TECTOQUINONE**. [171°]. Obtained from teak resin or by the distillation of teak wood (Romanis, C. J. Proc. 4, 116). Amber-yellow crystals, sol. alcohol. Reduced by zinc-dust and  $\text{HIOAc}$  to  $\text{C}_{16}\text{H}_{22}$ . Yields a nitro-derivative and a bromo-derivative [165°].

**TELLURATES**. Salts of telluric acid,  $\text{H}_2\text{TeO}_4$  (q.v., p. 643). The normal tellurates of monovalent metals have the composition  $\text{M}_2\text{TeO}_4.x\text{H}_2\text{O}$ ; there are also acid tellurates  $\text{MHTeO}_4.x\text{H}_2\text{O}$ ; and two classes of tetratellurates, (1)  $\text{M}_2\text{Te}_4\text{O}_{13}.x\text{H}_2\text{O}$ , which are soluble in water when M is an alkali metal, and (2)  $\text{M}_2\text{Te}_4\text{O}_{13}$ , which are insoluble in water. The hydrated tetratellurates may be represented as acid ditellurates derived from the hypothetical acid  $\text{H}_2\text{Te}_2\text{O}_{11}$ ; thus  $\text{K}_2\text{Te}_4\text{O}_{13}.4\text{H}_2\text{O} = 2\text{KHTe}_2\text{O}_{11}.3\text{H}_2\text{O}$ . Some acid salts may be represented as derived from hypothetical ditelluric acid, e.g.

$\text{PbTe}_2\text{O}_{11}$  (=  $\text{PbTeO}_4.\text{TeO}_2$ ).

The normal alkali tellurates are obtained by saturating  $\text{H}_2\text{TeO}_4$  with  $\text{MOHAq}$  or  $\text{M}_2\text{CO}_3\text{Aq}$  and crystallising. Alkali acid tellurates, and hydrated tetratellurates, are obtained by inter-actions of acids with the normal tellurates; anhydrous (insoluble) tetratellurates of the alkali

metals are formed by heating the acid tellurates; thus  $6\text{KHTeO}_4 = \text{K}_2\text{Te}_2\text{O}_7 + 2\text{K}_2\text{TeO}_4 + 3\text{H}_2\text{O}$ . Most of the other tellurates are obtained from the alkali salts by double decomposition.

The alkali tellurates, other than those of the form  $\text{M}_2\text{Te}_2\text{O}_7$ , are soluble in water; most of the other tellurates are insoluble or sparingly soluble in water. Tellurates generally dissolve easily in  $\text{HClAq}$ ; the solutions are not ppd. by water, but on boiling the solutions become yellow, give off  $\text{Cl}$ , and then yield a pp. of  $\text{H}_2\text{TeO}_5$  on addition of water. Acidulated solutions of tellurates are slowly decomposed by  $\text{H}_2\text{S}$ , probably with ppn. of  $\text{TeS}_2$  (v. TELLURIUM SULPHIDES, p. 655). Solutions of tellurates are slowly reduced by  $\text{SO}_2$ , more quickly on heating, with separation of  $\text{Te}$ . When tellurates are heated to redness they give off  $\text{O}$  and form tellurites; heated with  $\text{K}_2\text{CO}_3$  and charcoal, they give  $\text{K}_2\text{Te}$ .

The tellurates have been examined chiefly by Berzelius (*P.* 32, 577); and some of them also by Oppenheim (*J. pr.* 71, 267).

**Potassium tellurates.** The normal salt  $\text{K}_2\text{TeO}_4$  is obtained by dissolving  $\text{H}_2\text{TeO}_5$  and  $\text{K}_2\text{CO}_3$  in the ratio  $\text{H}_2\text{TeO}_5:\text{K}_2\text{CO}_3$  in hot water and crystallising; also by dissolving  $\text{H}_2\text{TeO}_5$  in excess of  $\text{KOH}$ aq, heating, and allowing to cool slowly. Crystallises in rhombic prisms, isomorphous with  $\text{K}_2\text{SO}_4$  (Hundl, *J.* 1861, 266). The crystals become moist in air and form  $\text{KH}_2\text{TeO}_4$  aq and  $\text{K}_2\text{CO}_3$ . The acid salt  $2\text{KH}_2\text{TeO}_4$  aq separates on adding to  $\text{K}_2\text{TeO}_4$ aq sufficient  $\text{H}_2\text{SO}_4$ aq, or other strong acid, to remove half the potassium; the salt is crystallised from hot water. This salt is slightly soluble in cold water, but much more soluble in hot water; when heated it is converted into  $\text{K}_2\text{TeO}_4$  and  $\text{K}_2\text{Te}_2\text{O}_7$ . The tetratellurate  $\text{K}_2\text{Te}_2\text{O}_7$  is obtained, as a yellow powder, by heating  $2\text{KH}_2\text{TeO}_4$  aq below redness and washing out  $\text{K}_2\text{TeO}_4$  in water.  $\text{K}_2\text{Te}_2\text{O}_7$  is insoluble in water, also in  $\text{HClAq}$  or  $\text{HNO}_3$ aq except after prolonged boiling. The hydrated tetratellurate  $\text{K}_2\text{Te}_2\text{O}_7 \cdot 4\text{H}_2\text{O}$ —which may also be regarded as an acid ditellurate  $2\text{KH}_2\text{Te}_2\text{O}_7 \cdot 3\text{H}_2\text{O}$ —is formed by adding  $\text{H}_2\text{SO}_4$ aq, or another strong acid, to  $\text{K}_2\text{TeO}_4$ aq in quantity to remove  $6\text{K}$  from  $4\text{K}_2\text{TeO}_4$  ( $4\text{K}_2\text{TeO}_4\text{aq} + 3\text{H}_2\text{SO}_4\text{aq} = \text{K}_2\text{Te}_2\text{O}_7\text{aq} + 3\text{H}_2\text{O} + 3\text{K}_2\text{SO}_4\text{aq}$ ), and crystallising. The salt is fairly soluble in cold water; it is partly decomposed to  $\text{KHTeO}_4$  and  $\text{H}_2\text{TeO}_5$ aq by repeatedly crystallising in aqueous solution.

The following tellurates have been described (Berzelius, *l.c.*; Oppenheim, *l.c.*): **Ammonium salts**  $(\text{NH}_4)_2\text{TeO}_4$ ,  $(\text{NH}_4)_2\text{Te}_2\text{O}_7$ ,  $(\text{NH}_4)_2\text{Te}_2\text{O}_7$ , obtained by ppg. solutions of the corresponding salts of  $\text{K}$  or  $\text{Na}$  with  $\text{NH}_4\text{Cl}$ . **Barium salts**  $\text{BaTeO}_4$  aq,  $\text{BaH}_2(\text{TeO}_4)_2$  aq,  $\text{BaTe}_2\text{O}_7$ , obtained by ppn. **Cadmium salt**  $\text{CdTeO}_4$ , obtained by ppn. **Calcium salt**  $\text{CaTeO}_4$ , obtained by ppn. **Lead salts**  $\text{PbTeO}_4$ ,  $\text{PbTe}_2\text{O}_7$ ,  $\text{PbTe}_3\text{O}_{10}$ , by ppn; a basic salt is also said to exist. **Silver salts**  $\text{Ag}_2\text{TeO}_4$ , and several basic salts  $x\text{Ag}_2\text{O} \cdot y\text{TeO}_2$ . **Sodium salts**  $\text{Na}_2\text{TeO}_4$  aq,  $\text{NaHTeO}_4$  aq,  $\text{NaHTe}_2\text{O}_7$  aq, and  $\text{Na}_2\text{Te}_2\text{O}_7$ , obtained similarly to the potassium salts. Tellurates of  $\text{Al}$ ,  $\text{Cr}$ ,  $\text{Co}$ ,  $\text{Cu}$ ,  $\text{Fe}$ ,  $\text{Li}$ ,  $\text{Mg}$ ,  $\text{Mn}$ ,  $\text{Hg}$ ,  $\text{Ni}$ , and  $\text{Sr}$  have also been described, but only very superficially.

M. M. P. M.

**TELLURHYDRIC ACID  $\text{H}_2\text{Te}$ ; v. HYDROGEN TELLURIDES**, vol. ii. p. 727.

**TELLURIUM ACID  $\text{H}_2\text{TeO}_5$** ; crystallises from solutions as  $\text{H}_2\text{TeO}_5 \cdot 2\text{H}_2\text{O}$ .

**Formation.**—1. By oxidising  $\text{Te}$  by *aqua regia*.—2.  $\text{K}_2\text{TeO}_4$  is formed by the interaction of  $\text{Cl}$  with  $\text{K}_2\text{TeO}_4$ aq, also by fusing  $\text{TeO}_2$  with  $\text{KNO}_3$  or  $\text{KClO}_3$ .

**Preparation.**—1. A mixture of  $\text{TeO}_2$ ,  $\text{KClO}_3$ , and  $\text{KOH}$ , in the ratio  $\text{TeO}_2:2\text{KClO}_3:2\text{KOH}$  is thoroughly fused; the fused mass is dissolved in water and  $\text{BaCl}_2$ aq is added; the pp. of  $\text{BaTeO}_4$  is purified by recrystallisation from hot water, and is then dried at  $100^\circ$ ; the dry  $\text{BaTeO}_4$  is mixed with its own weight of water and one-fourth its weight of conc.  $\text{H}_2\text{SO}_4$  and heated till decomposition is complete, when  $\text{BaSO}_4$  is removed by filtration, and the filtrate is evaporated at  $100^\circ$  to the crystallising point; the crystals that separate are dried, powdered, washed repeatedly with alcohol to remove  $\text{H}_2\text{SO}_4$ , and recrystallised from water (Oppenheim, *J. pr.* 71, 267). Berzelius (*P.* 28, 392; 32, 1) fused  $\text{TeO}_2$  with an equal weight of  $\text{K}_2\text{CO}_3$  or  $\text{Na}_2\text{CO}_3$ , dissolved in water, added  $\text{KOH}$  equal to the weight of  $\text{TeO}_2$  used, passed in  $\text{Cl}$  until the liquid smelt strongly thereof, ppd. by  $\text{BaCl}_2$ aq, and proceeded as described above.—2.  $\text{TeO}_2$  is dissolved in  $\text{HNO}_3$ aq, the solution is boiled with  $\text{PbO}$ , and filtered,  $\text{Pb}$  is ppd. from the filtrate by  $\text{H}_2\text{SO}_4$ aq, the filtrate from  $\text{PbSO}_4$  is evaporated to dryness at  $100^\circ$ , the residue is digested with alcohol and ether to remove  $\text{H}_2\text{SO}_4$ , and is then crystallised from hot water *in vacuo* (Becker, *A.* 180, 257).

**Properties and Reactions.**— $\text{H}_2\text{TeO}_5 \cdot 2\text{H}_2\text{O}$  is obtained by slow crystallisation in white, monoclinic crystals, resembling gypsum, *S.G.* 2.9939 at  $25.5^\circ$  (Clarke, *Am. S.* [3] 16, 401). When obtained by rapid evaporation  $\text{H}_2\text{TeO}_5 \cdot 2\text{H}_2\text{O}$  appears as a glassy solid. Heated to *c.*  $130^\circ$   $\text{H}_2\text{TeO}_5$  is obtained; decomposition begins at a little above  $160^\circ$  to  $\text{TeO}_2$  and  $\text{H}_2\text{O}$ , and at *c.*  $180^\circ$   $\text{TeO}_2$  begins to decompose to  $\text{TeO}$  and  $\text{O}$ , this decomposition being complete at *c.*  $350^\circ$  (Wills, *C. J.* 35, 704).  $\text{H}_2\text{TeO}_5$  has *S.G.* 3.425 at  $18.8^\circ$  (Clarke, *l.c.*).  $\text{H}_2\text{TeO}_5 \cdot 2\text{H}_2\text{O}$  is slightly soluble in cold water; it is dissolved fairly easily by boiling water; soluble in acid and alkali solutions; almost, if not quite, insoluble in alcohol.  $\text{H}_2\text{TeO}_5$  dissolves very slowly in boiling water. Aqueous solutions of  $\text{H}_2\text{TeO}_5$  have a metallic, not a sour, taste; they very slightly redden litmus. Thomsen (*Th.* 2, 277) gives the following *H.F.*:  $[\text{TeO}_5\text{aq}] = 98,380$ ;  $[\text{TeO}_5\text{aq}] = 21,200$ .  $\text{H}_2\text{TeO}_5$  dissolves gradually in hot, fairly conc.  $\text{HClAq}$ , with evolution of  $\text{Cl}$  and formation of  $\text{H}_2\text{TeO}_4$ aq.  $\text{H}_2\text{TeO}_4$ aq is not reduced by passing  $\text{H}_2\text{S}$  into it, but if the solution is saturated with  $\text{H}_2\text{S}$  and kept in a warm place, in a closed flask, for some time, the liquid becomes brown, and flakes, probably of  $\text{TeS}_2$  (v. TELLURIUM SULPHIDES, p. 655), are deposited.

$\text{H}_2\text{TeO}_5$ aq reacts with alkalis to form salts  $\text{M}_2\text{TeO}_5$  and  $\text{MH}_2\text{TeO}_5$ ; salts of the forms  $\text{MH}_2\text{TeO}_5$  and  $\text{M}_2\text{Te}_2\text{O}_7$  are also known (v. TELLURATES, p. 648).

M. M. P. M.

**TELLURIDES.** Any compound of  $\text{Te}$  with a single element more positive than itself is called a telluride. Tellurides of the heavier metals are generally formed by melting the metals with  $\text{Te}$ , also by passing  $\text{H}_2\text{Te}$  into solutions of salts of the metals; tellurides of  $\text{K}$  and  $\text{Na}$  are formed

by heating  $\text{TeO}_2$  with  $\text{K}_2\text{CO}_3$  or  $\text{Na}_2\text{CO}_3$  and charcoal; many tellurites and tellurates give tellurides when heated in a current of H. Te ppt. tellurides of Cu, Ag, and some other metals, by boiling solutions of salts of these metals with Te (Parkmann, *C. C.* 1862, 814). Tellurides of K and Na dissolve in water with a red colour; this colour is due either to polytellurides or to the presence of traces of oxides according to Demarcay (*Bl.* [2] 40, 99). Berthelot a. Fabre (*C. R.* 105, 92) obtained colourless solutions of alkali tellurides by passing pure  $\text{H}_2\text{Te}$  into solutions of alkalis; a trace of O produced a red colour and separated Te. Tellurides react with  $\text{HClAq}$  giving off  $\text{H}_2\text{Te}$ ; they are oxidised to tellurites by  $\text{HNO}_3\text{Aq}$ , and to tellurates and tellurates by *aqua regia*. Warmed in Cl tellurides give metallic chlorides and  $\text{TeCl}_4$ .

Tellurides of Sb, As, Bi, Au, Fe, K, Ag, and Na are mentioned under these metals (*cf.* Brauner, *C. J.* 55, 388). M. M. P. M.

**TELLURITES.** Salts of tellurous acid  $\text{H}_2\text{TeO}_3$  (*q. v.*, p. 656). The normal and acid tellurites of monovalent metals belong to the forms  $\text{M}_2\text{TeO}_3$  and  $\text{MHTeO}_3$ . Some salts are also known containing relatively more of the acidic radicle; these may be formulated as  $\text{M}_2\text{O}_x\text{TeO}_3$ , where  $x$  is 2 and 4; or they may be regarded as  $\text{M}_x\text{TeO}_3 \cdot x\text{TeO}_2$ , where  $x$  is 1 and 3; or finally these hyperacid salts may be looked on as  $\text{M}_2\text{Te}_x\text{O}_{3+2x}$  and  $\text{M}_x\text{Te}_x\text{O}_{3+2x}$ —that is, as derivatives of the hypothetical acids  $\text{H}_2\text{Te}_x\text{O}_3$  and  $\text{H}_x\text{Te}_x\text{O}_3$ .

Tellurites are generally formed by heating together basic oxides and  $\text{TeO}_2$  in the proper proportions; some tellurites of the heavier metals are obtained by pptn. from solutions of alkali tellurites. Tellurites of the alkali metals dissolve readily in water; those of the alkaline earth metals are less soluble; the others are insoluble in water. Most tellurites dissolve in  $\text{HClAq}$ , forming yellow solutions which do not give off Cl on heating; this reaction distinguishes them from tellurates (*v. p.* 649). Solutions of tellurites in a little  $\text{HClAq}$  deposit  $\text{H}_2\text{TeO}_3$  on dilution. Most tellurites are fusible, and crystallise on cooling; the hyperacid alkali tellurites form colourless glass-like solids after fusion. By strongly heating with charcoal and  $\text{K}_2\text{CO}_3$ , most tellurites give  $\text{K}_2\text{Te}$ .

Tellurites of potassium. The normal salt  $\text{K}_2\text{TeO}_3$ , and the acid salt  $\text{K}_2\text{TeO}_3 \cdot \text{TeO}_2$  ( $= \text{K}_2\text{Te}_2\text{O}_5$  or  $\text{K}_2\text{O} \cdot 2\text{TeO}_2$ ) are prepared by fusing  $\text{TeO}_2$  with  $\text{K}_2\text{CO}_3$  in the proper proportions.  $\text{K}_2\text{TeO}_3$  melts at a red heat; dissolves slowly in cold water, more quickly in boiling water; the aqueous solution has an alkaline taste and reaction, and is decomposed by the  $\text{CO}_2$  in the air.  $\text{K}_2\text{O} \cdot 2\text{TeO}_2$  melts below redness, and solidifies again to a transparent, colourless, crystalline mass; dissolved by boiling water, and the solution on cooling deposits  $\text{K}_2\text{O} \cdot 4\text{TeO}_2$ . The *tetratellurite* or *hyperacid tellurite*  $\text{K}_2\text{O} \cdot 4\text{TeO}_2 \cdot 4\text{H}_2\text{O}$  ( $= \text{K}_2\text{Te}_5\text{O}_{14} \cdot 8\text{H}_2\text{O}$  or  $\text{K}_2\text{Te}_5\text{O}_{14} \cdot 4\text{H}_2\text{O}$ ) is prepared by boiling  $\text{H}_2\text{TeO}_3\text{Aq}$  with  $\text{K}_2\text{CO}_3$  and filtering at  $100^\circ$ ; the salt is deposited on cooling in microscopic six-sided prisms and tablets. This salt reacts with cold water to give a solution of  $\text{K}_2\text{TeO}_3$  and  $\text{K}_2\text{Te}_2\text{O}_5$ , and a gelatinous ppt. of  $\text{H}_2\text{TeO}_3$ ; when heated  $4\text{H}_2\text{O}$  is given off, and  $\text{K}_2\text{O} \cdot 4\text{TeO}_2$  remains as a salt which melts at a

moderate red heat and solidifies on cooling to a colourless glass.

The tellurites have been examined chiefly by Berzelius (*P.* 32, 577; *v. also* Oppenheim, *J. pr.* 71, 267). Salts of the following metals have been isolated, but many have been studied in a very superficial way: Al,  $\text{NH}_4$ , Ba, Cd, Ca, Cr, Co, Cu, Fe, Pb, Li, Mg, Mn, Hg, Ni, Ag, Na, Sr, and Zn. M. M. P. M.

**TELLURIUM.** Te. At. w. c. 125 (*v. infra*). Mol. w. c. 250 (*v. infra*). Melts at c.  $455^\circ$  (Carnelley a. Williams, *C. J.* 37, 125). Boils at c.  $1390^\circ$  (Deville a. Troost, *C. R.* 91, 83). S.G. 6.2549 at  $0^\circ$  (after compression); 6.2322 at  $0^\circ$  (uncompressed) (Spring, *B. B.* 5, 854); 6.2549 at  $18.2^\circ$  (after melting in H) (Pfiwoznik, *C. C.* 1892, ii. 962; for further data *v.* Clarke's *Table of Specific Gravities* [2nd ed.] 10). V.D. at c.  $1390^\circ$  to c.  $1440^\circ = 130$  (Deville a. Troost, *C. R.* 56, 891). S.H. ( $21^\circ$  to  $51^\circ$ , crystalline) .0475 (Kopp, *T.* 1865, 71); (at  $98^\circ$ , crystalline) .0483; (at  $98^\circ$ , after distillation in  $\text{SO}_2$ ) .0518 (Fabre, *A. Ch.* [6] 14, 101). C.E. (linear, at  $0^\circ$ ) .0001675 (Fizeau, *C. R.* 68, 1125). E.C. .000777 at  $19.6^\circ$  (Ag at  $0^\circ = 100$ ) (Matthiessen, *P.* 103, 428); conductivity increases slightly when light falls on Te; the increase is very much less than in the case of Se (*v.* Adams a. Day, *Pr.* 21, 163; 25, 113). E.C. decreases slightly to p.  $100^\circ$ – $140^\circ$ , and then increases to  $200^\circ$ ; on cooling after fusion E.C. decreases regularly and markedly; the following values are given by Exner (*P.* 158, 625) .0035 at  $200^\circ$ , .00286 at  $20^\circ$  (after fusion), .000435 at  $20^\circ$  (after very slow cooling, from fusion). Te crystallises in rhombohedra;  $a:b = 1.1:3.298$ ; it is isomorphous with S and Se (*v.* Muthmann, *Z. P. C.* 8, 396). For emission-spectrum *v.* Plücker a. Hittorf (*Pr.* 13, 153); Thalen; Salet (*A. Ch.* [4] 28, 51); Ditte (*C. R.* 73, 622); Hartley a. Adeney (*T.* 1884 [1] 117). For absorption-spectrum of vapour of Te *v.* Gernz (*C. R.* 74, 1190). H.C. ( $\text{TeO}_3\text{Aq}$ ) = 98,380 (*Th.* 2, 276).

**Historical.**—Examining a mineral containing gold from the Seven Mountains in 1782 Müller von Reichenstein suspected the presence of a new metal (*Abhand. einer Privatgesellschaft in Böhmen*). He sent a specimen of the mineral to Bergmann, who said that it contained a metal which was not the same as that in blende. In 1798 Klaproth received some of the mineral from M. von R., and isolated the characteristic element, to which he gave the name tellurium (from *tellus* = the earth) (*K., Beiträge zur chem. Kenntniss der Mineralkörper*, 3, 1; *cf.* *Crell's Ann.* 1798, 91; and *G. A.* 12, 246). The compounds of Te were more fully examined by Berzelius (*S.* 6, 311; 34, 78; *P.* 8, 411; 28, 392; 82, 1, 577).

**Occurrence.**—Te is found native, in small quantities, and in a few localities—chiefly in Hungary and Transylvania, and in Virginia, U.S.; it generally accompanies Au and Ag; specimens have been obtained with 97–98 p.c. Te. Tellurides are also found in small quantities in Hungary, Mexico, California, Bolivia, and some other places; in considerable quantities in Colorado; these are generally compounds of Te with Bi, Ag, Pb, Bi and S, Ag and Au, Au, Pb and Sb; *tellurite* (or *tellurium-ochre*) containing  $\text{TeO}_2$  is found in small quantities in the Seven Mountains (*v.* G. Rose, *P.*

18, 64; Rammeisberg, *J. M.* 1874. 30; Burkart, *J. M.* 1873. 476; Silliman & Marvine, *Am. S.* (3) 8, 25; Mathewson, *J. M.* 1866. 93; Genth, *J. M.* 1875. 188, 314).

**Formation.**—1. Bypassing  $\text{SO}_2$  into  $\text{H}_2\text{TeO}_3\text{Aq}$ ;  $\text{H}_2\text{TeO}_3\text{Aq} + 2\text{SO}_2 + \text{H}_2\text{O} = 2\text{H}_2\text{SO}_4\text{Aq} + \text{Te}$ . Also by ppg. solution of  $\text{TeCl}_4$  in dilute  $\text{HClAq}$ , or of a  $\text{Te}$  compound in  $\text{H}_2\text{SO}_4\text{Aq}$ , by an alkali sulphite. 2. By reducing a boiling solution of  $(\text{NH}_4)_2\text{TeO}_3\text{Aq}$  by grape sugar (Stolba, *J.* 1873. 214).—3. By decomposing  $\text{K}_2\text{TeO}_4$  by air or oxygen (v. Oppenheim, *J. pr.* 71, 267; 81, 308; Himly, *J.* 1877. 213).—4. By ppn., by means of zinc, from solutions of  $\text{Te}$  compounds in  $\text{H}_2\text{SO}_4\text{Aq}$  (v. Löwe, *J. pr.* 60, 163).

**Preparation.**—There are several methods of preparing crude  $\text{Te}$  from the minerals that contain it. Native bismuth telluride is made into a paste with oil and  $\text{K}_2\text{CO}_3$ , and gradually heated to whiteness in a covered crucible;  $\text{K}_2\text{Te}$  is extracted from the fused mass by boiling water, and the solution deposits  $\text{Te}$  on standing in air. Or the mineral containing  $\text{Te}$  is powdered and treated with dilute  $\text{HClAq}$ ; the insoluble matter is gradually added to three times its weight of conc.  $\text{H}_2\text{SO}_4$ , and heating is continued until  $\text{SO}_2$  ceases to be given off; the solid that forms on cooling is dissolved in water containing a little  $\text{HCl}$ ; the solution is filtered from  $\text{AgCl}$ ,  $\text{Te}$  is ppd. from the filtrate by zinc, and undissolved zinc is removed by digestion with dilute  $\text{HClAq}$ . For details and other methods v. Berzelius (*I.* 8, 411; 28, 392); Löwe (*J. pr.* 60, 163); Wöhler (*A.* 84, 69); Oppenheim (*J. pr.* 81, 308); Schmitzer (*D. P. J.* 211, 434, 492); Schwarz (*D. P. J.* 186, 29).

To prepare pure  $\text{Te}$ , Brauner (*C. J.* 55, 382; cf. *M.* 10, 411) recommends to digest the crude material with  $\text{HClAq}$  in a large flask, and to oxidise by  $\text{HNO}_3\text{Aq}$  added little by little till the solid matter becomes white, to evaporate several times with conc.  $\text{HClAq}$  (to remove  $\text{HNO}_3$ ), and then to dilute cautiously with water, taking care not to add enough water to ppt.  $\text{H}_2\text{TeO}_3$  along with any  $\text{PbCl}_2$ , which may come down. He then adds some saturated  $\text{SO}_2\text{Aq}$ , warms to  $60^\circ\text{--}70^\circ$ , and ppt.  $\text{Te}$  by passing  $\text{SO}_2$  into the warm solution. The  $\text{Te}$  thus obtained generally contains a little copper and lead selenides. The pp. is dried and fused in small portions with  $\text{KCy}$ ; the fused mass, which contains  $\text{K}_2\text{Te}$ , is dissolved in water, from which air has been removed, in a stoppered flask; the liquid is allowed to clear (there is generally a small pp. of tellurides of heavy metals mixed with a trace of  $\text{Te}$ ) and is then poured off, and a current of air is passed through it, whereby  $\text{Te}$  is ppd. The  $\text{Te}$  is dried, placed in a porcelain boat, which is introduced into a wide tube of hard glass surrounded by wire gauze, and distilled in a current of pure dry  $\text{H}_2$ . (For a method of purification based on the ppn. of  $\text{Te}$  from  $(\text{NH}_4)_2\text{TeO}_3\text{Aq}$  by grape sugar, v. Stolba, *J.* 1873. 214.)

**Properties.**—As prepared by sublimation in  $\text{H}_2$ , tellurium is a white, shining, crystalline, very brittle solid, unchanged by exposure to air. During distillation in  $\text{H}_2$ , Brauner (*l.c.*) noticed that some  $\text{H}_2\text{Te}$  was formed, and was decomposed with deposition of needle-shaped crystals of  $\text{Te}$ , some of which were 1 centim. in length. The crystals of  $\text{Te}$  are hexagonal rhombohedra, iso-

morphous with  $\text{S}$  and  $\text{Se}$  (v. Muthmann, *Z. P. O.* 8, 396). By allowing  $\text{K}_2\text{TeAq}$  to decompose in air, H. Rose obtained six-sided prisms with rhombohedral summits (*P.* 21, 443; cf. Fabre & Berthelot, *C. R.* 104, 1405). Amorphous  $\text{Te}$  is obtained as a brown powder by ppg.  $\text{H}_2\text{TeO}_3\text{Aq}$  by  $\text{SO}_2$ ; on warming, the amorphous variety changes to the crystalline, giving off a large quantity of heat (*F. a. B., l.c.*).  $\text{Te}$  that has been melted and cooled quickly seems to contain both the crystalline and the amorphous varieties. According to Fabre (*A. Ch.* [6] 14, 100), both varieties have practically the same S.H. at  $c. 100^\circ$ .  $\text{Te}$  melts at  $c. 455^\circ$  and boils at  $c. 1390^\circ$ ; the vapour is golden yellow. Heated in air it burns with a brilliant blue-green flame to white clouds of  $\text{TeO}_2$ , which are poisonous; the smell, like that of decaying radishes, that is noticed on burning impure  $\text{Te}$  is due to the oxidation products of  $\text{Se}$ , which is commonly present in specimens of crude  $\text{Te}$ .  $\text{Te}$  dissolves in very conc. boiling  $\text{KOH Aq}$ , forming a red liquid that contains  $\text{K}_2\text{TeO}_3$  and  $\text{K}_2\text{Te}$ ; on allowing to cool, or on adding water, the whole of the  $\text{Te}$  separates.  $\text{HClAq}$  is without action on  $\text{Te}$ ; conc. hot  $\text{H}_2\text{SO}_4$  dissolves it slightly, but the  $\text{Te}$  separates on dilution; when heated strongly with conc.  $\text{H}_2\text{SO}_4$ ,  $\text{Te}$  dissolves to  $\text{H}_2\text{TeO}_3$  with evolution of  $\text{SO}_2$ .  $\text{Te}$  dissolves in  $\text{SO}_3$ , forming  $\text{TeSO}_3$ . Conc.  $\text{HNO}_3\text{Aq}$  forms a solution of  $\text{H}_2\text{TeO}_3$ ; *aqua regia* forms  $\text{H}_2\text{TeO}_3$  and some  $\text{H}_2\text{TeO}_4$ . Molten  $\text{KNO}_3$  produces  $\text{K}_2\text{TeO}_4$ .

In its physical properties  $\text{Te}$  approaches the metals, and especially resembles  $\text{Se}$ . In its chemical properties  $\text{Te}$  is, on the whole, non-metallic; but the oxide  $\text{TeO}_2$  combines with certain anhydrides of strong acids to form salt-like compounds, and the oxide  $\text{TeO}$  is said to dissolve in  $\text{H}_2\text{SO}_4\text{Aq}$ , forming  $\text{Te(SO}_3)_2$ .  $\text{Te}$  is closely related to  $\text{Se}$ , and less closely to  $\text{S}$ ; it shows distinct analogies with  $\text{Cr}$ ,  $\text{Mo}$ ,  $\text{W}$ , and  $\text{U}$  (v. OXYGEN GROUP OF ELEMENTS, vol. iii. p. 705, and CHROMIUM GROUP OF ELEMENTS, vol. ii. p. 168). The atom of  $\text{Te}$  is divalent in the gaseous molecules  $\text{TeH}_2$  and  $\text{TeCl}_2$ , and tetravalent in the gaseous molecule  $\text{TeCl}_4$ .

**Atomic weight of tellurium.** The at. w. of  $\text{Te}$  was determined by Berzelius in 1812, 1818, and 1832 by oxidising  $\text{Te}$  by  $\text{HNO}_3\text{Aq}$  and weighing the  $\text{TeO}_2$  produced; he obtained values varying from 127.9 to 128.5 (*P.* 8, 24; 28, 395; 32, 16). In 1857 von Hauer analysed  $\text{K}_2\text{TeBr}_6$ , and obtained values from 126.5 to 128.1 (*W. A. B.* 25, 435). In 1879 Wills determined the weight of  $\text{TeO}$ , obtained by oxidising  $\text{Te}$  by  $\text{HNO}_3\text{Aq}$  and by *aqua regia*, and he also made analyses of  $\text{K}_2\text{TeBr}_6$ ; his results varied from 126.1 to 129.3 (*C. J.* 35, 704). In 1883 Brauner obtained numbers varying from 124.94 to 125.4, by oxidising  $\text{Te}$  to  $\text{TeO}_2$ , by converting  $\text{Te}$  and  $\text{TeO}_2$  into  $(\text{TeO}_2)_2\text{SO}_3$ , and by synthesising  $\text{Cu}_2\text{Te}$  (*J. R.* 1883. [1] 433; abstract in *B.* 16, 3055). In 1889 Brauner made a very careful revision of the at. w. of  $\text{Te}$  (*C. J.* 65, 382):—(i.) by oxidising  $\text{Te}$  to  $\text{TeO}_2$ , he obtained values varying from 124.48 to 127.28; (ii.) by converting  $\text{TeO}_2$  into  $(\text{TeO}_2)_2\text{SO}_3$ , the numbers varied from 124.7 to 129 (one result gave 135.9); (iii.) by conversion of  $\text{Te}$  into  $(\text{TeO}_2)_2\text{SO}_3$ , the numbers varied from 124.3 to 129.7; (iv.) by syntheses of tellurides of  $\text{Ag}$ ,  $\text{Cu}$ , and  $\text{Au}$ , the numbers varied from 125.7

to 129.9; (v.) by analysis of  $\text{TeO}_2$ , the value 127.2 was obtained, but only one satisfactory analysis was made; (vi.) by analyses of  $\text{TeBr}_2$ , the numbers varied from 127.27 to 127.31. The results obtained by analysing  $\text{TeBr}_2$ , were more concordant than any obtained by the other methods; but the value 127.3 is almost .75 units greater than the at. w. of iodine; hence it seems as if the at. w. of Te is greater than that of I. But if this is so, Te must be separated from S, Se, and the chromium metals, which are placed in Group VI. in the periodic arrangement of the elements; and Te must be placed either with the halogens in Group VII. (I being put into Group VI.), or this element must find a place in Group VIII. (I remaining in Group VII., and an empty place being left in Group VI., Series 7). The chemical properties of Te show that it belongs to the same group as S and Se; and the chemical properties of I make it impossible to place that element elsewhere than with F, Cl, and Br.

*Is tellurium a homogeneous body?* Rather than doubt the applicability of the periodic law, Brauner made the hypothesis that tellurium is not a homogeneous body, but that it contains an admixture of foreign substances. He dissolved Te, and ppd. in fractions by  $\text{SO}_2$ , fused the fractions with  $\text{KCy}$ , dissolved in water, and ppd. fractionally by a current of air; he then distilled each fraction in H., and converted it into  $\text{TeBr}_2$ , and analysed each fraction. The values thus obtained for the at. w. of Te were almost identical, the mean being 127.33. Pure  $\text{TeO}_2$  was then dissolved in  $\text{HClAq}$ , and the solution was ppd. in eight fractions by ammonia; the filtrate from the eighth fraction was ppd. by  $\text{SO}_2$  in presence of  $\text{HClAq}$ ; after boiling off  $\text{SO}_2$  from the filtrate from the ninth fraction, the liquid was saturated with  $\text{H}_2\text{S}$ , and the  $\text{TeO}_2$  in solution was obtained, converted into Te, and this converted into  $\text{TeBr}_2$ ; the at. w. thus obtained (in three experiments) was 127.32, the three experiments agreeing extremely well. Te was then fused, but not distilled, in a current of H.; it was then converted into  $\text{TeBr}_2$ , which was freed from  $\text{TeBr}_2$  by fractional sublimation *in vacuo*, without converting the  $\text{TeBr}_2$  into vapour, and analysed; the values obtained for the at. w. of Te differed very much, ranging from 128.5 to 137.4. From these results Brauner concluded that 'if tellurium, obtained by any process of fractionation whatever, be subjected to distillation in a current of hydrogen, and the tetrabromide be prepared from this by sublimation in a vacuum, its analysis always gives the same atomic weight for tellurium. . . . If, however, the tellurium be only fused in a current of an indifferent gas, and the tetrabromide be not sublimed, higher numbers will be obtained. . . . It is therefore very probable that on distilling tellurium in a current of hydrogen, and the tetrabromide in a vacuum, one constituent of tellurium escapes partly, the presence of which in the last cases renders the atomic weight higher.' Brauner prepared  $\text{TeBr}_2$  by fusing  $\text{TeBr}_2$  with excess of Te, and subliming either *in vacuo* or in a current of  $\text{CO}_2$ ; the analyses of different specimens of  $\text{TeBr}_2$  showed percentages of Br varying from 54.658 to 55.14; the percentage of Br calculated for  $\text{Te} = 127.32$  is 55.6. Brauner concluded that 'tellurium is

not a simple substance.' This conclusion is still held by B. to be correct. In a private communication (January 1894) he says: 'I consider Te to be a mixture of two elements that cannot be separated by ordinary chemical means, not even by fractionation. It cannot, however, be shown that the at. w. of Te is about 125, for all attempts I have made in this direction have failed completely. All atomic weight determinations made by me, and others, giving values higher or lower than 127.3 are due, partly to impurities, but in most cases to some undetected source of error.'

*Molecular weight of tellurium.* Deville & Troost (*C. R.* 56, 891) found the V.D. of Te between  $c. 1390^\circ$  and  $c. 1440^\circ$  to be 130; this gives the mol. w. of c. 260. As the at. w. of Te is not known with certainty, it is not possible at present to correct the value deduced for the mol. w. from the determinations of V.D. The gaseous molecule of Te is diatomic.

*Reactions and Combinations.*—1. Heated in air, or oxygen, Te is burnt to  $\text{TeO}_2$ .—2. Heated in excess of chlorine  $\text{TeCl}_4$  is produced; with bromine  $\text{TeBr}_2$  is produced; with iodine the product is  $\text{TeI}_2$ .—3. Te and sulphur can be melted together in all proportions; it is doubtful whether definite compounds are formed or not (*v. TELLURIUM SULPHIDES*, p. 655). Te and selenium can also be melted together in all proportions; no definite compound has been isolated.—4. Nitric acid forms  $\text{H}_2\text{TeO}_3$ ; according to Klein & Morel (*Bl.* [2] 43, 198), cold  $\text{HNO}_3\text{Aq}$  first forms  $4\text{TeO}_2 \cdot \text{N}_2\text{O}_5 \cdot 22\text{aq}$  (*v. TELLURIUM DIOXIDE*, p. 655). *Aqua regia* produces a mixture of  $\text{H}_2\text{TeO}_3$  and  $\text{H}_2\text{TeO}_4$ .—5. Te dissolves in hot conc. potash solution, forming a red solution that contains  $\text{K}_2\text{Te}$  and  $\text{K}_2\text{TeO}_3$ ; on addition of water Te separates ( $2\text{K}_2\text{TeAq} + \text{K}_2\text{TeO}_3\text{Aq} = 3\text{K}_2\text{OAq} + 3\text{Te}$ ).—6. Fusion with potassium nitrate produces  $\text{K}_2\text{TeO}_4$ .—7. Fusion with potassium carbonate produces a mixture of  $\text{K}_2\text{Te}$  and  $\text{K}_2\text{TeO}_3$ .—8. Te dissolves in sulphur trioxide, forming  $\text{TeSO}_3$  (*v. thio-oxide* under **TELLURIUM OXIDES**, p. 655).

*Detection and Estimation.*—Free Te is readily detected by fusing with charred cream of tartar and dissolving in water, whereby a red solution is obtained that deposits Te in dark-brown flakes on standing in air. Tellurous acid and tellurites dissolve in dilute  $\text{HClAq}$ , and addition of water ppds. white  $\text{H}_2\text{TeO}_3$ ;  $\text{SO}_2$  ppds. Te from solutions of tellurites in dilute  $\text{HClAq}$  or  $\text{HNO}_3\text{Aq}$ . Solutions of tellurates in acids give no pps. with water; solutions in  $\text{HClAq}$  give off Cl on boiling, being reduced to tellurites, and are then ppd. by water. For a test for Te based on the formation of red  $\text{TeSO}_3$  by passing  $\text{TeH}_2$  into  $\text{H}_2\text{SO}_4\text{Aq}$  *v. Divers* & Shimose, *C. J.* 43, 329. Te is generally estimated by ppg. the element, from solution of  $\text{H}_2\text{TeO}_3$  or a tellurite, by alkali sulphite,  $\text{SO}_2$ , or grape sugar (Kastner, abstract in *C. J.* 29, 440; *cf.* Donath, abstract in *C. J.* 60, 242). In *C. J.* 59, 238, Brauner describes a method for the volumetric estimation of Te by  $\text{KMnO}_4\text{Aq}$ .

*Tellurium, acids of; tellurhydric acid*  $\text{H}_2\text{Te}$  (vol. ii. p. 727); *tellurous acid*  $\text{H}_2\text{TeO}_3$  (this vol., p. 656); *telluric acid*  $\text{H}_2\text{TeO}_4$  (this vol., p. 649). The existence of the potassium salt of  $\text{HCNTe}$  is probable (*v. TELLUROCTANIDES*, vol. ii. p. 353).

**Tellurium, alloys of.** The compounds of Te with metals are sometimes classed with the more definite alloys (v. TELLURIDES, p. 649).

**Tellurium, antimonides of.** v. ANTIMONY; *Combinations*, No. 7, vol. i. p. 283.

**Tellurium, arsenides of.** v. ARSENIC; *Combinations*, No. 6, vol. i. p. 303.

**Tellurium, bromides of.** Two bromides have been isolated,  $\text{TeBr}_2$  and  $\text{TeBr}_4$ ; both are formed by the direct combination of Te and Br. The bromides can be sublimed, under reduced pressure, without change. The V.D. of neither has been determined; but, from the analogy of  $\text{TeCl}_2$  and  $\text{TeCl}_4$ , the formulae are probably molecular.

**TELLURIUM DIBROMIDE  $\text{TeBr}_2$ .** Formula probably molecular, from analogy of  $\text{TeCl}_2$ . Prepared by fusing  $\text{TeBr}_3$  with excess of powdered Te, and subliming either *in vacuo* or in a current of dry  $\text{CO}_2$ . A blackish-green crystalline mass; obtained in steel-grey needles by slow sublimation (Brauner, *C. J.* 55, 410). Melts c.  $305^\circ$ , and boils c.  $343^\circ$  (Carnelley, *Melting- and Boiling-point Tables*, 1, 21).  $\text{TeBr}_2$  is very hygroscopic; it is decomposed by water to  $\text{H}_2\text{TeO}_3\text{Aq}$  and  $\text{HBrAq}$ . Dissolves in tartaric acid solution, forming  $\text{TeBr}$  and Te (Brauner, *l.c.*).

**TELLURIUM TETRABROMIDE  $\text{TeBr}_4$ .** (*Telluric bromide*.) Formula probably molecular, from analogy of  $\text{TeCl}_4$ . Prepared by shaking together powdered Te and Br, in the proportion  $\text{Te}:\text{Br}$ , warming in a current of dry  $\text{CO}_2$ , and then subliming *in vacuo* (for details and description of apparatus, v. Brauner, *C. J.* 55, 396). Forms a crystalline crust, which is fiery red when hot and orange coloured when cold. S.G.  $^{15^\circ} = 4.31$  (Brauner, *l.c.*, p. 407). Melts at c.  $380^\circ$ , and boils at  $414^\circ\text{--}427^\circ$ , according to Carnelley & Williams (*C. J.* 35, 563; 37, 125). Dissolves in a little water without change; on dilution a colourless liquid is obtained, containing  $\text{HBr}$  and  $\text{H}_2\text{TeO}_3$ ; crystals are obtained by evaporating over  $\text{H}_2\text{SO}_4$ , and are said by Berzelius to be  $\text{TeBr}_2 \cdot x\text{H}_2\text{O}$ . By adding  $\text{AgNO}_3\text{Aq}$  to a solution of  $\text{TeBr}_4$  in tartaric acid, Brauner (*C. J.* 55, 398) obtained  $\text{AgBr}$  and also crystalline scales probably  $(\text{C}_2\text{H}_3\text{O}_2)_2\text{Ag} \cdot \text{O} \cdot \text{TeO}_2 \cdot 2\text{aq}$ ; this compound is called by B. *tellurium-silver tartar emetic* (cf. Klein & Morel, *C. R.* 100, 1140).  $\text{TeBr}_4$  forms double salts with alkali bromides. The salt  $\text{TeBr}_2 \cdot 2\text{KBr}$  ( $=\text{K}_2\text{TeBr}_4$ ) is prepared by dissolving the proper quantity of  $\text{KBr}$  in water, adding Te, running in Br, shaking till the Te is dissolved, filtering, and evaporating at  $100^\circ$  (Wills, *C. J.* 35, 711; cf. von Ilancr, *W. A. B.* 25, 135). Dark-red, opaque, lustrous crystals; orthorhombic, *a:b:c* = 1.1:4901:1.3658 (*W. A. B.*); cf. Wheeler (*Am. S.* [3] 45, 267), where some other salts of the form  $\text{M}_2\text{TeBr}_4$  are described.

**Tellurium, chlorides of.** Two compounds are known,  $\text{TeCl}_2$  and  $\text{TeCl}_4$ ; both have been gasified, and the formulae of both are molecular. The chlorides are formed by the direct combination of their elements.

**TELLURIUM DICHLORIDE  $\text{TeCl}_2$ .** Mol. w. c. 196. Powdered Te is heated in a distillation-flask in a stream of Cl until the Te is completely converted into  $\text{TeCl}_2$ ; Te is added equal

in weight to the original quantity used, the whole is heated for a little time, an inverted condenser being attached to the flask, and the  $\text{TeCl}_2$  is then distilled off at  $320^\circ\text{--}380^\circ$  (Michaelis, *B.* 20, 2488).  $\text{TeCl}_2$  is a black, amorphous solid, melting at  $175^\circ$  (M., *l.c.*) to a black liquid; Carnelley & Williams give m.p. as  $209^\circ$  (*C. J.* 37, 125). Boils at  $327^\circ$  (C. A. W., *l.c.*). The vapour of  $\text{TeCl}_2$  is reddish, and gives a characteristic absorption-spectrum (M., *l.c.*). V.D. at  $410^\circ$ , in vapour of N, = 98.2 (M., *l.c.*). The vapour becomes yellowish in presence of air or O;  $\text{TeO}_2$  and  $\text{TeCl}_4$  are formed, and after continued heating these react to produce  $\text{TeOCl}_2$  (M., *l.c.*).  $\text{TeCl}_2$  absorbs moisture when exposed to the air, but does not fume; on addition of much water  $\text{H}_2\text{TeO}_3$  is formed;  $\text{HClAq}$  forms Te, and  $\text{TeO}_2$ , which remains dissolved in the acid (M., *l.c.*).

**TELLURIUM TETRACHLORIDE  $\text{TeCl}_4$ .** (*Telluric chloride*.) Mol. w. c. 269. Powdered Te is heated, in a distillation flask, in a stream of dry Cl until the solid becomes pale yellow, when it is distilled in a stream of dry  $\text{CO}_2$  (Michaelis, *B.* 20, 1780).  $\text{TeCl}_4$  is a colourless, crystalline solid, melting at  $214^\circ$ , and boiling without decomposition at  $380^\circ$  (M., *l.c.*; Carnelley & Williams give the m.p. as  $221^\circ$  [*C. J.* 37, 125], and the b.p. as  $414^\circ$  [*C. J.* 35, 563]). V.D. 131 at  $440^\circ$ , 125 at  $530^\circ$  (M., *l.c.*). The vapour of  $\text{TeCl}_4$  shows no absorption-spectrum (M., *B.* 20, 2488).  $\text{TeCl}_4$  dissolves without change in dilute  $\text{HClAq}$ . It deliquesces in the air, cold water ppts. an oxychloride, and  $\text{H}_2\text{TeO}_3$  is also formed; boiling water dissolves  $\text{TeCl}_4$ , and  $\text{H}_2\text{TeO}_3$  separates on cooling.

$\text{TeCl}_4$  combines with alkali chlorides to form salts  $\text{TeCl}_4 \cdot 2\text{MCl} = \text{M}_2\text{TeCl}_6$ ; these salts are best obtained by adding  $\text{HClAq}$  to a slight excess of  $\text{TeCl}_4$  dissolved in dilute  $\text{HClAq}$  and crystallising (v. Wheeler, *Am. S.* [3] 45, 267). The salts crystallise in regular yellow octahedra, without water. Weber (*P.* 104, 422) described a compound  $\text{TeCl}_4 \cdot 3\text{AlCl}_3$ , obtained by melting together  $\text{TeCl}_4$  and  $\text{AlCl}_3$ .  $\text{TeCl}_4$  absorbs  $\text{NH}_3$ , forming a greenish-yellow solid that is unchanged in air and has the composition  $\text{TeCl}_4 \cdot 2\text{NH}_3$  (Espenschied, *A.* 113, 101).

**Tellurium, fluorides of.** Only one fluoride of Te has been isolated. The formula  $\text{TeF}_6$  is probably molecular, from the analogy of  $\text{TeCl}_4$ .

**TELLURIUM HEXAFLUORIDE  $\text{TeF}_6$ .** (*Telluric fluoride*.) Prepared by dissolving  $\text{H}_2\text{TeO}_3$  in  $\text{HFAq}$ , evaporating at  $100^\circ$  to a syrup, allowing to cool, separating the white nodules that are formed, and heating in a Pt basin (Högborn, *Bl.* [2] 35, 60). If carbonate or hydroxide of an alkali metal, or of Ba, is added to the solution of  $\text{H}_2\text{TeO}_3$  in  $\text{HFAq}$  before evaporation, double salts of the forms  $\text{TeF}_6 \cdot \text{MF}$  and  $2\text{TeF}_6 \cdot \text{M}_2\text{F}_6$  are obtained; these salts are decomposed by water (H., *l.c.*).

**Tellurium, haloid compounds of.** These compounds belong to the forms  $\text{TeX}_4$  and  $\text{TeX}_6$ , where X = Cl, Br or I; the only fluoride that has been isolated is  $\text{TeF}_6$ . The chlorides  $\text{TeCl}_2$  and  $\text{TeCl}_4$  have been gasified, and the formulae are molecular; the formulae of the other haloid compounds are also probably molecular. An iodide containing more I than Te, — perhaps  $\text{TeI}_4$ , corresponding with  $\text{SI}_4$ , — may exist in the

solution of  $\text{H}_2\text{TeO}_3$  in  $\text{HIAq}$ . No compound corresponding with  $\text{S}_2\text{Cl}_2$ ,  $\text{Se}_2\text{Cl}_2$ ,  $\text{Se}_2\text{Br}_2$ , and  $\text{Se}_2\text{I}_2$  has been isolated. The haloid compounds of Te are more stable towards heat than the corresponding compounds of Se or S. The haloid compounds of Te are decomposed by water, giving  $\text{H}_2\text{TeO}_3$  and  $\text{HXaq}$ ; cold water is said to ppt. an oxychloride from  $\text{TeCl}_4$ . The compounds  $\text{TeX}$ , combine with the haloid compounds of the alkali metals to form salts  $\text{M}_2\text{TeX}_2$ ; when  $\text{X} = \text{F}$  the salts are said to be of the form  $\text{MTeF}_6$ .

Tellurium, hydride of,  $\text{TeH}_2$ , v. HYDROGEN TELLURIDE, vol. ii. p. 727.

Tellurium, iodides of. Two iodides have been isolated,  $\text{TeI}_2$  and  $\text{TeI}_4$ ; a third—perhaps  $\text{TeI}_3$ —may exist in the solution of  $\text{H}_2\text{TeO}_3$  in  $\text{HIAq}$ .  $\text{TeI}_2$  is formed by directly combining Te and I;  $\text{TeI}_4$  is obtained by digesting  $\text{H}_2\text{TeO}_3$  with  $\text{HIAq}$ .

TELLURIUM DI-IODIDE  $\text{TeI}_2$ . Prepared by gently warming a mixture of powdered Te and excess of I; may be sublimed as a black, crystalline crust; when strongly heated I is given off. Not changed, by water, hot or cold (Berzelius, *Lehrbuch*, 5th edit., 3, 1139).

TELLURIUM TETRA-IODIDE  $\text{TeI}_4$ . (*Telluric iodide*.) Obtained by digesting powdered  $\text{H}_2\text{TeO}_3$  with  $\text{HIAq}$  in a closed flask, whereby hard black granules are formed. Melts when heated, and gives off I. Boiling water causes decomposition, probably forming an oxyiodide. If a solution of  $\text{H}_2\text{TeO}_3$  in  $\text{HIAq}$  is evaporated over  $\text{H}_2\text{SO}_4$  and  $\text{CaO.H}_2\text{O}$  *in vacuo*, lustrous prisms are obtained that are perhaps a compound of  $\text{TeI}_4$  and  $\text{HI}$  (B., *l.c.*). By dissolving alkali iodides in  $\text{TeI}_4$  dissolved in dilute  $\text{HIAq}$ , and crystallising, black salts of the form  $\text{M}_2\text{TeI}_6$  are formed in regular octahedra; the potassium salt contains  $2\text{H}_2\text{O}$  and crystallises in monoclinic forms (Wheeler, *Am. S.* [3] 45, 267).

Tellurium, oxides of. Three oxides have been isolated,  $\text{TeO}$ ,  $\text{TeO}_2$ , and  $\text{TeO}_3$ .  $\text{TeO}$  is probably slightly basic;  $\text{TeO}_2$  is the anhydride of the weak acid  $\text{H}_2\text{TeO}_3$ , but it also shows feebly basic properties;  $\text{TeO}_3$  is a very weak acidic oxide. None of the oxides has been gasified; all are known in the solid state only. An oxide of Te and S,  $\text{TeS}_2\text{O}_3$ , is also known.

TELLURIUM MONOXIDE  $\text{TeO}$ . This oxide was prepared in 1883 by Divers a. Shimosé (*C. J.* 43, 819). It is obtained by long-continued heating  $\text{TeSO}_4$  to  $180^\circ\text{--}230^\circ$  *in vacuo* until  $\text{SO}_2$  ceases to be given off, powdering the residual solid, digesting it with water containing a little  $\text{Na}_2\text{CO}_3$ , washing with hot water, then with alcohol, and drying in a steam oven.  $\text{TeO}$  is a black, amorphous solid, with a slight brown shade, showing a graphitic lustre when pressed with a hard body. It is unchanged in air, but when heated it burns to  $\text{TeO}_2$ ; when strongly heated *in vacuo*  $\text{TeO}_2$  and Te are formed.  $\text{TeO}$  is scarcely affected by cold  $\text{KOHaq}$ ; boiling  $\text{KOHaq}$  decomposes it, giving  $\text{Te}$ .  $\text{SO}_2$ , even if boiling, scarcely acts on  $\text{TeO}$ . The oxide dissolves in hot  $\text{H}_2\text{SO}_4\text{aq}$ ; D. a. S. say that the solution deposits  $\text{Te}(\text{SO}_3)_2$  on cooling, but no analyses of the crystals that separate are given; Magnus (*P.* 10, 491) gave this formula to the product of the interaction of Te with hot conc.

$\text{H}_2\text{SO}_4$ . Heated in  $\text{HCl}$  gas  $\text{TeCl}_4$  is formed.  $\text{TeO}$  is slowly reduced to Te by  $\text{SO}_2$ .

TELLURIUM DIOXIDE  $\text{TeO}_2$ . (*Tellurous oxide*, *Tellurous anhydride*.)

Occurrence.—As *tellurite* or *tellurium ochre*, in the Seven Mountains.

Formation.—1. Te is heated in the air.—2. By decomposing a boiling solution of  $\text{TeCl}_4$  in  $\text{HClaq}$  by boiling water.—3. By heating  $\text{H}_2\text{TeO}_3$ . 4. By oxidising Te by  $\text{HNO}_3\text{aq}$ , and heating the solution.—5. According to Hilger (*J.* 171, 211) by heating Te with  $\text{H}_2\text{SO}_4$ ,  $\text{SO}_2$  is evolved and  $\text{TeO}_2$  separates on cooling.

Preparation.—Powdered Te is dissolved in warm  $\text{HNO}_3\text{aq}$ , S.G. 1.25, and the solution is heated somewhat above  $20^\circ$ ; below  $8^\circ$   $\text{H}_2\text{TeO}_3$  separates, between  $8^\circ$  and  $20^\circ$  both  $\text{TeO}_2$  and  $\text{H}_2\text{TeO}_3$  are formed, and the solid that forms from the solution above  $20^\circ$  is  $\text{TeO}_2$  only (Klein a. Morel, *Bull.* [2] 43, 198). By allowing the solution of Te in  $\text{HNO}_3\text{aq}$  to stand for some hours, and then adding some alcohol,  $\text{TeO}_2$  is obtained in crystals (Oppenheim, *J. pr.* 71, 267; cf. Berzelius, *P.* 28, 392).

Properties.—A white, crystalline solid; melts at a red heat to a transparent, yellow liquid, which on cooling forms a white crystalline mass, giving off so much heat that the solid glows feebly.  $\text{TeO}_2$  may be sublimed in a slow stream of air. Clarke (*Am. S.* [3] 14, 285) gives S.G. as  $5.7559$  at  $12.5^\circ$ . As obtained from a solution of Te in  $\text{HNO}_3\text{aq}$ ,  $\text{TeO}_2$  forms quadratic octahedra; S.G.  $5.65$  to  $5.68$  at  $0^\circ$  (K. a. M., *l.c.*). As obtained by heating  $\text{H}_2\text{TeO}_3$  till all water is removed and the residue melts,  $\text{TeO}_2$  forms orthorhombic needles; S.G.  $5.88$  to  $5.91$  at  $0^\circ$  (K. a. M., *l.c.*). Freshly-prepared  $\text{TeO}_2$  has no taste, but after a time it acquires a disagreeable metallic taste (Berzelius, *P.* 28, 392). It does not redden litmus paper. It is almost insoluble in water; 1 pt. dissolves in 150,000 pts. of water (K. a. M., *l.c.*).  $\text{TeO}_2$  is very slightly soluble in most acids; it is more soluble in  $\text{HClaq}$  (v. *infra*, *Reactions*, No. 3). Dissolves readily in solutions of caustic alkalis, but in alkali carbonate solutions and in ammonia only after long-continued boiling.  $\text{TeO}_2$  does not form  $\text{H}_2\text{TeO}_3$  by reacting with water, but as it is obtained by heating this acid it may be called tellurous anhydride.

Reactions and Combinations.—1. Reduced to Te by heating in hydrogen to the temperature whereat Te vaporises.—2. Easily reduced to Te by heating with carbon.—3.  $\text{TeO}_2$  absorbs hydrogen chloride, giving off much heat and forming compounds  $\text{TeO}_2 \cdot x\text{HCl}$ . At  $-10^\circ$ , after saturation with  $\text{HCl}$ , the compound  $\text{TeO}_2 \cdot 8\text{HCl}$  is formed; on slightly warming  $\text{HCl}$  is given off, and  $\text{TeO}_2 \cdot 2\text{HCl}$  remains, and does not change when heated to  $90^\circ$ ; on heating more strongly,  $\text{TeOCl}_2$  is formed (Ditte, *A. Ch.* [5] 10, 82). Hydrogen bromide is also absorbed by  $\text{TeO}_2$ ; by saturating  $\text{TeO}_2$  with  $\text{HBr}$  at  $-15^\circ$ , a black solid, resembling I, and having the composition  $\text{TeO}_2 \cdot 8\text{HBr}$ , is formed; this compound begins to decompose at  $-40^\circ$ , above this temperature  $\text{TeO}_2 \cdot 2\text{HBr}$  is produced, which remains unchanged to  $c. 800^\circ$ , at which temperature it decomposes to  $\text{TeOBr}$  and  $\text{H}_2\text{O}$  (D., *l.c.*). Hydrogen iodide and hydrogen fluoride are also absorbed by  $\text{TeO}_2$ , but the products have not been ex-

amined.—4. Tellurites (q. v., p. 650) are formed by dissolving  $\text{TeO}_2$  in caustic alkali solutions, or by fusing  $\text{TeO}_2$  with alkali carbonates.—5. A compound of  $\text{TeO}_2$  with sulphuric anhydride  $2\text{TeO}_2 \cdot \text{SO}_3$ —sometimes called basic tellurium sulphate—is formed by dissolving  $\text{TeO}_2$  in hot  $\text{H}_2\text{SO}_4$  diluted with 8 to 4 times its weight of water, and evaporating; it crystallises in rhombic tablets, somewhat soluble in cold dilute  $\text{H}_2\text{SO}_4$  (Klein, *C. R.* 99, 326).—6. A compound with nitric anhydride  $2(4\text{TeO}_2 \cdot \text{N}_2\text{O}_5) \cdot 3\text{H}_2\text{O}$  is described by Klein a. Morel (*Bk.* [2] 43, 198), as obtained, in rhombic needles, by dissolving  $\text{TeO}_2$  in moderately conc.  $\text{HNO}_3$ , and also by dissolving  $\text{Te}$  in excess of  $\text{HNO}_3$ , S.G. 1.15 to 1.35, and evaporating at a gentle heat. This compound—which is sometimes described as basic tellurium nitrate—is decomposed at c.  $330^\circ$ , giving off  $\text{N}$  oxides and leaving  $\text{TeO}_2$ ; with much hot water it gives a pp. of  $\text{TeO}_2$ .—7. A compound, probably  $\text{TeO}_2 \cdot \text{Ag}_2\text{O} \cdot (\text{C}_2\text{H}_3\text{O}_2)_2$ , 2aq, is formed by dissolving  $\text{TeO}_2$  in  $\text{HBrAq}$ , adding tartaric acid, and ppg. by  $\text{AgNO}_3$  (v. Brauner, *C. J.* 55, 398; cf. Klein a. Morel, *C. R.* 100, 1140).

TELLURIUM TRIOXIDE  $\text{TeO}_2$ . (Telluric oxide. Telluric anhydride.) Obtained, as an orange-yellow, crystalline mass, by heating  $\text{H}_2\text{TeO}_4$  (v. Telluric acid, p. 649) to somewhat above  $160^\circ$ . If the temperature becomes too high some of the  $\text{TeO}_2$  is decomposed to  $\text{TeO}$  and  $\text{O}$ ; it is advisable, therefore, to digest the residue with cold  $\text{HClAq}$  (to remove any  $\text{TeO}$ ), to wash out  $\text{HCl}$  by water, and to dry at  $100^\circ$ .  $\text{TeO}_2$  is not changed by cold, nor by boiling, water; nor is it acted on by cold  $\text{HClAq}$ , by hot or cold  $\text{HNO}_3$ , nor by dilute  $\text{KOH Aq}$ . Very conc. boiling  $\text{KOH Aq}$  slowly dissolves  $\text{TeO}_2$ , forming  $\text{K}_2\text{TeO}_4$ .  $\text{TeO}_2$  dissolves in boiling  $\text{HClAq}$ ,  $\text{Cl}$  is slowly given off, and  $\text{H}_2\text{TeO}_4$  is formed in the solution (v. Berzelius, *P.* 28, 392). Clarke (*Am. S.* [3] 14, 286) gives S.G. of  $\text{TeO}_2$  as 5.0704 at  $14.5^\circ$ .

TELLURIUM THIO-OXIDE  $\text{TeSO}_2$ . (Tellurium sulphoxide. Tellurium-sulphur trioxide.) This compound is obtained by dissolving pure  $\text{Te}$  in pure  $\text{SO}_2$ , and warming after a time to c.  $30^\circ$ , pouring off  $\text{SO}_2$ , and drying *in vacuo* (Weber, *J. pr.* [2] 25, 218; for description of apparatus, and details, v. Divers a. Shimosé, *C. J.* 43, 323).  $\text{TeSO}_2$  is a red amorphous solid, melting at  $30^\circ$ . When pure it remains unchanged, in a sealed tube, for months (D. a. S., *l.c.*). The colour gradually changes to brown by heating to  $35^\circ$ ; the change is instantaneous at  $90^\circ$ . The product, which is a brown solid, has the composition  $\text{TeSO}_2$  (D. a. S., *l.c.*). At c.  $180^\circ$   $\text{SO}_2$  is given off and black  $\text{TeO}$  remains (D. a. S., *l.c.*).  $\text{TeSO}_2$  is not acted on by  $\text{SO}_2$ ; it dissolves in  $\text{H}_2\text{SO}_4$ , giving an amethyst-red solution; water decomposes it to  $\text{H}_2\text{TeO}_4$ ,  $\text{TeO}$ ,  $\text{Te}$ ,  $\text{H}_2\text{SO}_4$ , and  $\text{H}_2\text{SO}_3$  (D. a. S., *l.c.*).

$\text{TeSO}_2$  may perhaps be regarded as tellurium sulphite.

Tellurium, oxyacids of,  $\text{H}_2\text{TeO}_4$ , v. TELLURIC ACID (p. 656);  $\text{H}_2\text{TeO}_3$ , v. TELLURIC ACID (p. 649).

Tellurium, oxybromide of,  $\text{TeOBr}$ . A pale-yellow solid; obtained by heating  $\text{TeO}_2 \cdot 2\text{HBr}$  (v. Tellurium dioxide; *Reactions*, No. 8, p. 654) above  $300^\circ$ . Melts at red heat, forming a very dark-coloured liquid, which gives off almost

black vapour with partial decomposition to  $\text{TeO}$ , and  $\text{TeBr}$ , (Ditte, *A. Ch.* [5] 10, 82).

Tellurium, oxychloride of,  $\text{TeOCl}$ . Prepared by heating  $\text{TeO}_2 \cdot 2\text{HCl}$  (v. Tellurium dioxide; *Reactions*, No. 8) to above  $90^\circ$ . Very similar to  $\text{TeOCl}$ , (Ditte, *A. Ch.* [5] 10, 82). Decomposed at fairly high temperature to  $\text{TeO}$ , and  $\text{TeCl}$ .

Tellurium, oxyiodide of. According to Berzelius (*Lehrbuch* [5th edit.] 3, 1141), a greyish-brown, heavy powder is formed by digesting  $\text{TeI}$  with boiling water, and this powder is probably an oxyiodide of  $\text{Te}$ ; no analyses are given.

Tellurium, salts of. No compounds have been prepared by directly replacing the  $\text{H}$  of oxyacids by  $\text{Te}$ . According to Divers a. Shimosé (*C. J.* 43, 319),  $\text{Te}(\text{SO}_3)_2$  is formed by dissolving  $\text{TeO}$  in hot  $\text{H}_2\text{SO}_4$  and cooling, but no analyses are given; Magnus (*P.* 10, 491) gave the formula  $\text{Te}(\text{SO}_3)_2$  to the product of the interaction of  $\text{Te}$  and hot conc.  $\text{H}_2\text{SO}_4$ . The compounds  $2\text{TeO}_2 \cdot \text{SO}_3$  and  $2(4\text{TeO}_2 \cdot \text{N}_2\text{O}_5) \cdot 3\text{aq}$  are sometimes called basic tellurium sulphate and basic tellurium nitrate respectively; the compound  $\text{TeSO}_2$  (v. *supra*, Tellurium thio-oxide) may perhaps be looked on as tellurium sulphite; and a compound, probably  $\text{TeO}_2 \cdot \text{Ag}_2\text{O} \cdot (\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 2\text{aq}$ , is called tellurium-silver tartar emetic (v. Tellurium dioxide; *Reactions*, Nos. 5, 6, and 7, *supra*).

Tellurium silver tartar emetic v. Tellurium dioxide; *Reactions*, No. 7, *supra*.

Tellurium, sulphides of. Berzelius (*P.* 8, 411) described two sulphides,  $\text{TeS}$ , and  $\text{TeS}_2$ , corresponding with the oxides  $\text{TeO}$ , and  $\text{TeO}_2$ . According to Becker (*A.* 180, 257),  $\text{CS}_2$  removes almost all the  $\text{S}$  from these supposed compounds. B. concludes that the substances described by Berzelius are not definite compounds; he thinks that compounds of  $\text{Te}$  and  $\text{S}$  are probably formed by passing  $\text{H}_2\text{S}$  into  $\text{TeO Aq}$  and  $\text{TeO Aq}$ . As the substances obtained by Berzelius seem to have very definite properties, they are shortly described here.

TELLURIUM DISULPHIDE  $\text{TeS}_2$ . A dark-brown pp. formed by passing  $\text{H}_2\text{S}$  into  $\text{H}_2\text{TeO}_4$ , or into an acidified solution of an alkali tellurite; softens when heated and cools to a gray, somewhat lustrous mass; gives off  $\text{S}$  when strongly heated.  $\text{TeS}_2$  reacts as an acidic sulphide, forming compounds  $\pi\text{MS} \cdot \text{TeS}_2$ , where  $\text{M} = (\text{NH}_4)_2, \text{Cd}, \text{Li}, \text{Fe}, \text{Mg}, \text{Pb}, \text{K}, \text{Na}, \text{Zn}, \text{&c.}$  The thiotellurites of the alkali metals are best obtained by saturating aqueous solutions of the tellurites with  $\text{H}_2\text{S}$ , and crystallising *in vacuo*; the thiotellurites of alkaline earth metals are formed by boiling the sulphides of these metals with  $\text{TeS}_2$  and water; the thiotellurites of the heavy metals are obtained by ppn. from solutions of the alkali salts (Berzelius, *P.* 8, 411).

TELLURIUM TRISULPHIDE  $\text{TeS}_3$ . A blackish grey, lustrous solid; formed by saturating  $\text{H}_2\text{TeO}_4$  with  $\text{H}_2\text{S}$ , and allowing to stand for some time in a closed vessel in a warm place. Thiotellurates of the alkali metals,  $\pi\text{M} \cdot \text{S} \cdot \text{TeS}_3$ , are formed by saturating  $\text{M}_2\text{TeO}_4$  with  $\text{H}_2\text{S}$  (v. Oppenheim, *J. pr.* 71, 267).

Tellurium, sulphoxide of, v. Tellurium thio-oxide, *supra*.

Tellurium, thio-oxide of, v. *supra*.

**Tellurium, thio-salts of, v. TELLURIUM DISULPHIDE, p. 655; and TELLURIUM TRISULPHIDE, p. 656.** M. M. P. M.

**TELEUROCYANIDES v. vol. ii. p. 853.**

**TELLUROUS ACID  $H_2TeO_3$ .**

**Formation.**—1. By dissolving Te in  $HNO_3$  Aq, S.G. 1.25, and at once ppg. by water; if the solution is left for some time before adding water the pp. is  $TeO_2$ .—2. By decomposing  $TeCl_4$  by cold water.

**Preparation.**— $TeO_2$  is fused with an equal weight of  $K_2CO_3$  or  $Na_2CO_3$  as long as  $CO_2$  is given off; the tellurite thus formed is dissolved in water, and  $HNO_3$  Aq is added until the liquid has a very distinctly acid reaction; the flocculent pp. thus produced is allowed to remain in contact with the liquid for some hours, and is then thoroughly shaken up with the liquid, a little  $HNO_3$  Aq being added if the acid reaction disappears during this process; the pp. is then washed with ice-cold water, and dried at the ordinary temperature (Berzelius, *P.* 28, 392; cf. Oppenheim, *J. pr.* 71, 267). The solution of the alkali tellurite in  $HNO_3$  Aq may be decomposed by adding water, but this must be done at once, as after standing water ppt.  $TeO_2$ .

**Properties and Reactions.**—A white, light, amorphous solid, with a bitter, metallic taste. Reddens litmus paper. Dissolves slightly in cold water; when the aqueous solution is heated to c.  $40^\circ$   $TeO_2$  separates. When slightly heated gives  $TeO_2$  and  $H_2O$ .  $H_2TeO_3$  dissolves in many acids; from the solution in  $HCl$  Aq, water or alkalis ppt.  $H_2TeO_3$ ; the solution in  $HNO_3$  Aq gives a pp. of  $TeO_2$  on addition of water after standing for some time. From the solution in  $H_2SO_4$  Aq and  $HNO_3$  Aq the compounds  $2TeO_3 \cdot SO_3$  and  $2(4TeO_3 \cdot N_2O_5) \cdot 3aq$  have been obtained (v. TELLURIUM DIOXIDE; *Reactions*, No. 5 and 6, p. 655).  $H_2TeO_3$  forms tellurites (q. v., p. 650). Thomsen (*Th.* 2, 278) gives  $[TeO_3 \cdot H_2O] = 77.180$ . M. M. P. M.

**TELLURIUM, Organic Compounds of.**

**Methyl telluride  $Me_2Te$ .** (82°). Formed by distilling  $K_2Te$  with  $Ba(SO_4)_2$  (Wöhler & Dean, *A.* 93, 233; Heeren, *Dissertation*, Göttingen, 1861). Pale-yellow, mobile, heavy oil, with persistent alliacous smell. Oxidised by  $HNO_3$  to  $Me_2TeO_2HNO_3$ , crystallising in prisms.— $Me_2TeHOAc$ . Transparent cubes, v. sol. water. Its solution gives with  $HCl$  a pp. of  $Me_2TeCl_2$ , which crystallises in long prisms [ $97.5^\circ$ ].— $Me_2TeBr$ , [89°]. Prisms.— $(Me_2Te)_2H_2CO_3$ . Difficult to crystallise.—Formate  $Me_2TeCH_3O_2$ . Deliquescent needles.— $Me_2TeI_2$ . Formed by heating  $Te$  with  $MeI$  at  $80^\circ$  (Demarçay, *Bl.* [2] 40, 100).— $(Me_2Te)_2H_2C_2O_4$ .— $Me_2TeO$ . Got from  $Me_2TeCl_2$  and  $Ag_2O$ . Deliquescent crystalline mass, alkaline to litmus.— $Me_2TeOCl_2$ . Got from the chloride and  $NH_3$  Aq. Short prisms (from alcohol).— $(Me_2Te)_2OBr_2$ .— $(Me_2Te)_2H_2SO_4$ . Cubes, v. sol. water, insol. alcohol.

**Methyl-iodide  $Me_2TeI_2$ .** Crystalline, sl. sol. water. Converted by moist  $Ag_2O$  into an alkaline base which yields  $(Me_2TeCl)_2PtCl_6$ .

**Ethyl telluride v. vol. ii. p. 519.**

**TEMPLIN OIL.** An essential oil obtained from fir cones (Flückiger, *J.* 1855, 642; Berthelot, *J. Ph.* [3] 29, 38). Colourless, becoming greenish-yellow in air. Boils at  $155^\circ$ – $177^\circ$ . S.G. 1.262. Yields on rectification a laboratory

terpene (172°) S.G. 1.856.  $HNO_3$  ( $\frac{1}{2}$  vol.) and alcohol ( $\frac{1}{2}$  vol.) yield terpin hydrate  $C_{10}H_{16}O_2$  aq [ $118^\circ$ ] ( $250^\circ$ ) S. 9 at  $100^\circ$ . Alcohol and  $HCl$  yield crystalline  $C_{10}H_{16}HCl$  and  $C_{10}H_{14} \cdot 2HCl$  [ $55^\circ$ ].

**TERACONIC ACID  $C_4H_6O_4$ , i.e.**

$OMe \cdot C(CO_2H) \cdot CH_2 \cdot CO_2H$ . *Propylidene-succinic acid*. [ $163^\circ$ ]. Formed in small quantity by distilling the isomeric terebic acid (Goisler, *A.* 208, 50).  $Na$  and  $NaOEt$  convert terebic ether into sodium ethyl teraconate (W. Roser, *B.* 15, 293). Formed also by treatment of the ether  $CO_2Et \cdot CBrPr \cdot CH_2 \cdot CO_2Et$  with alcoholic potash (Schleicher, *A.* 267, 130). Crystals, sol. alcohol and ether, v. sol. cold water. Above  $163^\circ$  it yields  $H_2O$  and an anhydride. Conc.  $HBr$  Aq at  $0^\circ$  forms terebic acid.

**Salts.**— $BzA''$ .— $CaA''$ . Pp. v. sl. sol. water.— $Ag_2A''$ . Needles, in. sol. water.

*Mono-ethyl ether  $EtHA''$ .* Oil. Decomposes  $Na_2CO_3$ , forming crystalline  $NaEtA''$ , a solution of which gives with  $AgNO_3$  a pp. of the unstable  $AgEtA''$ .

*Di-ethyl ether  $Et_2A''$ .* (255 i.v.). Oil.

**TERACRYLIC ACID  $C_4H_4O_4$ .** (218° i.v.). A product of the distillation of terpenylic acid (Pittig & Kraft, *B.* 10, 521, 1659, 1740; *A.* 208, 79; Amthor, *J. pr.* [2] 42, 389). Liquid, smelling like valeric acid, sl. sol. and lighter than water. Yields acetic acid on fusion with potash. Fuming  $HBr$  forms  $C_4H_5BrO_3$ , which gradually splits up into  $HBr$  and heptolactone  $C_7H_{12}O_3$ .— $CaA'$ , aq. Prisms or needles.— $AgA'$ : needles. *Ethyl ether  $EtA'$ .* (191°). Fruity oil.

**TERBIUM.** Tr. At. w. not determined with certainty; probably c. 162 (v. *infra*).

The examination of *gadolinite*, a rare Swedish mineral, by Mosander, Cleve, and others made probable the existence therein of at least seven earths, to one of which the name *terbia* was given (v. *Erastus*, vol. ii. p. 456, where the history of these earths is stated more fully, with references to original memoirs). It is still very doubtful whether the substance called *terbia* is a homogeneous body or a mixture of more than one compound (cf. *METALS*, rare, vol. iii. p. 242). Delafontaine (*A. Ch.* [5] 14, 238) prepared an orange-yellow, earthy compound, which he regarded as pure *terbia*, from *samaraskite*, by a long process of fractional ppn., first by  $K_2SO_4$  Aq, then by oxalic acid, and finally by formic acid (cf. *Marignac*, *A. Ch.* [5] 14, 247; Cleve, *Bl.* [2] 31, 197).

*Terbia*  $Tr_2O_3$  is described as an orange-yellow amorphous solid; when heated in  $H$  for some time it becomes white.  $Tr_2O_3$  dissolves in acids, forming salts of the type  $Tr_2X_3$ , where  $X = SO_4, CO_3, 2NO_3$ , &c. The emission spectrum of *terbia* has been mapped by Roscoe & Schuster (*C. J.* 41, 283). The at. w. of  $Tr$ —the supposed element has not been isolated—was determined by Delafontaine to be 113.5; Marignac found the value 118.5; Lecoq de Boisbaudran found 163.1, 161.4, and by later work 159.5 (*C. R.* 102, 895; 111, 474). M. M. P. M.

**TEREBENE v. TERPÈNES.**

**TEREBENTHENE v. TERPÈNES.**

**DITERBENTHYL  $C_{10}H_{16}$ .** V.D. 4.6. ( $345^\circ$ ). S.G. 1.2688. [ $n_D^{20}$ ] =  $59^\circ$ . A product of distillation of colophony (Renard, *C. R.* 105, 865; 106, 866). Oil, resinified by air.  $KMnO_4$  oxidises it

to propionic, acetic, and formic acids and  $\text{CO}_2$ . Cold fuming  $\text{HNO}_3$  forms  $\text{C}_{10}\text{H}_8(\text{NO}_2)_2$ , a yellow powder, sol. alcohol and ether. Br in  $\text{CS}_2$  at  $-10^\circ$  forms  $\text{C}_{10}\text{H}_6\text{Br}_2$ , which on heating yields dibromethylene  $\text{C}_2\text{H}_2\text{Br}_2$  (347°) S.G. 1.9821, whence Br forms  $\text{C}_2\text{H}_2\text{Br}_2$ .  $\text{HNO}_3$  produces  $\text{C}_{10}\text{H}_8(\text{NO}_2)_2$  and  $\text{H}_2\text{SO}_4$  forms  $\text{C}_{10}\text{H}_8\text{SO}_4\text{H}$ , all amorphous solids. Bromine-water gives rise to  $\text{C}_{10}\text{H}_8\text{Br}_2$ , a brown, amorphous solid. Gaseous  $\text{HCl}$  passed into the ethereal solution forms  $\text{C}_{10}\text{H}_8\text{HCl}$ .  $\text{H}_2\text{SO}_4$  yields  $\text{C}_{10}\text{H}_8\text{SO}_4\text{H}$ , which is sol. water, alcohol, and ether, forming fluorescent solutions. Dibromethylene passed through a red-hot tube forms  $\text{H}$ ,  $\text{C}_2\text{H}_2$ ,  $\text{C}_2\text{H}_4$ , pentane, hexane, hexylene, hexinene, heptinene, cymene, and other hydrocarbons.

**TEREBENTILIC ACID**  $\text{C}_{10}\text{H}_{16}\text{O}_4$  [90°]. (250°). Got by passing the vapour of the hydrate of oil of turpentine  $\text{C}_{10}\text{H}_{16}\text{O}_2\text{H}_2\text{O}$  over soda-lime at  $400^\circ$  (Personne, A. 100, 253; cf. Hempel, A. 180, 86). Crystalline powder, sol. hot water, v. sol. alcohol and ether. May be sublimed.— $\text{AgA}'$ . Crystalline.

**TEREBENTIC ACID**  $\text{C}_{10}\text{H}_{16}\text{O}_4$ . Got by digesting oil of turpentine with oxide of lead (Weppen, A. 41, 294). Crystals (from alcohol).

**TEREBIC ACID**  $\text{C}_{10}\text{H}_{16}\text{O}_4$ , i.e.

$\text{CMe}_2 \begin{smallmatrix} \text{CH}(\text{CO}_2\text{H}) \\ \text{O} \end{smallmatrix} \text{CO} \text{CH}_2$ . Mol. w. 158. [176°].

H.C.v. 766, 642 (Ossipoff, C. R. 108, 812). S. (ether) 2-856 at  $35^\circ$  (Amthor, J. pr. [2] 42, 385). Formed by the action of nitric acid on oil of turpentine (Bromeis, A. 37, 297; Rabourdin, J. Ph. [3] 6, 185; Cailliot, A. Ch. [3] 21, 27; Svanberg a. Fekmann, J. pr. 66, 220; Mielck, A. 180, 47; Bredt, A. 208, 37; Erdmann, A. 223, 179). Formed also by oxidising pinol (Wallach, A. 253, 256; 259, 317). Terebic acid is perhaps identical with oxyhexoic acid (Gorboff, J. R. 1887, 605). Monoclinic crystals (from alcohol), sl. sol. cold, v. sol. hot water. V. sol. alcohol and ether. Not attacked by fuming  $\text{HNO}_3$ . Split up by water at  $150^\circ$  into  $\text{CO}_2$  and pyroterebic acid. On boiling with  $\text{H}_2\text{SO}_4$  (2 pts.) and water (1 pt.) it is converted into the lactone of oxy-isohexoic acid  $\text{CMe}_2 \begin{smallmatrix} \text{CH}_2 \\ \text{O} \end{smallmatrix} \text{CO} \text{CH}_2$ ,  $\text{CO}_2$  being evolved. On distillation it yields pyroterebic (hexenoic) acid, oxy-isohexoic lactone, and a little tereonic acid. On heating for 15 hours at  $160^\circ$  with excess of a saturated solution of baryta it is converted into acetone and succinic acid (Frost, A. 226, 363). Fuming  $\text{HNO}_3$  yields  $\text{CH}_3\text{Pr.CH}_2\text{CO}_2\text{H}$ . Alkalis form salts of diaterebic acid, of which terebic acid is the lactone.

**Salts.**— $\text{NH}_4\text{A}'$ : very soluble prisms.— $\text{KA}'$ : aq.— $\text{NaA}'$ : aq.— $\text{BaA}'$ : 2aq.: amorphous.— $\text{AgA}'$ : Prisms, v. sol. water.

**Ethyl ether EtA'**. (274° i.v.). S.G. 1.111. Formed from terebic acid, alcohol, and  $\text{HCl}$ . Dilute  $\text{NaOH}$  dissolves it, forming monoethyl diaterebate; on cautious acidification the ether separates again, but only after warming (Ekmann). Sodium dissolves in its ethereal solution, giving off hydrogen and forming the sodium salt of acid ether of tereonic acid (q. v.). Alcoholic  $\text{NaOEt}$  acts in the same way, excess forming a white pp. of disodic tereonate.

**Diaterebic acid**

$\text{CMe}_2(\text{OH}).\text{CH}(\text{CO}_2\text{H}).\text{CH}_2\text{CO}_2\text{H}$ . The salt  $\text{BaA}''$  3aq. is formed by boiling terebic acid with excess of baryta-water. It crystallises from

vac. IV.

alcohol, but on acidification at once yields the lactone, terebic acid.  $\text{AgNO}_3$  added to a solution of the Ba salt ppt.  $\text{AgA}''$ .— $\text{CaA}''$  3aq.— $\text{CaA}''$ .— $\text{PbA}''$  3aq.— $\text{PbA}''$ .  $\text{H}_2\text{O}$ , aq.

**Ethyl ether EtA'**. Formed from  $\text{AgA}''$  and  $\text{EtH}$ . Oil. Converted by acetyl chloride into  $\text{CMe}_2(\text{OAc}).\text{CH}(\text{CO}_2\text{Et}).\text{CH}_2\text{CO}_2\text{Et}$ , an unstable oil.

**$\beta$ -Bromo-terebic acid**  $\text{C}_{10}\text{H}_{15}\text{BrO}_4$ , i.e.

$\text{CMe}_2 \begin{smallmatrix} \text{CBr}(\text{CO}_2\text{H}) \\ \text{O} \end{smallmatrix} \text{CO} \text{CH}_2$ . [151°]. Formed by

adding Br (1 mol.) to powdered tereonic acid (1 mol.) covered with water (Frost, A. 226, 363). Large crystals, m. sol.  $\text{CS}_2$ , v. sl. sol. chloroform and benzene. Decomposed by boiling with water into  $\text{HBr}$  and terebilic acid  $\text{C}_{10}\text{H}_{16}\text{O}_4$ . Reduced by sodium-amalgam to terebic acid.

**References.**—CHLORO- and OXY-TEREBIC ACID.

**TEREBILENIC ACID**  $\text{C}_{10}\text{H}_{16}\text{O}_4$ , i.e.

$\text{CMe}_2 \begin{smallmatrix} \text{C}(\text{CO}_2\text{H}) \\ \text{O} \end{smallmatrix} \text{CO} \text{CH}_2$  (?) [169]. Formed by

heating  $\alpha$ -chloro-terebic acid at  $200^\circ$  (Rosser, B. 15, 296; A. 220, 261) and by evaporating  $\beta$ -chloro-terebic acid with water (Frost, A. 226, 370). Small prisms or needles (from water), v. sol. alcohol and ether. Crystallises from alcohol or conc.  $\text{HBrAq}$  in trimetric forms;  $a:b:c = .809:1:858$ . May be sublimed. Excess of  $\text{KOH}$  forms the diaterebilenate  $\text{K}_2\text{C}_{10}\text{H}_{14}\text{O}_4$ , but this splits up on warming with water into  $\text{KOH}$  and potassium terebilenate. Does not combine with  $\text{Br}$  or  $\text{HBr}$ . Sodium-amalgam reduces it to terebic acid.— $\text{CaA}''$ .— $\text{AgA}'$ . Prisms.

**Reference.**—CHLORO-TEREBILENIC ACID.

**TERECHRYSIC ACID**  $\text{C}_{10}\text{H}_{16}\text{O}_4$ . A product

of the action of  $\text{HNO}_3$  (S.G. 1-2) on turpentine (Cailliot, A. 64, 376). Orange-red crystals, v. o. sol. water, alcohol, and ether.— $\text{PbA}''$ : crystals.

**TERELACTONE**  $\text{C}_{10}\text{H}_{16}\text{O}_4$ , i.e.  $\text{C}_{10}\text{H}_{16} \begin{smallmatrix} \text{O} \\ \text{CO} \end{smallmatrix}$ . [12°].

(210° i.v.). Formed by the action of boiling water on di-bromo-isohexoic acid derived from pyroterebic acid and Br (Geisler, A. 208, 47). Mobile liquid, sol. water. Boiling baryta-water converts it into amorphous  $\text{Ba}(\text{C}_{10}\text{H}_{14}\text{O}_4)_2$ , which is sol. water and deposits  $\text{BaCO}_3$  on boiling.

**TEREPHTHALIC ACID**  $\text{C}_8\text{H}_6\text{O}_4$ , i.e.  $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_2$ . *p*-Phthalic acid. Mol. w. 166. H.C.p. 770,900. H.C.v. 771,200. H.F. 188,100 (Stohmann, J. pr. [2] 40, 139).

**Formation.**—1. By the action of  $\text{HNO}_3$  on oil of turpentine (Cailliot, A. Ch. [3] 21, 28; De la Rue a. Hugo Müller, A. 121, 86; Schreder, B. 7, 704; cf. W. C. Williams, B. 6, 1094).—2. By the oxidising action of chromic acid mixture on *p*-xylene (Beilstein, A. 133, 32; 137, 301), cuminic acid, camiric aldehyde, cymene (Hofmann, A. 97, 197), *p*-toluic acid (Beilstein A. Yssel, A. 137, 308), di-ethyl-benzene, and amyltoluene (Fittig, A. 141, 167).—3. By the action of boiling dilute  $\text{HNO}_3$  on cymene and on terpenes (Schwanert, A. 132, 257; Homeyer, Ar. Ph. [3] 5, 326).—4. By oxidation of *o*-ethyltoluene by aqueous  $\text{KMnO}_4$  (Claus a. Pieszeck, B. 19, 3083).—5. By fusing potassium *p*-sulphobenzoate with sodium formate (Remsen, B. 5, 379).—6. From its nitrile, which is obtained by distilling  $\text{K}_2\text{FeCy}_4$  with potassium benzene *p*-disulphonate (Garrick, Z. 1869, 551), *p*-chlorobenzene sulphonate (Nötting, B. 8, 1118), or *p*-

U U

bromo-benzene sulphonate (Ireland, Z. 1869, 184; Barth a. Senhofer, A. 174, 242; Limprieh, A. 180, 88).—7. The semi-nitrile is also formed by the action of a hot solution of cuprous potassium cyanide upon *p*-diazobenzoic acid (Sandmeyer, B. 18, 1497).—8. By heating *p*-di-bromo-benzene with chloroformic ether and, 1 p.c. sodium-amalgam at 110° and saponifying the product (Bonz, B. 18, 2305).—9. By the action of 5 p.c.  $\text{KMnO}_4$  on an oil (258°–263°) which remains as a residue in the manufacture of aniline and toluidine (Hell a. Hockenbach, B. 22, 505).

**Preparation.**—1. Br (2 mols.) is added to boiling *p*-xylene (100 g.), and the resulting  $\text{C}_6\text{H}_4(\text{CH}_2\text{Br})_2$  decomposed by alcoholic KOAc on the water-bath. After evaporating the alcohol the  $\text{C}_6\text{H}_4(\text{OAc})_2$  is extracted with ether, and oxidised by adding 4.5 litres of 10 p.c.  $\text{KMnO}_4$  to its solution in water (1 litre) and NaOH (500 g. of S.G. 1.22). Finally more  $\text{KMnO}_4$  is added till the solution remains violet, the solution kept at 100° for 3 hours, filtered, and ppd. by HCl (Baeyer, A. 245, 139).—2. By oxidising *p*-xylene with chromic acid mixture (Beilstein, A. 133, 41). 3. From *p*-toluidine by Sandmeyer's reaction, the resulting *p*-toluic acid being oxidised by  $\text{KMnO}_4$  (Baeyer a. Herb, A. 258, 1).

**Properties.**—White crystalline powder, nearly insol. water, alcohol, ether, chloroform, and HOAc. Sublimes without previous fusion. Does not yield an amide on boiling with aniline (Michael a. Palmer, B. 19, 1376). It is ppd. from its salts by phthalic acid. Yields benzene when distilled with slaked lime. Reduced by sodium-amalgam in a current of  $\text{CO}_2$  to the  $\Delta^2$  or (1,4)-dihydride. If  $\text{CO}$  be not used the product is the  $\Delta^4$  or (3,6)-dihydride, which is also got by boiling the (1,4)-dihydride with NaOHAq (Baeyer, A. 269, 153; cf. Mohs, Z. [2] 3, 68). The (1,4)-dihydride gives benzoic acid on oxidation by  $\text{MnO}_2$  and dilute  $\text{H}_2\text{SO}_4$ , while the (3,6)-dihydride forms terephthalic acid (Baeyer, A. 269, 182). By heating its alkaline solution with sodium-amalgam terephthalic acid is reduced to a tetrahydride, and this is further reduced by HIAq at 240° to a hexahydride (Baeyer, B. 19, 1805).

**Salts.**— $(\text{NH}_4)_2\text{A}''$ . Small crystals. —  $\text{CaA}''$  3aq. S. 0.8 at 6°. —  $\text{BaA}''$  4aq. S. 2.8 at 5°. —  $\text{SrA}''$ . S. 1.9 at 17°. —  $\text{Ag}_2\text{A}''$ . Curdy pp.

**Mono-methyl ether**  $\text{MeHA}''$ . [c. 230°]. Formed by the action of conc.  $\text{H}_2\text{SO}_4$  or alcoholic potash on the di-methyl ether (Baeyer, A. 245, 141). Needles, sol.  $\text{Na}_2\text{CO}_3$  aq and hot water.

**Di-methyl ether**  $\text{Me}_2\text{A}''$ . [140°]. S. 3 at 100°. H.F. 172,300 (Stohmann, J. pr. [2] 43, 2). Formed by heating the acid with  $\text{PCl}_5$  on the water-bath and pouring the product into methyl alcohol. Trimetric plates;  $a:b:c = .843:1.3:0.83$ . Insol. cold water, sl. sol. hot  $\text{MeOH}$ , m. sol.  $\text{EtOH}$ .

**Di-ethyl ether**  $\text{Et}_2\text{A}''$ . [44°]. Prisms. **Propyl ether**  $\text{Pr}_2\text{A}''$ . [31°]. Needles. **Isopropyl ether**  $\text{Pr}_2\text{A}''$ . [56°]. Plates. **n-Butyl ether**  $(\text{C}_4\text{H}_9)_2\text{A}''$ . Liquid. **Isobutyl ether**  $(\text{CH}_3)_2\text{CH}(\text{C}_4\text{H}_9)_2\text{A}''$ . [52.5°]. Needles, v. sol. ether (Berger, B. 10, 1742). **Isosamyl ether**  $(\text{C}_5\text{H}_{11})_2\text{A}''$ . Pearly scales. **Phenyl ether**  $\text{Ph}_2\text{A}''$ . [194°] (Baeyer, A. 258, 44). Formed from the chloride and phenol. Leaflets.

**Chloride**  $\text{C}_6\text{H}_4(\text{COCl})_2$ . [78°]. (259°).

**Amic acid**  $\text{C}_6\text{H}_4(\text{CONH}_2)_2\text{CO}_2\text{H}$ . [214°]. Formed from *p*-diazobenzoic acid by Sandmeyer's reaction (Sandmeyer, B. 18, 1498). Minute plates (from water), m. sol. cold water.

**Amide**  $\text{C}_6\text{H}_4(\text{CONH}_2)_2$ . Formed from the chloride and  $\text{NH}_4\text{Aq}$ . Amorphous.

**Nitrile**  $\text{C}_6\text{H}_4(\text{CN})_2$ . [220°] (Luckenbach, B. 17, 1428). Formed from the amide and  $\text{P}_2\text{O}_5$ . Got also by distilling calcium bromo-benzene *p*-sulphonate with  $\text{K}_2\text{FeCy}_4$ . Conc. HIAq forms  $\text{C}_6\text{H}_4(\text{Cl}_2\text{NH})_2$  (Biltz, B. 25, 2543).

**cistrans  $\Delta^{2,5}$  or (1,4)-Dihydride**

$\text{CO}_2\text{H}.\text{CH} < \begin{smallmatrix} \text{CH}:\text{CH} \\ \text{CH}:\text{CH} \end{smallmatrix} > \text{CH}.\text{CO}_2\text{H}$ . S. 3 in the

cold. H.F. 182,600 (Stohmann, J. pr. [2] 43, 538). Formed by reducing terephthalic acid in a current of  $\text{CO}_2$  by sodium-amalgam (Baeyer, A. 251, 257; 269, 153). Monoclinic prisms (from  $\text{EtOAc}$ );  $a:b:c = .982:1.1:0.19$ ;  $\beta = 78^\circ 2'$ . M. sol. ether. Not attacked by sodium-amalgam in the cold. Unites with bromine (4 atoms). Transformed into the  $\Delta^4$  isomeride by boiling with water, and into the  $\Delta^4$  acid by boiling with NaOHAq. Alkaline  $\text{KMnO}_4$  re-oxidises the acid to terephthalic acid. A warm solution of the acid readily reduces  $\text{AgNO}_3$ . On warming with aqueous cupric acetate it gives off  $\text{CO}_2$  and forms a white pp. which, on adding HOAc and warming, yields  $\text{Cu}_2\text{O}$ , the liquid then containing benzoic acid. The (3,6), (3,4), and (2,3) isomerides do not reduce  $\text{AgNO}_3$  and cupric acetate. The Ba salt crystallises in plates, and is v. sol. water.

**Methylether**  $\text{Me}_2\text{A}''$ . [77°]. Yields a di- and a tetra-bromide. Br in  $\text{CHCl}_3$  forms a di-bromide [170°] and a tetrabromide [98°].

**Di-phenylether**  $\text{Ph}_2\text{A}''$ . [146°]. Formed from the chloride and phenol at 100°. Small crystals, sl. sol. alcohol, ether, and ligroin.

**cis  $\Delta^{2,5}$  or (1,4)-Dihydride**

$\text{CO}_2\text{H}.\text{CH} < \begin{smallmatrix} \text{CH}:\text{CH} \\ \text{CH}:\text{CH} \end{smallmatrix} > \text{C}(\text{CO}_2\text{H})_2$ . Extracted by

ether from the mother-liquor from which the preceding isomeride has separated. Closely resembles its *cistrans* isomeride, but the *cis* acid and its salts are the more soluble.

**$\Delta^{1,5}$  or (3,4)-Dihydride**

$\text{CO}_2\text{H}.\text{CH} < \begin{smallmatrix} \text{CH}:\text{CH} \\ \text{CH}_2:\text{CH} \end{smallmatrix} > \text{C}.\text{CO}_2\text{H}$ . S. 0.42 in the

cold. H.F. 185,300. Formed by boiling the (1,4)-dihydride with water, and obtained, therefore, by reducing terephthalic acid with sodium-amalgam (Baeyer, A. 245, 142; 251, 257; 269, 148). Converted into the (3,6)-acid by NaOHAq. Sodium-amalgam in the cold reduces it to the  $\Delta^2$  tetrahydride. —  $\text{BaA}''$  4aq. Trimetric crystals;  $a:b:c = .319:1:352$  (Baeyer a. Herb, A. 258, 22). **Methylether**  $\text{Me}_2\text{A}''$ . [40°].

**$\Delta^{1,4}$  or (3,6)-Dihydride**

$\text{CO}_2\text{H}.\text{C} < \begin{smallmatrix} \text{CH}_2:\text{CH} \\ \text{CH}_2:\text{CH} \end{smallmatrix} > \text{C}.\text{CO}_2\text{H}$ . S. 0.059 in the

cold. H.F. 191,900. Formed by reduction of terephthalic acid in a 'kaline solution by sodium-amalgam (Baeyer, A. 245, 142). Got also by boiling the (1,4)-dihydride with NaOHAq. slender needles (from water), almost insol. ether. Much resembles terephthalic acid. On sublimation it is partially converted into terephthalic

acid. Immediately oxidised by  $\text{KMnO}_4$ . Forms  $\text{CH}(\text{CO}_2\text{H})\langle\text{CH}_2, \text{CHBr}\rangle\text{CH}(\text{CO}_2\text{H})$  by uniting with  $\text{HBr}$ . Sodium-amalgam in the cold reduces it to a slight extent, forming the two isomeric  $\Delta^2$  tetrahydrides.— $\text{BaA}''$  4aq. Crystals, resembling its  $\Delta^{1,5}$  and  $\Delta^{1,3}$  isomerides.

*Mono-methyl ether*  $\text{MeA}''$ . [225°]. Got from  $\text{Me}_2\text{A}''$  and alcoholic potash. Needles (from hot-water).

*Di-methyl ether*  $\text{Me}_2\text{A}''$ . [130°]. H.F. 172,700. Formed from the dihydride by successive treatment with  $\text{PCl}_5$  (2 mols.) and  $\text{MeOH}$ . Monoclinic plates (from  $\text{EtOAc}$ );  $a:b:c = 1.52:1.2:79$ ;  $\beta = c. 74^\circ$ . Sl. sol. water, m. sol. hot alcohol, v. e. sol. ether. Br in  $\text{CHCl}_3$  yields a dibromide  $\text{C}_6\text{H}_2\text{Br}_2(\text{CO}_2\text{Me})_2$  [90°] and a tetrabromide [150°]. Excess of Br yields  $\text{CO}_2\text{Me} \cdot \text{C}_6\text{H}_2\text{Br}_4 \cdot \text{CO}_2\text{Me}$  [188°].  $\text{HBr}$  forms  $\text{C}_6\text{H}_2\text{Br}_2(\text{CO}_2\text{H})_2$  which yields  $\text{C}_6\text{H}_2\text{Br}_2(\text{CO}_2\text{Me})_2$  [166°].

*Di-phenyl ether*  $\text{Ph}_2\text{A}''$ . [191°]. Formed by treating the chloride with phenol (Baeyer & Herb, A. 258, 31). Small scales (from hot  $\text{MeOH}$ ), sl. sol. ether.

$\Delta^{1,3}$  or (5,6)-Dihydride

$\text{CO}_2\text{H} \cdot \text{C} \langle \text{CH}_2, \text{CH} \rangle \text{C} \cdot \text{CO}_2\text{H}$ . S. 0053 in the cold. Formed by the action of alcoholic potash on the dibromide of the  $\Delta^2$  tetrahydride and on the tetrahydride of di-bromo-terephthalic acid got by bromination of the hexahydride. Unites with hydrogen bromide (2 mols.) forming  $\text{CO}_2\text{H} \cdot \text{CH} \langle \text{CH}_2, \text{CHBr} \rangle \text{CH} \cdot \text{CO}_2\text{H}$ . Easily reduced by Zn and  $\text{HOAc}$  and by sodium-amalgam to the two  $\Delta^2$  tetrahydrides. Boiling water converts it into the (3,4)-isomeride. Boiling  $\text{NaOH}$  forms the (3,6)-isomeride.— $\text{BaA}''$  4aq. Needles (from hot water).

*Methyl ether*  $\text{Me}_2\text{A}''$ . [85°]. Monoclinic plates;  $a:b:c = 2.21:1.3:591$ ;  $\beta = 87^\circ 13'$ . Slowly converted by  $\text{HBr}$  into (2,3)-di-bromo-terephthalic acid hexahydride, which is reduced by zinc-dust and acetic acid to the  $\Delta^2$  tetrahydride of terephthalic acid. Yields a dibromide [64°].

*Di-phenyl ether*  $\text{Ph}_2\text{A}''$ . [175°]. Large needles (from  $\text{MeOH}$ ), sl. sol. cold alcohol.  $\Delta^1$  or (3,4,5,6)-Tetrahydride.

$\text{CH}(\text{CO}_2\text{H})\langle\text{CH}_2, \text{CH}\rangle\text{CH}(\text{CO}_2\text{H})$ . [above 300°]. S. 102 at  $16^\circ$ ; 83 at  $100^\circ$ . H.F. 214,200 (Stohmann, J. pr. [2] 43, 5). Formed by boiling a solution of terephthalic acid (1 pt.) in  $\text{NaOH}$  4aq for twenty hours with gradual addition of 4 p.c. sodium-amalgam (100 pts.) (Baeyer, B. 19, 1805; A. 245, 160; 258, 32). Prisms, more sol. water than terephthalic acid or its dihydrides. Combines with  $\text{HBr}$  and with Br (1 mol.). Immediately reduces alkaline  $\text{KMnO}_4$ , yielding oxalic acid.— $\text{BaA}''$  3aq. M. sol. cold water. Reduced by  $\text{HIAq}$  at  $240^\circ$  to the hexahydride.— $\text{Ag}_2\text{A}''$ . Amorphous.

*Methyl ether*  $\text{Me}_2\text{A}''$ . [39°]. H.F. 196,200. Plates. Its ethereal solution shows blue fluorescence and gives a fugitive rose-red pp. with  $\text{NaOEt}$ .  $\text{HBr}$  gives  $\text{C}_6\text{H}_2\text{Br}(\text{CO}_2\text{H})$ , whence  $\text{Me}_2\text{A}''$  [95°]. Bromine forms  $\text{C}_6\text{H}_2\text{Br}_2(\text{CO}_2\text{Me})_2$  [81°].

*Di-phenyl ether*  $\text{Ph}_2\text{A}''$ . [145°]. Formed

from the acid by successive treatment with  $\text{PCl}_5$  and phenol. Monoclinic crystals;  $a:b:c = 2.824:1.2:470$ , mp. sol. cold alcohol and ether.

$\Gamma$  *cis*trans  $\Delta^2$  or (1,4,5,6)-Tetrahydride

$\text{CH}(\text{CO}_2\text{H})\langle\text{CH}_2, \text{CH}\rangle\text{CH}(\text{CO}_2\text{H})$ . [c. 220°].

S. 17. Formed by reducing  $\Delta^{1,5}$  dihydride and also the dibromide of the  $\Delta^{1,3}$  dihydride. Oxidised by  $\text{KMnO}_4$  in the cold to succinic acid and a soluble acid [150°]. Alkaline  $\text{K}_2\text{FeCy}_4$  gives terephthalic acid. Yields three dibromides  $\text{CH}(\text{CO}_2\text{H})\langle\text{CH}_2, \text{CHBr}\rangle\text{CH}(\text{CO}_2\text{H})$  [171°],

[51°], and [91°]. The Ba and Cd salts are more sol. water than those of the  $\Delta^1$  isomeride.

*Methyl ether*  $\text{Me}_2\text{A}''$ . [c. 3°].

*Amide*. Dimetric needles;  $a:c = 1:2:151$ .

*Diphenyl ether*  $\text{Ph}_2\text{A}''$ . Formed, in two modifications [107°] and [c. 190°] by the successive action of  $\text{PCl}_5$  and phenol (Baeyer & Herb, A. 258, 39). The modification [c. 190°] probably is a mixture containing the  $\Delta^1$  isomeride.

*Dibenzyl ether*  $(\text{C}_6\text{H}_5)_2\text{A}''$ . [48°]. From  $\text{Ag}_2\text{A}''$  and benzyl chloride.

$\Gamma$  *cis*  $\Delta^2$  or (1,4,5,6)-Tetrahydride. [150°–155°]. S. 2.7 in the cold. Formed, together with the *cis*trans isomeride, by reducing the  $\Delta^{1,4}$  dihydride by sodium-amalgam in the cold. The Ba, Cd, and Ag salts are amorphous. This acid and the *cis*trans isomeride are converted into the  $\Delta^1$  isomeride by boiling with  $\text{NaOH}$  4aq.

$\Gamma$  *cis*trans Hexahydride

$\text{CO}_2\text{H} \cdot \text{CH} \langle \text{CH}_2, \text{CH} \rangle \text{CH} \cdot \text{CO}_2\text{H}$ . *Fumaroid or stable modification*. [300°]. S. 086 at  $13^\circ$ ; 1.3 at  $100^\circ$ . H.F. 236,500 (Stohmann, J. pr. [2] 43, 7). Formed by heating the tetrahydride with  $\text{HIAq}$  for 6 hours at about  $240^\circ$  (Baeyer, B. 19, 1806; 245, 170; 251, 257). Formed also by heating ethyl butane tetracarboxylate with  $\text{NaOEt}$  and ethylene bromide at  $100^\circ$ ; the product being hydrolysed and heated at  $220^\circ$  till evolution of  $\text{CO}_2$  ceases (Mackenzie & Perkin, jun., C. J. 61, 174). Prepared by reducing the hexahydride of bromo-terephthalic acid with zinc-dust and  $\text{HOAc}$ . Small prisms, sol. hot water. May be sublimed. Not oxidised by cold alkaline  $\text{KMnO}_4$ . Br (2 mols. at  $100^\circ$ ) forms  $\text{C}_6\text{H}_2\text{Br}(\text{CO}_2\text{H})_2$  [71°], and a maleic isomeride [205°]. Treatment with  $\text{PCl}_5$  followed by Br at  $150^\circ$  forms  $\text{C}_6\text{H}_2\text{Br}_2(\text{CO}_2\text{H})_2$  in a fumaroid modification which yields  $\text{Me}_2\text{A}''$  [150°] and a maleic modification which yields  $\text{Me}_2\text{A}''$  [68°] and an anilide [200°]. The K and Ba salts are v. sol. water; the Ca salt is sl. sol. water.

*Methyl ether*  $\text{Me}_2\text{A}''$ . [71°]. S. 5 at  $100^\circ$ . H.F. 218,100. Exhibits no fluorescence. Volatile with steam.

*Diphenyl ether*  $\text{Ph}_2\text{A}''$ . [151°]. Needles.  $\Gamma$  *cis* Hexahydride

$\text{CO}_2\text{H} \cdot \text{CH} \langle \text{CH}_2, \text{CH} \rangle \text{C}(\text{CO}_2\text{H})_2$ . *Maleic or labile modification*. [163°]. H.F. 237,400.

Formed by reducing the very soluble hexahydride of bromo-terephthalic acid with zinc-dust and  $\text{HOAc}$ . Plates (from water), v. sol. alcohol and ether. Changes on heating with  $\text{HCl}$  4aq at  $180^\circ$  into its isomeride. Its Ba salt and methyl ether do not crystallise.

*References*.—BROMO-, CHLORO-, NITRO- and OXY-TEREPHTHALIC ACID.

## TEREPHTHALIC ALDEHYDE

$C_8H_6(CHO)_2$  [1.4]. [116°]. (247°). S. 1-7 at 100°. Formed by boiling  $C_8H_4(CH_2Cl)_2$  or  $C_8H_4(CH_2Br)_2$  (1 pt.) with lead nitrate (1 pt.) and water (20 pts.) (Grimaux, *C. R.* 83, 825; Löw, *A.* 231, 363). Formed also by the action of fuming  $HNO_3$  on di-*o*-bromo-*p*-xylene (Löw, *B.* 18, 2072), and by boiling  $C_8H_4(CHCl)_2$  with water (Colson & Gautier, *Bl.* [2] 45, 6, 508). Obtained from  $CH_2(OH).C_6H_4.CH_2.OEt$  by successive treatment with  $PCl_5$  and water (Colson, *Bl.* [2] 42, 152).

**Preparation.**—*p*-Xylene (1 pt.) is heated with Br (6 pts.) at 140° to 200° with inverted condenser. The crystalline tetra-*o*-bromo-xylene [169°] thus obtained is heated with three times its weight of  $H_2SO_4$  (S.G. 1.825 at 120°-130°), the product poured into water, and the needles that separate recrystallised from water (Hönig, *M.* 9, 1153).

**Properties.**—Long needles, v. sl. sol. hot water and cold ether, v. sol. alcohol. Slightly volatile with steam. Dissolves in 25 pts. of saturated aqueous  $NaHSO_3$  at 45°.

**Reactions.**—1. Oxidised by chromic acid mixture to *o*-*p*-aldehyde-benzoic acid and then to terephthalic acid.—2. Conc.  $NaOH$  aq. forms terephthalic acid, *o*-oxy-toluic acid, and di-*o*-oxy-xylene.—3.  $KNO_3$  and excess of  $H_2SO_4$  at 110° form nitro-terephthalic aldehydes.—4. Cold conc.  $NH_4$  aq. forms tri-*p*-aldehyde-hydrobenzamide ( $C_8H_4(CHO).CH_2.NH_2$ ), a crystalline powder, insol. water, alcohol, and ether, yielding on oxidation by  $KMnO_4$  crystalline  $N_2(CH_1.C_6H_4.CO_2H)_2$  (Oppenheimer, *B.* 19, 574).—5. Dry or alcoholic  $NH_3$  forms crystalline  $C_8H_4(CH_2.NH_2)_2$ .—6.  $NaOAc$  and  $Ac_2O$  give *p*-aldehyde-cinnamic acid.—7. Acetone and dilute  $NaOH$  give a white pp. of  $C_8H_4(CH_2.CH_2.CO.CH_3)_2$ , which crystallises from ether-acetone in matted needles [156°], insol. water and alcohol, and gives a deep-red solution in conc.  $H_2SO_4$ . An intermediate body is  $C_8H_4(CH(OH).CH_2.CO.CH_3)_2$ .—8.  $NPhMe_2$  and  $ZnCl_2$  form  $C_8H_4(CHO).CH_2(C_6H_4.NMe_2)_2$ , the leuco derivative of the aldehyde of malachite green.—9. Cold conc. aqueous  $KClO_3$  added to a cold saturated alcoholic solution of the aldehyde ppts. amorphous  $C_8H_4O_2$ , which probably has the formula  $C_8H_4(CHO).CH(OH).CO.C_6H_4(CHO)$  [170°-174°]. This body reduces cold ammoniacal  $AgNO_3$ , forming a mirror. It also reduces warm Fehling's solution and combines with phenyl-hydrazine.  $KMnO_4$  oxidises it to benzoic di-*p*-carboxylic acid.  $NaOHAq$  dissolves it, forming benzoic di-*p*-carboxylic acid, di-*o*-oxy-*p*-xylene, and other bodies (Oppenheimer, *B.* 19, 1814).

**Phenyl-hydrazide** [230°].

**Oxim**  $C_8H_4(CH:NOH)_2$  [200°]. Formed from the aldehyde and an alkaline solution of hydroxylamine (Westenberger, *B.* 16, 2994). Crystalline, v. sol. alcohol and ether, sl. sol. water. Yields  $C_8H_4(CH:NOEt)_2$  [55°] and  $C_8H_4(CH:NOAc)_2$  [155°].

**Reference.**—NITRO-TEREPHTHALIC ALDEHYDE.

**TEREPHTHALIC AMIDINE**  $C_8H_4N_2$ , i.e.  $C_8H_4(C(NH).NH)_2$ . The salt  $BH_2Cl$ , formed by digesting terephthalic imido-ethyl ether with alcoholic  $NH_3$ , is crystalline, and yields  $BH_2PtCl_4$  (Luckenbach, *B.* 17, 1436).

**TEREPHTHALOPHENONE** v. **PHTHALOPHENONE**.

**TERPENES**  $C_{10}H_{16}$ ; also **Sesquiterpenes**  $C_{15}H_{24}$ , and **Polyterpenes**  $(C_{10}H_{16})_n$ . The greater number of these hydrocarbons exist ready formed as constituents of essential oils secreted by plants. Others are produced from the natural terpenes by the action of heat or of chemical agents. A dihydrocymene isomeric with the natural terpenes has been obtained synthetically from methyl-isopropyl succino-succinic ester and the homologous dihydroparaxylene and dihydrobenzene by corresponding processes (Baeyer, *B.* 25, 1840, 2122; 26, 232). The natural terpenes are generally optically active liquids, with right- or left-handed rotatory power. The only exception is the racemic compound dipentene (*q. v.*). The following isomerides are known:—

1. **Pinene**. This includes two varieties, australene or dextropinene and terebenthene or levopinene. American spirit of turpentine consists chiefly of dextropinene. (156°).  $[a]_D^{25} = +21.5$  (Berthelot, *A.* 83, 105; 88, 345, 110, 367, *Suppl.* ii. 226). S.G.  $\frac{0}{25} = .8765$ ;  $\frac{25}{25} = .8586$ ;  $\frac{100}{25} = .8278$  (Tilden, *unpubl. expts.*). French turpentine oil consists almost wholly of levopinene. (156-5°).  $[a]_D^{25} = -40.32$ . S.G.  $\frac{0}{25} = .8767$ ;  $\frac{17.88}{17.88} = .8619$  (Riban, *C. R.* 78, 788; 79, 314). It is also present in oil of rosemary (Bruylants, *J.* 1879, 944), oil of lemon (Tilden, *P.* 3 [3] 9, 654), sage and juniper (*C. J.* 31, 554), thyme and anise (Brühl, *B.* 21, 156), and other essential oils.

For production and properties of turpentine oils v. **OILS, ESSENTIAL**, Thorpe's **DICTIONARY OF APPLIED CHEMISTRY**.

Different specimens of the pinenes, both dextro- and levo-, obtained by fractional distillation from turpentine exhibit considerable variations in their rotatory power. An optically inactive liquid has been obtained by Wallach (*A.* 258, 343) from pinene nitroschloride by treatment with aniline, whereby a diazo-compound is formed, which with the neighbouring chlorine atom gives rise to diazobenzenechloride and regenerates the hydrocarbon

$-CCl - CNO - + H.NC.NH_2$   
 $= -CCl - C(N:NC.NH_2) - + H_2O$  and  
 $-CCl - C(N:NC.NH_2) - = -C=C - + ClN.C_6H_5$ .  
 The hydrocarbon thus obtained boils at 155°-156°, has a density .858 at 20°, a refractive index for  $D$  1.46553 at 21°, and is supposed to be identical in constitution with the pinenes. It is apparently not resolvable into a mixture of dextro- and levo- pinenes, but with nitrosyl chloride and other reagents it behaves in the same manner as pinene.

Dry pinene unites with one molecule of dry hydrogen chloride, forming a crystalline compound formerly called artificial camphor [125°], which appears quite saturated, as it is unacted upon either by excess of hydrogen chloride or bromine. The hydrochloride prepared from dextropinene is dextrorotatory, while that from levopinene is levorotatory. The compound is very stable; it may be distilled almost without change, mere traces of hydrogen chloride being evolved; and it is unacted upon by aqueous solutions of the alkalis, except at high temperatures under pressure. Heated with sodium stearate, benzoate, or acetate, or with alcoholic potash, it loses the elements of hydrogen chloride and yields solid camphene (v. **CAMPHERE**, *infra*). In the presence

of water, alcohol, ether, or acetic acid, pinene takes up two mols. of hydrogen chloride, producing a compound of different character [60°], which on the application of heat is readily split up into hydrogen chloride and a mixture of liquid hydrocarbons (*v. DIPENTENE, infra*). Nitrosyl chloride passed into a solution of pinene in chloroform at -10° yields a compound  $C_{10}H_{16}NOCl$  [103°], which is pptd. as a white crystalline powder on the addition of alcohol (Tilden, *C. J.*, June 1875). The same compound is formed by adding hydrochloric acid to a cooled mixture of the terpene with amyl nitrite and glacial acetic acid (Wallach, *A.* 215, 245). The nitrosochloride gently heated with alcoholic potash yields a nitroso-compound,  $C_{10}H_{15}NO$  [129°] (Tilden). For crystallography *n. Story-Maskelyne* (*C. J.*, June 1875, and *Phil. Mag.*). Nitrosopinene unites with two atoms of bromine, forming a crystalline dibromide, which decomposes on melting [132°]. Mixed with alcohol and nitric acid both pinenes form crystallised terpin hydrate  $C_{10}H_{16}(OH)_2 \cdot OH_2$  (Wiggers, *A.* 33, 358; 57, 247; Tilden, *C. J.* 33, 217; Hempel, *A.* 180, 71). Pinene dissolved in carbon tetrachloride and mixed with bromine yields a mixture of products, from which a well-defined crystalline dibromide  $C_{10}H_{16}Br_2$  [169°-170°] may be isolated. On heating this with aniline it gives up hydrogen bromide, and ordinary cymene is produced. The yield, however, amounts only to about 10 p.c. of the bromide employed (Wallach, *A.* 264, 1). Exposed to the action of air or oxygen, in sunlight, the pinenes produce a crystalline compound  $C_{10}H_{14}O_2$  (Sobrero, *C. R.* 33, 66) which when distilled with dilute acid yields a compound called by Armstrong 'Sobreronne' (Armstrong a. Pope, *C. J.* 59, 311), which is identical with one of the products of the action of nitrous acid on pinene, isolated by Wallach a. Otto, and called by them 'Pinol' (*A.* 253, 249). Pinene distilled with bleaching powder and water yields a large quantity of chloroform. Picric acid has no action upon pinenes in the cold, but at the b.p. of the latter a brisk reaction sets in, and if the liquid is afterwards allowed to cool a compound is deposited in colourless scales, which on boiling with alkali yield borneol (Lextrait, *C. R.* 102, 555; Tilden a. Forster, *C. J.* 63, 1383).

2. **Limonene.** This compound, like pinene, occurs in two optically active varieties. Dextro-limonene (175°-176°), S.G.  $\frac{20}{4}$  = 846,  $[\alpha]_D^{20}$  = +106.8 (Wallach, *A.* 252, 145) occurs in oils of the fruit of oranges and lemons, also in caraway and dill, &c. The most convenient source is the essential oil of sweet orange, *Citrus aurantium*. Lævo-limonene is obtained from the oil distilled from the leaves of *Pinus sylvestris* and *P. picca*. This oil occurs in the drug houses as 'Fir-Wool oil,' but is now much adulterated with common turpentine, and the commercial oil seldom yields more than a small percentage of limonene. (175°-176°), S.G.  $\frac{20}{4}$  = 846,  $[\alpha]_D^{20}$  = -105° (Wallach, *A.* 227, 287, 246, 221). The limonenes, treated with perfectly dry hydrogen chloride, yield a liquid monochloride. In the presence of alcohol they give, with excess of hydrogen chloride, a quantitative yield of a dihydrochloride [50°], identical with the compound obtained from the pinenes. By the action of nitrosyl

chloride (Tilden a. Shenstone, *C. J.* May, 1877), or by the use of amyl or ethyl nitrite and hydrogen chloride (Wallach), they yield a crystalline nitrosochloride, which, whether formed from dextro- or lævo-limonene, is always a mixture of two isomerides separable from each other by cold chloroform or ether. There are therefore four isomeric limonene nitroso-chlorides, as follows:

FROM <i>d.</i> LIMONENE:		
$\alpha$ compound	[103°-104°]	$\alpha_D^{20}$ = +318°
$\beta$ "	[105°-106°]	$\alpha_D^{20}$ = +240°
FROM <i>l.</i> LIMONENE:		
$\alpha$ compound	[103°-104°]	$\alpha_D^{20}$ = -314°
$\beta$ "	[100°]	$\alpha_D^{20}$ = -242°

From the nitroso-chlorides by the action of heat (Tilden a. Shenstone), or by boiling with alcohol (Goldschmidt a. Zürer, *B.* 18, 2220), is produced an isonitroso-limonene, which when made from lævo-limonene is identical in every respect with carvozim  $C_{10}H_{14}N.OH$ , from carvol, extracted from oil of caraway (Goldschmidt a. Zürer, *B.* 18, 1732). For a comparison of the rotatory powers of the two limonenes and their derivatives, see Wallach (*A.* 252, 141). The limonenes are further characterised by the formation of a crystalline tetrabromide [104°-105°] by direct addition of bromine (Wallach, *A.* 227, 277).

By mixing together equal quantities of dextro- and lævo-limonenes an optically inactive mixture is obtained, which behaves in many respects as a distinct hydrocarbon, and appears to be identical with dipentene (*q. v.*). Strong sulphuric acid acting upon citrene (*d.*-limonene), causes polymerisation, the chief product being a colophene (310°-320°) (Bouchardat a. Lafont, *C. R.* 115, 1083).

The oil of *Licariakanali* contains a compound, licareol  $C_{10}H_{16}O$ , from which a hydrocarbon, licarene  $C_{10}H_{16}$ , is obtainable by the action of acetic anhydride at 150° (Barbier, *C. R.* 114, 674, and *C. R.* 116, 993, and 1062). This terpene appears to consist of impure *d.*-limonene, as it boils at 176°-178°, gives a tetrabromide [103°-104°], forms a nitrosochloride, from which carvozim [72°] is formed by alcoholic potash; but its specific rotatory power is low,  $[\alpha]_D^{20}$  = 7.51°.

3. **Sylvestrene** occurs in Swedish turpentine (Atterberg, *B.* 10, 1206) and in Russian turpentine (Wallach, *A.* 230, 245), in company with australene and other hydrocarbons of higher boiling-point. (176°-177°). S.G.  $\frac{16}{4}$  = 8510;  $\frac{20}{4}$  = 8470.  $[\alpha]_D^{20}$  = +66.32 (Wallach, *A.* 245, 197). The odour of sylvestrene differs from that of pinene and limonene, and resembles the odour of fresh firwood. It forms a liquid monohydrochloride, and a crystalline dihydrochloride [72°], from which the hydrocarbon may be recovered unchanged by heating with aniline. Sylvestrene also gives a nitrosochloride [106°-107°], which, by treatment with alcoholic potash, yields only oily products. The tetrabromide crystallises in monoclinic tables [135°] (Wallach, *A.* 239, 29).

4. **Phellandrene.** The seeds of *Phellandrium aquaticum* were found by Pesci (*G.* 16, 226) to yield about 2½ p.c. of a volatile oil, consisting chiefly of a dextro-rotatory terpene (171°-172°). The same hydrocarbon is contained in the oil of bitter fennel, *Feniculum vulgare* (Wallach, *A.*

239, 40), and in the oil of elemi. Lævo-phellandrene is found, according to Wallach (A. 246, 232), in the oil of *Eucalyptus amygdalina*. Phellandrene is characterised by the formation of a nitroso-nitrite  $C_{10}H_{16}N_2O_2$ . Pesci obtains it by the action of a nitrite and dilute sulphuric acid upon the hydrocarbon. It crystallises in needles [94°], and although obtained from the dextrorotatory hydrocarbon it rotates the plane of polarisation to the left.  $[\alpha]_D = -183.5^\circ$  (Pesci). By reducing agents this compound is converted into a base  $C_{10}H_{16}(NH_2)_2$  (209°-214°). Ammonia converts it into nitrophellandrene  $C_{10}H_{16}NO_2$  and an acid.

5. Dipentene, formerly called terpinene or terpylene. As already stated, this compound is produced when equal quantities of dextro- and lævo-limonenes are mixed together (see *Pentylenes*). It is formed by heating isoprene to a temperature of about 300°. It is also the chief constituent of 'isoterebenthene,' formed by the action of heat on lævo-pinene. It occurs among the products of the destructive distillation of caoutchouc. Dipentene is also produced, together with terpinene, terpinolene, and terpineol, by the action of sulphuric acid or phosphoric acid on terpin, or by the action of sulphuric acid on the pinenes under certain conditions (Armstrong & Tilden, C. J. November, 1879). It is also formed from the dihydrochloride [50°], whether made from pinene or limonene, either by the action of heat upon the chloride alone (Tilden, B. 12, 1133) or by boiling it with a mixture of sodium acetate and acetic acid, or with alcohol and aniline (Wallach). The products thus obtained were formerly supposed to consist of a single hydrocarbon, to which the name 'terpinene' was given. The hydrocarbons known as cinene and cajuputene derived from cineol and cajuputol respectively also consist of dipentene. Dipentene occurs readily formed in the volatile oil of the camphor tree, also in oil of elemi and in Russian and Swedish turpentine (Wallach, A. 227, 236, &c.).

Dipentene boils at about 176°, and has a pleasant smell of lemons. It combines with bromine forming a tetrabromide [124°], and unites with 2HCl forming a chloride [50°], from which it may be regenerated by methods given above. It is to be noted, however, that in all cases more or less isomeric change occurs, and the hydrocarbon, whether reproduced by heat alone or by the action of aniline, always contains terpinene and terpinolene, beside cymene and a small quantity of a paraffinoid hydrocarbon (Tilden & Williamson, C. J. 63, 292). The nitrosochloride  $C_{10}H_{15}NOCl$  yields an inactive carboxim  $C_{10}H_{15}NOH$  [98°] (A. 245, 267). A mixture of equal volumes of dextro- and lævo-limonene behaves in many respects as though it were a distinct hydrocarbon, as it was supposed to be previously to Wallach's researches. Thus the tetrabromide melts at 124°, while the limonene compound melts at 104°. The inactive isonitrosodipentene or carboxim, melting at 93°, is formed by mixing together equal quantities of lævo-carboxim [72°] from dextro-limonene and dextro-carboxim [72°] from lævo-limonene. The resulting compound gives, by Raoult's freezing-point method, a molecular weight corresponding to the simple formula  $C_{10}H_{16}NO$  (Wallach, A. 246, 236).

Certain derivatives of dipentene exist in two optically inactive forms. When d-limonene-nitrosochloride, prepared from either dextro- or lævo-limonene, is warmed with an alcoholic solution of piperidine, a mixture of two crystallisable nitrolamines is formed in each case, as follows:

NITROLPIPERIDINES  $C_{10}H_{16}NONC_4H_9$ , FROM LÆVOLIMONENE:

- (a) [93°-94°] Rhombic, from alcohol.  $[\alpha]_D = -67.60^\circ$ . Hydrochloride dextrorotatory.  
(b) [110°-111°]. Monoclinic.  $[\alpha]_D = +60.18^\circ$ . Hydrochloride almost inactive.

FROM DEXTROLIMONENE:

- (a) [93°-94°]. Rhombic.  $[\alpha]_D = +67.95^\circ$ . Hydrochloride levorotatory.  
(b) [110°-111°]. Monoclinic.  $[\alpha]_D = -60.48^\circ$ . Hydrochloride (?).

When the two  $\alpha$ -piperidine bases [93°-94°] are dissolved in petroleum-spirit, and the solutions mixed, an inactive nitrolamine [154°] is at once precipitated. A second inactive compound [152°] is formed by mixing the  $\beta$ -piperidine bases (Wallach, A. 252, 123). Similar results have been obtained by the employment of aniline and benzylamine. The salts of the bases thus produced possess a rotatory power opposite in direction to that of the free base. No method is at present known of producing from limonene active addition-compounds with two molecules of hydracid. With excess of hydrogen chloride the same inactive dipentene dihydrochloride [50°] is always obtained. The corresponding dihydrochloride seems to crystallise in two forms differing slightly in melting-point (Wallach, A. 239, 13).

6. Terpinene. (180° about). This compound is formed, together with dipentene, by the action of acids upon pinene and terpin, &c. It is said to occur in oil of cardamoms (Ev. Weber, A. 238, 98). Terpinene has not been obtained in an absolutely pure state, but is characterised by forming a nitrosoneitrite  $C_{10}H_{16}N_2O_2$  [155°] (Wallach, A. 239, 33). The tetrabromide is fluid, and it yields no crystallisable hydrochloride. The nitrosoneitrite by the action of bases yields nitrolamines  $C_{10}H_{15} \begin{smallmatrix} \text{NOH} \\ \text{NH}_2 \end{smallmatrix}$  [116°-118°],  $C_{10}H_{15} \begin{smallmatrix} \text{NOH} \\ \text{NHC}_4H_9 \end{smallmatrix}$  [130°-131°], &c. (A. 241, 315).

7. Terpinolene. (185° about). This hydrocarbon is formed along with dipentene and terpinene by the action of acids upon pinene, &c.

With hydrogen chloride and hydrogen bromide terpinolene unites to form the dipentene dihydrochloride [50°] and dihydrobromide [64°]. It forms an optically inactive tetrabromide which crystallises in monoclinic tables [116°] but is gradually converted at ordinary temperatures into a porcelain-like mass.

8. Fenchene. A liquid isomeride of camphor (190°-193°), obtained from oil of fennel, is treated with alcohol and sodium, by which it is reduced to the alcohol  $C_{10}H_{17}OH$ , a colourless crystalline compound. By treating this with phosphoric chloride the chloride  $C_{10}H_{17}Cl$  is formed, and from this, by heating with aniline, fenchene  $C_{10}H_{16}$  (158°-160°) may be obtained. Fenchene is optically inactive. It differs from other terpenes in resisting the action of nitric acid unless heated (Wallach, A. 263, 149).

## SYNOPSIS OF TERPENES AND THEIR CHIEF DERIVATIVES.

Boiling-points approximately stated. Rotatory power +, -, or 0.

Pinene (186°)	Limone (176°)	Dipentene (176°)	Sylvestrene (176°)	Phellandrene (170°)	Terpinene (180°)	Terpinolene (185°)	Fenchene (160°)

## Isoterpenes.

**Camphene**  $C_{10}H_{16}$ . Pinene monohydrochloride [125°] was formerly described under the name 'artificial camphor,' from its resemblance to camphor in appearance and to a certain extent in odour. This compound is remarkably stable, but may be decomposed by heating with sodium stearate or benzoate, with potassium acetate, with alcoholic potash, or, better, with a mixture of sodium acetate and alcoholic soda (Brühl, *B.* 25, 147). The resulting hydrocarbon is a camphene [51°-52°] (160°), dextro- or laevo-rotatory or inactive according to the nature of the hydrochloride used and the reagent employed, though the exact conditions which determine the production of one or other are scarcely known (Riban, *A. Ch.* [5] 6, 353).

Camphene is also formed from bornyl chloride by the action of alcoholic potash (Riban), by the action of water and magnesia (Kachler, *A.* 197, 86), or by heating with aniline to the boiling-point of the latter (Wallach, *A.* 230, 234); it is also formed from camphor chloride and from pinene hydrochloride by the action of sodium (Montgolfier, *C. R.* 89, 102). In the last case it is accompanied by a liquid hydrocarbon (170°),  $C_{10}H_{16}$ , which behaves like a paraffin, and is probably identical with a liquid obtained by the action of hydrogen iodide on turpentine (Berthelot), also by the action of iodine (Armstrong a. Gaskell, *B.* 12, 1756) and by the action of sulphuric acid on turpentine (Armstrong, *B.* 12, 1759).

Camphene is also formed by the action of strong sulphuric acid on turpentine, and constitutes the characteristic ingredient in the liquid formerly known as 'terebene' (Armstrong a. Tilden, *C. J.* 1879, 733).

Camphene closely resembles camphor in appearance and even somewhat in odour. It is soluble in alcohol, ether, and benzene, and crystallises in leaflets from a concentrated solution. It is incapable of combining with bromine, but it forms a compound [157°] with hydrogen chloride, which is distinguished from pinene hydrochloride by its instability, being rapidly

decomposed by water with reproduction of camphene (Riban, *C. R.* 80, 1330). It is also dissociated into camphene and hydrogen chloride when volatilised (Ehrhardt, *C. N.* 54, 239). Camphene hydrochloride is said to be identical with bornyl chloride (Kachler a. Spitzer, *A.* 200, 310; v. also Brühl, *B.* 25, 160). Camphene does not combine with nitrosyl chloride. In contact with bromine it is slowly attacked, forming an oily monobromo-derivative (230°-240°).

Oxidised by chromic liquor, camphene yields camphor, dextro-, laevo-rotatory or inactive according to the character of the camphene.

By the action of phosphorus pentachloride on camphene, and subsequent treatment of the mass with an alkaline solution, salts of two phosphonic acids are formed (Marsh a. Gardner, *C. J.* 65, 35).

When camphene is heated to about 300° it is converted into liquid products which seem to include dipentene, but have not been sufficiently investigated.

## Homologues of camphene.

**Ethyl-camphene** obtained by the conjoint action of sodium and ethyl iodide upon camphor monochloride  $C_{10}H_{15}Cl$ , is a colourless mobile liquid having a smell like turpentine (197.9°-199.9°, bar. 713.1 mm.). Isobutyl-camphene is also a liquid (228°-229°, bar. 750.4 mm.) (Spitzer, *B.* 11, 1817).

Sesquiterpenes  $C_{15}H_{24}$ .

Oils of clove, calamus, cascarilla, patchouli, and cubeba contain a hydrocarbon of this composition (Gladstone, *C. J.* 1872), as also do the oils of galbanum, and saffron and 'huile de cade,' a kind of tar made by distillation of the wood of *Juniperus oxycedrus* (Wallach, *A.* 238, 81). The hydrocarbon obtained from cade or cubeba (274°-275°) (S.G.  $d_{20}^{20} = 0.921$ ) forms the following crystalline compounds:  $C_{15}H_{24}2HCl$  [117°-118°],  $C_{15}H_{24}2HBr$  [124°-125°],  $C_{15}H_{24}2HI$  [105°-106°]. The hydrocarbon, especially when partially resinified by exposure to the air, gives the following characteristic colour reaction: dissolved in chloroform or glacial acetic acid and then

shaken up with a few drops of strong sulphuric acid, the liquid assumes an intense green and then blue colour, which, when heated, passes into red (Wallach). An attempt to prepare from isoprene a polymeride of the composition  $C_{10}H_{16}$  proved unsuccessful (Wallach).

Conimene  $C_{10}H_{16}$ , a liquid (264°) having a pleasant odour, is obtained from the incense resin (*Icica heptaphylla*) of British Guiana (Stenhouse a. Groves, *C. J.* 1871, i. 175).

*Polyterpenes*  $C_{20}H_{32}$ , &c.

This group includes (1) the constituents of certain natural essential oils; (2) products of artificial polymerisation of terpenes; and (3) caoutchouc and guttapercha.

1. Oleo-resin or so-called 'balsam' of copaiba (*Copaifera Langsdorffii* and other species) is a mixture of a resin with an oil (250°–260°). The latter unites with water and absorbs hydrogen chloride, with production of a deep violet colour but no crystalline hydrochloride. A similar hydrocarbon is obtained from Gurjun balsam or 'wood oil', the product of various species of *Dipterocarpus* growing in the East, and from other essential oils.

2. When turpentine oil and other terpenes are heated for some time to about 300°, or treated with concentrated sulphuric or phosphoric acid or other agents, a large part of the hydrocarbon undergoes polymerisation. The name 'colophene' was given by Deville to the less volatile portions of the product obtained in this manner from French turpentine, apparently under the impression that it was closely related to the oil obtained by distillation of resin. Resin-oil, however, contains oxygen, and exhibits quite different characters.

Colophene is a yellowish viscid fluid, usually

fluorescent, which begins to boil at about 300°, but the distillation even under reduced pressure is attended by decomposition. The boiling-point continually rises, and even at a temperature approaching dull redness a viscid residue is left which on cooling becomes nearly solid (Armstrong a. Tilden, *C. J.* Nov. 1879). The portions which distil at 300° and upwards appear to consist of saturated compounds, for they absorb mere traces of hydrogen chloride. By the action of antimony trichloride upon turpentine a solid,  $C_{10}H_{16}$ , is formed. This combines with hydrogen chloride to form two compounds  $C_{10}H_{16}HCl$ , and  $C_{10}H_{16} \cdot 2HCl$  (Ribân, *C. R.* 1874, 389).

3. CAOUTCHOUC *v.* vol. i. p. 677. For further information concerning the products of its decomposition by heat *v.* PENTENES (vol. iii. p. 807) and DIPENTENE (*supra*).

GUTTAPERCHA, *v.* vol. ii. p. 658.

Caoutchouc is formed from isoprene by polymerisation, which sometimes occurs spontaneously under circumstances not fully understood (Tilden, *C. N.*, May 1892).

*Oxidised compounds connected with terpenes.*

A considerable number of oxidised compounds are known which are evidently closely connected with the terpenes, and in many cases directly derivable from them. Some of these, as, for example, borneol and camphor, occur as natural products in essential oils; others, such as terpin, are the products of the addition of water to a terpene, or, like camphor and some of its isomerides, may be formed from terpenes by oxidation. These compounds are enumerated in the following table, together with the hydrocarbons with which they are presumably immediately connected.

Hydrocarbons	Alcohols	Glycols	Ketones (?)
Cymene $C_{10}H_{14}$ (ii. 361)	Carveol $C_{10}H_{15}OH$ (i. 711)	—	Carvol $C_{10}H_{14}O$ (i. 711)
Pinene $C_{10}H_{16}$ ( <i>v. supra</i> )	Myristicol and absinthol ( <i>v. infra</i> )	Sobrerol $C_{10}H_{16}(OH)_2$ ( <i>v. infra</i> )	Sobrerone (pinol) $C_{10}H_{16}O$ ( <i>v. infra</i> )
Dipentene $C_{10}H_{16}$ ( <i>v. supra</i> )	Terpineol $C_{10}H_{17}OH$ ( <i>v. infra</i> )	Terpin $C_{10}H_{16}(OH)_2$ ( <i>v. infra</i> )	—

Tetrahydrocamphene $C_{10}H_{20}$ ( <i>v.</i> DECYLENE, ii. 869, <i>et infra</i> )	—	—	—

Cymene  $C_{10}H_{16}$  (176°); ii. 361.

Dipentene  $C_{10}H_{18}$  (176°); v. *supra*.

Fenchene  $C_{10}H_{16}$  (160°); v. *supra*.

Camphene  $C_{10}H_{16}$  (160°); v. *supra*.

Menthene  $C_{10}H_{16}$  (167°); iii. 202.

Dihydromenthenes  $C_{10}H_{18}$ , v. DECYLENE, ii. 367.

The liquid produced, together with the solid monohydrochloride, by passing hydrogen chloride into pinene, yields when treated with sodium a mixture from which a liquid hydrocarbon  $C_{10}H_{18}$  (148°–149°), having a smell of oranges, may be separated by fractionation, &c. (Bouveault, *C. R.* 116, 1067).

• Tetrahydromenthenes  $C_{10}H_{18}$  (DECYLENE, ii. 367). A liquid obtained by the action of hydrogen iodide and phosphorus upon oil of turpentine (Berthelot) and another (160°) by action of phosphonium iodide on turpentine (Baeyer) have this composition. The same formula is ascribed by Armstrong (*B.* 12, 1758) to a liquid (160°–170°) obtained by the action of iodine upon oil of turpentine and upon camphor, also by the action of sulphuric acid upon turpentine. All these products are insoluble in strong sulphuric acid, and resemble the paraffins in chemical characters.

Carveol  $C_{10}H_{18}O$  (219°); i. 711.

Terpineol  $C_{10}H_{18}O$  (185°). (215°–218°). Wiggers, *A.* 33, 358; 57, 247; List, *A.* 67, 362; Tilden, *O. J.* 33, 247, and 35, 286; Wallach, *B.* 18, 618, Ref.; Kannonnikoff a. Flawitzky, *J. pr.* [2] 32, 497; Bouchardat a. Voiry, *C. R.* 104, 996. Dextro- and levo-terpineol are obtained by the action of alcoholic sulphuric acid upon *d*- and *l*-pinene respectively, or inactive by distilling terpin with very dilute sulphuric or hydrochloric acid. Terpineol as thus obtained is a viscous liquid, having an odour of white lilac. By fractional distillation under reduced pressure a portion is obtained (130°–135° at 40 m.m.), which may be crystallised by cooling to –50°, or by the introduction of a crystal of the same. These crystals melt at 30°–32°, and boil undecomposed at 218° (Bouchardat a. Voiry, *C. R.* 104, 996). Terpineol treated with sodium evolves hydrogen, but in consequence of its viscosity the action soon ceases. Contact with dilute acids converts terpineol into terpin hydrate. Hydrogen chloride and iodide react to form  $C_{10}H_{19}Cl$  [50°] and  $C_{10}H_{19}I$  [77°] respectively. Potassium hydrogen sulphate at 200° produces dipentene. Terpineol unites with two atoms of bromine, but excess of bromine gives rise to dipentene tetrabromide. With phenyl cyanate it yields phenylterpinyl-urethane  $C_{10}H_{17}NH.CO.OC_6H_5$  [110°]. These and other reactions have been repeated by Wallach, using crystallised terpineol (*A.* 275, 103). Terpineol oxidised by permanganate yields a substance  $C_{10}H_{16}O_2$  [121°–122°], which probably has the constitution of an oxyterpin  $C_{10}H_{17}(OH)_2$ . Further oxidised by means of chromic acid this yields a crystalline compound  $C_{10}H_{16}O_3$  [62°–63°] (Wallach, *A.* 275, 145).

Cineol  $C_{10}H_{18}O$  (176°); ii. 187. Cineol appears to contain no hydroxyl, since it is not acted upon by metallic sodium nor by benzoyl chloride at 120°. It is also unaffected by hydroxylamine and by phenylhydrazine. Hence it appears to be neither an alcohol nor a ketone. Its relation to terpineol (*infra*) is shown by the fact that when heated with

alcohol and sulphuric acid cineol is converted into terpinene and terpinolene; also that terpineol, and therefore also terpin, are partly converted into cineol by prolonged heating with phosphoric acid. Cineol oxidised by permanganate of potassium yields the potassium salts of carbonic, oxalic, and cineolic acids, with a small quantity of acetic acid. Cineol yields 45 p.c. of its weight of cineolic acid. This compound forms well-defined anhydrous crystals, which dissolve in 70 pts. of water at 15°, and in 15 pts. at 100°. They melt with decomposition at 196°–197°.

Calcium cineolate  $C_{10}H_{17}CaO_4.4H_2O$  is soluble in cold water, but is completely precipitated by boiling the aqueous solution. Silver cineolate  $C_{10}H_{17}AgO_4.H_2O$  is soluble in both water and alcohol, but cannot be crystallised. Ethyl cineolate  $C_{10}H_{17}(C_2H_5O)_2$ , obtained by passing hydrogen chloride gas into an alcoholic solution of the acid, is a colourless liquid (155° under 11–12 mm.). By dry distillation cineolic acid yields cineolic anhydride, water, carbon dioxide, and a liquid which appears to consist of a monobasic acid (*A.* 246, 265).

Fenchol  $C_{10}H_{17}(OH)$ . Fenchyl alcohol [40°–41°]. (201°). (Wallach, *A.* 263, 143; 272, 99–125). S.G. 82–933 (W.).  $[\alpha]_D^{20} + 10.36$  (W.). Dextro- and levo-fenchyl alcohols are obtained by the reduction with sodium and alcohol of levo- and dextro-fenchones respectively. Concentrated  $HNO_3$  oxidises *l*-fenchyl alcohol to *d*-fenchone.  $PCl_5$  gives rise to fenchyl chloride  $C_{10}H_{17}Cl$  (84°–86° at 14 mm.).

Borneol  $C_{10}H_{17}O$  (111°), i. 522.

Geraniol  $C_{10}H_{17}O$  (111°), ii. 609.

Linalool  $C_{10}H_{17}O$  (111°), iii. 146. Linalool is said to be convertible into the isomeric geraniol by treatment with acetic anhydride, and saponifying the resulting ester with alcoholic potash (Bouchardat, *C. R.* 116, 1253).

Menthol  $C_{10}H_{19}(OH)$  (101°), iii. 203.

Terpin  $C_{10}H_{18}(OH)_2$  (104°–105°). (258°) (Wiggers, *A.* 33, 358; 57, 247; Tilden, *C. J.* 33, 247; 35, 286; Wallach, *A.* 230, 225–272). Terpin is best known in the form of its hydrate  $C_{10}H_{18}O_2.H_2O$  [116–117°], a beautifully crystalline compound which on heating to 100° loses water and leaves terpin as a vitreous mass. Terpin hydrate is readily obtained by shaking turpentine oil with alcohol acidified with sulphuric or nitric acid (Flawitzky, *B.* 12, 1022; Tilden, *C. J.* 33, 247; 35, 286), and leaving the liquid to evaporate. It is an optically inactive, saturated compound, slightly soluble in boiling water, soluble in alcohol and crystallising in rhombic prisms (Rammelsberg, *P.* 63, 570; Maskelyne, *P. M.* 1879). It possesses the characters of a glycol and with hydrogen chloride yields dipentene dihydrochloride [50°]. Boiled with water containing a mere trace of mineral acid, terpin dissolves with production of terpineol and water.

Camphene glycol  $C_{10}H_{16}(OH)_2$  [192°] (*G.* Wagner, *B.* 23, 2311).

**Formation.**—By the oxidation of camphene in benzene solution with a 1 p.c. solution of  $KMnO_4$  (*l.c.*).

**Properties.**—Colourless prismatic needles (from benzene) very readily soluble in ether, alcohol,  $CS_2$ , and chloroform. Exhibits the

same phenomenon as camphor when thrown on water. Sublimes when heated above 100°. Melts when warmed with water, but only dissolves in it with difficulty. Heated with acetic anhydride in a closed tube at 120°, the greater part loses water, only a small portion being converted into the acetic ester. Treatment with dilute HCl results in the loss of 1 mol. of H<sub>2</sub>O, giving rise to a solid body, C<sub>10</sub>H<sub>16</sub>O, isomeric with camphor, which reduces ammoniacal AgNO<sub>3</sub> and reacts with hydroxylamine.

Carvol C<sub>10</sub>H<sub>16</sub>O (228°), *v. i.* 711.

Fenchone C<sub>10</sub>H<sub>16</sub>O. [5°-6°]. (192°-193°) (Wallach, A. 263, 130; 272, 102). S.G. 1.29465 (W.). R<sub>D</sub> 44.23 (W.). [α]<sub>D</sub> +71.70 and -66.94.

**Occurrence.**—Dextro-fenchone is present in fennel oil, the fraction boiling between 190° and 195° consisting almost exclusively of the ketone, together with traces of anethol; derived from Thuya oil, fenchone possesses levorotatory optical properties. *D*- and *L*-fenchone form a series of derivatives which bear to one another a relation similar to that subsisting between the two tartaric acids, and the analogy extends to the formation of racemic modifications when equal proportions of the two classes of derivatives are mixed together.

**Preparation.**—The fraction of fennel oil boiling between 190° and 195° is treated with concentrated HNO<sub>3</sub>, the ketone remaining unattacked. After being freed from acid and distilled in a current of steam, the dry oil is cooled, and the fenchone crystallises out.

**Reactions.**—With bromine in the cold, an addition compound is formed, substitution taking place if the mixture becomes heated. P<sub>2</sub>O<sub>5</sub>, P<sub>2</sub>S<sub>5</sub>, and PCl<sub>5</sub> have the same action upon fenchone as upon camphor. Fenchone is dissolved by cold concentrated HCl, being thrown out of solution on warming. HNO<sub>3</sub> has but little action in the cold, but in a sealed tube at 120° HCN is formed (A. 263, 134). KMnO<sub>4</sub> oxidises fenchone to a mixture of oxalic, acetic, and dimethyl-malonie acids. *D*- and *L*-fenchone yield *d*- and *L*-fenchyl alcohols respectively on reduction with Na and alcohol (*v. Fenchol*). On heating *d*- and *L*-fenchone with ammonium formate, *L*- and *d*-fenchylamines respectively are formed. Fenchone does not react with phenyl-hydrazine or with alkaline sulphites, but both varieties form oxims [161°] with hydroxylamine.

*d*-Fenchon-oxim C<sub>10</sub>H<sub>15</sub>NOH [161°] (240°) loses water on treatment with dilute H<sub>2</sub>SO<sub>4</sub>, an unsaturated dextrorotatory nitrile (218°) being formed.

*L*-Fenchon-oxim C<sub>10</sub>H<sub>15</sub>NOH [161°] behaves in a similar manner on treatment with dilute H<sub>2</sub>SO<sub>4</sub>. The resulting nitrile yields with potash a levorotatory α-isoxim C<sub>9</sub>H<sub>13</sub>CONH<sub>2</sub> [114°-115°] which is readily converted by dilute H<sub>2</sub>SO<sub>4</sub> into the β-isoxim [136°-137°].

Camphor C<sub>10</sub>H<sub>16</sub>O (*i.* 669).

Menthone C<sub>10</sub>H<sub>16</sub>O (306°) (*iii.* 204).

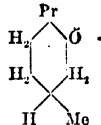

Pulegone C<sub>10</sub>H<sub>16</sub>O. (130°-131° under 60 mm.). (Beckmann a. Fleissner, A. 262, 1; Wallach, A. 272, 122; Semmler, B. 25, 3515). S.G. 22.9323 (B. a. P.); R<sub>D</sub> 45.55 (B. a. P.); [α]<sub>D</sub> 22.89 (B. a. P.). Pulegone is the chief constituent of Spanish oil of pennyroyal (*Mentha pulegium*). It is a dextrorotatory colourless liquid, having

an odour of peppermint, and rapidly becoming yellow on exposure to the air.

**Reactions.**—With HBr it combines forming a levorotatory ([α]<sub>D</sub> = -33.8) addition compound C<sub>10</sub>H<sub>16</sub>O.HBr (40.5°). When heated with ammonium formate, Wallach (A. 272, 123) failed to obtain a base isomeric with fenchylamine and thujonamine, a mixture of bases being formed. Slow oxidation with KMnO<sub>4</sub> gives rise to acetone and β-methyl-adipic acid [84.5°]. Rapid oxidation with the same reagent yields a γ-valero-lacton-γ-acetic acid (Semmler, B. 25, 3516). Pulegone combines with hydroxylamine to form pulegonoxim C<sub>10</sub>H<sub>15</sub>NO<sub>2</sub> [157°]. The oxim contains one molecule of H<sub>2</sub>O more than camphoroxim. It is levorotatory ([α]<sub>D</sub> -83.4) and forms a hydrochloride [117°-118°], a benzoyl ester [137°-138°], and an acetyl ester [149°]. On heating its hydriodide pulegonamine C<sub>10</sub>H<sub>15</sub>O.NH is formed.

Pulegone hydrobromide C<sub>10</sub>H<sub>15</sub>O.HBr [40.5°] is levorotatory; it forms an oxim [38°] which becomes converted on standing into normal pulegonoxim [157°]. Pulegone hydrobromide, on treatment with moist silver or lead oxide, loses HBr, pulegone being regenerated. Distillation with zinc dust gives rise to an oil which resembles menthone in every respect but the melting-point of its oxim (85° instead of 59°).

**Constitution.**—From the results of oxidation experiments carried on under various conditions with KMnO<sub>4</sub>, Semmler (B. 25, 3519) attributes to pulegone the constitution:

Puleone is the name given to a compound isomeric with camphor, obtained by Barbier (B. 25, 110c), from pennyroyal oil, described as boiling at 222°-223°, and possessing the following physical properties: S.G. .9482; *n*<sub>D</sub> .9293; [α]<sub>D</sub> +29.15. Its oxim C<sub>10</sub>H<sub>15</sub>NOH is an oil (170° under 48 mm.) yielding a liquid anhydride C<sub>10</sub>H<sub>14</sub>O on treatment with dilute H<sub>2</sub>SO<sub>4</sub>. Chromic acid mixture oxidises it to carbonic, acetic, and propyl-succinic [89°-91°] acids.

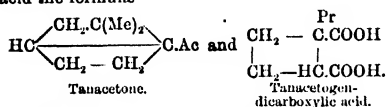

Tanacetone C<sub>10</sub>H<sub>16</sub>O (195°-196°; 84.5 at 13 mm.), identical with the thujone of Wallach (A. 272, 109; Bruylants, B. 11, 450; Semmler, B. 25, 3343, 3519; Wallach, *l.c.*). S.G. 22.9126 (S.). R<sub>D</sub> 44.54 (S.).

Tanacetone occurs in tansy, sage, wormwood, and thuya oils. It has ketonic properties, and possesses an optical rotatory power amounting to +38° 30' in a 2-dm. column.

**Reactions.**—Sodium in alcoholic solution reduces it to tanacetyl alcohol (92.5° at 13 mm.). With alkaline hypobromite it yields bromoform and tanacetogen-dicarboxylic acid (113.5° at 15 mm.). Oxidised with KMnO<sub>4</sub> it yields tanacetocarboxylic acid, which exists in two modifications, the α and β thujal-ctonic acids of Wallach (*l.c.*), [75°-76°] and [78°-79°] respectively. Heated with ammonium formate, it gives tanacetylamine (198°-199°), the same body being formed when tanacetoxim (see below) is reduced with sodium and alcohol. The hydrochloride of

this base on dry distillation yields tanacetene (172°-175°), a hydrocarbon of the formula  $C_{10}H_{16}$ , identical with Wallach's thujene. Tanacetone reacts with hydroxylamine to form tanacetoxim  $C_{10}H_{15}NOH$  (51.6°) (185°-186° at 22 mm.), which yields tanacetylamine on reduction, while treatment with dilute alcoholic  $H_2SO_4$  converts it into a cyimidine ( $Pr:NH_2:Me:1:3:4$ ), which gives carvacrol with nitrous acid. Tanacetophorone  $C_{10}H_{16}O$  (89°-90° at 13 mm.).  $R_d$  37.6. When tanacetogen-dicarboxylic acid (produced by the action of  $NaBrO$  upon tanacetone-carboxylic acid) is heated with soda-lime, tanacetophorone is formed. It has ketonic properties, and combines with hydroxylamine.

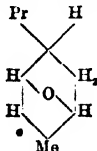

**Constitution.**—Semmler (*B.* 25, 3519) suggests for tanacetone and tanacetogen-dicarboxylic acid the formulae

**Sobrerone**  $C_{10}H_{16}O$ . *Pinol*. (183°-184°) (Wallach, *A.* 253, 254; Armstrong, *C. J. Proc.* 1890, 100).  $S.G. 25$  953 (W.);  $\mu_d$  1.469 (W.). Sobrerone is obtained from the mother-liquors accumulated in the preparation of pinene nitrosochloride; also by boiling sobrerol with dilute  $H_2SO_4$  (Armstrong, *loc.*).

**Reactions.**—It combines readily with  $Br$  to form a dibromide [94°], from which, on treatment with alcoholic potash, sobrerone is regenerated. Sobrerone and its dibromide yield terebic acid (175°-176°) on oxidation with  $KMnO_4$ ,  $HNO_3$  produces the same result. It forms a nitroso-chloride [103°] which, by the action of bases, is readily converted into nitrolamines, e.g. sobrerone-nitrol-piperidine [154°] and sobrerone-nitrol-benzyl-aniline [133°-131°]. The dibromide  $C_{10}H_{14}OBr_2$  [91°] (143°-144° at 11 mm.) yields on treatment with alcoholic potash, in addition to sobrerone, its glycol-ether  $C_{10}H_{16}O(OCH_2)_2$  [52°-53°]. Sobrerone-glycol-diacetate is easily obtained by heating the dibromide to 150° with lead acetate in glacial acetic acid solution. When heated at 100° for three hours with formic acid, sobrerone dibromide is converted into pinene.

**Constitution.**—Its behaviour towards bromine and nitrosyl chloride and its molecular refraction indicate the existence of one ethylene linking, while its indifference towards acid chlorides, hydroxylamine, phenylhydrazine and  $H_2S$  render it probable that the  $O$ -atom is united to two different  $C$ -atoms. From these facts, and from its behaviour on oxidation, Wallach (*A.* 253, 259) assumes the constitution

**Sobrerol**  $C_{10}H_{16}O_2$  [150°] (Sobrero, *O. R.* 33, 66; Armstrong, *C. J. Proc.* 1890, 100; *C. J.* 59, 315). Sobrerol is obtained by oxidizing French and American turpentine in

sunlight. It occurs in two optically active forms, both melting at 150°, and on allowing a mixed solution to crystallise inactive sobrerol. [181°] separates out. When boiled with dilute  $H_2SO_4$ , it loses 1 mol. of  $H_2O$ , sobrerone—identical with Wallach's pinol—being formed.

**Eucalyptol**  $C_{10}H_{18}O$  (176°) (Jahns, *B.* 17, 2941; Bouchardat a. Voiry, *C. R.* 106, 863). Identical with cineol, spiccol, cajepulol, and terpan (*B. a. V.*).

**Myristicol**  $C_{10}H_{18}O$  (221°) (Wright, *B.* 6, 1320; Gladstone, *C. J.* 23, 147; 25, 1; Brühl, *B.* 21, 471).  $S.G. 25$  9446 (G.).  $R_d$  46.42 (G.). Myristicol is a dextrorotatory alcohol, obtained from the ethereal oil of nutmeg, *Myristica aromatica*. It yields a chloride with  $PCl_5$ , and is converted into cymene by the action of  $ZnCl_2$ .

**Abainthol**  $C_{10}H_{16}O$  (217°) (Beilstein a. Kupfer, *B.* 6, 1183; Wright, *loc.* 1320; Gladstone, *C. J.* 45, 241; Brühl, *B.* 21, 471).  $S.G. 25$  9128 (G.).  $R_d$  44.62 (G.). Abainthol is obtained from oil of wormwood, and is dextrorotatory. It is converted by  $ZnCl_2$  and  $P_2S_5$  into cymene. In what form the oxygen exists is at present unknown.

#### Constitution of the terpenes.

**I. Pinene.** The following facts must be taken into consideration:

1. Dry pinene combines with one molecule of hydrogen chloride to form a saturated compound, from which hydrogen chloride is withdrawn with difficulty, the resulting hydrocarbon being a solid camphene. Moist pinene combines with  $2HCl$ , yielding dipentene-dihydrochloride. This also is saturated. The formation of both these compounds is undoubtedly attended by isomeric change, inasmuch as pinene cannot be recovered from either of them; but on removal of the elements of hydrogen chloride a new hydrocarbon results.

2. Pinene seems to combine with two atoms or with four atoms of bromine, according to the method of operating. By adding bromine to a cooled solution of pinene in carbon tetrachloride, Wallach has obtained a crystalline dibromide  $C_{10}H_{16}Br_2$  [170°]. The yield is, however, very small, about 7 p.c. of the hydrocarbon employed (*A.* 264, 1). By shaking up a solution of pinene in chloroform, with an excess of sodium hypobromite, acidified with hydrochloric acid, so as to liberate the bromine, and immediately afterwards determining the unabsorbed excess of bromine, Widen obtained results which pointed to the union of the terpene with four atoms of bromine. The combination is, however, very unstable, and hydrogen bromide is soon evolved (*C. J.* 53, 882). Schtschukoff finds that a chloroform solution of pinene takes up, in the dark, four atoms of bromine, but the bromide formed is unstable, and quickly gives off hydrogen bromide, thus  $C_{10}H_{16}Br_4 \rightarrow HBr + C_{10}H_{12}Br_3$  (*B.* 23, 432, *Ref.*, *J. pr.* 47, 191-6).

3. Pinene combines with  $NOCl$  to form a saturated compound which is not an oxim but a nitroso-compound, and yields up the  $NOCl$  by the action of aniline, with liberation of an optically inactive pinene.

4. By addition of two atoms of bromine to pinene, and subsequently heating the product

alone, or, better, with aniline (Oppenheim, *B. 5*, 629), cymene is formed.

5. In contact with slightly diluted mineral acids, or when heated above its boiling-point, pinene is gradually converted into an optically inactive mixture of dipentene with terpinene, terpinolene, and polymerised terpene ('colophene').

6. When heated to a temperature short of visible redness, pinene yields a considerable quantity of isoprene  $C_5H_8$ , together with a notable amount of *meta*-xylene.

7. Pinene submitted to oxidation yields about 1 p.c. of its weight of *p*-toluic or terephthalic acid. This is perhaps due to the presence of a little cymene. It must, however, be remembered that the oxidising agent usually employed is either nitric acid or acidified chromic liquor, and hence that the pinene is first changed into dipentene or one of the other hydrocarbons referred to above (5). When nitric acid is used oxalic acid is the most abundant product, accom-

panied by terebic acid

and dimethylfumaric acid

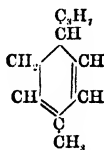

Beckurts, *B. 18*, 826). By treatment with chromate and sulphuric acid pinene yields much acetic acid, together with some terebic acid and terpenylic acid

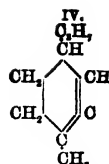

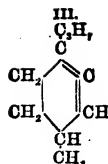

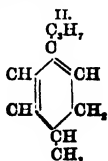

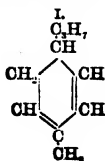

8. Natural pinene rotates the plane of polarisation to the right or to the left. It therefore must be supposed to contain an asymmetric atom of carbon.

In order to epitomise these facts many formulae have been proposed. The most important fall under two classes—namely, those in which pinene is represented as a dihydrocymene, and those in which a cross- or para-linkage is assumed.

Of the former class, the first example is the formula given many years ago by Oppenheim (*B. 5*, 98)—

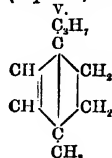

This kind of formula is now attributed with greater probability to limonene, and it must be remarked that of the possible formulae of this type there are only four which contain an asymmetric carbon atom and *iso*-propyl.

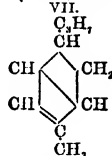

It has been shown that cymene, with which pinene is closely connected, contains *iso*- and not normal propyl (Widman, *B. 24*, 439). Hence pinene and its isomerides are believed also to be *isopropyl* compounds.

Formulae containing cross- or para-linkages have been proposed as follows:—

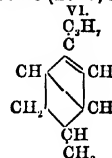

Kannonikoff  
(*J. pr.* 32, 517)

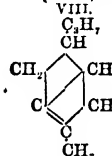

Wallach  
(*B. 24*, 1539)

Wallach (*A. 239*, 49)  
Collie (*B. 25*, 1108)

Wagner  
(*B. 24*, 2187)

II. Limonene.—1. Dry limonene combines with one molecule of hydrogen chloride, but unlike the hydrochloride derived from pinene the resulting compound is optically active and is not saturated, as it combines with halogens, with nitrosyl chloride, and, in the presence of moisture, with a second molecule of hydrogen chloride (Wallach, *A. 270*, 188). Limonene in the presence of water or alcohol readily yields dipentene dihydrochloride [50°], identical with the product formed from pinene. The dihydrochloride is optically inactive.

2. Limonene unites with four atoms of bromine, forming a crystalline tetrabromide.

3. Limonene unites with one molecule of nitrosyl chloride. The product, of which two (stereo?) isomerides occur, gives the reactions of an oxim.

4. Limonene readily yields abundance of cymene identical with that which is obtained from pinene (Oppenheim, *B. 5*, 628).

5. Limonene is polymerised by heat much less readily than pinene, and is not convertible into camphene.

6. Limonene vapour at a low red heat yields isoprene in the same way as pinene.

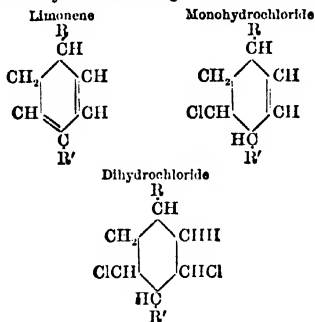

7. Limonene oxidised by nitric acid or by chromate yields oxalic, acetic, terebic or terpenylic acids according to circumstances, usually without any trace of toluic or terephthalic acid.

8. Limonene is dextro- or levo-rotatory. A

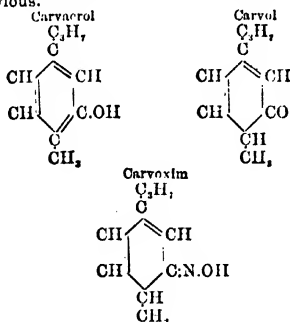

mixture of equal volumes of the active hydrocarbons constitutes dipentene, which, on account of its peculiarities, quite different from those of its components, was long regarded as a distinct hydrocarbon.

The formula which agrees best with the characters of limonene is either I. or II. given above (see *Pinene*).

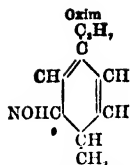

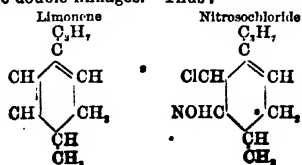

In both of these there is an asymmetric carbon atom, and as the mono-hydrochloride is optically active while the dihydrochloride is inactive, these compounds will probably be represented by the following formulae:—

Limonene nitrosochloride deprived of the elements of hydrogen chloride yields a compound which has been identified with carvoxim. If the following formulae be assumed for carvacrol and carvol, the interrelation of these compounds is obvious.

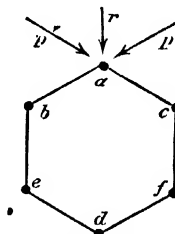

The corresponding formula for limonene should be No. II., but if that correctly represents the constitution of the hydrocarbon, the production of the nitrosochloride, or of the oxim from it, must be attended by isomeric change involving a re-distribution of the hydrogen and of the double linkages. Thus:—

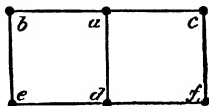

The oxim is optically active.

The very ready conversion of pinene into dipentene (=limonene) is a point of considerable importance, and it appears probable that the products formed by the action of heat and acid oxidising agents are in reality derived, not directly from pinene, but from the isomeric hydrocarbon into which it is first converted. The splitting up of pinene by heat into isoprene has been regarded (Wallach, A. 239, 48; Collie, B. 25, 1111) as supporting the formula already given VI. and VII., in which a para- or cross linkage is adopted. But remembering that isoprene is converted by polymerisation, not back again into pinene, but into dipentene, this evidence is of little importance. On the other hand, the difficulties involved in the assumption of a cross link in a cycloid of six carbon atoms are very considerable. In any closed ring of carbon atoms, the stability of the ring is easily accounted for upon simple mechanical principles. For if we consider six carbon atoms situated at the angles of a regular hexagon, and each attracted to its two neighbours on either side, whatever be the forces of attraction between them the resultant of those forces will have the effect of urging each carbon atom toward the centre of the figure. Thus, if the carbon atom  $\alpha$  is attracted towards the carbon atom  $b$  with a force represented by  $p$ , and towards  $c$  with a force represented by  $p'$ , in the figure, the resultant of these two pressures will be  $r$ , which acts towards the centre; and so with each of the five other atoms.

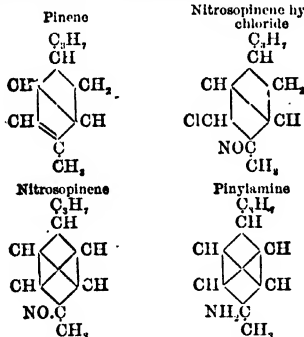

This conception is, of course, independent of any hypothesis concerning the fourth unit of valency, and the formula has no reference to the well-known 'centric' formula. The modern hypothesis according to which the carbon atom is supposed to be situated at the centre of a regular tetrahedron while the radicals with which it is united are placed at the angles of the same supplies no distinction between the force and the direction of the unit of affinity. The difference of specific volume observed between carbon compounds of the aromatic and fatty series seems to indicate that carbon atoms in the former are more closely united together, but it appears that no compounds are known in

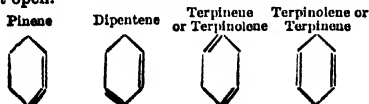

which the specific volume of carbon differs very greatly from its normal value. Hence it appears probable that the carbon atom, in uniting with other atoms, preserves a nearly constant distance from them, and in the figure above to suppose that *a* is combined with *d* as firmly as with *b* or *c* requires the assumption that a carbon atom is capable of acting through a distance twice as great in one case as in another. If this is possible, and we imagine the force of attraction between *a* and *d* to be as great as between *a* and *b* or *c*, then, unless *c* acts upon *e* and *b* acts upon *f* at the same time with the same force the figure will be changed from the hexagon to a double square.

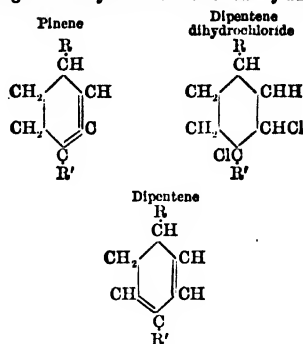

A compound of this kind would be incapable of many of the changes which are characteristic of pinene, and a second cross linkage between *c* and *e*, or between *b* and *f*, would be impossible. Hence the following formulae, which are attributed by Wallach to nitrosopinene and pinylamine cannot be accepted even if a single diagonal is allowed in the formula of pinene.

Formulae III. and IV. now remain to be considered. So far as the writer is aware, formulae of this type have not been proposed for any of the terpenes. Nevertheless there is much to be said in favour of an expression of this kind for a compound so unstable as pinene, which appears to be incapable of withstanding the action of heat or of contact with any reagent without isomeric change. For example, the conversion of pinene into dipentene, terpinene, and terpinolene may be explained with the minimum amount of hypothesis by the following formulae, in which the tendency towards the conversion of an unsymmetrical into a symmetrical molecule is clearly shown. The question as to the relative positions of the methyl and propyl groups is left open.

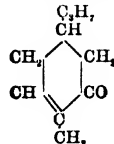

The conversion of pinene into dipentene through the dihydrochloride is readily shown.

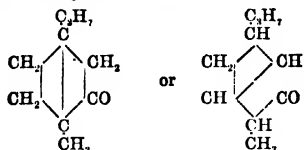

Such a formula for pinene also explains the extreme instability of its tetrabromide.

III. CAMPHENE. Camphene behaves towards all reagents—such as bromine and nitrosyl chloride—as a saturated compound, but with hydrogen chloride it unites, forming a compound which in external appearance resembles pinene monochloride, but differs from that compound by its instability. When camphene is oxidised by chromic acid it yields camphor, but when treated with permanganate a glycol is formed. This compound crystallises in odourless small monoclinic prisms, which sublime at temperatures above 100° (192° ca.). Its most characteristic property is seen in its reaction with dilute acids, whereby water is separated and a compound isomeric with camphor formed. This reaction appears to indicate the existence of one ethylenic bond in camphene (G. Wagner, *B.* 23, 2307). Brühl (*B.* 25, 160) also finds, as the result of his latest determinations of the molecular refraction and dispersion of camphene, that this hydrocarbon contains one ethylenic linkage. Wallach (*B.* 24, 1555) upon other grounds appears to hold the same view. Camphene is, however, so closely connected with camphor that the constitution of the latter compound when settled may serve as a guide in determining the constitution of the former. The formula for camphor given by Kekulé (*B.* 6, 931) was based upon the supposed intimacy of its relation to cymene and carvacrol.

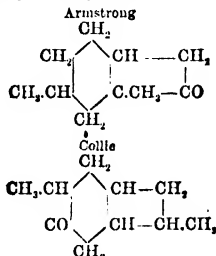

There can be no serious doubt of its character as a ketone, inasmuch as it yields an oxim, though it gives no compound with  $\text{NaHSO}_3$ ; but the action of dehydrating agents upon camphor is very complicated, and there can be no doubt that the production of cymene is attended by isomeric change. Armstrong & Kipping (*C. J.*, Jan. 1893) have shown that among the products of the action of strong sulphuric acid upon camphor

there is a considerable quantity of acetyl-orthoxylylene ( $C_6H_4Me.Me.Ac$ ,  $Me:Me:Ac = 1:2:4$ ). From observation of its molecular refraction Brühl (*B.* 21, 467) suggests a formula containing a para-linkage, either

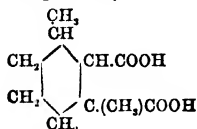

The former of these two formulae has also been used by Wallach (*B.* 24, 1555). These expressions are equivalent to representing camphor as a derivative of tetramethylene.

A formula of a different character has been suggested by Armstrong a. Miller (*B.* 16, 2260) (*v.* vol. I. p. 670), and another of somewhat similar type by Collie (*B.* 25, 1114):

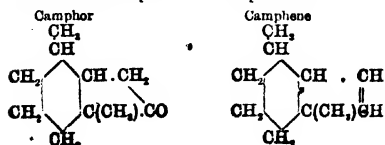

Camphor by oxidation with nitric acid yields camphoric acid in large quantity, and as the characteristic and chief product. Camphoric acid is therefore probably derived from camphor by an operation of a simple kind without constitutional disturbance. The following formula proposed by Collie (*B.* 25, 1116) has been shown to possess a very high degree of probability (Walker, *C. J.*, April 1893):

This formula sufficiently accounts for the chief facts concerning camphoric acid, viz. that it is a saturated dibasic acid, which readily yields the anhydride by heating; that it is optically active, and when treated with hydrogen iodide yields tetrahydro- and hexahydro-*m*-xylene.

From this formula are deducible the following formulae for camphor and camphene:

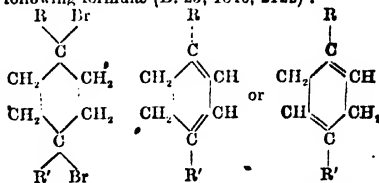

This formula for camphene explains pretty well all its relations, except its derivation from pinene, if either of the formulae containing a para-linkage be adopted. The chief objections to such formulae are stated above.

J. Brett (*B.* 26, 3047) has recently proposed formulae for camphene, camphor, and camphoric acid, which are derived from a pentamethylene ring.

#### Synthesis of Terpenes.

Von Baeyer in a series of papers has shown that various dihydro-derivatives of benzene and its homologues may be synthetically produced. Starting with succino-succinic ester, this compound, by treatment with dilute sulphuric acid, yields diketo-hexamethylene, and this, by reduction with sodium-amalgam, gives the corresponding glycol. This glycol possesses the characters of a sugar, and has been named chinito or quinito (*B.* 25, 1037). It occurs in two isomeric forms, which by treatment with hydrogen bromide yield two dibromohexamethylenes. Both of these by heating with quinoline yield dihydrobenzene (*B.* 25, 1840), a liquid which has nearly the same boiling-point as benzene, but combines with HBr and with Br<sub>2</sub>. It also reduces permanganate. By a corresponding series of processes dihydro-*p*-xylene was obtained from dimethylsuccino-succinic ester (*B.* 25, 2122). Dihydro-*p*-xylene (134° ciren) smells of turpentine, unites with hydrogen bromide, but forms no crystallisable nitrosite.

In order to produce a dihydrocyclohexane it is necessary to start from the methyl-propyl compound of succino-succinic ester. This compound was obtained by heating the sodium compound of the monopropryl ether with methyl iodide (*B.* 25, 233). Methyl-isopropyl-dihydrobenzene boils at about 174°. It smells like turpentine and resinifies in the air. It decolourises permanganate and unites with bromine, forming an uncrystallisable bromide. Although closely resembling a terpene, however, it is obvious that this hydrocarbon is not identical with any natural terpene known, containing, as it does, no asymmetric carbon. It may be identical with terpinene. The relations of the paradibromohexamethylene, or of its alkyl derivatives, to the corresponding hydrocarbon is shown in the following formulae (*B.* 25, 1840, 2122):

W. A. T.

**TERPENYLIC ACID**  $C_{10}H_{16}O_4$ , [72°] (Fittig); [58°] (Wallach). Formed, together with terebic acid, by oxidising oil of turpentine and other terpenes with chromic acid mixture (Hempel, *B.* 8, 357; A. 180, 77; Fittig, *A.* 208, 71). Formed also by oxidising pinol hydrate [181°] with  $KMnO_4$  (Wallach, *A.* 259, 318). Monoclinic prisms (containing aq).

**Reactions.**—1. Yields acetic acid and  $CO_2$  on

further oxidation by *chromic acid*.—2. On *dry distillation* it yields *teracrylic acid* (218°), a very little *oxy-heptioic lactone* (212°), and other bodies (Amthor, *J. pr.* [2] 42, 388).—3. Reduced by HI and P to  $\beta$ -isopropyl-glutaric acid (Schryver, *C. J.* 63, 1844).

**Salts.**—BaA'. Amorphous, powder, v. e. sol. water. Converted by boiling with baryta into barium diaterpenylate  $\text{Ba}(\text{C}_{10}\text{H}_{16}\text{O}_2)_2$ , aq, which separates in needles on heating the cold saturated solution and is v. sl. sol. water. On adding an acid the liberated diaterpenylic acid at once changes to its lactone, terpenylic acid.—CuA', zaq.—AgA'. Crystalline mass. Silver diaterpenylate  $\text{Ag}_2\text{C}_{10}\text{H}_{16}\text{O}_2$  is pptd. by adding  $\text{AgNO}_3$  to a solution of barium diaterpenylate.

**Ethyl ether EtA'.** [38°]. (305° i.v.). Monoclinic crystals;  $a:b:c = 1.051:1:1.381$ ;  $\beta = 50^\circ 58'$ . V. sol. alcohol and ether, sl. sol. cold water. Sodium converts it into (a)- and (b)-diterpodilactone  $\text{C}_{10}\text{H}_{16}\text{O}_2$ .

(a)-Diterpodilactone  $\text{C}_{10}\text{H}_{16}\text{O}_2$ . [154°]. Formed as above (Fittig, *A.* 256, 213). Long needles (from water), m. sol. alcohol. Yields  $\text{CaC}_2\text{H}_2\text{O}_6$ , Gaq,  $\text{Ag}_2\text{C}_{10}\text{H}_{16}\text{O}_2$ , and  $\text{BaC}_2\text{H}_2\text{O}_6$ , Gaq crystallising in monoclinic prisms;  $a:b:c = .935:1:1.595$ ;  $\beta = 65^\circ 54'$ , which, when decomposed by HCl and immediately extracted with ether yields (a)-diterpolactonic acid  $\text{C}_{10}\text{H}_{14}\text{O}_4$  [160°]. This acid decomposes above 160° into water and its lactone.

(b)-Diterpodilactone  $\text{C}_{10}\text{H}_{16}\text{O}_2$ . [135°]. A product of the action of Na on terpenylic ether (Fittig, *A.* 256, 122). Needles, m. sol. alcohol. Converted by baryta into (b)-diterpolactonic acid [187°] and (b)-diterpoxylic acid  $\text{C}_{10}\text{H}_{14}\text{O}_4$ . (b)-diterpolactonic acid forms trimetric crystals;  $a:b:c = .732:1:2.59$  and is re-converted by heat into the lactone. (b)-Diterpoxylic acid forms the salts BaA'' 8aq, CaA'', and AgA''.

(a)-Diterpylic acid  $\text{C}_{10}\text{H}_{14}\text{O}_4$ . (a)-Diterpodilactone carboxylic acid. [216°]. An intermediate product of the action of Na on terpenylic ether. Needles, m. sol. alcohol. Converted by boiling  $\text{HCl}$  aq or by heating above 216° into (a)-diterpodilactone.

#### TERPILENE v. TERPENES.

**TERPILENOL**  $\text{C}_{10}\text{H}_{18}\text{O}$ . [ $\alpha$ . 32°]. ( $\alpha$ . 130° at 50 mm.). S.G.  $\alpha$ . .95. H.C. (inactive) 113,318; (active) 102,923 (Lougouine, *C. R.* 107, 1163). Got by saponification of the terpilene acetates  $\text{C}_{10}\text{H}_{17}\text{HOAc}$  or terpilene formates  $\text{C}_{10}\text{H}_{17}\text{CH}_2\text{O}_2$  by alcoholic potash (Lafont, *A. Ch.* [6] 15, 205). Crystals, insol. water, v. sol. oil of turpentine, alcohol, and ether. Boils with decomposition at 220°. Occurs in several forms varying in their action on polarised light.

**Reactions.**—1. HCl forms  $\text{C}_{10}\text{H}_{18}\text{2HCl}$  [48°], which is inactive even if the terpenol were active.—2. Alcohol and  $\text{HNO}_3$  give  $\text{C}_{10}\text{H}_{17}\text{O}_3$  [104°].—3. *Phthalic anhydride* forms terpilene  $\text{C}_{10}\text{H}_{16}$ .—4.  $\text{Ac}_2\text{O}$  at 100° forms the acetyl derivative or terpilene acetate.

**Acetyl derivative**  $\text{C}_{10}\text{H}_{17}\text{OAc}$  or  $\text{C}_{10}\text{H}_{17}\text{HOAc}$ . (220°). S.G.  $\alpha$ . .971. V.D. 6.6. Obtained by heating terpilene with  $\text{HOAc}$  at 150°. Liquid (Bouchardat & Lafont, *C. R.* 102, 1565).

**Formyl derivative**  $\text{C}_{10}\text{H}_{17}\text{O.CHO}$ . [ $\alpha$ ]<sub>D</sub> = -69° 25'. S.G.  $\alpha$ . .999. Formed from oil of turpentine and cold formic acid (Lafont, *C. R.*

106, 140). By heating with water at 100° 65 p.a. of the ether is saponified.

#### TERPIN v. TERPENES.

##### TERPINOL v. TERPENES.

**TERPYLONIC ACID**  $\text{C}_8\text{H}_{10}\text{O}_4$ . [185°]. A product of the oxidation of turpentine by chromic acid mixture (Schryver, *C. J.* 63, 1328). Needles, v. e. sol. water, m. sol. ether. Differs from camphoronic acid in electrical conductivity.

##### TETANINE v. PROMAINES.

**TETRADECANAPHTHENE**  $\text{C}_{14}\text{H}_{22}$ . (241° cor.). S.G.  $\alpha$ . .839. Occurs in petroleum from Baku (Markownikoff & Ogloblin, *J. R.* 15, 339).

**n-TETRADECANE**  $\text{C}_{14}\text{H}_{30}$ . *Diheptyl*. [45°]. (253°). S.G.  $\frac{4}{4}$  .775;  $\frac{15}{15}$  .768. Formed by heat-myristic acid with HI and P (Krafft, *B.* 15, 1700). Got also by the action of Na on n-heptyl iodide (Krafft, *B.* 19, 2223; Sorabji, *C. J.* 47, 37).

##### Reference.—DI-BROMO-TETRADECANE.

**TETRADECENOIC ACID**  $\text{C}_{14}\text{H}_{26}\text{O}_2$  i.e.  $\text{C}_8\text{H}_{17}\text{.CH=C(C}_2\text{H}_5)_2\text{.CO}_2\text{H}$ . *Amylterylacrylic acid*. Formed by the action of alcoholic potash on  $\alpha$ -nanthol (Perkin, *B.* 15, 2803; 16, 211). Liquid, boiling *in vacuo* at 275° to 280°.

**TETRADECENOIC ALDEHYDE**  $\text{C}_{14}\text{H}_{24}\text{O}$  i.e.  $\text{CH}_3(\text{CH}_2)_6\text{.CH=C(CH}_3)_2\text{.CHO}$ . (278°). S.G.  $\frac{15}{15}$  .819. Formed by the action of alcoholic potash or of  $\text{ZnCl}_2$  on  $\alpha$ -nanthol (Perkin, *C. J.* 43, 47). Oil, not solid at -20°. Forms crystalline  $\text{C}_{14}\text{H}_{23}\text{ONaHSO}_4$ . Yields hexoic and heptioic acids on oxidation.

**TETRADECENYL ALCOHOL**  $\text{C}_{14}\text{H}_{28}\text{O}$ . (282°). S.G.  $\frac{15}{15}$  .852. Formed by reducing the preceding aldehyde with sodium-amalgam (Perkin, *B.* 15, 2808). It is also a product of the action of sodium-amalgam on a solution of  $\alpha$ -nanthol in  $\text{HOAc}$  (Perkin, *C. J.* 43, 68). Oil. May be reduced to  $\text{C}_{14}\text{H}_{30}\text{O}$ .

**Acetyl derivative**  $\text{C}_{14}\text{H}_{27}\text{OAc}$ . (285°-290°). S.G.  $\frac{15}{15}$  .868. Combines with Br (3 atoms).

**TETRADECINENE**  $\text{C}_{14}\text{H}_{24}$  i.e.  $\text{CMe(C}_2\text{H}_5)_2\text{C}_6\text{H}_{13}$ . [6-5°]. (134° at 15 mm.). S.G.  $\frac{65}{65}$  .8064;  $\frac{15}{15}$  .8000. Formed from tetradecylene bromide and alcoholic potash at 150° (Krafft, *B.* 17, 1372; 25, 2249).

**TETRADECOIC ACID**  $\text{C}_{14}\text{H}_{28}\text{O}_2$  i.e.  $\text{C}_8\text{H}_{17}\text{.CH(C}_2\text{H}_5)_2\text{.CO}_2\text{H}$ . (300°-310°). Got by the action of moist  $\text{Ag}_2\text{O}$  on the corresponding aldehyde (Perkin, *C. J.* 43, 74). Liquid, not solid at -10°.

##### Tetradecic acid v. MYRISTIC ACID.

##### Reference.—OXYTETRADECOIC ACID.

**TETRADECOIC ALDEHYDE**  $\text{C}_{14}\text{H}_{26}\text{O}$  i.e.  $\text{C}_8\text{H}_{17}\text{.CH(C}_2\text{H}_5)_2\text{.CHO}$ . [30°]. (267°). S.G.  $\frac{35}{35}$  .827. A product of the action of Na on an ethereal solution of  $\alpha$ -nanthol (Perkin, *C. J.* 43, 71). Tables, v. sol. alcohol. Reduces ammoniacal  $\text{AgNO}_3$ . Yields heptioic, hexoic, and acetic acids on oxidation.

##### Isomeride v. MYRISTIC ALDEHYDE.

**n-TETRADECYL ALCOHOL**  $\text{C}_{14}\text{H}_{30}\text{O}$ . [88°]. (167° at 15 mm.). S.G.  $\frac{15}{15}$  .8153. Formed by reducing myristic aldehyde (Krafft, *B.* 16, 1720).

**Acetyl derivative**  $\text{C}_{14}\text{H}_{29}\text{OAc}$ . [18°]. (176° at 15 mm.).

**Tetradecyl alcohol**  $\text{C}_8\text{H}_{17}\text{.CH(C}_2\text{H}_5)_2\text{.CH}_2\text{OH}$ . (270°-275°). S.G.  $\frac{15}{15}$  .8368. Formed by reducing the corresponding aldehyde or the alde-

hyde  $C_4H_8O$  (Perkin, B. 15, 2811; C. J. 43, 76). Liquid, solidifying at  $-10^\circ$ .

Acetyl derivative  $C_{11}H_{20}OAc$ . (o. 278°). S.G.  $\frac{1}{4}$  856. Oil, not solid at  $-10^\circ$ .

**n-TETRADECYLENE**  $C_{14}H_{28}$  i.e.  $CH_2:CH.C_6H_{13}$ . [ $-12^\circ$ ]. ( $127^\circ$  at 15 mm.) S.G.  $\frac{1}{4}$  7852;  $\frac{1}{2}$  7745. Formed by distilling tetradecyl palmitate at 500 mm. (Krafft, B. 16, 3021). Liquid.

Bromide v. Di-BROMO-TETRADECANE.

**TETRADECYLENE GLYCOL** v. Di-iso-BUTYL FINACONE.

**TETRADECYL-MALONIC ACID**  $C_{17}H_{32}O_4$  i.e.  $C_4H_9.CH(CO_2H)_2$ . [ $118^\circ$ ]. Formed by boiling its nitrile with alcoholic potash (Hell a. Jordanoff, B. 24, 988). White powder (from HOAc), insol. water, v. sl. sol. ether, sl. sol. cold alcohol. At  $150^\circ$ – $170^\circ$  it is split up into  $CO_2$  and palmitic acid.—Ag $_2$ A'' : white pp.

Amide  $C_{17}H_{32}N_2O_4$ .  $CH(CO_2H)(CONH_2)$ . Pearly scales. At c.  $140^\circ$  it yields palmitic amide.

Nitrile  $C_{17}H_{30}N_2$ .  $CH(CO_2H).CN$ . [ $76^\circ$ ]. Formed by heating *p*-bromo-palmitic ether with alcoholic KCy. Silky plates (from HOAc).

**n-TETRA-ICOSANE**  $C_{24}H_{50}$ . [ $51^\circ$ ]. ( $213^\circ$  at 15 mm.). S.G.  $\frac{7}{8}$  763;  $\frac{9}{10}$  748. Formed by the action of HI and P on  $C_{12}H_{25}CCl_2.C_6H_5$ , made from the ketone obtained by distilling barium stearate with barium heptate (Krafft, B. 15, 1718).

**TETRA-ICOSOIC ACID**  $C_{24}H_{48}O_4$ . [ $72.5^\circ$ ]. Occurs in the soap got by heating carnaúba wax with aqueous NaOH (Stäcker, A. 223, 307). Crystalline powder, v. sol. hot alcohol.—PbA $_2$ . [ $111^\circ$ ]. Sol. toluene and hot HOAc.

**TETRAZOLE**  $N \begin{smallmatrix} \diagup N \\ \diagdown N \end{smallmatrix} CH.NH$  [ $155^\circ$ ]. Formed by treating amido-phenyl-tetrazole carboxylic acid with alkaline  $KMnO_4$  followed by  $HNO_3$  (Bladin, B. 25, 1412). Plates (from toluene). Reddens blue litmus.

**TETRAZYL-HYDRAZINENH.NH.C**  $\begin{smallmatrix} N-N \\ \diagup \diagdown \\ NH.NH \end{smallmatrix}$  [ $199^\circ$ ]. Formed from amido-tetrazotic acid by diazotisation and reduction by  $SnCl_2$  (Thiele, A. 273, 155). Yellowish crystalline aggregates, v. sol. hot water.—B $^{27}HCl$ . [ $176^\circ$ ]. Acetoacetic ether forms  $\begin{smallmatrix} CH.CO \\ \diagup \diagdown \\ CMe.NH \end{smallmatrix} > N.C \begin{smallmatrix} \diagup N \\ \diagdown N \end{smallmatrix} NH.NH$  [ $215^\circ$ ] crystallising in needles.

**TETRIC ACID**  $C_{10}H_{16}O_8$  i.e.  $CH_2.C(OH).CMe < \begin{smallmatrix} O \\ \diagup \diagdown \\ CO.O \end{smallmatrix} > CMe.C(OH).CH_2$

(Nef, A. 266, 92) or  $CH_2.CO.C(CO_2H)_2.CH_2$ . Acetyl-acrylic acid. [ $189^\circ$ ]. ( $262^\circ$ ). S. 1.5 at  $14^\circ$ . Electrical conductivity: Walden, B. 24, 2027. Got by heating  $CH_3.CO.CMe.Br.CO_2Et$  at  $100^\circ$ , but not by heating the isomeric acid  $CH_3.Br.CO.CMe.CO_2Et$  (Nef; cf. Pawloff, B. 16, 486).

Formed by successive action of bromine and alcoholic potash on methyl-acetoacetic ether (Demarcay, C. R. 87, 351; 88, 126). Triclinic prisms (from water), v. sol. hot water, alcohol, and ether. Gives a violet-red colour with  $FeCl_3$ .  $PCl_5$  gives rise to several compounds boiling between  $160^\circ$  and  $185^\circ$  which take up chlorine forming  $C_4H_5Cl_2O$  (Pawloff, Bl. [2] 45, 181; C. R. 97, 99). Demarcay obtained oily  $C_4H_5Cl_2O$  (?) which united with  $Cl$  and  $Br$  forming  $C_4H_4Cl_3O$  [ $48^\circ$ ] and  $C_4H_4Cl_2Br_2O$  [ $67^\circ$ ]. Resinified by dilute  $HClAq$  at  $160^\circ$ . Potash-

Vol. IV.

fusion gives formic and propionic acids. Distillation with lime forms methyl ethyl ketone. Sodium-amalgam has no action.

Salts.— $(NH_4)_2A''$ . Crystals, v. sol. water.— $Na_2A''$  6aq.— $K_2A''$ .— $BaA''$  8aq. Needles, v. e. sol. water.— $BaA''$  2aq.— $Ba_2(OH)_2A''$ . Sl. sol. water.— $CaA''$  2aq.— $MgA''$  10aq.— $ZnA''$  aq.— $CuA''$ .— $Ag_2A''$ . Needles, sl. sol. water.

Ethyl ether  $\begin{smallmatrix} CMe.C(OEt) \\ \diagup \diagdown \\ CO-CH_2 \end{smallmatrix} > O$  (?). [ $30^\circ$ ]. ( $180^\circ$  at 70 mm.) (Moseholes, B. 21, 2607).

Amide  $C_{11}H_{20}N_2O_4$ . [ $212^\circ$ ]. Got by heating the acid with alcoholic  $NH_3$ .

**TETROLE CYANURAMIDE** v. Nitrile of PYRROLE CARBOXYLIC ACID.

**TETROLIC ACID**  $C_4H_6O_4$  i.e.  $CH_3.C(CO_2H)_2$ . Butyrolic acid. Mol. w. 84. [ $77^\circ$ ]. ( $203^\circ$ ). Formed by boiling  $\beta$ -chloro-crotonic acid or  $\beta$ -chloro-iso-crotonic acid with dilute potash (Geuther, Z. 1871, 245; Friedrich, A. 219, 343; Kahlbaum, B. 12, 2338). Formed also by the action of Na and  $CO_2$  on allylene chloride (Pinner, B. 14, 1081).

Preparation.—From acetoacetic ether and  $PCl_5$ , the product being freed from  $POCl_3$  by heating to  $115^\circ$ , mixed with water, and freed from chloro-crotonic acid by distillation with steam. The residue is treated with alcoholic potash (Fittig a. Clutterbuck, A. 268, 96; cf. Friedrich, A. 219, 322).

Properties.—Plates (from ligroin). May be sublimed. V. e. sol. water, alcohol, and ether. Not reduced by sodium-amalgam to crotonic acid (F. a. C.; cf. Aronstein, B. 22, 1181). Slightly volatile with steam.

Reactions.—1. Br forms di-bromo-crotonic acid [ $120^\circ$ ], which is reduced by sodium-amalgam to tetrollic acid. Bromine also yields  $C_4H_5Br_2O_2$  [ $97^\circ$ ] (Pinner).—2.  $HBr$  forms bromo-crotonic acid [ $91^\circ$ ].—3. Heated with conc.  $KOHAq$  it forms acetone.—4. Fuming  $HClAq$  at  $15^\circ$  in a few weeks converts it into  $\beta$ -chloro-crotonic acid [ $91.5^\circ$ ].—5. Boiling with Na and  $MeOH$  yields butyric acid (A.).—6. Chlorine forms  $C_4H_5Cl_2O_2$ .—7. On heating with iodine in  $CHCl_3$  in sealed tubes it yields di-iodo-crotonic acid (B. 26, 843).—8. Split up at  $211^\circ$  into  $CO_2$  and allylene.—9.  $KMnO_4$  forms acetic acid.

Salts.— $NaA'$ . Crystalline.— $KA'$  (dried at  $100^\circ$ ). Prisms (from alcohol).— $NH_4A'$ .— $LiA'$  aq.— $MgA'_2$  3aq.— $BaA'_2$  3aq.— $CaA'_2$  3aq. Small needles.— $ZnA'_2$  2aq (Lagermark, J. B. 12, 290).— $ZnA'_2$  2aq (Fittig). Groups of prisms.— $CdA'_2$  4aq.— $PbA'_2$  aq. S. 1.5 in 92 p.c. alcohol at  $20^\circ$ .

Chloride  $C_4H_5OCl$ . Fuming liquid, carbonised by heat. Quickly decomposed by water (Lagermark, Bl. [2] 35, 171).

**DI-TETROLUREA** v. CARBONYL-PYRROL.

**TETROLE-URETHANE** v. Ethyl ethyl of PYRROLE CARBOXYLIC ACID.

**TEUGRIN**  $C_{24}H_{42}O_{11}$  or  $C_{24}H_{40}O_{11}$ . [ $230^\circ$ ]. A glucoside occurring in *Tenerium fruticosans*, a plant used in Sicily as febrifuge. Extracted by alcohol (Ogilaloro, G. 9, 440; 13, 498). Slender yellow prisms. Boiling dilute nitric acid forms anisic, tartaric, and oxalic acids. Boiling dilute  $H_2SO_4$  yields glucose and a yellow insoluble residue.

**TEWFIKÖSE**. [ $a_D$ ] =  $53.1^\circ$ . A sugar occurring in the milk of the Egyptian buffalo (Bos

X X

*bubalus*). Yields glucose on hydrolysis (Pappel a. Richmond, *C. J.* 57, 759), v. SUGARS.

**THALICTRINE.** *Macrocarpine*. Occurs in *Thalictrum macrocarpum* (Harriot a. Doassans, *Bl.* [2] 84, 83). Yellow needles, insol. water, sol. alcohol and ether. Resembles aconitine, but is less poisonous.

**THALLIN** v. OXY-QUINOLINE.\*

**THALLIUM.** Tl. At. w. 203.64. Mol. w. 407.28 as gas at c. 1700° (v. *infra*). Melts at 293.9° (Crookes, *C. J.* 17, 123; cf. Lamy, *A. Ch.* [3] 67, 385). Boils at full red heat. S.G. pressed 11.88, cast 11.81, in wire 11.91 (Crookes, *L.c.*; cf. Lamy, *L.c.*; Werther, *J. pr.* 91, 385; de la Rive, *C. R.* 56, 588). V.D. 232.7 at 1636°, 203.7 at 1728° (Biltz a. V. Meyer, *B.* 22, 725). S.H. 0.0325 (Lamy, *L.c.*); 0.0335 (17°–100°) (Regnault, *A. Ch.* [3] 67, 437). C.E. (linear) 0.0003021 at 40°, 0.0003135 at 50° (Fizeau, *C. R.* 68, 1125). E.C. 5.225 at 0° (Hg at 0° = 1) (Bénoit, *P. M.* [4] 45, 814; cf. Matthiessen, *P.* 118, 431). H.C. [Tl<sub>2</sub>O] = 42,240 (*Tl.* 3, 354). Latent heat of fusion c. 1010 for 203.6 g. (Heycock a. Neville, *C. J.* 65, 35). The characteristic green line of the emission spectrum has the wave-length 5347 according to Huggins (*T.* 1864, 139), 5349.6 according to Mascart (*Ann. de l'écol. norm.*, 4, 7 [1867]), and 5349.5 according to Thalén (*Determin. des long. d'onde des raies métalliques* [Upsala, 1868]). Concerning the emission spectrum of Tl v. also Crookes, *Pr.* 12, 536; Nicklès, *C. R.* 58, 132; Kirchhoff a. Bunsen, *A.* 155, 230, 366; Lockyer a. Roberts, *Pr.* 23, 344; Jörveing a. Dewar, *Pr.* 27, 132; Hartley a. Adeney, *T.* 1884, 104; Becquerel, *C. R.* 99, 376; Wilde, *Pr.* 53, 369.

*Historical.*—In 1861 Crookes was preparing Se from the flue-dust of a sulphuric acid manufactory at Tinkelrode in the Harz mountains, when on distilling the impure Se he obtained a residue which showed a marked single green line in the spectrum; this line was not known to belong to the spectrum of any element, hence Crookes supposed that the impure Se contained a new element. Crookes isolated the element towards the end of 1861, and called it thallium. (from *θαλλός* = a green bud) (v. *C. N.* 3, 193, 303). Lamy (*A. Ch.* [3] 67, 385) noticed a new green line in the spectrum of a leaden chamber deposit about the same time as Crookes was investigating the cause of the line he had observed; in 1862 Lamy isolated a specimen of the metal which Crookes had obtained a few months before.

*Occurrence.*—Never uncombined. Compounds of Tl are widely distributed, but only in very small quantities. The sulphide occurs in minute quantities in many specimens of *copper pyrites* and *iron pyrites* (v. Crookes, *C. J.* 17, 112; Lamy, *L.c.*; Wöhler, *A.* 142, 263; Carstanjen, *J. pr.* 102, 65; Gunning, *Ar. N.* 3, 86); also in native sulphur from Lipari and Spain. Compounds of Tl are found in small quantities in many ores of As, Bi and Hg, and in preparations from these ores; also in commercial Se and Te, probably as selenide and telluride (v. Crookes, *L.c.*; Röppler, *Am. S.* [2] 35, 420; Herapath, *Ph.* 4, 802; Werther, *J. pr.* 89, 129). Some specimens of *lepidolite* contain small quantities of Tl compounds (v. Schrötter, *W. A. B.* 48 (ii.) 734; 50 (ii.) 268). A Swedish

mineral called *crookesite* was found by Norden-skjöld to contain from 16.3 to 18.55 p.c. Tl as selenide, along with selenides of Cu and Ag (*Bl.* [2] 7, 409). Small quantities of TlCl are found in some mineral springs and in the saline deposits from such springs (v. Böttger, *J. pr.* 89, 378; 90, 22; 96, 294). Traces of Tl alum have been found accompanying the double sulphates of Cs, Li, and Rb in *alumite* from the island of Volcano (Cossa, *Acad. dei Lincei* [3] 2). Small quantities of Tl compounds have been noticed in *carnallite*, *sydnone*, and *kainite* (Schramm, *A.* 219, 374). Many specimens of commercial sulphuric and hydrochloric acids contain traces of Tl compounds (v. Crookes, *L.c.*).

*Formation.*—(Crookes, *L.c.*; or *T.* 1872).—1. By reducing Tl<sub>2</sub>CO<sub>3</sub> by fusion with KCN.—2. By electrolysis of Tl<sub>2</sub>CO<sub>3</sub> covered with water.—3. By electrolysis of Tl<sub>2</sub>SO<sub>4</sub>.—4. By heating Tl<sub>2</sub>C<sub>2</sub>O<sub>4</sub> in a covered crucible.—5. By ppg. by zinc from solution of a thallous salt to which excess of NH<sub>4</sub>Aq or NaOH<sub>4</sub>Aq has been added.

*Preparation.*—The most economical source is the flue-dust from sulphuric acid manufactories where pyrites or sulphur containing Tl compounds has been used. Many specimens of flue-dust contain no Tl compounds; in some specimens 8 p.c. Tl has been found, but only in a very few does the quantity amount to 25 p.c. Tl (Crookes). After having been heated to dull redness, to remove any HCl, the dust is well stirred in wooden tubs with its own weight of boiling water and allowed to settle for 12 hours; the liquid is siphoned off, and the residue is again stirred with boiling water and let settle; the mixed liquids are pph. by a considerable excess of conc. HCl<sub>4</sub>Aq; the pp., which is crude TlCl, is well washed on a calico filter and squeezed dry. About 68 lbs. crude TlCl were thus obtained from 3 tons flue-dust (Crookes, *T.* 1872). The crude TlCl is heated with its own weight of pure conc. H<sub>2</sub>SO<sub>4</sub> in a Pt dish till all HCl and most of the H<sub>2</sub>SO<sub>4</sub> are removed; the TlHSO<sub>4</sub> is dissolved in c. 20 times its weight of water, the solution is nearly neutralised by CaCO<sub>3</sub>, filtered, pph. by conc. HCl<sub>4</sub>Aq, and the TlCl so obtained is well washed, and is then boiled for a few minutes with (NH<sub>4</sub>)<sub>2</sub>SAq; the pp. of TlS is filtered off, well washed with water containing H<sub>2</sub>S, and dissolved in dilute H<sub>2</sub>SO<sub>4</sub>Aq; the solution is boiled to remove H<sub>2</sub>S, ammonia is added in slight excess, and after boiling the solution is filtered and crystallised; (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, being much more soluble in water than Tl<sub>2</sub>SO<sub>4</sub>, remains in solution when Tl<sub>2</sub>SO<sub>4</sub> crystallises out.

If small quantities of Tl are to be prepared from Tl<sub>2</sub>SO<sub>4</sub>, the salt is dissolved in c. 20 times its weight of water, the solution is acidulated with H<sub>2</sub>SO<sub>4</sub>, and electrolysed, Pt electrodes being used. If large quantities of Tl are to be prepared, Tl<sub>2</sub>SO<sub>4</sub> is placed in a deep porcelain dish (holding about 4½ litres) and covered with water (c. 3 kilos Tl<sub>2</sub>SO<sub>4</sub> are used at a time) and plates of pure zinc are arranged vertically around the sides of the vessel; heat is applied, and the whole of the Tl separates in a few hours as a spongy mass easily detached from the zinc by shaking. The spongy Tl is washed several times, pressed by the fingers, and then fused with KCy in a porcelain crucible to get it into a

lamp (for details *v.* Crookes, *l.c.*; *v.* also Gunning, *J. pr.* 105, 843).

Crookes (*l.c.*) gives several methods for preparing pure Tl. If the starting-point is commercial  $\text{Tl}_2\text{SO}_4$ , he recommends to dissolve this salt in water, to saturate the cold solution with pure  $\text{H}_2\text{S}$ , filter, heat to boiling, and pour into boiling, dilute, pure  $\text{HClAq}$ ; to filter while hot, and allow to cool; to wash the  $\text{TlCl}$  that crystallises out, by decantation, till the washings are free from  $\text{H}_2\text{SO}_4$ , and to purify by re-crystallising twice from water. The  $\text{TlCl}$  thus obtained is dried, mixed with pure  $\text{Na}_2\text{CO}_3$ , and projected, in small successive portions, into molten pure  $\text{KCy}$  in an unglazed porcelain crucible; reduction to metal is rapid. After cooling, the contents of the crucible are treated with water, the ingot of Tl is boiled for some time in water, dried, and fused over a spirit lamp (coal-gas should not be used on account of the S compounds in it) in an unglazed porcelain crucible, with free access of air and frequent stirring with a piece of unglazed porcelain, to facilitate oxidation, and the metal is poured into a porcelain mould.

*Properties.*—A white metal without any tinge of blue; when fused under coal-gas, liquid Tl is exactly like Hg; may be highly polished by rubbing under water; very soft, may be cut with the nail, or scratched by lead. Less tenacious than lead; does not become brittle between  $-18^\circ$  and its m.p.; very malleable, Lamy (*A. Ch.* [3] 67, 385) says that plates  $\frac{1}{16,000}$  mm. thick

can be obtained; can be squeezed, but not drawn, into wire; very inelastic. Tl crystallises very easily in octahedral forms; it crackles like tin when bent; a wire of Tl seems amorphous when prepared, but under water it soon becomes crystalline. Tl quickly tarnishes in air; the film of oxide formed protects the mass of metal. The metal may be kept unchanged for years under water that has been deprived of air (*v.* Böttger, *D. P. J.* 197, 374). Tl melts easily (at  $294^\circ$ ) without first becoming pasty; it expands considerably before melting is complete, and contracts much on cooling. Tl boils below white heat; it may be distilled in a current of H. Pieces of the metal may be welded together by pressure at the ordinary temperature. Tl is nearly as diamagnetic as bismuth. Tl gives an intense green colour to a non-luminous flame (*v. infra*, *Detection*). Heated in air, Tl readily burns to  $\text{Tl}_2\text{O}$ ; it combines with S, Se, P, Cl, Br, I, &c., when heated with these elements; it dissolves in solutions of most acids (*v. Reactions*). The compounds of Tl are very poisonous, producing symptoms like those of lead poisoning.

The at. w. of Tl has been determined (1) by ppg. Cl as  $\text{AgCl}$  from  $\text{TlCl}$  by  $\text{AgNO}_3\text{Aq}$  (Lamy, *A. Ch.* [3] 67, 385 [1862]; Heberling, *A.* 134, 11 [1865]); (2) by ppg. I from  $\text{TlI}$  by  $\text{AgNO}_3$  (Werther, *J. pr.* 92, 136 [1864]); (3) by converting  $\text{Tl}_2\text{SO}_4$  into  $\text{BaSO}_4$  (Lamy, *l.c.*; Heberling, *l.c.*); (4) by converting Tl into  $\text{TlNO}_3$  (Crookes, *T.* 1873, 277); (5) by determining S.H. of Tl (Lamy, *l.c.*; Regnault, *A. Ch.* [3] 67, 437 [1862]); (6) by determining V.D. of  $\text{TlCl}$  (Roscoe, *Pr.* 27, 426).

The mol. w. of Tl in the gaseous state is double the at. w.; in other words, the gaseous

molecule is diatomic (Biltz & Meyer, *B.* 22, 725). Ramsay (*C. J.* 55, 521) determined the depression produced in the vapour pressure of Hg by dissolving Tl in that solvent; assuming that equal volumes of dilute solutions contain equal numbers of molecules, and that the mol. w. of liquid Hg is 200, the results obtained by R. indicated the molecule of Tl dissolved in Hg to be monatomic.

Tl is distinctly a metallic element; no compounds have been isolated wherein Tl certainly forms part of the negative radicle, although there are indications of the existence of such compounds (*v.* THALLIUM DIOXIDE, p. 680); the compounds which  $\text{TlBr}$ ,  $\text{TlCl}_3$ , and  $\text{TlI}$  form with alkali halides may contain Tl in the negative radicles. Tl is the last element in the odd-series family of Group III.; this family comprises Al, Ga, In, and Tl. The element Tl also shows marked resemblances to the alkali metals; and in its physical properties it is more like lead than any other element. The position assigned to Tl by the periodic classification of the elements clearly indicates the relations between this element and other elements. The relations of Tl (III.-11) to Al (III.-3) should be similar to those of Hg (II.-11) to Mg (II.-3), and also similar to those between Pb (IV.-11) and Si (IV.-3). The resemblances between the compositions and properties of the oxides of Hg and Mg on the one hand, and of the oxides of Pb and Si on the other hand, are shown only in the highest oxides of these elements: there is  $\text{HgO}$  but no  $\text{Mg}_2\text{O}$ , there is  $\text{PbO}$  but no  $\text{SiO}$ ;  $\text{HgO}$  and  $\text{MgO}$  are basic,  $\text{PbO}_2$  and  $\text{SiO}_2$  are feebly acidic. Nevertheless Hg and Pb form lower oxides than HgO and  $\text{PbO}_2$ ; these lower oxides,  $\text{Hg}_2\text{O}$  and  $\text{PbO}$ , are basic;  $\text{Hg}_2\text{O}$  feebly, and  $\text{PbO}$  strongly, basic. Hence it is likely that the resemblances between the oxides of Tl and Al will be shown in the highest oxides. This supposition is confirmed;  $\text{Tl}_2\text{O}$  and  $\text{Al}_2\text{O}_3$  are basic, forming salts  $\text{M}_2\text{X}_2$ , where X = the radicle of a dibasic acid; these oxides are more basic than  $\text{PbO}_2$  and  $\text{SiO}_2$ , but less basic than  $\text{HgO}$  and  $\text{MgO}$ . As Hg and Pb form lower oxides than HgO and  $\text{PbO}_2$ , and these lower oxides are more basic than HgO and  $\text{PbO}_2$ , so Tl will likely form an oxide lower than  $\text{Tl}_2\text{O}$ , and this oxide will be more basic than  $\text{Tl}_2\text{O}$ ; Tl forms the strongly basic oxide  $\text{Tl}_2\text{O}$ . Then consider the position of Tl in series 11. Consider the oxides of the members of this series: the lower oxides  $\text{Hg}_2\text{O}$ ,  $\text{PbO}$ , and  $\text{Bi}_2\text{O}_3$  are basic; the higher oxides  $\text{HgO}$ ,  $\text{PbO}_2$ , and  $\text{Bi}_2\text{O}_5$  pass from basic ( $\text{Hg}_2\text{O}$ ) to feebly acidic ( $\text{PbO}_2$  and  $\text{Bi}_2\text{O}_5$ ); therefore it is probable that the higher oxide of Tl will be less basic than  $\text{HgO}$ , but that it will not be acidic;  $\text{Tl}_2\text{O}_3$  is a feebly basic oxide.

If the chlorides of series 11 are considered, the position of Tl in III.-11 is seen to be justified:  $\text{HgO}$  gives  $\text{HgCl}_2$ , which can be gasified unchanged,  $\text{PbO}_2$  gives  $\text{PbCl}_4$ , which is very easily decomposed by heat, no chloride corresponding with  $\text{Bi}_2\text{O}_3$  has been isolated; therefore  $\text{Tl}_2\text{O}$  will probably give a chloride more stable towards heat than  $\text{PbCl}_4$ , but less stable than  $\text{HgCl}_2$ .  $\text{TlCl}_3$  is decomposed by heating to c.  $80^\circ$  into  $\text{TlCl}$  and Cl.  $\text{Hg}_2\text{O}$  gives  $\text{HgCl}$ ,  $\text{PbO}$  gives  $\text{PbCl}_2$ , and  $\text{Bi}_2\text{O}_3$  gives  $\text{BiCl}_3$ , and these chlorides can all be gasified unchanged; there-

fore the chloride of Tl corresponding with  $Tl_2O$  will probably not be decomposed by heat;  $TlCl$  has been gasified unchanged. The relations between the elements Hg, Tl, Pb, Bi, and Mg, Al, Si may be summarised in the expressions  $Tl : Hg : Pb : Al : Mg : Si$ ; and  $Tl : Hg = Pb : Tl = Bi : Pb$ . (For a further working out of the relations of Tl, v. Mendeleeff, *C. N.* 1880. 2; v. also ALKALIS, METALS OF THE, vol. i. p. 114; and EARTHIS, METALS OF THE, vol. ii. p. 424.) The atom of Tl is monovalent in the gaseous molecule  $TlCl$ ; the V.D. of no other compound of Tl has been determined.

**Reactions and Combinations.**—1. Exposed to air or oxygen, a film of  $Tl_2O$  is at once formed; when heated in air or O to somewhat below redness (c.  $300^\circ$ ) Tl burns to  $Tl_2O_3$ , and at a higher temperature this gives  $Tl_2O$  and O (Lamy, *A. Ch.* [3] 67, 385). Moist ozone acts on Tl giving  $TlO_3H_3$ .—2. A compact piece of Tl does not decompose boiling water, decomposition begins at a red heat; but spongy Tl, as pptd. by zinc, dissolves in water forming  $TlOH.Aq.$ —3. Tl dissolves in solutions of most acids, forming thallous salts  $TlX$ , where  $X = 2Cl, 2NO_3, SO_4$ , &c.—4. Tl combines with sulphur and selenium (v. sulphides and selenides).—5. Forms alloys with many metals (v. alloys).—6. Forms compounds with antimony and arsenic (v. antimoniide and arseniide).—7. A phosphide is formed by heating Tl in vapour of phosphorus (v. phosphide).—8. Combines with chlorine, bromine, and iodine, when heated with these elements (v. chlorides, bromides, and iodides).—9. Tl ppts. the noble metals, also copper, lead, and mercury from solutions of salts of these metals (Kleid, *C. N.* 12, 242).

**Detection and Estimation.**—Tl is best detected by the intense green colour which the metal and its compounds give to the non-luminous flame of the Bunsen lamp; according to Lamy (*L.c.*)  $\frac{1}{50,000}$  mgm. can be detected by the use of the spectroscopic; if induction sparks are used it is said that  $\frac{1}{800,000,000}$  mgm. can be detected (Cappel, *P.* 139, 628). Tl is generally estimated as  $TlI$  or  $Tl_2SO_4$ ; it can also be determined volumetrically by  $KMnO_4.Aq$  (Willm, *Z.* 1863, 479).

**Thallium, alloys of.** Several alloys of Tl were prepared by Carstanjen in 1867 (*J. pr.* 102, 62) by heating the metals together. Many of the alloys are soft, and most of them readily tarnish in the air; the alloy with  $\frac{1}{2}$  pt. Sb is fairly hard; and those with Bi and Pb, Bi and Cd, and Bi and Sn are hard and brittle. Alloys are described with Al, Sb, Cd, Cu, Pb, Mg (v. also Mellor, *C. N.* 19, 245), Hg (v. also Crookes, *L.c.*, and Regnault, *C. R.* 64, 60), K, Na, and Zn; also with Bi and Cd, Bi and Pb, and Bi and Sn.

**Thallium, antimoniide of.** A hard, grey, crystalline solid was obtained by fusing together Tl and Sb in the ratio Tl : Sb; with cold dilute  $H_2SO_4.Aq$  the substance gave off  $SbH_3$  (Carstanjen, *L.c.*).

**Thallium, arseniide of.** Carstanjen (*L.c.*) obtained a white, crystalline, soft substance by fusing Tl and As in the ratio Tl : As; with cold acids  $AsH_3$  was formed.

**Thallium, bromides of.** The compounds  $TlBr$  and  $TlBr_2$  have been isolated, and also two compounds the simplest formulæ of which are

$Tl_2Br_3$ , and  $TlBr_3$ . As none of the bromides has been gasified, the formulæ are not necessarily molecular; but from the analogy of  $TlCl$ , the formula  $TlBr$  probably represents the composition of the gaseous molecule of this compound.

**Thallous bromide  $TlBr$ .** (*Thallium monobromide*.) Tl reacts very slowly with Br. Thallous bromide is obtained, as a white pp., by adding  $HBr.Aq$  or solution of a bromide to solution of a thallous salt; almost insoluble in water (Willm, *A. Ch.* [4] 5, 28).  $TlBr$  melts at  $458^\circ$  to a brownish-yellow liquid, which solidifies to a yellow solid (Carnelley, *C. J.* 33, 278). Thomsen gives H.F.  $[Tl, Br] = 41,290$  (*Th.* 3, 354).

**Thallic bromide  $TlBr_3$ .** (*Thallium tribromide*.) Prepared by adding Br to  $TlBr$  suspended in water until solution is effected, and evaporating *in vacuo*.  $TlBr_3$  forms a yellow, crystalline solid; it is very deliquescent, becoming gradually brown and giving off Br. Very soluble in water, also in alcohol. Reduced to  $TlBr$  by  $SO_2.Aq$  and other reducing agents (Willm, *L.c.*). Thomsen gives H.F.  $[Tl, Br_3.Aq] = 56,450$  (*Th.* 3, 354).  $TlBr_3$  combines with  $NH_3$  to form  $TlBr_3.3NH_3$ ; a white solid that gives off  $NH_3$  and Br at  $100^\circ$ , and when more strongly heated leaves  $TlBr$  (W., *L.c.*). Also combines with  $NH_4Br$  and  $KBr$ , forming  $TlBr_3.NH_4$  and  $TlBr_3.KBr.2aq$  (W., *L.c.*; Nickles, *C. R.* 58, 537). Rammelsberg (*P.* 146, 597) described  $2TlBr_3.3KBr.3aq$ .

**Thallium dibromide  $TlBr_2$**  (or  $TlBr.TlBr$ , =  $Tl_2Br_3$ ). Obtained in long, yellow, needles by adding  $TlBr$  to boiling  $TlBr_3.Aq$ , in the ratio  $TlBr:TlBr_3$ , and cooling. Not decomposed at  $100^\circ$ ; water forms  $TlBr_3.Aq$  and  $Tl_2Br$ , (v. *infra*) (W., *L.c.*).

**Thallium sesquibromide  $Tl_2Br_3$** , or  $TlBr_3.3TlBr = Tl_4Br_6$ . (*Thallo-thallic bromide*.) Orange-red hexagonal leaflets; obtained by adding  $HBr.Aq$  to a mixture of a thallous and a thallic salt in solution; also by adding  $TlBr$  to  $TlBr_3.Aq$ , or by adding a little water to  $TlBr_2$  ( $3TlBr_3 + Aq = Tl_4Br_6 + TlBr_3.Aq$ ) (W., *L.c.*).

**Thallium, chlorides of.** Tl and Cl combine to form at least four compounds:  $TlCl$ ,  $Tl_2Cl_3$ ,  $TlCl_2$ , and  $TlCl_3$ .

**Thallous chloride  $TlCl$ .** Mol. w. 239.01. Melts at  $427^\circ$  (Carnelley, *C. J.* 33, 277). Boils at  $708^\circ$ – $719^\circ$  (C. a. Williams, *C. J.* 33, 284). S.G. 7.02, after fusion (Lamy, *J.* 15, 184). V.D. at  $830^\circ$  to  $1025^\circ = 117.8$  (Roscoe, *Pr.* 27, 426). S.  $\cdot 19$  at  $0^\circ$ ,  $\cdot 27$  at  $16^\circ$ ,  $\cdot 28$  at  $16.5^\circ$ ,  $1.6$  at  $63^\circ$  (Hebberling, *A.* 134, 15). H.F.  $[Tl, Cl] = 48,580$ ;  $[Tl, Cl.Aq] = 38,480$  (*Th.* 3, 354).

**Formation.**—1. By heating Tl in Cl, keeping the Tl in excess.—2. By boiling powdered Tl in  $HCl.Aq$ , and dissolving the film of  $TlCl$  that forms in much boiling water.—3. By adding  $SO_2.Aq$  to  $TlCl_3.Aq$ .

**Preparation.**— $HCl.Aq$ , or solution of a chloride, is added to the solution of a thallous salt; the white curdy pp. that forms is washed with cold water, dissolved in a large quantity of boiling water, and the salt that separates as the solution cools is purified by two or three recrystallisations from boiling water (Crookes, *C. J.* 17, 112).

**Properties and Reactions.**—A white, crystalline solid; resembling  $PbCl_2$ , but separating from solution in hot water in smaller and less shining crystals than  $PbCl_2$ . Becomes slowly

violet coloured when exposed to light (Hebberling, *A. 134*, 15). Melts at 427° to a clear yellow liquid, which solidifies to a white crystalline mass. Very slightly soluble in water (*v. supra*); less soluble in water containing a little HCl; insoluble in alcohol; insoluble in ammonia; soluble in hot Na<sub>2</sub>CO<sub>3</sub>Aq, KOHAq, or Na<sub>2</sub>SO<sub>4</sub>Aq. Hot conc. sulphuric acid forms Ti<sub>2</sub>SO<sub>4</sub> and HCl; oxidisers such as ClAq, aqua regia, KMnO<sub>4</sub>Aq and HClAq, form TiCl<sub>3</sub>, Ti<sub>2</sub>Cl<sub>3</sub>, or TiCl<sub>2</sub> (*v. these chlorides*). TiCl<sub>3</sub> is reduced to Ti by zinc and sulphuric acid, also by adding aluminium to TiCl<sub>3</sub>Aq at 90° (Cossa, *Acad. dei Lincei* [3] 2). Fusion with sodium hydrogen sulphate produces Ti<sub>2</sub>SO<sub>4</sub> (Krause, *D. P. J.* 217, 323; Nietzki, *D. P. J.* 219, 262).

**Combinations.**—1. With platinum chloride to form 2TiCl<sub>3</sub>PtCl<sub>3</sub> (= Ti<sub>2</sub>PtCl<sub>6</sub>); obtained, as a pale-yellow, crystalline powder, by mixing solutions of TiCl<sub>3</sub> and PtCl<sub>3</sub>; this salt is extremely insoluble in water, one part dissolving in 15,585 parts water at 15°, and in 1948 parts boiling water (Crookes, *l.c.*).—2. With mercuric chloride, to form TiCl<sub>2</sub>HgCl<sub>2</sub>; white lustrous needles, separating from a hot solution of TiCl<sub>3</sub> in HgCl<sub>2</sub>Aq; all HgCl<sub>2</sub> is removed at 200° (Carstanjen, *J. pr.* 102, 141; Jørgensen, *J. pr.* [2] 6, 82).—3. With ferric chloride to form 3TiCl<sub>3</sub>FeCl<sub>3</sub>; small red prisms; obtained by adding TiCl<sub>3</sub> to a hot solution of FeCl<sub>3</sub> in HClAq, and crystallising the red pp. from hot conc. HClAq; decomposed to its constituent salts by water (Wöhler, *A. 144*, 350).—4. With chromic chloride, to form 3TiCl<sub>3</sub>CrCl<sub>3</sub> (*v. Neumann, A. 244*, 328).—5. According to Lepierre a. Lachaud (*C. R.* 119, 196), a conc. solution of chromium trioxide reacts with TiCl<sub>3</sub> to form small red prisms of CrO<sub>3</sub>·TiCl<sub>3</sub> [CrO<sub>3</sub>(OTiCl<sub>3</sub>)] which are decomposed by water to TiCl<sub>3</sub> and CrO<sub>3</sub>Aq.

**Thallous chloride** TiCl<sub>2</sub>. Mol. w. not certainly known; from analogy of AlCl<sub>3</sub>, GaCl<sub>3</sub>, and InCl<sub>3</sub>, the formula TiCl<sub>2</sub> is probably molecular.

**Formation.**—1. By heating TiCl with hot aqua regia and evaporating the solution in Cl (Willm, *A. Ch.* [4] 5, 28).—2. By dissolving freshly ppd. TiO<sub>2</sub>H<sub>2</sub> in HClAq, adding HNO<sub>3</sub>Aq, and evaporating in Cl.—3. By heating TiCl at its melting-point in Cl; it is doubtful whether the product is pure TiCl<sub>2</sub>, or contains also TiCl<sub>3</sub> or Ti<sub>2</sub>Cl<sub>3</sub> (Lamy, *l.c.*).

**Preparation.**—Cl is passed into water containing TiCl in suspension until a little of the solution ceases to give a turbidity with PtCl<sub>3</sub>Aq; excess of Cl is removed by a stream of CO<sub>2</sub>, and the solution is evaporated *in vacuo*. Crystals of TiCl<sub>2</sub>·H<sub>2</sub>O separate, which lose water at c. 40° (Werther, *J. pr.* 91, 385).

**Properties and Reactions.**—The hydrate forms large colourless prisms; the dehydrated salt is a white crystalline solid. Werther (*l.c.*) also obtained a hydrate 2TiCl<sub>2</sub>·15H<sub>2</sub>O from a solution of TiCl<sub>3</sub> prepared as described. Cl begins to be given off at c. 50° to 60°; at 100° a mixture of TiCl and chlorides intermediate between TiCl and TiCl<sub>3</sub> remains (Werther, *l.c.*; Lamy, *l.c.*). TiCl<sub>2</sub> is very deliquescent; it dissolves very easily in water. Thomsen gives [TiCl<sub>2</sub>·Aq] = 89,250 (*Th.* 3, 354). On diluting a conc. aqueous solution considerable quantities of TiO<sub>2</sub>H<sub>2</sub> and HClAq are formed. Reducing agents, such as SO<sub>2</sub>, form TiCl.

**Combinations.**—1. With ammonia to form TiCl<sub>3</sub>·3NH<sub>3</sub> (Willm, *A. Ch.* [4] 5, 28). A white, crystalline powder. Obtained by passing NH<sub>3</sub> over TiCl<sub>3</sub>; by adding an alcoholic solution of NH<sub>3</sub> to TiCl<sub>3</sub> suspended in absolute alcohol; or by boiling TiO<sub>2</sub>H<sub>2</sub> with conc. NH<sub>3</sub>ClAq, ppg. by NH<sub>3</sub>Aq, washing with alcoholic ammonia, then with absolute alcohol, and drying *in vacuo*. The compound is unchanged in air; water forms NH<sub>3</sub>ClAq and Ti<sub>2</sub>O<sub>3</sub>; when heated NH<sub>3</sub>, NH<sub>4</sub>Cl, and N are given off and TiCl<sub>3</sub> remains. Dissolves in HClAq, forming TiCl<sub>3</sub>·3NH<sub>4</sub>Cl.

2. With ammonium chloride to form TiCl<sub>3</sub>·3NH<sub>4</sub>Cl; obtained by adding NH<sub>4</sub>Cl to a solution of TiO<sub>2</sub>H<sub>2</sub> in HClAq, and evaporating *in vacuo*; large, white, quadratic crystals, probably with 2H<sub>2</sub>O (Rammelsberg, *P.* 146, 597; *v. also* Nicklès, *J. Ph.* [4] 1, 25).—3. Compounds with potassium chloride, cesium chloride, and rubidium chloride, TiCl<sub>3</sub>·3MCl, zmg, have been obtained (*v. Rammelsberg, l.c.*, also *W.* 16, 709; Godefroy, *Zeit. des allg. u. spec. Pharm. Apotheker-Ver.* 1880 No. 9; Neumann, *A. 244*, 348; Willm, *l.c.*). Neumann (*l.c.*) also describes a compound of TiCl<sub>3</sub> with beryllium chloride.—4. Willm (*l.c.*) describes a compound with cupric chloride, 2TiCl<sub>3</sub>·CuCl<sub>2</sub>.—5. According to Nicklès (*C. R.* 58, 537) TiCl<sub>3</sub> forms a compound with ether and hydrochloric acid, to which he gives the composition TiCl<sub>3</sub>·Et<sub>2</sub>O·HCl·H<sub>2</sub>O; it is described as a yellow fuming liquid.

**Thallium dichloride** TiCl<sub>2</sub> (or TiCl<sub>3</sub>·TiCl<sub>2</sub> = Ti<sub>2</sub>Cl<sub>5</sub>). Lamy (*A. Ch.* [3] 67, 402) obtained a yellow, slightly hygroscopic, easily fusible solid, to which he assigned the composition TiCl<sub>2</sub>, by heating Ti and TiCl<sub>3</sub> in a stream of Cl so that the product always remained liquid, and allowing to cool when saturated; the substance gave off Cl, and Ti<sub>2</sub>Cl<sub>3</sub> remained.

**Thallium sesquichloride** Ti<sub>2</sub>Cl<sub>3</sub>, or TiCl<sub>3</sub>·3TiCl<sub>2</sub> = Ti<sub>4</sub>Cl<sub>9</sub> (*Thallothallic chloride*). Formed by heating dry TiCl<sub>3</sub> somewhat above 100° as long as Cl is given off; the brown liquid cools to a clear yellow, crystalline mass (Lamy, *l.c.*, p. 403). Also formed by the direct combination of Cl with molten Ti (*l.c.*); also by ppg. a solution containing a thallos and a thallic salt by HClAq (Willm, *l.c.*). Also obtained by dissolving Ti or TiCl<sub>3</sub> in aqua regia, evaporating, heating till Cl ceases to be given off, and crystallising from water slightly acidified with aqua regia (Lamy, *l.c.*; Crookes a. Church, *C. N.* 8, 1). According to Werther (*J. pr.* 91, 390) the product of this reaction, dried at 100°, is a mixture of compounds of TiCl and TiCl<sub>3</sub>, besides Ti<sub>2</sub>Cl<sub>3</sub>. Ti<sub>2</sub>Cl<sub>3</sub> crystallises in yellow, hexagonal leaflets; unchanged in air; melting between 400° and 500° to a dark-brown liquid that solidifies with much contraction, forming a yellowish mass with S.G. 5.9 (Lamy, *l.c.*). Very slightly soluble in water; S. 26 at 15°, 29 at 17°, 1.9 at 100° (Crookes; Hebberling, *A. 134*, 21). The solution is said to show the reactions both of thallos and thallic compounds. Heated above 500° Cl is given off; heating in H<sub>2</sub>S produces Ti<sub>2</sub>S<sub>3</sub> S, and HCl (Hebberling, *l.c.*). Heating in NH<sub>3</sub> produces TiCl, NH<sub>4</sub>Cl, and N (Crookes a. Church, *C. N.* 8, 1). TiCl<sub>2</sub> reacts with KOHAq to form TiO<sub>2</sub>H<sub>2</sub>, TiCl, and KCl.

**Other thallo-thallic chlorides.** According to Werther (*J. pr.* 91, 390), two compounds

besides  $Tl_2Cl_4$ , are obtained by evaporating  $TlCl$  in *aqua regia*, heating till  $Cl$  ceases to be given off, crystallising from water slightly acidified with *aqua regia*, and drying at  $100^\circ$ . To these compounds W. gives the formulae  $3TlCl \cdot 4TlCl_4$ ,  $-Tl_2Cl_4$ , and  $TlCl \cdot 15TlCl_4 = Tl_2Cl_4$ .

Thallium, cyanide of; v. vol. i. p. 347.

Thallium, ferrocyanide of; v. vol. ii. p. 337.

Thallium, fluorides of. Only one fluoride of  $Tl$  has been isolated with certainty; there are indications of the existence of another.

THALLOUS FLUORIDE  $TlF$ . Formula probably molecular, from analogy of  $TlCl$ . Prepared by dissolving  $Tl_2CO_3$  in  $HFAq$ , evaporating to dryness, heating gently to remove  $HF$ , and crystallising from water; forms white, lustrous, regular octahedra (Büchner, *J. pr.* 96, 404).  $TlF$  is also said to be formed as a white sublimate by heating  $Tl_2O$  in  $HF$  gas (Kuhlmann, *C. R.* 58, 1037). Sol. in water;  $S. = 80$  at  $15^\circ$ , and increases with increase of temperature; solution in water has alkaline reaction; somewhat sol. in alcohol. A hydrate  $TlF \cdot H_2O$  forms in monodimic crystals by evaporating a solution of  $Tl_2O$  or  $Tl_2CO_3$  in  $HFAq$ ; it is deliquescent, and acts on glass (Kuhlmann, *l.c.*; Willm, *A. Ch.* [4] 5, 5). A compound with fluorhydric acid,  $TlF \cdot H_2F = TlHF_2$ , is obtained by evaporating a solution of  $TlF$  in  $HFAq$  over  $H_2SO_4$ . Decomposed above  $100^\circ$  to  $TlF$  and  $HF$ . V. sol. water;  $S. = 100$  at ordinary temperature; the solution has an acid reaction (Büchner, *l.c.*).

THALLO FLUORIDE. By digesting  $Tl_2O \cdot H_2$  with  $KFAq$ , and also by adding  $HFAq$  to  $Tl(NO_3)_3$ , Willm (*A. Ch.* [4] 5, 5) obtained a dark olive-green solid, becoming brown when heated, and melting to an orange-yellow liquid that became white on cooling, insoluble in water and in cold  $HClAq$ . This substance was probably thallic fluoride, or perhaps a thallo-thallic fluoride; no analyses are given.

Thallium, hydride of. Herapath (*Ph.* 4, 802) supposed that a compound of  $Tl$  and  $H$  existed; but Crookes (*C. J.* 17, 132) failed to obtain any compound either by the interaction of an acid with  $Tl$ -Zn alloy, or by heating  $Tl$  in a stream of  $H$ ; the escaping  $H$  burnt with a green flame, but this was found to be due to particles of  $Tl$  carried by the stream of  $H$ .

Thallium, hydroxides of.  $Tl$  forms three compounds with  $O$  and  $H$ , namely,  $TlOH$ ,  $Tl_2O \cdot H_2$  (or  $Tl_2O \cdot OH$ ), and  $Tl_2O \cdot H_2$ .

THALLOUS HYDROXIDE  $TlOH$ . (Hydrated thalious oxide  $Tl_2O \cdot H_2O$ .) Mol. gr. not known with certainty. Thomsen (*Th.* 3, 354) gives  $H.F.$   $[Tl_2O \cdot H_2] = 56,915$ ;  $[Tl_2O \cdot H_2O] = 45,470$ ;  $[Tl_2O \cdot H_2O] = 3,230$ .

Formation.—1. By dissolving  $Tl$  in water containing air, and evaporating.—2. By decomposing  $Tl_2SO_4$  by  $BaOAq$ , filtering, and evaporating.—3. By the interaction of  $CaOAq$  and  $Tl_2O \cdot O \cdot Aq$ .—4. By dissolving  $Tl_2O$  in water and evaporating.

Preparation.—1.  $Tl$  ppd. by zinc is allowed to oxidise in warm, moist air, and the oxide is dissolved in boiling water; these operations are repeated till a saturated hot solution is obtained, and this solution is evaporated a little, filtered from any  $Tl_2CO_3$  that may have separated, and allowed to crystallise (Crookes, *C. J.* 17, 132).—2.  $Tl_2SO_4$  is mixed with the proper quantity

of  $BaOAq$ , and the solution, filtered from  $BaSO_4$ , is crystallised *in vacuo*; this method is tedious, and there is much difficulty in getting rid of all  $BaO$ .—3. Thin plates of  $Tl$  are suspended over a shallow dish containing absolute alcohol, within a bell-jar from which air has been exhausted, and pure  $O$  is passed into the jar, the temperature being kept at  $20^\circ$ – $25^\circ$ ; after several hours or days,  $C_2H_5TlO$  is formed as an oil in the dish; excess of alcohol is removed by heating to  $100^\circ$ ; a little water is added, whereby  $TlOH$  is ppd.; the pp. is drained, and exposed to warm dry air till all water and alcohol are removed (Lamy, *A. Ch.* [3] 67, 385).

Properties and Reactions.—Pale-yellow, prismatic crystals. At  $100^\circ$  in air, or *in vacuo* over  $H_2SO_4$ , at the ordinary temperature, the crystals become black from formation of  $Tl_2O$ , without altering their crystalline form. Easily soluble in water; Thomsen (*Th.* 3, 354) gives  $[TlOH, Aq] = -3,155$ . The solution in water resembles  $KOHAq$  and  $NaOHAq$  in its properties; it is strongly alkaline, absorbs  $CO_2$ , pppts. heavy metals as hydroxides or oxides, feels soapy to the touch, stains the skin, neutralises acids, &c. The solution absorbs a little  $O$  on heating; when evaporated to dryness and the residue re-dissolved, a little  $Tl_2O$ , generally remains.

THALIC HYDROXIDES. Two thallic hydroxides are known,  $TlO \cdot OH$  and  $Tl_2O \cdot H_2$ .

I. Monohydrated thallic oxide,  $TlO \cdot OH = Tl_2O \cdot H_2O$ . Mol. w. not known with certainty.

Formation.—1. By ppg.  $TlCl_3$  by alkali and drying at  $100^\circ$  (Lamy, *A. Ch.* [3] 67, 385).—

2. By passing ozonised air through  $TlOH$  (Schönbein, *J. pr.* 93, 35).—3. By the action of  $H_2O_2$  on  $Tl$ ; according to Veltzien (*A.* 138, 120) a mixture of  $TlOH$  and  $TlO \cdot OH$  is thus obtained.—4. Various oxidisers—e.g.  $KMnO_4$ , hypochlorite solutions, &c.—convert  $TlOH$  into  $TlO \cdot OH$  (Schönbein, *l.c.*).—5. By electrolysis a neutral or ammoniacal solution of  $Tl_2(SO_4)_3$  or  $Tl(NO_3)_3$ ; the hydroxide separates on the positive (Pt) electrode (Flemming, *J. Z.* 1863, 292).

Preparation.— $TlCl_3$  is ppd. by a slight excess of  $KOHAq$  or  $NH_4Aq$ , the pp. is thoroughly washed, and dried at  $100^\circ$  (Lamy, *A. Ch.* [3] 67, 397; Crookes, *C. J.* 17, 132; Werther, *J. pr.* 91, 388). The air-dried pp. has the composition  $TlO \cdot OH$  (Carnelley a. Walker, *C. J.* 53, 88).

Properties and Reactions.—A brown powder; insoluble in water and dilute alkali solutions. Heated to  $c. 60^\circ$  begins to lose water; completely dehydrated at  $115^\circ$ , according to Werther (*J. pr.* 91, 385), but the residue contains some  $Tl_2O$ , as well as  $Tl_2O_3$  (cf. Birnbaum, *A.* 138, 133). According to Carnelley a. Walker (*C. J.* 53, 88), dehydration is complete at  $230^\circ$ , and the residue is  $Tl_2O_3$ , which is stable to  $360^\circ$ . Dissolves in  $HClAq$ , forming  $TlCl_3$ ; in conc. acid  $Cl$  is given off and some  $TlCl$  is produced. Dissolves in dilute  $H_2SO_4$  and  $Aq$ ; with conc. acid some  $O$  is given off. Dissolves in  $SO_4$ ,  $As_2O_3$ , hot tartaric acid solution, and boiling oxalic acid solution, in each case forming a salt of  $Tl_2O$ .  $TlO \cdot OH$  dissolves in warm conc.  $NH_4ClAq$ , giving off  $NH_3$ , and forming  $TlCl_3 \cdot 3NH_3$ ; on adding water  $Tl_2O_3$  is ppd. as a black powder (Willm, *A. Ch.* [4] 5, 5).

II. Trihydrated thallic oxide,  $Tl_2O \cdot 3H_2O$ . Formed, as light-brown, lustrous,

microscopic, hexagonal plates, by dissolving  $\text{TiO}_2\text{OH}$  in molten  $\text{KOH}$ , fusing for some time, cooling, washing with hot water, then with alcohol, and drying at  $100^\circ$ . Insoluble in water. Not decomposed at  $340^\circ$ ; soluble in dilute acids (Carnegie, *C. N.* 60, 113).

**Thallium, iodides of.**  $\text{TI}$  combines directly with  $\text{I}$ . At least two compounds are known:  $\text{TII}$  and  $\text{TI}_2\text{I}$ ;  $\text{TI}_2\text{I}_2$ , and probably one, or perhaps more than one, other compound of  $\text{TII}$  and  $\text{TI}_2$ , seem also to exist.

**Thallos iodide  $\text{TII}$ .** (*Thallium monoxide*.) Mol. w. not known with certainty, but formula  $\text{TII}$  is probably molecular from analogy of  $\text{TiCl}$ .

**Formation.**—1. By heating together  $\text{TI}$  and  $\text{I}$  in the ratio  $\text{TI}:\text{I}=2$ . 2. By adding  $\text{KIAq}$  to solution of a thallos salt.

**Preparation.**— $\text{KIAq}$  is added to a dilute solution of a thallos salt, and the yellow pp. is thoroughly washed with water and dried at  $100^\circ$  (Lamy, *A. Ch.* [3] 67, 405; Crookes, *C. J.* 17, 137).

**Properties and Reactions.**—A citron-yellow powder; melts at  $439^\circ$  (Carnelley, *C. J.* 33, 279), and boils at  $800^\circ\text{--}806^\circ$  (C. a. Williams, *C. J.* 33, 284). S.G. 7.072 at  $15.5^\circ$ , after fusion 7.0775 at  $14.7^\circ$  (Twitcheil, *Clarke's Table of Spec. Grav.* [2nd edit.] 35). Very slightly soluble in water. Determinations of solubility vary considerably; Werther (*J. pr.* 92, 130) says that 1 pt. requires 20,000 pts. water to dissolve it at  $15^\circ$ , and Crookes (*l.c.*) gives solubility as 1 in 4450 of water at  $15^\circ$  (v. also Hebbeling, *A.* 134, 16). Crookes says  $\text{TII}$  is somewhat more soluble, Hebbeling says it is decidedly less soluble, in  $\text{KIAq}$  than in water.

When heated to  $c. 190^\circ$   $\text{TII}$  becomes red, and when it melts a red liquid is formed which solidifies to a red crystalline mass having the composition  $\text{TII}$  (Hebbeling, *l.c.*, p. 18); the red variety is also obtained by crystallising from hot  $\text{KOH.Aq}$  (Willm, *A. Ch.* [4] 5, 28); also by crystallising from hot  $\text{K}_2\text{CO}_3.\text{O.Aq}$  (Werther, *l.c.*). The red form of  $\text{TII}$  is produced by adding  $\text{KIAq}$  to a warm conc. solution of a thallos salt (Hebbeling, *l.c.*, p. 16). Red  $\text{TII}$  crystallises in octahedral forms (W., *l.c.*). The red variety slowly changes on keeping to the yellow form.

When freshly ppd. yellow  $\text{TII}$  is exposed to the sun's rays it becomes green and crystalline without any change in composition. The green variety of  $\text{TII}$  is somewhat more soluble in hot water than the yellow form; it crystallises from hot water in green microscopic crystals that are very refractive. The green variety changes slowly to the yellow on keeping; the change is hastened by heating in water containing  $\text{I}$  or  $\text{KI}$ , but not by heating with pure water. When strongly heated, green  $\text{TII}$  becomes red (v. Knösel, *B.* 7, 576, 893).

$\text{TII}$  is decomposed by warm  $\text{HNO}_3.\text{Aq}$ , with separation of  $\text{I}$ . It is dissolved, without  $\text{I}$  being separated, by  $\text{ClAq}$  or *aqua regia*; Willm (*l.c.*) supposes that an iodochloride is formed. Fusion with  $\text{KCN}$  produces  $\text{TI}$  (Werther, *l.c.*).

**Thallic iodide  $\text{TI}_2\text{I}$ .** This compound has not been isolated with certainty. By treating  $\text{TI}$  with an ethereal solution of  $\text{I}$ , Nicklès (*C. R.* 58, 537) obtained a brown liquid from which brown needles gradually separated. These crys-

tals may have been  $\text{TI}_2\text{I}$ ; no analyses are given.

**Double salts of  $\text{TII}$ , with alkali iodides** have been prepared by digesting  $\text{TII}$  with solutions of  $\text{I}$  and alkali iodides in ether; these salts have the composition  $\text{TII}.\text{MI}.\text{xH}_2\text{O}$ , where  $\text{M}=\text{NH}_4$  and  $\text{K}$  (v. Nicklès, *J. Ph.* [4] 1, 25; Willm, *A. Ch.* [4] 5, 5; Rammelsberg, *P.* 146, 597). A compound  $\text{TI}_2.\text{CuI}_2.\text{NH}_3$  is described by Jørgensen (*J. pr.* [2] 6, 82).

**THALLIUM SENQUI-IOXIDE  $\text{TI}_2\text{I}_3$  or  $\text{TII}_3.3\text{TII}=\text{TI}_4\text{I}_3$ .** (*Thallothallic iodide*.) Black, lustrous needles; insoluble in water, slightly soluble cold alcohol, decomposed by boiling alcohol; decomposed slowly at ordinary temperature, quickly on heating; obtained by long-continued heating yellow  $\text{TII}$  with excess of  $\text{IAq}$  (Knösel, *B.* 7, 576, 893).

**OTHER THALLO-THALLIC IOXIDES.** By evaporating a solution of  $\text{TII}$  in  $\text{HIAq}$ , in presence of  $\text{I}$ , at  $70^\circ$ , small, brown, rhombic, crystals were obtained by Jørgensen (*l.c.*).<sup>9</sup> The composition of the crystals is represented by  $\text{J}$ . as  $6\text{TII}.\text{TI}_2$ , or perhaps  $5\text{TII}.\text{TI}_2$ . The same compound is said to be obtained by digesting  $\text{TII}$  with an ethereal solution of  $\text{I}$ . Heating to  $c. 100^\circ$  drives off  $\text{I}$ , and leaves yellow  $\text{TII}$ ; boiling alcohol, and also  $\text{KIAq}$ , withdraws  $\text{I}$ , forming  $\text{TII}$ .

**Thallium, oxides of.** Two oxides have been isolated,  $\text{Ti}_2\text{O}$  and  $\text{Ti}_2\text{O}_3$ ; there is evidence in favour of the existence of a third oxide, probably  $\text{TiO}_2$ .

**THALLOUS OXIDE  $\text{Ti}_2\text{O}$ .** (*Thallium monoxide*.) Mol. w. not known with certainty. ( $\text{Ti}_2\text{O}$ ) = 42.240 (*Th.* 3, 354). Prepared by heating  $\text{TI}$  in air to not above  $100^\circ$  (to prevent formation of  $\text{Ti}_2\text{O}_3$ ); also by heating  $\text{TiOH}$  to  $100^\circ$  out of contact with air; also by heating  $\text{Ti}_2\text{O}$ , to full redness. A black powder; melting at  $c. 300^\circ$  to a dark-yellow liquid, which acts on glass, forming a silicate of  $\text{Ti}$ .  $\text{Ti}_2\text{O}$  absorbs moisture from the air, forming  $\text{TiOH}$ ; it dissolves easily in water, forming a strongly alkaline solution of  $\text{TiOH}$  (v. THALLOUS HYDROXIDE, p. 678). Soluble in absolute alcohol, forming  $\text{C}_2\text{H}_5\text{OTi}$ , a colourless, heavy oil (S.G. 3.55); this oil is decomposed by a little water with separation of  $\text{TiOH}$  (v. THALLOUS HYDROXIDE, *Preparation*, No. 3, p. 678). (Crookes, *C. J.* 17, 128; Lamy, *A. Ch.* [3] 67, 385).  $\text{Ti}_2\text{O}$  is reduced to  $\text{TI}$  by heating to redness in  $\text{H}_2$ , or in  $\text{CO}$ , or with  $\text{Mg}$  (Winkler, *B.* 23, 788).

**THALLIC OXIDE  $\text{Ti}_2\text{O}_3$ .** Mol. w. not known with certainty. Prepared by ppig. a thallic salt with  $\text{KOH.Aq}$  or  $\text{NH}_3.\text{Aq}$ , washing the pp. thoroughly, drying, and heating it to  $c. 260^\circ$  (Crookes, *l.c.*, p. 132). Also formed by burning  $\text{TI}$  in air to a little below redness; at a lower temperature the product is chiefly  $\text{Ti}_2\text{O}$ , and at a full red heat  $\text{Ti}_2\text{O}$  is decomposed to  $\text{Ti}_2\text{O}_3$  and  $\text{O}$  (Lamy, *l.c.*).  $\text{Ti}_2\text{O}_3$  is also formed by passing an electric current (from a couple of Grove cells) through neutral  $\text{Ti}_2\text{SO}_4.\text{Aq}$ , using  $\text{Pt}$  electrodes;  $\text{TI}$  deposits on the negative electrode, and  $\text{Ti}_2\text{O}_3$  forms, as a brown cake, on the positive electrode; the  $\text{H}_2\text{SO}_4.\text{Aq}$  formed should be neutralised from time to time by  $\text{NH}_3.\text{Aq}$  (Crookes, *l.c.*). For other methods of formation v. Wöhler (*A.* 146, 263, 375), and Willm (*A. Ch.* [4] 5, 19).  $\text{Ti}_2\text{O}_3$  is a brownish-black solid; insoluble in water. Melts at  $c. 760^\circ$  (?) (Carnelley a. O'Shea, *C. J.*

45, 409). Gives off O at a full red heat, forming  $Tl_2O$ . Dissolves in hot  $H_2SO_4$  Aq, forming  $Tl_2SO_4$  Aq and giving off O. Soluble cold  $HCl$  Aq, forming  $TlCl$  Aq, and some  $TlCl$  with evolution of Cl. Takes fire in dry  $H_2S$ , forming  $Tl_2S$ , (Carstanjen, *J. pr.* 102, 65). A mixture of  $Tl_2O$ , and S takes fire when rtr.ck (Böttger, *J. pr.* 90, 27). Reduced by heating in H or CO to  $Tl_2O$ , and then to  $Tl$ .  $Tl_2O$  absorbs  $NH_3$  when heated in that gas; no definite compound has been isolated. For compounds with  $H_2O$  v. THALLIC HYDROXIDES, p. 678).

THALLIUM DIOXIDE ( $?Tl_2O_2$ ). When a rapid stream of Cl is passed into conc.  $KOH$  Aq, holding freshly ppd.  $Tl_2O$  in suspension, a violet-coloured solution is obtained; mineral acids added to this solution form thallous salts, and give off O, or Cl with  $HCl$  Aq. Carstanjen (*J. pr.* 101, 55) supposed the violet solution to contain a thallate of potassium. Piccini (*G.* 17, 450) obtained a violet pp. by adding  $Ba(NO_3)_2$  Aq to the violet solution; analyses of this pp. were not satisfactory, but the results indicated that an oxide of Tl of the composition  $Tl_2O_2$  is formed by the method described. Piccini says that the same violet solution is obtained by electrolyzing 30 p.c.  $KOH$  Aq, using a plate of Tl as anode; also by digesting 1 pt.  $KOH$  with 4 pts.  $KClO$ , in water, and adding  $Tl_2SO_4$ .

Thallium phosphide of. No compound of Tl and P has been isolated with certainty. According to Crookes (*C. J.* 17, 135), the black substance formed by passing P hydride into ammoniacal  $Tl_2SO_4$  Aq is a phosphide of Tl. Carstanjen (*J. pr.* 102, 80) failed to obtain a phosphide by reducing  $Tl_3PO_4$  by C or H, or by heating the elements together. Flemming (*Bl.* [2] 10, 35) noticed that a thin, black coating formed on molten Tl when pieces of P were thrown on to it; by heating solution of a thallous salt with P in a sealed tube, he obtained a black solid, perhaps a phosphide, and also a phosphite and hydride of P (cf. Willm, *A. Ch.* [4] 5, 6).

Thallium, platino-cyanide of; v. vol. ii. p. 345.

Thallium, salts of. Two series of salts are formed by replacing the H of acids by Tl; thallous salts,  $TlX$ , and thallie salts,  $TlX_2$ , where  $X = SO_3, CO_3, 2NO_3, 2IO_3, \frac{2}{3}PO_4$ , &c. The chief thallous salts of oxyacids are arsenates, carbonates, chlorate and perchlorate, chromate, dichromate and trichromate, dithionate and trithionate, hypophosphite, iodate and periodate, molybdates, nitrate, phosphates, selenite and selenates, silicates, sulphates and sulphite, tellurate, thiosulphate. The principal thallie salts are arsenate, iodate and periodate, nitrate, phosphates, sulphates (v. CARBONATES, NITRATES, SULPHATES, &c.). Several double salts of both series are also known.

Thallium, salts of oxyacids of. No compounds of this kind have been isolated with certainty, but there is evidence in favour of the existence of salts of the hypothetical thallie acid, probably analogous to plumbates (v. THALLIUM DIOXIDE, *supra*).

Thallium, selenides of.  $Tl_2Se$  has been isolated; another selenide, perhaps  $Tl_2Se_2$ , probably exists.

THALLOUS SELENIDE  $Tl_2Se$ . Mol. w. not known. Obtained by fusing the elements to-

gether in the ratio  $2Tl:Se$  (Willm, *A. Ch.* [4] 5, 5; Carstanjen, *J. pr.* 102, 79); also by ppdg.  $Tl_2CO_3$  Aq by  $H_2Se$  (Kuhlmann, *Bl.* [2] 1, 330). A grey, lustrous, crystalline solid; melting at c.  $840^\circ$  (Kuhlmann, *l.c.*). Dissolves in  $H_2SO_4$  Aq and  $HCl$  Aq, giving off  $H_2Se$ .

THALLIC SELENIDE ( $?Tl_2Se_3$ ). By fusing the elements together in the ratio  $2Tl:3Se$ , Carstanjen (*l.c.*) obtained greyish-black prismatic crystals, resembling Sb; not acted on by dilute  $H_2SO_4$  Aq; decomposed by hot conc.  $H_2SO_4$ , with separation of Se and evolution of  $SO_2$ . The composition of this substance has not been determined.

Thallium, silicofluoride of,  $Tl_2SiF_6$ . Obtained by dissolving  $Tl_2CO_3$  in  $H_2SiF_6$  Aq, and evaporating. Colourless, regular, octahedra (Werther, *J. pr.* 91, 385). According to Kuhlmann (*Bl.* [2] 1, 330), the crystals are  $Tl_2SiF_6 \cdot H_2O$ . Easily soluble in water. Volatile without decomposition, according to Kuhlmann (*l.c.*).

Thallium, sulphides of.  $Tl_2S$  and  $Tl_2S_3$  have been isolated, and also probably more than one compound of these two sulphides.

THALLOUS SULPHIDE  $Tl_2S$ . Mol. w. not known.

Formation.—1. By fusing the elements together in the ratio  $2Tl:S$  (Carstanjen, *J. pr.* 102, 76).—2. By ppdg. an alkaline solution of a thallous salt by  $H_2S$ .—3. By ppdg. slightly acidified  $Tl_2SO_4$  Aq by  $H_2S$  (Heberling, *A.* 134, 11).—4. By heating an alkaline solution of a thallous salt with  $Na_2S_2O_3$  (C., *l.c.*).

Preparation.—A cold, fairly conc., aqueous solution of  $Tl_2SO_4$  is acidulated with a trace of  $H_2SO_4$  Aq, and saturated with  $H_2S$ , and the bluish-black pp., consisting of microscopic crystals, is washed with  $H_2SA$  Aq and dried over  $H_2SO_4$  (Heberling, *l.c.*).

Properties and Reactions.—Prepared by ppn. from slightly acidulated  $Tl_2SO_4$  Aq,  $Tl_2S$  forms very minute, blue-black, lustrous tetrahedra; prepared by heating together Tl and S it is a black, crystalline, brittle solid; prepared by ppn. from alkaline solutions it is a black amorphous solid. When the amorphous solid is dried, and strongly heated, it melts, and solidifies on cooling to a black crystalline mass. After melting, S.G. is  $8.0$  (Lamy, *J.* 15, 185). H.F. [ $Tl_2S$ ] = 21,660 (*Th.* 3, 354). Moist ppd.  $Tl_2S$  oxidises in air to  $Tl_2SO_4$ . On long continued heating  $Tl_2S$  is completely decomposed (Lamy, *l.c.*).  $Tl_2S$  is insoluble in solutions of alkalis, alkali sulphides, carbonates, and cyanides; it dissolves readily in  $H_2SO_4$  Aq and  $HNO_3$  Aq, and less readily in  $HCl$  Aq. By ppdg. from a very dilute solution of a thallous salt, and dialysing, Winssinger (*Bl.* [2] 49, 452) obtained a reddish-brown aqueous solution of colloidal  $Tl_2S$ .

Combination.—By passing  $H_2S$  into  $Tl_2SO_4$  Aq containing  $As_2O_3$  Aq, and acidulated with dilute  $H_2SO_4$  Aq, Gunning (*Ar. N.* 3, 86) obtained a red pp. of  $Tl_2S \cdot As_2S_3$ ; the same compound was obtained by mixing a solution of  $As_2S_3$  in  $NH_4$  Aq with an ammoniacal solution of a thallous salt. Heat decomposes the compound into its constituent sulphides; alkali solutions dissolve out  $As_2S_3$ , leaving  $Tl_2S$ .

THALLIC SULPHIDE  $Tl_2S_3$ . Obtained as a black, amorphous, easily fusible, solid, by melting Tl with excess of S, and removing uncon-

bined S by heating out of contact with air (Carstanjen, *J. pr.* 102, 65). Below  $12^{\circ}$   $\text{Ti}_2\text{S}_3$  is hard and brittle; above  $12^{\circ}$  it is so soft that it may be drawn out like pitch. It dissolves in warm dilute  $\text{H}_2\text{SO}_4$  without separation of S. Strecker (*J. pr.* [2] 2, 162) obtained a lustrous, brown-black pp. by passing  $\text{H}_2\text{S}$  into a solution of a thallic salt mixed with sodium tartrate and excess of  $\text{NH}_4\text{Aq}$ , followed by boiling; this pp. was  $\text{Ti}_2\text{S}_3$  according to Strecker. When  $\text{H}_2\text{S}$  is passed into an aqueous solution of a thallic salt, the pp. is a mixture of  $\text{Ti}_2\text{S}_3$  and S.  $\text{Ti}_2\text{S}_3$  combines with potassium and sodium sulphides, forming  $\text{Ti}_2\text{S}_3\cdot\text{K}_2\text{S}$  and  $\text{Ti}_2\text{S}_3\cdot\text{Na}_2\text{S}$ . These compounds are obtained by fusing together 1 pt.  $\text{Ti}_2\text{SO}_3$ , 6 pts. S, and 9 pts.  $\text{K}_2\text{CO}_3$  or  $\text{Na}_2\text{CO}_3$ , and washing the fused mass with water. The K compound is more stable than the compound of Na; when heated it melts, and then gives off S, leaving K<sub>2</sub>S and  $\text{Ti}_2\text{S}_3$ ; it is not changed by water or alkali solutions, but is decomposed by mineral acids (v. Schneider, A. 135, 215; cf. Krüss, B. 19, 2738). These compounds may be regarded as  $\text{KTiS}_2$  and  $\text{NaTiS}_2$ , that is, as salts of a hypothetical thio-thallic acid.

**THALLO-THALIC SULPHIDES.** By adding  $(\text{NH}_4)_2\text{SAq}$  to a solution of  $\text{Ti}_2\text{Cl}_3$ , a black pp. is obtained which is more fusible than  $\text{Ti}_2\text{S}_3$ , and after melting solidifies to large greyish-black prisms. This pp. contains Ti and S. Similar substances are formed by heating together  $\text{TiS}_2$  and  $\text{Ti}_2\text{S}_3$ , and by melting Ti with more S than  $2\text{Ti}:\text{S}$ , and less than  $2\text{Ti}:\text{S}^3$ ; Carstanjen (*J. pr.* 102, 65) gave the formula  $5\text{Ti}_2\text{S}_3\cdot 3\text{Ti}_2\text{S}_2 = \text{Ti}_{10}\text{S}_{14}$ , and  $\text{Ti}_2\text{S}_3\cdot\text{Ti}_2\text{S}_2 = \text{TiS}_2$  to compounds obtained in this way. By heating  $\text{Ti}_2\text{S}_3\cdot\text{Na}_2\text{S}$  (v. supra) with water, Schneider (A. 135, 215) obtained a compound to which he gave the formula  $\text{Ti}_2\text{S}_3\cdot 2\text{Ti}_2\text{S}_2 = \text{Ti}_2\text{S}_5$ .

**Thallium, sulphocyanide of;** v. vol. ii. p. 352.

**Thallium, thiosalts of.** The compounds of  $\text{Ti}_2\text{S}_3$  with K<sub>2</sub>S and Na<sub>2</sub>S may be regarded as K and Na thiothallates (v. THALIC SULPHIDE, supra). M. M. P. M.

**THALLIUM ETHIDE  $\text{TiEt}$ .** Has not been obtained in the free state.

**Ethylchloride  $\text{TiEtCl}$ .** S. 276 in the cold; 3·37 at  $92^{\circ}$ . S. (alcohol) 33 at  $78^{\circ}$ . Formed from  $\text{TiCl}_3$  and  $\text{ZnEt}_2$  in ether (Hartwig, A. 176, 257). Scales (from water), explodes feebly at  $190^{\circ}$ , yielding  $\text{TiCl}_3$ . Reacts with silver salts forming:  $\text{TiEt}_2\text{NO}_3$ , S. 5·67 at  $70^{\circ}$ , exploding at  $236^{\circ}$ .— $(\text{TiEt}_2)_2\text{SO}_4$ , S. 65·4 in the cold; 87·3 at  $90^{\circ}$ ; exploding at  $205^{\circ}$  and converted by  $\text{BaI}_2$  into  $\text{TiEt}_2\text{I}$ , S. 1, exploding at  $195^{\circ}$ .— $(\text{TiEt}_2)_2\text{PO}_4$ , S. 23·7 in the cold; 20·7 at  $75^{\circ}$ , exploding at  $189^{\circ}$ .— $\text{TiEt}_2\text{OAc}$  crystallising in needles [212°] ( $245^{\circ}$ ), exploding if rapidly heated.

**Ethylhydroxide  $\text{TiEtOH}$ .** S. 15·1 in the cold; 8 at  $88^{\circ}$ . Formed from  $(\text{TiEt}_2)_2\text{SO}_4$  and baryta. Silky needles (from water). More sol. cold than hot water, forming an alkaline solution. Does not unite with  $\text{CO}_2$ , but forms the above salts with other acids.

**THAPSIC ACID  $\text{C}_{10}\text{H}_{16}\text{O}_8$ .** [124°]. Obtained from the root-bark of *Thapsia garganica*. The bark is extracted with ether, which leaves on evaporation an amber-coloured resin.\* The resin dissolves in potash with evolution of heat, and the solution, on acidification, yields a neutral resin,  $\alpha$ -octoic acid and thapsic acid. The

alkaline solution on standing deposits potassium thapsate (Canzoneri, G. 13, 514). White scales (from alcohol), nearly insol. water and benzene, sol. alcohol and ether.

**Salts.**— $\text{K}^+\text{A}^-$  2aq. Prisms.— $\text{BA}^+$  (dried at  $120^{\circ}$ ). Crystalline pp.— $\text{Ag}^+\text{A}^-$ : amorphous.

**Anhydride  $\text{C}_{10}\text{H}_{16}\text{O}_8$ .** [71°]. Crystalline powder (from benzene).

**Anilide  $\text{C}_{10}\text{H}_{16}\text{O}_8(\text{NHPh})$ .** [163°].

**THEBAÏNE  $\text{C}_{10}\text{H}_{16}\text{NO}_8$ .** [193°]. S.G. 1·8.

$[\alpha]_D = -219^{\circ}$  in 97 p.c. alcohol at  $15^{\circ}$ ;  $= -230^{\circ}$  in  $\text{CHCl}_3$ ; S. (ether) 7 at  $10^{\circ}$ ; S. (isoamyl alcohol) 1·67 in the cold; S. (benzene) 5·27 in the cold (Kubly, J. 1866, 823). Occurs in opium to the extent of about 6 p.c. (Pelletier, J. Ph. 21, 569; Couerbe, A. Ch. [2] 59, 155; Kane, A. 19, 9; Anderson, A. 80, 179; Hesse, B. 3, 367; A. 153, 47; 176, 196). Prepared by treating the aqueous extract of opium with  $\text{Na}_2\text{CO}_3$  or lime, exhausting the filtrate with ether, agitating the ether with dilute acetic acid, and pouring the acid liquid into dilute  $\text{KOH}$  Aq. The pp. is collected after 24 hours, warmed with dilute alcohol and dilute  $\text{HOAc}$  is added till just acid. The alcohol is evaporated off at  $50^{\circ}$ , papaverine and narcotine removed by filtration, and thebaïne acid tartrate ppd. by adding powdered tartaric acid to the filtrate. The tartrate is re-crystallised from water (Hesse, A. Suppl. 8, 262). Thebaïne may also be obtained by adding  $\text{NaOAc}$  to a solution of the hydrochlorides of the opium alkaloids, allowing to stand, filtering, evaporating, again filtering, and adding sodium salicylate. After 24 hours thebaïne salicylate crystallises (Plugge, Ar. Ph. [3] 24, 993; 25, 343).

**Properties.**—Colourless leaflets (from dilute alcohol) or prisms (from conc. alcohol). Tasteless. Alkaline in reaction. Very poisonous. Begins to sublime at  $135^{\circ}$ ; at  $160^{\circ}$  the sublimate contains needles, cubes, and prisms (Blyth). V. sol. alcohol and chloroform. Ppd. by alkalis and alkaline carbonates, the pp. being slightly soluble in  $\text{NH}_4\text{Aq}$  and lime-water. Conc.  $\text{H}_2\text{SO}_4$  gives a deep-red solution. Boiling dilute  $\text{H}_2\text{SO}_4$  converts it into thebenine and thebaïcine. Hot conc.  $\text{HCl}$  Aq at  $90^{\circ}$  yields  $\text{MeCl}$  and morphothebaïne (Howard, B. 17, 527).  $\text{HI}$  Aq gives  $\text{MeI}$  (2 mols.) (Howard & Roser, B. 19, 1597). Bromine-water forms  $\text{C}_{10}\text{H}_{16}\text{BrNO}_8$ , a flocculent pp. converted by excess of Br into  $\text{C}_{10}\text{H}_{16}\text{Br}_2\text{NO}_8$ , a yellow pp. Solutions of its salts give a pp. of the dichromate on adding  $\text{K}_2\text{Cr}_2\text{O}_7$ .

**Salts.**— $\text{B}^+\text{HClAq}$ . Large trimetric prisms. S. 6·8 at  $10^{\circ}$ .  $[\alpha]_D = -168\cdot 32 + 2\cdot 33p$ .— $\text{B}^+\text{H}_2\text{P}_4\text{Cl}$  2aq. Amorphous pp., quickly changing to orange prisms. Decomposed by boiling water (O. De Coninck, B. [2] 45, 131).— $\text{B}^+\text{H}_2\text{C}_2\text{O}_6$  6aq. S. 1·03 at  $10^{\circ}$ .— $\text{B}^+\text{H}_2\text{C}_2\text{O}_8$  aq. S. 2·3 at  $20^{\circ}$ .— $\text{B}^+\text{C}_2\text{H}_3\text{O}_8$  aq. Prisms, very soluble in hot alcohol. S. 77 at  $20^{\circ}$ .—Meconate  $\text{B}^+\text{C}_2\text{H}_3\text{O}_8$  6aq. White prisms (from alcohol).— $\text{B}^+\text{H}_2\text{FeCy}_6$  (Plugge, Ar. Ph. [3] 25, 793).

**Methylo-iodide  $\text{B}^+\text{MeI}$ .** Crystallises from alcohol in prisms (containing  $\text{EtOH}$ ), m. sol. water.

**Ethylchloride  $\text{B}^+\text{EtCl}$ .** Needles.

**Ethyl-iodide  $\text{B}^+\text{EtI}$ .** Needles (from alcohol) (Howard, B. 17, 527).

**Benzylchloride  $\text{B}^+\text{C}_6\text{H}_5\text{Cl}$ .** Crystals.

**Morphothebaïne  $\text{C}_{10}\text{H}_{16}\text{O}_8\text{N}$  [191°].** Obtained by heating thebaïne with strong aqueous  $\text{HCl}$  or

HBr, MeCl (or EtCl) being split off; the yield being 60 p.c. of the thebaïne. Yellowish crystals. Soluble in alcohol, ether, and benzene, sparingly in water. It dissolves in  $H_2SO_4$  to a colourless solution.

**Salts.**—B'HCl. Small glistening crystals, sol. water, insol. alcohol.—B'HBr. fine silky needles.—B'HNO<sub>3</sub> 2aq: small white crystals, v. sol. water and alcohol.—A'  $H_2SO_4$  7aq: small crystals, v. sol. water, insol. alcohol. The oxalate is a sparingly soluble amorphous pp. The picrate is a yellow pp. which melts under water. Insoluble pps. are produced with potassium ferrocyanide, ammonium molybdate,  $HgCl_2 \cdot K_2I_2$ ,  $K_2Cr_2O_7$ , and bismuth-potassium iodide.

**Acetyl derivative**  $C_{11}H_{16}AcO_2N$ . [183°]: glistening plates (Howard, B. 17, 529).

**Ethyl-iodide** B'EtI. Crystallises from acetic acid.

**Methylo-iodide** B'MeI. Dimetric tables, insol. alcohol, sol. HOAc.

**Benzoyl-chloride** B'C<sub>6</sub>H<sub>5</sub>Cl. Needles, m. sol. water, sl. sol. alcohol (Howard a. Roser, B. 19, 1596).

**Thebenine**  $C_{15}H_{21}NO_3$ . Formed by boiling thebaïne with HClAq (S.G. 1.04) (Hesse, A. 153, 69). Amorphous. Insol. benzene and ether, sl. sol. boiling alcohol. Conc.  $H_2SO_4$  forms a blue solution. V. sol. KOH aq.—B'HCl 3aq. S. 1. Plates.—B' $H_2HgCl_2$  2aq. Very long efflorescent prisms.—B' $H_2SO_4$  2aq. Plates, insol. cold water.—B' $H_2C_2O_4$  aq. Prisms, sl. sol. hot water.

**Thebaïne**. Formed by boiling thebaïne or thebenine with conc. HClAq (Hesse). Yellow amorphous pp., insol. ether, benzene, and water, sl. sol. hot alcohol, v. sol. KOH aq. Conc.  $H_2SO_4$  forms a dark-blue solution. The salts are resinous.

**Theïne v. Caffeïne.**

**THEOBROMINE**  $C_7H_9N_2O_2$  i.e.

$CO \begin{smallmatrix} \diagup NMe.C:CH.NMe \\ \diagdown =C.NH.CO \end{smallmatrix}$  Mol. w. 180. Di-methyl-xanthine. S. 0.62 at 17°; .7 at 100°. S. (alcohol) .02 at 17°; .2 at 78°. S. (ether) .006 in the cold; .17 at 35°. S. (boiling CHCl<sub>3</sub>)

1. Occurs in the seeds of *Theobroma cacao* to the extent of 1.3 to 4.6 p.c. (Woskresensky, A. 41, 125; Glasson, A. 61, 335; Keller, A. 92, 71; Roehleder, A. 71, 9; 79, 124; Strecker, A. 118, 151). Formed by heating the lead salt of xa-thine  $C_7H_9PbN_2O_2$  (4 pts.) with MeI (5 pts.) for twelve hours at 130° (Fischer, B. 16, 454; A. 215, 311). Prepared by ppg, the aqueous extract of the seeds with lead acetate, filtering, removing excess of lead by  $H_2SO_4$ , adding  $MgCO_3$ , evaporating to dryness, and extracting with alcohol (Dragendorff, Ar. Ph. [3] 1P, 1). Got also by freeing cacao from oil by pressure, adding slaked lime, and extracting with 80 p.c. alcohol (Schmidt a. Pressler, A. 217, 287).

**Properties.**—Minute trimetric crystals, sl. sol. hot water, alcohol, and ether. Tastes bitter. At 184° it begins to sublime; at 170° (Blyth) or 290° (S. a. P.) it yields a crystalline sublimate. Very slowly attacked by pure HNO<sub>3</sub> (Franchimont, R. Z. C. 6, 223). Not attacked by boiling KOH aq. Its salts are more or less easily decomposed by water. Ammoniacal AgNO<sub>3</sub> gives a gelatinous pp. which dissolves on warming, and deposits, on boiling, crystalline  $C_7H_9AgN_2O_2$

(Strecker). Theobromine is ppd. by sodium phosphotungstate (Wolfram, C. J. 36, 406; Fr. 18, 346).

**Reactions.**—1. Yields methyl-parabanic acid on oxidation by  $CrO_3$ .—2.  $KClO_3$  and HClAq at 50° yield methyl-alloxan and methyl-urea (Fischer, A. 215, 304). Chlorine-water yields amalic acid.—3. Will not combine with MeI to form a methyl-iodide. But in presence of dilute alcoholic KOH it reacts with MeI, forming caffeine, even in the cold; better at 100°. But the reaction is never complete, some theobromine being decomposed.—4. Conc. HCl has no action below 200°. At 250° it decomposes it, producing formic acid, carbonic acid, ammonia, methylamine and sarcosine,  $C_7H_9N_2O_2 + 6H_2O = 2CO_2 + NMeH_2 + 2NH_3 + C_2H_5NO_2 + CH_3O_2$ ; the  $NH_3$  and  $NMeH_2$  occur in the proportion indicated by the formula (Schmidt, A. 217, 298). Boiling aqueous Ba(OH)<sub>2</sub> effects in 40 hours the same decomposition.—5. HNO<sub>3</sub> forms CO<sub>2</sub>, methyl-parabanic acid and methylamine, but no ammonia.

**Salts.**—B'HCl aq. Rosettes of needles.—B'HBr aq. Tables.—B' $H_2PtCl_6$  4aq. —B' $H_2PtCl_6$  5aq. —B'HAuCl<sub>4</sub>. —B' $H_2NO_3$ . —B'HOAc.—B' $H_2I_4$ . Nearly black prisms, decomposed by alcohol (Jörgensen, Z. [2] 5, 676).—B'HAq(NO<sub>3</sub>)<sub>2</sub>. Silvery needles, v. sl. sol. water.—C<sub>7</sub>H<sub>9</sub>AgN<sub>2</sub>O<sub>2</sub> 1.5aq.—Ba(C<sub>7</sub>H<sub>9</sub>N<sub>2</sub>O<sub>2</sub>)<sub>2</sub> (dried at 105°). Got by adding theobromine to baryta-water (Maly a. Andreanich, M. 4, 379). Needles (from hot water).

**Bromo-theobromine**  $C_7H_9N_2O_2Br$ . From theobromine and bromine (Fischer, A. 215, 305). Crystalline powder. Sl. sol. hot water. Sol. HCl, but reppd. by water. Sol. aqueous NaOH, not in NH<sub>3</sub>. Does not give an ethoxy- derivative with alcoholic KOH (unlike bromo-caffeine). After warming with ammonia it gives with ammoniacal AgNO<sub>3</sub> a silver salt that can be converted by EtI into bromo-ethyl-theobromine  $C_7H_9EtN_2O_2Br$ , whence alcoholic KOH forms eth- oxy- ethyl- theobromine  $C_7H_9EtN_2O_2(OEt)$  [153°] as needles. Boiling HCl converts this into EtCl and oxy- ethyl- theobromine  $C_7H_9EtN_2O_2(OH)$ , whence bromine and alcohol form the di-ethyl derivative of tri-oxy-di-hydro-ethyl-theobromine  $C_7H_9Et_2N_2O_2(OH)(OEt)_2$  [152°]. This body on treatment with hot dilute HCl gives methylamine and apo-ethyl-theobromine (?); and with chlorine at -10° forms hypo-ethyl-theobromine  $C_7H_9N_2O_2$  [142°].

**Methyl-theobromine** is Caffeïne.

**Ethyl-theobromine**  $C_7H_9EtN_2O_2$  [above 270°]. Formed from  $C_7H_9AgN_2O_2$  and EtI (Philips, B. 9, 1308). Small crystals, m. sol. hot water. Weak base.

**THEOPHYLLIN**  $C_7H_9N_2O_2$  i.e.

$CO \begin{smallmatrix} \diagup NH.C:CH.NMe \\ \diagdown =C.NH.CO \end{smallmatrix}$  [264°]. Occurs in alco-

holic extract of tea, from which it may be separated by means of its Ag salt (Kossel, B. 21, 2164). Monoclinic tables (containing aq. v. e. sol. warm water and very dilute ammonia. May be sublimed. When evaporated with chlorine-water it yields a scarlet residue, which is coloured violet by NH<sub>3</sub> aq. MeI converts its Ag salt into caffeine.  $KClO_3$  and HClAq yield dimethyl-alloxan.

**Salt.**— $\text{AgC}_6\text{H}_4\text{N}_2\text{O}_2$ , 2aq. Amorphous pp., which may be crystallised from  $\text{NH}_4\text{Aq}$ .

**THETINES.** A name given by Crum-Brown and Letts to compounds of the form  $\text{CO}_2\text{H}\cdot\text{CH}_2\cdot\text{SR}_2\cdot\text{OH}$  or their anhydrides  $\text{CH}_2\cdot\text{SR}_2$ , where R is a hydrocarbon radicle; v. CO-O

**Di-ETHYL-THETINE and Di-METHYL-THETINE.**

**THEVETIN**  $\text{C}_8\text{H}_{12}\text{O}_4$ , 3aq. [170°]. S. 8 at 14°.  $\alpha = -85.5^\circ$ . A poisonous glucoside occurring in the kernels of *Thevetia nereifolia* (Blas, J. 1868, 768; De Vrij, R. T. C. 3, 167; Warden, Bk. [3] 12, 417). Crystalline powder, v. sol. hot water and alcohol, insol. ether. Sol. acids and alkalis. Levorotatory. Conc.  $\text{H}_2\text{SO}_4$  gives a dirty-brown colour. Decomposed by boiling dilute  $\text{HClAq}$  into glucose and theveresin  $\text{C}_{12}\text{H}_{20}\text{O}_4$ , 2aq, a white powder [140°], v. sl. sol. cold water, sol. alkalis.

**THIACETIC ACID** v. THIO-ACETIC ACID.

**THIALDINE**  $\text{C}_6\text{H}_7\text{NS}_2$ , i.e.

$\text{NH} \begin{smallmatrix} \text{CHMe.S} \\ \text{CHMe.S} \end{smallmatrix} \text{CHMe.}$  Mol. w. 163. [43°].

Formed by passing  $\text{H}_2\text{S}$  for four hours into a solution of aldehyde-ammonia (1 pt.) in water (15 pts.), and a little  $\text{NH}_4\text{Aq}$  (Vöhler & Liebig, A. 61, 2; Hofman, A. 103, 93; Brusewitz & Cathander, J. pr. 98, 315). Monoclinic crystals (from ether-alcohol). May be distilled with steam. V. sl. sol. water, v. sol. alcohol, v. c. sol. ether. Boiling dilute  $\text{H}_2\text{SO}_4$  forms thio-acetic aldehyde.  $\text{KMnO}_4$  forms  $\text{CH}_3\cdot\text{CH}(\text{SO}_3\text{K})_2$  (Guarachi, B. 11, 1384, 1692). Boiling  $\text{AgNO}_3$  forms aldehyde. Mol in ether forms crystalline  $\text{C}_6\text{H}_7\text{MeNS}_2\text{I}$  (Hofmann, A. 103, 93). I in KI forms amorphous  $(\text{CHMe})_2\text{S}$  (Fassbender, B. 20, 460).

**Salts.**— $\text{B}^+\text{HCl}$ . Prisms, v. sol. water.— $\text{B}^+\text{HBr}$ .— $\text{B}^+\text{HI}$ .— $\text{B}^+\text{HNO}_3$ .— $\text{B}^+\text{HSO}_4$ . Prisms.— $\text{B}^+\text{H}_2\text{PO}_4$ , aq. Needles, v. sol. water.

**THIAZOLE**  $\text{N} \begin{smallmatrix} \text{CH.S} \\ \text{CH:CH} \end{smallmatrix}$  (116.8° cor.). S.G.

1.1979; 1.1998. Formed by the action of boiling alcohol on the diazo-compound of amido-thiazole, obtained from di-chloro-di-ethyl oxide and thio-urea (Hantzsch & Popp, B. 21, 2582; A. 250, 274). Formed also from  $\text{N} \begin{smallmatrix} \text{CCL.S} \\ \text{CH:CH} \end{smallmatrix}$

and the corresponding  $\mu$ -bromo-thiazole by reduction with zinc-dust and  $\text{HOAc}$  (Schatzmann, A. 261, 12). Mobile liquid, very volatile, hygroscopic, and highly refractive. Miscible with water, alcohol, and ether. Insol.  $\text{KOH}$  aq. Smells like pyridine. Neutral in reaction.—**Salts.**— $\text{B}^+\text{H}_2\text{PtCl}_4$ , 2aq. — $\text{B}^+\text{HAuCl}_4$ . [250°]. — $\text{B}^+\text{C}_6\text{H}_5\text{N}_3\text{O}_4$ . [151°]. — $\text{B}^+\text{HHgCl}_2$ . [101°]. — $\text{B}^+\text{HgCl}_2$ . [204°]. Crystalline pp., sl. sol. water.

**$\mu$ -Amido-thiazole**  $\text{N} \begin{smallmatrix} \text{C(NH}_2\text{).S} \\ \text{CH:CH} \end{smallmatrix}$  Thiazol-

ine. **Thiazylamine.** [90°]. Formed by the action of chloro-acetic aldehyde on thio-urea (Traumann, A. 249, 36). Prepared by boiling  $\text{CH}_3\text{Cl}\cdot\text{CHClOEt}$  (1 pt.) with thio-urea (1 pt.) and water (5 pts.). Yellowish plates, sl. sol. water, alcohol, and ether. Strong base.— $\text{B}^+\text{HCl}$  aq. Needles.— $\text{B}^+\text{H}_2\text{PtCl}_4$ . Yellow tables.

**Acetyl derivative.** [203°]. Needles.

**THIAZOLE-TRIAZOLE** (so called)

$\text{CH} \begin{smallmatrix} \text{S-C:N} \\ \text{CH.N:N} \end{smallmatrix} \text{CH}$ . Formed by the action of  $\text{HClAq}$  on methyl-nitroso-imido-thiazoline (Näf, A. 265, 123). Liquid, v. sol. water. Alkaline;

reduces Fehling's solution. Nitrous acid reproduces nitroso-methyl-imido-thiazoline. —  $\text{B}^+\text{HCl}$  2aq. [220°]. Needles.— $\text{B}^+\text{HBr}$  2aq.

**THIENONE** is Di-THIENYL KETONE.

**DITHIENYL**  $\text{C}_6\text{H}_4\text{S}_2$ , i.e.  $\text{C}_6\text{H}_4\text{S}_2\text{C}_6\text{H}_4\text{S}_2$ . [88°]. (266° cor.). Formed on passing thiophene through a red-hot tube (Nahnsen, B. 17, 789, 2197). Plates (from alcohol). Conc.  $\text{H}_2\text{SO}_4$  gives a reddish-brown solution with deep-green fluorescence. On warming with isatin and  $\text{H}_2\text{SO}_4$ , it gives a violet-blue colour.

**Sulphonic acid**  $\text{C}_6\text{H}_4\text{S}_2(\text{SO}_3\text{H})$ . Got by heating with  $\text{H}_2\text{SO}_4$  (20 pts.) at 100°. Yields a crystalline  $\text{BaA}_2$  aq.

**Reference.**—Hexa-bromo-dithienyl.

**THIENYL-ACETIC ACID**  $\text{C}_6\text{H}_4\text{S}_2\text{CH}_2\text{CO}_2\text{H}$ . [76°]. Formed from  $\text{C}_6\text{H}_4\text{S}_2\text{CH}(\text{OH})\text{CO}_2\text{H}$  [115°].  $\text{HIAq}$ , and P (Ernst, B. 19, 3281). Crystalline, sol. hot water, alcohol and ether.— $\text{BaA}_2$  (dried at 130°). Crystals.— $\text{AgA}$ : pp.

**Reference.**—Oxy-thienyl-acetic acid.

**THIENYL-ACRYLIC ACID**  $\text{C}_6\text{H}_4\text{S}_2$ , i.e.  $\text{C}_6\text{H}_4\text{S}_2\text{CH}=\text{CH}\cdot\text{CO}_2\text{H}$ . [138°]. Formed by boiling thiophenic aldehyde with  $\text{NaOAc}$  and  $\text{Ac}_2\text{O}$  (Biedermann, B. 19, 1855). Needles (from water), sol. hot water and alcohol.  $\text{FeCl}_3$  gives an amorphous orange pp.— $\text{AgA}$ : white pp.

**THIENYLAMINE** v. AMIDO-THIOPHENE.

**THIENYL-BROMO-ETHANE** v. Bromo-THIENYL-ETHANE.

**THIENYL-BROMO-ETHYLENE** v. Bromo-THIENYL-ETHYLENE.

**THIENYL BROMO-METHYL KETONE**

$\text{C}_6\text{H}_4\text{S}_2\text{CO}\cdot\text{CH}_2\text{Br}$ . *w-Bromo-acetylthienone*. Formed by adding Br (2 at.) to thienyl methyl ketone (1 mol.) dissolved in  $\text{CS}_2$  (Brunswig, B. 19, 2891). Pungent yellow oil, may be distilled *in vacuo*. V. sol. alcohol and ether. Solidified by cold. Alcoholic  $\text{NH}_3$  forms a deep-blue colour. Oxidised to (a)-thiophenic acid [126.5°]. Aniline yields  $\text{C}_6\text{H}_4\text{S}_2\text{CO}\cdot\text{CH}_2\text{NHPh}$  (80°).

**Thienyl di-bromo-methyl ketone**

$\text{C}_6\text{H}_4\text{S}_2\text{CO}\cdot\text{CHBr}_2$ . [c. 0°]. Formed from thienyl methyl ketone and  $\text{Br}_2$ . Pungent oil, almost insol. ligroin.

( $\beta$ )-**THIENYL-CARBINOL**  $\text{C}_6\text{H}_4\text{S}_2\text{CH}_2\text{OH}$ . (207° cor.). Formed by shaking ( $\beta$ )-thiophenic aldehyde with aqueous potash (Biedermann, B. 19, 639). Liquid.  $\text{HCl}$  forms  $\text{C}_6\text{H}_4\text{S}_2\text{CH}_2\text{Cl}$ , a pungent oil boiling with partial decomposition at 175°.

**THIENYL CHLORO-ETHANE** v. CHLORO-THIENYL-ETHANE.

**THIENYL CHLORO-ETHYLENE** v. CHLORO-THIENYL-ETHYLENE.

(a)-**THIENYL CHLORO-METHYL KETONE**  $\text{C}_6\text{H}_4\text{S}_2\text{CO}\cdot\text{CHCl}$ . [47°]. (259° cor.). Formed by chlorination of thienyl methyl ketone (Peter, B. 18, 539). Pungent white crystals. Yields (a)-thiophenic acid on oxidation.

**THIENYL-ETHYLAMINE**  $\text{C}_6\text{H}_4\text{NS}$ , i.e.  $\text{C}_6\text{H}_4\text{S}_2\text{CHMe}\cdot\text{NH}_2$ . (186°). Got by reducing the oxim of thienyl methyl ketone in alcoholic solution by adding sodium-amalgam and  $\text{HOAc}$  (Goldschmidt & Schultze, B. 20, 1700). Liquid, sol. water. Absorbs  $\text{CO}$  from the air.— $\text{B}^+\text{HOAc}$ . Needles, v. c. sol. water.

**Benzoyl derivative.** [35°]. Needles.

**THIENYL ETHYL KETONE**  $\text{C}_6\text{H}_4\text{S}_2\text{CO}\cdot\text{C}_2\text{H}_5$ . *Propiothienone*. (228° cor.). Formed from propionyl chloride, thiophene, and  $\text{AlCl}_3$  (Kreker,

*B. 19, 677*). Liquid. Hot conc.  $\text{H}_2\text{SO}_4$  forms propionic and thiophene (a)-sulphonic acids. Chromic acid mixture yields (a)-thiophenic acid. Oxim  $\text{C}_6\text{H}_4\text{S.CEt.NOH}$ . [56°].

#### THIENYL DIETHYL PHOSPHINE

$(\text{C}_6\text{H}_4\text{S})\text{P}(\text{Et})_2$ . [225°]. Formed from thienyl-chloro-phosphine and  $\text{ZnEt}_2$  in ether (Sachs, *B. 25, 1517*).

*Ethyl-iodide*  $(\text{C}_6\text{H}_4\text{S})\text{P}(\text{Et})\text{I}$ .

*Methyl-iodide*  $(\text{C}_6\text{H}_4\text{S})\text{P}(\text{Et})\text{MeI}$ . [122°].

White powder, v. sol. water insol. ether.

THIENYL-GLYCOLLIC ACID v. OXY-THIENYL-ACETIC ACID.

#### (a)-THIENYL-GLYOXYLIC ACID

$\text{C}_6\text{H}_4\text{SO}_2$ , aq. i.e.  $\text{C}_6\text{H}_4\text{S.CO.CO}_2\text{H}$ . [91°]. Formed by oxidising thienyl methyl ketone with alkaline  $\text{KMnO}_4$  (Peter, *B. 18, 537*; Biedermann, *B. 19, 687*; Bradley, *B. 19, 2115*). Formed also, together with thiophene (a)-carboxylic acid, by oxidation of (a)-ethyl-thiophene by alkaline  $\text{KMnO}_4$ . Crystals (containing aq, possibly as  $\text{C}_6\text{H}_4\text{S.C(OH).CO}_2\text{H}$ ), v. sol. warm water. Melts at 59° when hydrated. May be extracted by ether from its aqueous solution. If a drop of crude benzene, followed by  $\text{H}_2\text{SO}_4$ , be added to its solution in  $\text{HOAc}$ , a brown colour is formed, which on addition of more  $\text{H}_2\text{SO}_4$  passes through blue-green, green, violet, red, and bluish-violet to blue.

*Reactions*.—1. On heating it splits up into  $\text{CO}_2$  and thiophenic aldehyde. —2. On heating with di-methyl-aniline and  $\text{ZnCl}_2$  it yields the leuco-base of a green dye  $\text{C}_6\text{H}_4\text{S.CH(C}_6\text{H}_4\text{NMe}_2)_2$ . —3.  $\text{PCl}_5$  forms thiophenic chloride.

*Salts*. —  $\text{BaA}'$ , aq. Slender efflorescent needles, v. sol. water. —  $\text{CaA}'$ , 2aq. —  $\text{CuA}'$ , 2aq. —  $\text{ZnA}'$ , 2aq. —  $\text{AgA}'$ , aq. amorphous pp., probably  $\text{C}_6\text{H}_4\text{S.C(OH).CO}_2\text{Ag}$ .

*Methyl ether*  $\text{MeA}'$ . [28-5°].

*Ethyl ether*  $\text{EtA}'$ . (265° uncor.). Oil.

*Amide*  $\text{C}_6\text{H}_4\text{S.CO.CO.NH}_2$ . [88°]. Needles, almost insol. water, v. sol. alcohol and ether.

*Oxim*  $\text{C}_6\text{H}_4\text{S.C(OH).CO}_2\text{H}$ . [146°].

(Hantzsch, *B. 24, 48*). Slender white needles. Exhibits Liebermann's reaction (Bradley, *B. 19, 2119*). —  $\text{BaA}'$ , 1½aq. —  $\text{AgA}'$ : amorphous pp. —  $\text{MeA}'$  [105°]. Converted by  $\text{NaOMe}$  and  $\text{MeI}$  into liquid  $\text{C}_6\text{H}_4\text{S.C(ONMe).CO}_2\text{Me}$ . —  $\text{EtA}'$ . [128°]. Needles.

*Acetyl derivative of the oxim*. [87°].

*Phenyl-hydrazide*

$\text{C}_6\text{H}_4\text{S.C(N}_2\text{HPh).CO}_2\text{H}$ . [165°]. Deep-yellow needles (from ether).

*Reference*. — NITRO-THIENYL-GLYOXYLIC ACID.

#### THIENYL HEXYL KETONE $\text{C}_{11}\text{H}_{16}\text{SO}$ i.e.

$\text{C}_6\text{H}_4\text{S.CO.C}_6\text{H}_{13}$ . (304° cor.). Formed from thiophene, heptyl chloride, and  $\text{AlCl}_3$  in ligroin (Schleicher, *B. 19, 664*). Yellow oil, yielding (a)-thiophenic acid on oxidation. Conc.  $\text{H}_2\text{SO}_4$  forms thiophene (a)-sulphonic and heptonic acids.

*Oxim* [49°]. — Crystals (from alcohol).

#### THIENYL-INDOLE $\text{C}_{12}\text{H}_9\text{NS}$ i.e.

$\text{C}_6\text{H}_4\text{S.C(NH).C}_6\text{H}_5$ . [162°]. Formed by heating the phenyl-hydrazide of thienyl methyl ketone with  $\text{ZnCl}_2$  (Brunck, *A. 272, 201*). Light-yellow needles, insol. water, v. sol. ether, m. sol. alcohol. Colours pine-wood, moistened with  $\text{HCl}$ , bluish-violet. Yields  $\text{C}_6\text{H}_4\text{Br.NS}$  [278°] and  $\text{C}_6\text{H}_4\text{OH(C}_6\text{H}_4\text{NS)}$ , [245°]. —  $\text{B'C}_6\text{H}_4\text{N}_2\text{O}$ , [187°]. Dark red plates, v. sol. alcohol.

*Nitrosamine*  $\text{C}_{12}\text{H}_9\text{(NO)NS}$ . [241°].

DI-THIENYL KETONE  $(\text{C}_6\text{H}_4\text{S})_2\text{CO}$ . [88°]. (328° uncor.). Formed from thiophene,  $\text{COCl}_2$ , and  $\text{AlCl}_3$ . Obtained also by distilling calcium a-thiophenate (Gattermann, *B. 18, 3012*). Needles or plates, sol. alcohol.

*Phenyl-hydrazide* [187°].

#### THIENYL MERCAPTAN $(\text{C}_6\text{H}_4\text{S})_2\text{SH}$ . (166°).

Got by reducing thiophene (a)-sulphonic acid with zinc and  $\text{HClAq}$  (Biedermann, *B. 19, 1616*). Got also in small quantity from succinic acid and  $\text{P}_2\text{S}_5$  (V. Meyer a. Neure, *B. 20, 1757*). Stinking oil, volatile with steam. —  $\text{AgSC}_6\text{H}_4\text{S}$ . [231°].

*Acetyl derivative*  $(\text{C}_6\text{H}_4\text{S})_2\text{SAC}$ . (186°).

*Methyl ether*  $(\text{C}_6\text{H}_4\text{S})_2\text{SMe}$ . (186°).

#### DI-THIENYL METHANE $\text{C}_6\text{H}_4\text{S}_2$ i.e.

$\text{CH}_2(\text{C}_6\text{H}_4\text{S})_2$ . (267°). Got by adding  $\text{H}_2\text{SO}_4$  to a solution of thiophene and methylal in  $\text{HOAc}$  (Peter, *B. 17, 1345*). Oil, smelling like oranges. Volatile with steam. Gives a red colour with isatin and  $\text{H}_2\text{SO}_4$ .

(a)-THIENYL METHYL KETONE  $\text{C}_6\text{H}_4\text{SO}$  i.e.  $\text{C}_6\text{H}_4\text{S.CO.CH}_3$ . *Acetothienone*. (213° cor.). S.G. 2: 1.167. Formed from thiophene,  $\text{AcCl}$ , and  $\text{AlCl}_3$  (Peter, *B. 17, 2643*; Biedermann, *B. 19, 636*; Bradley, *B. 19, 2115*). Formed also from  $\text{C}_6\text{H}_4\text{(HgCl)S}$  and  $\text{AcCl}$  (Volhard, *A. 267, 178*). Liquid, smelling like acetophenone. Gives a blue colour with isatin and  $\text{H}_2\text{SO}_4$ . Oxidised by  $\text{KMnO}_4$  to (a)-thienyl-glyoxylic and thiophenic acids. Mercuric chloride and  $\text{NaOAc}$  form the compound  $(\text{CH}_3\text{CO.C}_6\text{H}_4\text{S})_2\text{HgCl}_2$  crystallising in white needles. Oxalic ether (1 mol.) and  $\text{NaOEt}$  give  $\text{C}_6\text{H}_4\text{S.CO.CH}_2\text{CO.CO}_2\text{Et}$  [42°], which forms large yellow crystals, converted by boiling alcoholic hydroxylamine hydrochloride into the compound  $\text{C}_6\text{H}_4\text{S.C}\begin{smallmatrix} \text{CH}:\text{C}_6\text{H}_4\text{S} \\ \text{N} \end{smallmatrix}$  or

$\text{CO}_2\text{Et.C}\begin{smallmatrix} \text{CH}:\text{C}_6\text{H}_4\text{S} \\ \text{N} \end{smallmatrix}$  crystallising in colourless needles [48°] (Angeli, *B. 24, 232*).

*Oxim*  $\text{C}_6\text{H}_4\text{S(NOH)}$ . [112°].

*Phenyl-hydrazide*  $\text{C}_6\text{H}_4\text{S(N}_2\text{HPh)}$ . [96°].

*Reference*. — Bromo-, Chloro-, Iodo-, and Nitro-THIENYL METHYL KETONE.

THIENYL PHENYL - AMIDO - METHYL KETONE  $\text{C}_6\text{H}_4\text{S.CO.CH}_2\text{NHPH}$ . [80°]. Formed by mixing  $\text{C}_6\text{H}_4\text{S.CO.CH}_2\text{Br}$  with aniline in alcohol (Brunswig, *B. 19, 2892*). Plates. Yields a nitrosamine  $\text{C}_6\text{H}_4\text{S.CO.CH}_2\text{NPh(NO)}$  [81°], and acetyl derivative  $\text{C}_6\text{H}_4\text{S.CO.CH}_2\text{NPhAc}$  [142°].

#### THIENYL PHENYL KETONE

$\text{C}_6\text{H}_4\text{S.CO.C}_6\text{H}_5$ . [55°]. (c. 300°). Formed by the action of  $\text{AlCl}_3$  on a mixture of thiophene and  $\text{BzCl}$  (Corney, *B. 17, 790*). Formed also by heating  $\text{C}_6\text{H}_4\text{(HgCl)S}$  with  $\text{BzCl}$  at 100° (Volhard, *A. 267, 179*). Long needles (from dilute alcohol), insol. water. Gives a blue colour on heating with isatin and  $\text{H}_2\text{SO}_4$ . Yields thiophene and benzoic acid on heating with soda-lime.

*Oxims*  $\text{C}_6\text{H}_4\text{S.CPh.NOH}$ . Hydroxylamine forms two stereo-isomeric (?) oxims [93°] and [114°] (Hantzsch, *B. 23, 2332*; 24, 59).

#### THIENYL-PHENYL-METHANE

$\text{CH}_2\text{Ph.C}_6\text{H}_4\text{S}$ . (265°). Formed by the action of  $\text{H}_2\text{SO}_4$  on a mixture of thiophene and benzyl alcohol dissolved in  $\text{HOAc}$  (Peter, *B. 17, 1346*). Liquid with fruity smell, volatile with steam. Gives a red colour with isatin and  $\text{H}_2\text{SO}_4$ .

Thienyl-di-phenyl-methane  $\text{CHPh}_2\text{C}_6\text{H}_4\text{S}$ . [63°]. (330°-340°). Formed from thiophene, di-phenyl-carbinol, and  $\text{P}_2\text{O}_5$  (Levi, *B. 19, 1624*).

Plates (from alcohol) or needles (from ligroin), v. sol. HOAc, alcohol, and ether. Crystallises from cold benzene in needles  $C_6H_5SC_2H_3$  [48°].

#### THIENYL ISOPROPYL KETONE

$C_6H_5S.CO.CHMe_2$  (232° cor.). Formed from isobutryl chloride, thiophene, and  $AlCl_3$  (Krekeler, B. 19, 675). Liquid. Yields (a)-thiophenic acid on oxidation. Fuming  $H_2SO_4$  reacts with formation of the sulphonic acid  $C_6H_5(SO_3H)S.CO.CHMe_2$ , which yields the salts  $BaA'$ ,  $PbA'$ , 2aq, and is converted by phenyl-hydrazine into  $C_6H_5(SO_3N_2HPh)S.C(N_2HPh).CHMe_2$ , crystallising from hot water in plates.

Oxim  $C_6H_5S.C(NOH).CHMe_2$  [108°]. Pearly plates (from dilute alcohol).

#### THIENYL STYRYL KETONE v. STYRYL THIENYL KETONE.

**THIENYL DISULPHIDE**  $(C_6H_5S)_2S$ . [56°]. Formed by atmospheric oxidation of a solution of thienyl mercaptan in alcoholic  $NH_3$  (Meyer a. Neure, B. 20, 1757). Needles.

**THIENYL SULPHOCYANO - METHYL KETONE**  $CH_3(SCy).CO.C_6H_5S$ . [88°]. Formed from  $CH_3Br.CO.C_6H_5S$  and  $KSCy$  in alcohol (Brunswig, B. 19, 2893). Plates (from ether), sl. sol. water and ligroin, m. sol. alcohol.

**DI-THIENYL-THIOPHENE**  $C_6SH_2(C_6SH_3)_2$ . [147°]. (357°). V.D. 8.6. One of the products of the passage of benzene and sulphur-vapour through a red-hot tube (Renard, C. R. 112, 49). Yellowish needles (from alcohol), m. sol. benzene.  $H_2SO_4$  forms a rose-coloured solution, turned violet and finally blue on heating. Fuming  $H_2SO_4$  at 120° forms a trisulphonic acid, which yields  $(C_6H_5S_3(SO_3)_3)_2Ca$ , as an amorphous powder, v. sol. water. Fuming  $HNO_3$  at 160° forms  $C_{12}H_8S_6O_4$  [313°], crystallising in white plates, v. sl. sol. benzene. Br forms  $C_{12}H_8Br_2S_6$  [293°], and amorphous  $C_{12}H_8Br_2S_6$ .

**THIENYL TOLYL KETONE**  $C_6H_5SO$  i.e.  $C_6H_5Me.CO.C_6H_5S$ . Formed from o-toluic chloride, thiophene, and  $AlCl_3$  (Ernst, B. 19, 3279). Oil. Yields an oily oxim.

**THIO-**. This prefix is employed to denote the replacement of O by S. Most inorganic salts of thio-acids are described under the heading of the oxy-salts; thus *thio-carbonates* are described under CARBONATES. In some cases thio-salts are described under the heading of the characteristic element of the salts: *thio-arsenates* are to be found under ARSENIC. Certain thio-salts are described under headings placed in their strictly alphabetical position; for instance, THIOSULPHATES. *Thiocyanides* are described as SULPHOCYANIDES.

The following addition should be made to the sub-article THIO-OXYORTHOPHOSPHATES (p. 147). By heating metallic chlorides or sulphides with excess of  $P_2S_5$  Glatzel has prepared a number of *tetrathio-oxyorthophosphates*, i.e. salts of the hypothetical acid  $H_4PS_4$  (Zeit. für anorg. Chemie, 4, 186). These salts are crystalline—generally green to black in colour; they are burnt in air, giving off  $SO_2$ ; some are decomposed to sulphides and  $P_2S_5$ , but the mercuric and arsenic salts distil unchanged when heated out of contact with air. These salts are insol. in dilute acids; they are decomposed by strong acids. G. isolated the thiophosphates of Sb, As, Bi, Cd, Cu (ous), Fe (ous), Pb, Mn, Hg (ic), Ni, Ag, Tl, Sn (ous), and Zn; he could not obtain the salts of Ca, K, Na, or Sr.

M. M. P. M.

#### THIOACETAMIDE $CH_3CS.NH_2$ [108°].

Formed from acetonitrile and  $H_2S$  (Bernthsen, A. 192, 46), and from acetamide and  $P_2S_5$  (Hofmann, B. 11, 340). Monoclinic plates, v. sol. water and alcohol, m. sol. ether.  $HgO$  forms  $HgS$ .  $AgNO_3$  gives  $Ag_2S$ .  $CuSO_4$  and  $Pb(OAc)_2$  give, on boiling,  $CuS$  and  $PbS$ .  $HgCl_2$  forms a crystalline compound. *n*-bromo-acetoacetic ether forms  $CH_3.C(NH).S.CH_2.CO.CH_2.CO_2Et$  [94°], and

finally  $S < \overset{CMe:N}{CH} . \dot{C}CH_2.CO_2Et$  (239°), the ether of methyl-thiazyl-acetic acid [121°] (Steude, A. 261, 36). The ether melting at 91° is converted by warming with water into the compound  $CH_3.CO.S.CH_2.CO.CH_2.CO_2Et$  (155° at 15 mm.), whence  $H_2SO_4$  forms an acid  $C_4H_6SO_4$  [168°].

**THIO-ACETIC ACID**  $C_2H_3SO$  i.e.  $CH_3.CO.SH$ . Mol. w. 76. (93°). S.G. 1.074. Prepared by distilling acetic acid with  $P_2S_5$  (Kekulé, A. 90, 311; Ulrich, A. 109, 272; Kekulé a. Linne-mann, A. 123, 273). Obtained also from  $AcCl$  and  $KSH$  (Jacquemin a. Vossellmann, J. 1859, 354), by heating lead acetate with  $Na_2S_2O_3$  (Fröhde, Z. 1866, 543), and by the action of  $KSH$  on an alcoholic solution of  $PhSAc$  (Kekulé, Z. [2] 3, 196). Colourless liquid, turning yellow on keeping. Smells like acetic acid and  $H_2S$ . Not solid at -17°. M. sol. warm water, v. sol. alcohol and ether. Violently attacked by fuming  $HNO_3$ .  $PCl_5$  yields  $AcCl$ ,  $PSCl_5$ , and  $HCl$ . Its neutral solutions give pps. with  $AgNO_3$  and  $HgCl_2$ , which quickly turn black. Molten  $ZnCl_2$  forms  $CMeS_2.CMe$  [225°], which may be crystallised from hot alcohol (Bongartz, B. 19, 2182).  $HCl$  passed into a mixture of thio-acetic acid and benzoic aldehyde forms  $(CH_3.CO.S)_2CHPh$  [148°], crystallising from hot ether in slender needles.

Salts.— $KA'$ . Crystals, v. sol. water and alcohol.— $NaA'$  3aq.— $BaA'$  3aq.— $SrA'$  2aq.— $CaA'$  2aq.— $PbA'$ . Silky needles (from hot water or alcohol). Quickly decomposes, with separation of  $PbS$ .

*Methyl ether*  $MeA'$ . (96°). Formed by heating  $AcEt$  with  $Me_2S$  at 100° (Cahours, B. 25, 562; Wallach a. Bleibtreu, B. 12, 1062). Formed also from  $AcCl$  and  $Pb(SMe)_2$  (Obermeyer, B. 20, 2920).

*Ethyl ether*  $EtA'$ . (116° i.v.). Formed from  $AcCl$  and  $NaSEt$  (Saytzeff, Z. [2] 4, 642; Beckmann, J. pr. [2] 17, 461). Formed also from  $PhOAc$  and  $NaSEt$  (Seiffert, J. pr. [2] 31, 468). Colourless liquid, with alliaceous odour. Oxidised by  $AgMnO_2$  to acetic acid and ethane sulphonic acid.

*n*-Propyl ether  $PrA'$ . (136°).

*Isopropyl ether*  $PrA'$ . (126°).

*Isobutyl ether*  $CH_3PrA'$ . (149°).

*Anhydride* v. ACETYL SULPHIDE.

Thio-acetic acid  $CH_3CS.OH$ .

*Amide* v. THIOACETAMIDE.

*Anilide*  $CH_3CS.NHPh$ . [75°]. Formed from  $CH_3.CCl:NPh$  and  $H_2S$  (Leo, B. 10, 2184). Prepared by heating acetanilide with  $P_2S_5$  at 100° (Hofmann, B. 11, 339; Jacobsen, B. 19, 1071). Yellowish needles (from water). Sol.  $NaOH$  aq. and reppd. by acids. On oxidation with alkaline  $K_2FeO_4$ , it yields ethenyl-amido-phenyl mercaptan.  $MeI$  forms  $CH_3NSMeI$  or  $(CH_3CS.NPhMe)HI$  [139°], which yields an aqueous solution from which  $AgNO_3$ , at once

pts. AgI, and which is converted by AgCl into  $C_6H_5NSMeCl$ , whence  $(C_6H_5NSMeCl)_2PtCl_2$  may be got (Bernthsen, A. 192, 56). NaOEt forms  $CH_3C(SNa):NPh$ , whence MeI yields the ether  $CH_3C(SMe):NPh$  (245°) (Wallach a. Bleibtreu, B. 12, 1061; 13, 529), which is decomposed by MeI at 100° into methyl thioacetate and methyl-aniline. NaOEt and EtBr yield the corresponding  $CH_3C(SEt):NPh$ , a heavy oil, insol. alkalis, split up by warm HClAg into thioacetic ether and aniline. 'Ethyl-iso-thioacetanilide' yields  $(C_6H_5)_2NS, H_2PtCl_2$ .

**Methyl anilide**  $CH_3CS.NMePh$ . [59°]. (290°). Formed from AcNMePh and  $P_2S_3$  (Wallach, B. 13, 528). Monoclinic tables, v. sol. alcohol.

**o-Toluide**  $CH_3CS.NHC_6H_4$ . [68°]. Yields  $CH_3C(SEt):NC_6H_4Me$  (262°), an oil which reacts with bases forming amidines and ESH.

**p-Toluide** [132°]. Yields oily  $CH_3C(SEt):NC_6H_4$ . (273°) (Wallach a. Wüsten, B. 16, 147).

**Xylidide**  $CH_3CS.NHC_6H_4Me$ . [80°] (G.); [95°] (Jacobsen). Formed by heating acetyl-xylidine with  $P_2S_3$  on the water-bath (Gudeman, B. 21, 2551).

**ψ-Cumitide**  $CH_3CS.NHC_6H_4Me$ . [114°]. Prisms (Jacobsen a. Elley, B. 22, 907).

(a) **Naphthalide**  $CH_3CS.NHC_{10}H_7$ . [96°]. Tables. Formed from naphthyl-acetamidine and  $CS_2$  (Bernthsen a. Trompetter, B. 11, 1760).

(b) **Naphthalide**. [146°]. Needles or plates (Jacobsen, D. 21, 2627). Oxidised by  $K_2FeCy$ .

to  $C_6H_5\langle S \rangle^N CMe$  [81°].

**Tri-thio-ortho-acetic acid**  $CH_3C(SH)_3$ . **Ethyl ether**  $CH_3C(SEt)_3$ . Formed from mercaptan,  $CHCl_3$ , and NaOH at 100° (Laves, B. 25, 854). Brownish liquid. Oxidised by  $KMnO_4$  and  $H_2SO_4$  to the trisulphone.

**Benzyl ether**  $CH_3C(SC_6H_5)_3$ . [46°]. Formed from benzyl mercaptan,  $CHCl_3$ , and (2 p.c.) NaOHAg (Laves). Crystals, v. sol.  $CHCl_3$ , m. sol. alcohol.

**THIO-ACETIC ALDEHYDE**. On passing  $H_2S$  into an aqueous solution of aldehyde, crude thioacetic aldehyde separates as an oil, which solidifies at  $-8^\circ$ , and then melts at  $-2^\circ$ . This oil (V.D. 60 ( $H=1$ )) is a mixture of thioacetic aldehyde and its polymerides, and may be represented, in a state of vapour, as  $C_6H_5S + C_6H_5S_2$  (Pinner, B. 4, 258; Klinger, B. 9, 1893; 10, 1877; 11, 1023). On distillation, or on passing HCl through the liquid, it is converted into the polymeric tri-thio-tri-acetic aldehyde.

**Tri-thio-tri-acetic aldehyde**  $C_6H_5S_3$ . Mol. w. 180. [46°]. V.D. 89.7 (calc. 90) (Hömann, B. 3, 589; Z. [2] 6, 699). Formed by passing  $H_2S$  into an acid solution of aldehyde (Klinger; cf. Weidenbusch, A. 66, 152; Crafts, C. R. 54, 1279). Formed also from paraldehyde and  $H_2S$ . White needles, sol. alcohol and ether. Smells like garlic.  $AgNO_3$  added to its alcoholic solution forms crystalline  $C_6H_5S_3AgNO_3$ . Chlorine forms ethylidene chloride (Pinner, A. 179, 21).  $KMnO_4$  oxidises it to  $CH_3CH(SO_2H)_2$ , and oxysulphides, including  $C_6H_5S_2O_2$ , [217°], which crystallises from hot water in needles (Guarreschi, A. 222, 801). Zinc permanganate produces  $C_6H_5S_2O_2$ , which does not melt below

245°.  $C_6H_5S_2O_2$ , [112°-116°], and  $C_6H_5S_2O_3$ , [228°-231°] (cf. Baumann, B. 28, 2074).

(a) **Tri-thio-tri-acetic aldehyde**  $C_6H_5S_3$ , i.e.

$CHMe\langle S.CHMe \rangle S$ . [102°]. (247°). V.D. 6

(air = 1). Formed by the long-continued action of  $H_2S$  on a mixture of equal parts of water, conc. HClAg and aldehyde. Long prisms (from acetone). Reduced by HI to  $Et_3S$ . Oxidised by  $KMnO_4$  to  $C_6H_5S_2O_2$ , [284°] (S. 1 at 100°; 116 at 20°), and  $C_6H_5S_2O_3$  or  $C_6H_5\langle SO_2.C_6H_5 \rangle SO_2$ , which softens at 340° and is converted by MeI into  $C_6H_5S_2O_3$ , [302°]. Yields crystalline  $C_6H_5S_3AgNO_3$  and  $C_6H_5S_3AgNO_3$ .

(b) **Tri-thio-tri-acetic aldehyde**  $C_6H_5S_3$ , [126°]. (247°). V.D. 6.0. Formed by the action of AcCl or  $H_2SO_4$  on its (a)-isomeride. Prepared by passing  $H_2S$  into a mixture of aldehyde (1 pt.) and alcohol previously saturated with HCl (3 pts.) (Baumann a. Fromm, B. 22, 2600; 26, 2074). Long needles (from alcohol). Oxidised by  $KMnO_4$  to the same sulphones as the (a)-isomeride. Reacts with MeI, yielding  $SMeI$ . Distillation with Cu forms ψ-butylene. Forms crystalline  $C_6H_5S_3AgNO_3$  and  $C_6H_5S_3AgNO_3$ .

(c) **Tri-thio-tri-acetic aldehyde**  $C_6H_5S_3$ , [76°]. (242°). Formed, together with  $C_6H_5NS$ , by boiling thialdine sulphocyanide with water (Marekwald, B. 19, 1827; 20, 2817). Needles (from alcohol), insol. water, v. sol. ether and  $CS_2$ . Volatile with steam. Sol. conc.  $H_2SO_4$  and reppd. by water. When mixed with EtI (4 pts.) and left for some weeks it suddenly changes to a crystalline mass of the (b)-isomeride.  $C_6H_5S_3AgNO_3$ . 'Plates, v. sol. water. Yields  $Ag_2S$  on boiling with alcohol.

'Di-thioaldehyde thiocarbimide'  $C_6H_5NS$ , [138°]. Formed as above. Needles, m. sol. ether. Yields  $C_6H_5NSAgNO_3$ , v. sol. water, and  $(C_6H_5NS)_2PtCl_2$ .

**Di-thio-acetic orthoaldehyde**. **Ethyl ether**  $CH_3CH(SEt)_2$ . Formed by passing HCl into a mixture of acetic aldehyde and EtSH (Baumann, B. 18, 884). Mobile oil.

**THIOACETIC ANHYDRIDE v. ACETYL SULPHINE**.

**THIO-ACETONE**  $\cdot CH_3CS.CH_3$ . A product of the action of  $H_2S$  on acetone, and formed also when  $CMe_2(SEt)_2$  is heated above 160° (Baumann a. Fromm, B. 22, 2592). Volatile oil, with very persistent and disagreeable smell. Unstable.

**Duplo-thioacetone**  $C_6H_5S_2$ , i.e.  $S\langle CMe_2 \rangle S$ . V.D. 5.08 (calc. 5.11). (184° cor.). Formed by heating acetone with  $P_2S_5$  at 125° (Wislicenus, Z. [2] 5, 324; Autenrieth, B. 20, 875). Formed also by heating tri-thio-tri-acetone at 200° for some time (Fromm a. Baumann, B. 22, 1043). Oil. Its alcoholic solution gives a white pp. with  $HgCl_2$ . Reduced by sodium-amalgam to isopropyl mercaptan (Spring, Bl. [3] 40, 69). Oxidised by a 5 p.c. solution of  $KMnO_4$  to the disulphone  $SO\langle CMe_2 \rangle SO_2$ , [220°-225°].

**Tri-thio-tri-acetone**  $C_6H_5S_3$ , i.e.  $S\langle CMe_2S \rangle CMe_2$ . [24°]. (130° at 15 mm.). Formed, together with  $C_6H_5S_2$ , [171°], by passing  $H_2S$  into a cooled mixture of acetone and

conc. HClAq (Fromm a. Baumann, B. 22, 1037, 2597). Needles (from alcohol); insol. water, v. sol. alcohol and ether. Boils, with much decomposition, at 225°-230°. Gives a white pp. with HgCl<sub>2</sub> and a yellow pp. with lead acetate. Potassium permanganate and H<sub>2</sub>SO<sub>4</sub> yield the trisulphone  $\text{SO}_2 \cdot \langle \text{CMe}_2 \cdot \text{SO}_2 \rangle \text{CMe}_2$ , [302°] and

$\text{S} \langle \text{CMe}_2 \cdot \text{SO}_2 \cdot \text{CMe}_2 \cdot \text{SO}_2 \rangle \text{CMe}_2$ , [208°].

Duplo-di-thio-acetone ( $\text{Me}_2\text{CS}_2$ )<sub>2</sub>, [98°]. (c. 243°). Formed from acetone and yellow ammonium sulphide in the cold (Willgerodt, B. 20, 2467). Dimetric crystals, a:c = 1:868, insol. water. Partially decomposed on distillation.

Di-thio-orthoacetone. Di-ethyl ether  $\text{CMe}_2(\text{SEt})_2$ . Acetone-thiol-mercaptol. (191°). Formed by passing dry HCl into a mixture of acetone (1 pt.) and mercaptan (2 pts.) (Baumann, B. 18, 887). Liquid.

Di-phenyl ether  $\text{CMe}_2(\text{SPh})_2$ ; v. Di-phenyl-propyldiene disulphide.

THIOACETONURAMIC ACID v. ACETONYL THIOCARBAMATE.

THIO - ACETOPHENONE  $\text{C}_6\text{H}_5\text{CS.C}_6\text{H}_5$ , [119.5°]. Formed by the action of alcoholic ammonium sulphide on acetophenone (Engler, B. 11, 930). Colourless leaflets or needles, insol. water, sl. sol. alcohol, v. sol. ether. May be sublimed.

THIO-ACETYL-TOLUIDINE v. Toluide of THIO-ACETIC ACID.

THIO-ALLOPHANIC ACID. Ethyl ether  $\text{C}_6\text{H}_5\text{N}_2\text{SO}_2$  i.e.  $\text{NH}_2\text{CO.NH.CO.SET}$ , [180°]. Formed by heating urea with ClCO.SET at 80°-90° (Peitzsch a. Salomon, J. pr. [2] 7, 477). Pearly needles (from water), v. sl. sol. cold water and alcohol. Aqueous  $\text{NH}_3$  at 100° forms biuret and mercaptan. Boiling baryta-water gives allophanic acid and mercaptan. Aniline yields di-phenyl-biuret and mercaptan.

Isoamyl ether  $\text{NH}_2\text{CO.NH.CO.SC.H}_{11}$ , [176°]. Needles (Schöne, J. pr. [2] 32, 251). AcCl yields an acetyl derivative [85°].

Phenyl ether [218°] (Gattermann, A. 244, 43).

Isothio-allophanic ether  $\text{NH}_2\text{CS.NH.CO}_2\text{Et}$ , [170°-175°]. Formed by the action of thio-urea on COClCO<sub>2</sub>Et (Peitzsch, B. 7, 896). Prisms (from alcohol).

Di-thio-allophanic ether  $\text{NH}_2\text{CS.NH.CO}_2\text{SET}$ . Formed from KSCy, alcohol, and HCl (Blankenhorn, J. pr. [2] 16, 358). Pearly prisms, insol. cold water, sol. hot ether. Alcoholic  $\text{NH}_3$  at 150° forms thio-urea. Baryta-water yields mercaptan,  $\text{CO}_2$ , and thio-urea.

DI-THIO-AMMELIDE  $\text{C}_6\text{H}_5\text{N}_2\text{S}_2$  i.e.  $\text{C}_6\text{H}_5(\text{NH})_2(\text{SH})_2$ , S. 3 at 100°. Formed by boiling pseudosulphocyanogen  $\text{C}_6\text{H}_5\text{N}_2\text{S}$  with KSH or ammonium sulphide solution (Jamieson, A. 59, 339; Ponomareff, J. R. 8, 222). Small needles, nearly insol. cold water, alcohol and ether, v. sol. aqueous ammonium sulphocyanide. Acid in reaction, decomposing carbonates.

Reactions.—1. Yields cyanuric acid when heated with HClAq.—2.  $\text{NH}_4\text{Aq}$  forms melamine  $\text{C}_6\text{H}_6\text{N}_6$  by heating in a sealed tube.

Salts.—NaHA' 1½ aq. Tables.—KHA' 2 aq. White prisms, v. e. sol. water and alcohol.—MgH<sub>2</sub>A' 6 aq.—CaH<sub>2</sub>A' 2 aq.—BaH<sub>2</sub>A' 5 aq.—BaH<sub>2</sub>A' 6 aq. Monoclinic crystals, sl. sol. cold

water.—SrH<sub>2</sub>A' 4 aq.—AgHA'. Flocculent pp., insol. water.

Methyl ether  $\text{C}_6\text{H}_5(\text{NH})_2(\text{SMe})_2$ , [200°]. Formed by heating  $\text{C}_6\text{H}_5\text{N}_2(\text{SMe})_2$  with alcoholic  $\text{NH}_3$  for five hours at 100° (Hofmann, B. 18, 2756). Trimetric tables, v. sl. sol. water, v. sol. alcohol. Boiling conc. HClAq forms MeSH, cyanuric acid, and  $\text{NH}_3$ .—B'HAUCl<sub>2</sub>. Needles.

Ethyl ether EtA'. [113°]. Formed by heating tri-thio-cyanuric ether with alcohol  $\text{NH}_3$  at 180° (Klason, J. pr. [2] 33, 298). Trimetric prisms. Converted by acids into ammeline.

Isoamyl ether ( $\text{C}_5\text{H}_{11}$ )<sub>2</sub>A'. [82°].

Di-thio-methyl-ammeline di-methyl ether  $\text{Cy}_2(\text{NHMe})(\text{SMe})_2$ , [175°]. Formed by heating  $\text{Cy}_2(\text{SMe})_2$  with aqueous  $\text{NMeH}_2$  (Hofmann, B. 18, 2761). Needles or prisms (from dilute alcohol).

THIO-AMMELINE  $\text{C}_6\text{H}_5\text{N}_2\text{S}$  i.e.

$\text{C}(\text{SH}) \langle \text{N.C}(\text{NH}_2) \rangle \text{N}$ . S. 77 at 100° (K.).

Formed by adding HCl to an aqueous solution of dicyan-diamide and ammonium sulphocyanide at 100° (Rabke, B. 18, 3106; 20, 1059; 23, 1675). Formed also from  $\text{C}_6\text{H}_5(\text{NH}_2)_2\text{Cl}$  and KSH (Klason, J. pr. [2] 33, 296) and by heating  $\psi$ -sulphocyanogen with conc.  $\text{NH}_4\text{Aq}$  at 100° (Ponomareff, C. R. 80, 1384). Needles, sl. sol. hot water, v. sol. acids and alkalis. Yields a canary-yellow pp. on boiling with ammoniacal  $\text{CuSO}_4$ . Conc. HClAq at 130° yields cyanuric acid,  $\text{H}_2\text{S}$ , and  $\text{NH}_3$ . Ethylenobromide forms crystalline  $\text{C}_6\text{H}_5\text{N}_2\text{SHBr}$ . Conc.  $\text{NH}_4\text{Aq}$  at 200° forms melamine. Boiling NaOH aq yields ammeline. Ammoniacal silver nitrate ppts.  $\text{C}_6\text{H}_5\text{N}_2\text{SAg}$  and  $\text{C}_6\text{H}_5\text{N}_2\text{SAg}_2$ . Bromine added to a solution of thio-ammeline in  $\text{HBrAq}$  forms  $\text{S}_2(\text{C}_6\text{H}_5\text{N}_2)_2$ , which dissolves in alkalis, and is split up by boiling with acids into ammeline, thio-ammeline, and S.

Salts.—Et'NO<sub>2</sub>. Needles.—B'H<sub>2</sub>SO<sub>4</sub> 3 aq.—B'H<sub>2</sub>CO<sub>2</sub> aq. Needles, v. sl. sol. cold water.

Methyl ether MeA'. [268°]. Formed by heating tri-methyl tri-thiocyanurate for five hours with conc. alcoholic  $\text{NH}_3$  at 160° (Hofmann, B. 18, 2757). Tables (from water).—B'H<sub>2</sub>PtCl<sub>4</sub>.

Ethyl ether EtA'. [165°].

Isoamyl ether  $\text{C}_5\text{H}_{11}\text{A}'$ , [178°].

Reference.—TRI-PHENYL-THIO-AMMELINE.

THIO-ANILINE v. DI-AMIDO-DI-PHENYL SULPHIDE.

THIOANISOIC ACID (so called)  $\text{C}_6\text{H}_4\text{SO}_4$ . Got by boiling anethol with  $\text{HNO}_3$  (S.G. 1-1), distilling the product and shaking the fraction 215°-245° with conc.  $\text{NaHSO}_4\text{Aq}$  and some alcohol (Städeler a. Wächter, A. 116, 163). Crystalline (containing 2 aq), v. e. sol. water, alcohol, and ether.— $\text{NH}_4\text{A}'$  aq.— $\text{NaA}'$  aq. S. 15 in the cold.— $\text{BaA}'$  3 aq. S. 8-5 in the cold.— $\text{CaA}'$  2 aq.— $\text{MgA}'$  5 aq.— $\text{AgA}'$ . Plates, m. sol. water.

THIOBENZAMIDE v. Amide of THIOBENZOIC ACID.

(a)-THIO-BENZOIC ACID  $\text{C}_6\text{H}_4\text{CO.SH}$ . Mol. w. 138. [c. 24°].

Formation.—1. From BzCl and alcoholic K.S. (Engelhardt a. Tatschinoff, Z. [2] 4, 853).—2. By boiling EtOBz, PhOBz, and Bz<sub>2</sub>O with alcoholic KSH.

Properties.—Yellow oil or white crystalline mass with unpleasant smell, volatile with steam. Decomposed by distillation. V. sol. alcohol and

ether. Its solutions, when exposed to air, deposit crystals of  $Bz_2S_2$ . Nitric acid also oxidises it to benzoyl disulphide. A neutral solution gives with  $CuSO_4$  a greenish-yellow pp., turning bright red; the pp. then containing  $Bz_2S_2$ .

**Salts.**— $KA'$ . Large prisms (from alcohol), v. sol. water.— $NaA'$ .— $BaA'$ , aq. Laminæ (from alcohol).— $PbA'$ .— $AgA'$ . Yellowish-white pp.

**Methyl ether**  $C_6H_5COSMe$ . (232°). Formed from  $Pb(SMe)_2$  and  $BzCl$  (Obermeyer, B. 20, 2922).

**Ethyl ether**  $EtA'$ . (243°). Formed by the action of  $BzCl$  on  $Pb(SET)_2$  in presence of ether (Tütschelt, *Petersb. Acad. Bull.* 5, 295), and got also by boiling  $AgA'$  and  $EtI$ , and from  $PhOBz$  and  $NaSEt$  (Seiffert, *J. pr.* [2] 31, 471). Oil, with unpleasant smell, sol. alcohol and ether. Boiling alcoholic KOH forms  $KOBz$  and  $KSEt$ . Alcoholic KSH yields  $KSBz$  and  $KSEt$ . Oxidised by  $AgMnO_4$  to benzoic and ethane sulphonic acids (Beckmann, *J. pr.* [2] 17, 461).

**Isoamyl ether**  $C_5H_{11}A'$ . (271°).

**Phenyl ether**  $PhS.Bz'$  [56°]. Formed from phenyl mercaptan and  $BzCl$  (Schiller a. Otto, B. 9, 1635). Needles (from benzene).

**Di-nitro-phenyl ether**  $C_6H_3(NO_2)_2A'$ . [118°]. Formed from (a)-chloro-m-di-nitro-benzene, alcoholic KSH, and  $BzCl$  (Willgerodt, B. 18, 328). Needles (from alcohol).

**Benzyl ether**  $C_6H_5A'$ . [39.5°]. Formed from benzyl mercaptan and  $BzCl$  (Otto a. Lüders, B. 13, 1285). Triclinic crystals, yielding  $PhCH_2SO_2H$  on oxidation.

**p-Tolyl ether**  $C_6H_4A'$ . [75°] (S. a. O.).

**Anhydride v. BENZOYL SULPHIDE.**

( $\beta$ )-Thio-benzoic acid  $C_6H_4CS.OH$ . Formed by boiling thiobenzoic aldehyde with nitric acid (S.G. 1.3) (Fleischer, A. 140, 234). Needles (containing  $\frac{1}{2}$  aq), sol. alcohol and benzene. More sol. hot water than benzoic acid. When heated strongly it blackens without melting.— $BaA'$ , 4 aq. \* Small nodules, v. sol. water and ppd. by alcohol.

**Amide**  $C_6H_5CS.NH_2$ . **Thiobenamide**. [116°]. Formed by passing  $H_2S$  into an alcoholic solution of benzonitrile containing a little  $NH_3$ , and heating on a water-bath (Cahours, C. R. 27, 329; Bernthsen, B. 10, 1241; A. 192, 49; Gabriel a. Heymann, B. 23, 157). Formed also by heating benzylamine (2 mols.) with S (1 mol.) at 180° (Wallach, A. 259, 304). Long needles (from hot water). Decomposed by  $HgO$ , yielding  $HgS$  and benzonitrile. Sodium-amalgam acting on its alcoholic solution forms amorphous thiobenzoic aldehyde, benzonitrile, benzylamine, and benzoic aldehyde. Iodine added to its alcoholic solution reacts with formation of di-benzoyl-azo-sulphim

$C_6H_5C \begin{smallmatrix} N \\ \diagup \\ S \end{smallmatrix} C_6H_5$ , crystallising in long colourless needles [90°] converted by boiling  $H_2SO_4$  into a base  $C_6H_5N_2$  [71°], which yields  $B'H_2PtCl_4$  (Hofmann, B. 2, 645; B. 25, 1597; Wanzlat, B. 6, 335). Zinc and HCl reduce thiobenamide in alcoholic solution to benzylamine. Hydroxylamine forms  $C_6H_5C(NOH).NH_2$ . Ethylene bromide at 100° forms the compound  $C_6H_5(S.C(NH)C_6H_5)_2$  2HBr [233°] decomposed by boiling water into  $C_6H_5(SBz)_2$  (Gabriel a. Heymann, B. 24, 783). Chloral (1 mol.) forms, on warming, a compound  $C_6H_5Cl.NSO$  or  $C_6H_5CS.NH.CH(OH).CCl$  (?) crystallising in

silky plates [104°], sl. sol. water, v. sol. alcohol (Spica, G. 16, 182).

**Anilide**  $C_6H_5CS.NHPh$  or  $C_6H_5C(SH).NPh$ . **Thiobenanilide**. [102°]. Formed by the action of  $P_2S_5$  (1 pt.) on benzanilide (2 pts.), and by heating phenyl-benzamidide or s-di-phenyl-benzamidide  $CPh(NPh)(NPhH)$  with  $H_2S$  or with  $CS_2$  (Bernthsen, B. 11, 503; A. 192, 31). Formed also by passing  $H_2S$  into a solution of  $C_6H_5.CCl.NPh$  in benzene (Leo, B. 10, 2133), and from benzophenone oxim and  $P_2S_5$  (Dodge, A. 264, 184). Obtained by heating benzyl-aniline (1 mol.) with S (2 at.) at 220° as long as  $H_2S$  escapes (Wallach, A. 259, 301). Thin prisms (from  $EtOAc$ ), nearly insol. boiling water, v. sol. alcohol and ether. V. sol. KOHAq. Converted into benzanilide by heating with dry  $PbO$  or with alcoholic potash at 150°. Yields benzoyl-o-amido-phenyl-mercaptan on dry distillation, on heating with S, and also on treatment in alkaline solution with  $K_2FeCy_4$  (Jacobsen, B. 19, 1068). Hydroxylamine yields  $C_6H_5C(NOH).NHPh$ .

**o-Toluide**  $C_6H_4CS.NHC_6H_4Me$  [1.2]. [86°]. Formed by melting  $BzNHC_6H_4Me$  with  $P_2S_5$  (Stieglitz, B. 22, 3160). Yellow, six-sided prisms (from benzene). Hydroxylamine in alcohol forms, on heating,  $C_6H_4C(NOH).NHC_6H_4$  [147°], crystallising in needles.

**p-Toluide**. [129°]. Formed in like manner (Müller, B. 22, 2405), and also by the action of  $H_2S$  on  $C_6H_4.CCl.NC_6H_4$  (Leo, B. 10, 2134; Pfitzinger a. Gattermann, B. 22, 1065), and by heating p-tolyl-benzamidide with  $CS_2$  (Bernthsen a. Trompeter, B. 11, 1759). Long yellow needles, insol. water, v. sol. alcohol, ether, and NaOHaq.

**Xylide**  $C_6H_4CS.NHC_6H_4Me_2$ . [90°]. Formed by heating the benzoyl derivative of (4,2,1)-xylidine with  $P_2S_5$  (Gudeman, B. 21, 2552). Small needles (from alcohol). Oxidised by

$K_2FeCy_4$  to oily  $C_6H_4Me_2 \begin{smallmatrix} N \\ \diagup \\ S \end{smallmatrix} CPh$ .

**Di-phenyl-amide**  $C_6H_5CS.NPh_2$ . [151°]. Triclinic crystals (Bernthsen, A. 192, 37).

(a) **Naphthalide** v. vol. iii, p. 474.

**Di-thio-benzoic Acid**  $C_6H_4CS.SH$ . Formed by adding an alcoholic solution of  $K_2S$  to  $C_6H_5.CCl_2$  (Engelhardt a. Latschinoff, Z. [2] 4, 455; Klinger, B. 15, 862). Heavy, red oil, v. sol. alcohol and ether. Its dilute ethereal solution is crimson. Resinifies when exposed to air.— $PbA'$ . Thin orange-red needles (from alcohol or xylene).— $HgA'$ . Golden plates (from alcohol).— $AgA'$ . Brown pp., insol. water and benzene.

**References.**—OXY-THIO-BENZOIC ACID and AMIDO-THIO-BENZAMIDE.

(a) **THIO-BENZOIC ALDEHYDE**  $C_6H_5CHS$ . **Benzylidene sulphide**. Formed by passing  $H_2S$  into an alcoholic solution of benzoic aldehyde (Laurent, A. Ch. [3] 1, 292; Klinger, B. 9, 1895; 15, 863; Böttiger, B. 12, 1056), or of hydrobenzamide (Cahours, C. R. 25, 457). White amorphous powder, softening at 85°, decomposed at a higher temperature. Insol. water and cold alcohol, v. e. sol. benzene and chloroform. Does not combine with  $KHSO_4$  or  $HCl$ . Potash-fusion yields benzyl mercaptan. On heating with copper it forms  $CuS$  and s-di-phenyl-ethylene. Alcoholic KSH on heating forms  $Ph.CS.SK$  and di-benzyl disulphide. Thiogly-

sollic acid forms  $C_6H_5CH(S.OH.CO_2H)_2$  [124°] (Bongartz, *B.* 21, 479).

( $\beta$ )-Thio-benzoic aldehyde  $(C_6H_5.CHS)_2$  [225°]. Formed from the ( $\alpha$ )-isomeride by treatment with  $AcCl$ ,  $EtI$ , or a little iodine in benzene (Klinger, *B.* 10, 1877). Prepared by passing  $H_2S$  into a mixture of benzoic aldehyde and alcoholic  $HCl$  (Baumann a. Fromm, *B.* 22, 2604). Needles. Crystallises from benzene as  $(C_6H_5)_2C_2H_4$ , and gives off its benzene at 130°-140°. V. sol. hot  $HOAc$ , m. sol. alcohol. On heating with copper-powder it yields  $CuS$  and di-phenyl-ethylene. An oily compound  $(C_6H_5)_2H_2S$  is formed, together with benzyl disulphide and di-thio-benzoic acid, by the action of alcoholic  $KSH$  on benzylidene chloride (Klinger, *B.* 15, 864). This compound yields benzoic acid on treatment with dilute  $HNO_3$ .

( $\gamma$ )-Thio-benzoic aldehyde  $C_6H_5.CHS$ . [167°]. Occurs in the benzene mother-liquor in the preparation of the ( $\beta$ )-isomeride (*B.* a. F.). Small pointed needles, much more sol. benzene and chloroform than the ( $\beta$ )-modification, sl. sol. alcohol and ether. Its crystals do not contain benzene of crystallisation. By adding iodine to its solution in benzene it is changed to the ( $\beta$ )-isomeride.

Thio-benzoic orthaldehyde  $C_6H_5.CH(SH)_2$ .

Methyl ether  $C_6H_5.CH(SMe)_2$ . Formed by passing  $HCl$  into a mixture of benzoic aldehyde and  $MeSH$  (Bongartz, *B.* 21, 487). Oil. Oxidised by  $KMnO_4$  to  $C_6H_5.CH(SO_2CH_3)_2$  [163°].

Ethyl ether  $C_6H_5.CH(SET)_2$ . Oil (Baumann, *B.* 18, 885).

*p*-Bromophenyl ether  $C_6H_4Br.CH(SC_2H_5)_2$ . [80°]. Silky needles (Baumann, *B.* 18, 885).

Reference.—NITRO-THIO-BENZOIC ALDEHYDE.

THIO-BENZOPHENONE  $C_6H_5.CS.C_6H_5$ .

Formed by heating  $CSCl_2$  (5g.) with benzene (25 g.) and  $AlCl_3$  (9 g.) (Bergreen, *B.* 21, 337). Reddish-brown oil, v. sol. ether, benzene, and hot alcohol. Decomposed by distillation. Reacts with hydroxylamine, forming  $Ph_2C:NOH$  and with phenyl-hydrazine, with production of  $CPh_2.N_2.HPh$ .

Thio-benzophenone  $(CSPH_5)_2$ . [146-5°].

Formed from  $CCL_2Ph_2$  and  $K_2S$  (Engler, *B.* 11, 922). Small white needles. Converted by  $CrO_3$  and  $HOAc$  into benzophenone. Does not react with hydroxylamine or phenyl-hydrazine.

THIO-BENZOYL-( $\alpha$ )-NAPHTHYLAMINE v. vol. iii. p. 474.

THIOBENZPINACONE  $C_{20}H_{12}S$ , i.e.

$CPh_2(SH).CPh_2(SH)$  or  $CPh_2I.S.CPh_2I$ . [151°]. Formed from benzophenone by the action of alcoholic ammonium sulphide (Engler, *B.* 11, 922) or  $P_2S_5$  (Japp a. Roschen, *C.* J. 49, 479), and, together with thiobenzophenone, by the action of  $KSH$  on  $C_6H_5.CCl_2.C_6H_5$  (Behr, *B.* 5, 970). Formed also by the action of alcoholic  $KSH$  on  $(C_6H_5)_2CHCl$ , and of  $P_2S_5$  on di-phenyl-carbinol. Slender needles (from alcohol), v. sol.  $CS_2$ . In alcoholic solution it is converted by finely-divided copper into tetra-phenyl-ethane  $CHPh_2.CHPh_2$ .

THIO-BIURET  $C_8H_8N_2OS$ . Formed by boiling carbimido-urea ('amidodicyanic acid') with ammonium sulphide (Wunderlich, *B.* 19, 452). Needles (containing aq.). Sol. hot water and alkalis, v. sl. sol. ether. Gives a white pp

Vol. IV.

with copper salts. By ammoniacal  $AgNO_3$  it is converted back into carbimido-urea.

THIO-BUTYRIC ACID  $C_4H_7SO$ , i.e.

$CH_3.CH_2.CH_2.CO.SH$ . (130°). Formed by distilling butyric acid with  $P_2S_5$  (Ulrich, *A.* 109, 280). Liquid with disgusting smell, v. sl. sol. water, v. sol. alcohol— $PbA_2$ . Small crystals (from hot water).

Thio-isobutyric acid. Methyl ether  $C_4H_9SO$ , i.e.  $Pr.CO.SMe$ . (c. 142°). V.D. 57.5. Formed from  $Pb(SMe)_2$  and isobutyryl chloride (Obermeyer, *B.* 20, 2922). Oil.

THIO-ISOBUTYRIC ALDEHYDE  $Pr.CHS$ . (70°-90°). A product of the action of  $S$  on isobutyric aldehyde at 180° (Barbaglini, *G.* 18, 85). Oil.

( $\alpha$ )-THIO-CARBAMIC ACID  $NH_2.CO.SH$ . This acid, set free by adding acids to a solution of its ammonium salt, splits up at once into  $COS$  and ammonia. The ammonium salt  $NH_4.CO.SNH_4$  is prepared by passing gaseous  $COS$  into alcoholic  $NH_3$  (Berthelot, *J.* 1868, 160) or into  $NH_4Aq$  at 0° (Schmidt, *B.* 10, 191; Kretschmar, *J. pr.* [2] 7, 474). It forms colourless crystals, v. c. sol. water, m. sol. alcohol, insol. ether. The dry salt becomes yellow in air, forming ammonium sulphocyanide. The dry salt forms thio-urea when heated in a sealed tube at 135°. Thio-urea is also formed when  $Pb(OH)_2$  is added to its cold aqueous solution.  $HgO$  forms, in the cold, ammonium cyanate (Fleischer, *B.* 9, 438). Water at 100° forms  $NH_4SH$  and  $(NH_4)HCO_3$ .  $FeCl_3$  gives a red liquid, and finally a red pp. (Mulder, *A.* 168, 228).

Methyl ether  $NH_2.CO.SMe$ . [c. 98°]. Formed, together with a small quantity of the ( $\beta$ )-isomeride, by adding  $HCl$  to a solution of potassium sulphocyanide in boiling  $MeOH$  (Blankenhorn, *J. pr.* [2] 16, 375). Monoclinic prisms (from ether). Decomposed by alcoholic  $NH_3$  into  $MeSH$  and urea. Aniline at 100° forms  $MeSH$ , *s*-di-phenyl-urea and  $NH_3$ .

Ethyl ether  $NH_2.CO.SET$ . [102°] (Pinner, *B.* 14, 1083); [108°] (F.). Formed in like manner (*B.*) and also by passing  $NH_3$  into  $Cl.CO.SET$  (Salomon, *J. pr.* [2] 7, 256) and by the action of  $EtI_3$  on  $NH_2.CO.SNH_4$  (Fleischer, *B.* 9, 991). Plates, v. sol. hot water, alcohol, and ether. Decomposed at 150° into mercaptan and cyanuric acid.  $P_2O_5$  converts it into ethyl sulphocyanide.

Isoamyl ether  $CO(NH_2).SC_5H_{11}$ . [107°]. From  $CO(SC_5H_{11})Cl$  and  $NH_3$  (Schöue, *J. pr.* [2] 32, 247). Glittering plates (from ether). Sol. hot water, but decomposed by boiling water. Gives amorphous pps., insol. water, alcohol, and ether with  $AgNO_3$ ,  $HgCl_2$  and  $PtCl_4$ .

Reactions.—Alcoholic  $NH_3$  forms urea and amyl mercaptan.—2. Alcoholic  $KOH$  forms  $K_2CO_3$ ,  $NH_3$ , and amyl mercaptan.—8. Heated with aniline it forms  $NH_3$ ,  $HSC_5H_{11}$ , and di-phenyl-urea.

( $\beta$ )-Thio-carbamic acid  $NH_2.CO.SH$ .

Methyl ether  $NH_2.CO.SOMe$ . [43°]. Formed by the action of alcoholic  $NH_3$  on  $MeO.CO.SMe$  or on  $MeO.CO.SET$  (Salomon, *J. pr.* [2] 8, 115).

Ethyl ether  $NH_2.CO.OEt$ . Xanthogenamide. [38°]. Formed by the action of  $NH_3$  on xanthogenic ether  $EtS.CO.OEt$ , on  $MeS.CO.OEt$ , and on  $(EtO.CO)_2S_2$  (Debus, *A.* 72, 1; 75, 121; 82, 259; Y Y

Chance, *J.* 1851, 513; Salomon a. Maintz, *J. pr.* [2] 8, 114). Monoclinic prisms, sl. sol. water, miscible with alcohol and ether. Decomposed on distillation into mercaptan and cyanic acid. Boiling KOHAq resolves it into alcohol and potassium sulphocyanide.  $P_2O_5$  forms ethyl sulphocyanide (Coprari, *J. pr.* [2] 10, 34). Nitrous acid passed into water containing xanthogenamide, in solution forms crystalline  $C_2H_5N_2SO_3$ .  $CuSO_4$  followed by HClAq ppts.  $C_2H_5NOSCuCl$  as a white crystalline powder, nearly insol. water, sol. hot alcohol. Compounds of  $CuCl$  with 2, 3, and 4 mols. of xanthogenamide may be obtained. KI added to a boiling alcoholic solution of  $(C_2H_5NOS)_2CuCl$  forms crystals of  $(C_2H_5NOS)_2CuI$  and  $(C_2H_5NOS)_2CuI$ . Compounds  $(C_2H_5NOS)_2CuSCy$  and  $C_2H_5NOSCuSCy$  may also be prepared (Debus). Isovaleric aldehyde in presence of HCl and alcohol forms  $C_2H_5CH(NH.CS.OEt).108^\circ$  (Bischoff, *B.* 7, 1083).  $\beta$ -Iodo-propionic acid forms  $NH_2.CO.S.CH_2.CH_2.CO_2H$  [147-5], which yields  $CaA_2.3aq$ ,  $BaA_2.2aq$ , and  $Ag_2A$  (Tänglet, *B.* 24, 3849).  $\beta$ -Iodopropionic acid and  $Ac_2O$  yield sinapane propionic acid  $CO<\underset{NH.CO}{S}-CH_2>CH_2$  [159°], v. sol. hot water, converted by  $H_2O$  into the mercaptide of  $\beta$ -thiolactic acid.

*Isobutyl ether*  $NH_2.CS.OCH_2Pr$ . [36°]. Tables (from alcohol or ether) (Mylus, *B.* 5, 976; Blankenhorn, *J. pr.* [2] 16, 380).

*Isoamyl ether*  $NH_2.CS.OOC_2H_5$ . Oil (Johnson, *C. J.* 5, 242).

**Di-thio-carbamic acid**  $NH_2.CS.SH$ . Mol. w. 93. The ammonium salt  $NH_4.CS.SNH_4$  is formed by passing  $NH_3$  (from 150 pts.  $NH_4Cl$ ) into 95 p.c. alcohol (600 pts.) containing  $CS_2$  (96 pts.) (Mulder a. Bettink, *J. pr.* 103, 178; cf. Zeise, *A.* 48, 95; Debus, *A.* 73, 26). It is also formed by heating  $(NH_4)_2CS_3$ . On gradually adding HClAq to a cooled conc. solution of the ammonium salt the free acid separates as colourless needles, v. sol. water, alcohol, and ether; acid in reaction. An alcoholic solution of the acid gradually decomposes into  $CS_2$  and the  $NH_4$  salt. An aqueous solution of the acid decomposes on heating into  $H_2S$  and  $H_2CS_3$ . The di-thio-carbamates also split at  $100^\circ$  into  $H_2S$  and sulphocyanides. An alcoholic solution of iodine decomposes  $NH_4.CS.SNH_4$  forming  $EtNCs$  and  $EtNH_2$  (Hofmann, *Z.* [2] 5, 671). Ammoniac di-thio-carbamate treated with HCl and solution of I gives crystals of the bisulphide  $S_2(CS.NH_2)_2$  (Klason, *J. pr.* [2] 36, 62).  $FeCl_3$  added to a solution of the  $NH_4$  salt gives a black pp. turned white by excess.  $AgNO_3$  gives a yellow pp., turning black. A solution of aldehyde forms carbothialdine  $2NH_4.CS.SN(C_2H_5)_2$ . Benzoic aldehyde, isovaleric aldehyde, and acrolein form analogous bodies.

**Salts.**— $NH_4A$ . Deliquescent lemon-yellow prisms. On heating with KOHAq it forms  $K_2S$ ,  $KSCy$ , and  $NH_3$ .— $CuA_2$ . Yellow powder, insol. water.— $PbA_2$ . White pp., blackening on boiling with water.— $ZnA_2$ : white pp.

*Ethyl ether*  $NH_2.CS.SET$ . Mol. w. 121. [42°]. Formed by passing  $H_2S$  under pressure into ethyl sulphocyanide at  $100^\circ$  (Jeanjean, *J.* 1866, 501; Salomon a. Conrad, *J. pr.* [2] 10, 29). Trimetric crystals (from ether), insol. water, v. sol. alcohol. Alcoholic  $NH_3$  or KOHAq in the

cold forms mercaptan and ammonium sulphocyanide.

*Isopropyl ether*  $NH_2.CS.SPr$ . [97°]. Trimetric plates (Gerlich, *A.* 178, 82).

*Acetyl derivative of the ethyl ether*  $NHAc.CS.SET$ . [123°]. Formed by heating thio-acetic acid with ethyl sulphocyanide (Chalaroff, *B.* 15, 1987). Yellow needles (from alcohol), v. sol. hot water. Decomposed by distillation into thio-acetic acid and ethyl sulphocyanide. Boiling baryta-water forms mercaptan and acetic acid. Hot dilute HClAq forms  $NH_2.CS.SET$ .

**Isothiocarbamic ether v. Di-ethyl-(a)-thio-carbonate.** *Amide.*

**THIO-CARBAMIDE v. THIO-UREA.**

**THIOCARBAMYL SULPHIDE**  $C_2H_5N_2S_2$ , i.e.  $(NH_2.CS)_2S$  (?) Very unstable oil, got by adding HCl to its ammonium salt. Quickly decomposes into  $CS_2$ , sulphur,  $H_2S$ , and ammonium sulphocyanide. The ammonium salt  $C_2H_5(NH_2)_2N_2S_2$  is a product of the action of  $CS_2$  on alcoholic  $NH_3$  in the cold (Zeise, *B. J.* 4, 98; Hlasiwetz a. Kachler, *A.* 166, 137). It forms colourless prisms, v. sol. water, m. sol. alcohol, sl. sol. ether. The moist salt slowly decomposes into  $H_2S$  and ammonium sulphocyanide. The cupric salt  $CuO_2.C_2H_5N_2S_2$  is canary-yellow.

**Thiocarbamyl disulphide**  $C_2H_5N_2S_2$ , i.e.  $(NH_2.CS)_2S_2$ . Formed by the action of Cl on a solution of the ammonium salt of the preceding body, and on ammonium di-thio-carbamate (Debus, *A.* 73, 27). Petri plates, v. sol. hot alcohol, insol. water. Decomposed by boiling water into  $CS_2$ , ammonium sulphocyanide, and S.

**THIOCARBIMIDES.** *Mustard oils.* Compounds  $RN:CS$ . Essential oil of mustard is allyl thiocarbimide. They are formed by the action of  $CSCl_2$  on primary amines (Latilke, *A.* 167, 218), and by the action of aqueous  $HgCl_2$  on the dithiocarbamates  $RNH.CS.SNH_2R$  obtained by heating primary amines with  $CS_2$  and alcohol or ether (Hofmann, *B.* 1, 171; 2, 452; 7, 811; 8, 106; Rudneff, *J. R.* 10, 188). Methyl sulphocyanide is partially converted into methyl thiocarbimide by heating at  $180^\circ$ . Allyl sulphocyanide changes to the mustard oil on boiling. Thiocarbimides are also got by distilling alkyl cyanates with  $P_2S_5$  (Michael a. Palmer, *Am.* 6, 258). The thiocarbimides are pungent oils. They are reduced by Zn and HClAq to amines and  $CH_3S$ , whereas sulphocyanides yield  $HCy$ , mercaptans, and other products. Amines convert thiocarbimides into thio-ureas; thus aniline combines with phenyl thiocarbimide, forming *s*-di-phenyl-thio-urea. Alcoholic potash, or alcohol at  $100^\circ$  forms thio-carbamic ethers  $NH.R.CS.OEt$  (Hofmann, *B.* 2, 117; Schiff, *B.* 9, 1316). Water at  $200^\circ$ , or HClAq at  $100^\circ$ , forms amine,  $CO_2$ , and  $H_2S$ , while with sulphocyanides it yields  $Et_2S$ ,  $CO_2$ , and  $NH_3$ . Conc.  $H_2SO_4$  forms amine and  $CO_2$ .  $HNO_3$  forms amine and  $CO_2$ ; whereas with the isomeric sulphocyanides it forms a sulphonic acid. Hydroxylamine unites with thiocarbimides, forming oxy-thio-ureas  $NH.R.CO.NH.OH$  (Tiemann, *B.* 22, 1939). Chlorine unites with  $PhN:CS$ , forming unstable  $(PhNCS)_2Cl_2$ , whence boiling water

forms  $(\text{PhNCS})_2\text{O}$  [118°], crystallising in yellow needles (Helmers, *B.* 20, 786).

**THIOCARBIMIDO-ACETIC ACID**  $\text{C}_6\text{H}_5\text{NCSO}_2$ , i.e.  $\text{CH}_2(\text{NCS})\text{CO}_2\text{H}$ . Formed by boiling thiohydantoin with  $\text{HClAq}$  (Volhard, *J. pr.* [2] 9, 6), and by boiling isoamyl sulphocynoacetate with fuming  $\text{HClAq}$  (Clässon, *B.* 10, 1352; Heintz, *A.* 186, 232). Trimetric plates, v. s. sol. hot water. Oxidised by  $\text{HNO}_3$  to  $\text{H}_2\text{SO}_4$  and oxalic acid. Weak acid.— $\text{BaA}'$  aq. Four-sided prisms, sl. sol. cold water. Benzoic aldehyde and  $\text{NaOHAq}$  (1 mol.) react, forming the compound  $\text{CHPh:C}(\text{CO}_2\text{Na})\text{S.CO.NH}_2$ , which crystallises with  $1\frac{1}{2}\text{aq}$  and is converted by  $\text{HCl}$  into  $\text{CO.S NH.CO} > \text{C:CHPh}$  [242°] (Andreasch, *M.* 10, 73).

**THIOCARBIMIDO-BENZOIC ACID** v. *m*-AMIDO-BENZOIC ACID.

#### THIOCARBONIC ACID.

Thiocarbonates v. vol. i. p. 703. The thiocarbonic ethers that have not been treated of in former articles are described below.

Methyl thiocarbonates v. vol. iii. p. 399.

Methyl iso-dithiocarbonate  $\text{CO}(\text{SMe})_2$  (169°). Formed by warming methyl sulphocyanide with  $\text{H}_2\text{SO}_4$  (Schmitt a. Glutz, *B.* 1, 166).

Ethyl thiocarbonates v. vol. ii. p. 520.

Ethylene thiocarbonates v. vol. ii. p. 493.

Ethylene di-ethyl di-thio-di-carbonate  $\text{C}_2\text{H}_4(\text{S.CO.Et})_2$ . Formed by heating  $\text{C}_2\text{H}_4\text{Br}_2$  with  $\text{KS.CO.Et}$  in alcohol (Welde, *J. pr.* [2] 15, 52). Thick oil, converted by alcoholic potash into  $\text{C}_2\text{H}_4(\text{SH})_2$  and  $\text{KO.CO.Et}$ .

Isobutyl di-thio-carbonic acid  $\text{CH}_3\text{Pr.O.CS.H}$ . Salts.— $\text{NaA}'$ . Formed from  $\text{C}_4\text{H}_9\text{ONa}$  and  $\text{CS}_2$ . Yellowish white needles, v. s. sol. water and alcohol.— $\text{KA}'$ . Needles (from alcohol). *S.G.* 1.371 (Clarke, *B.* 11, 1505). Chlorine gas passed into its aqueous solution forms oily  $(\text{CH}_3\text{Pr.O.CS})_2\text{S}_2$  (Mylius, *B.* 5, 976).

Ethyl ether  $\text{EtA}'$ . (228°).

Isobutyl ether  $\text{CH}_3\text{Pr.O.CS.SCH}_3\text{Pr}$ . (249°). *S.G.* 1.009 (Mylius, *B.* 5, 975).

Isoamyl ether  $\text{CH}_2\text{Pr.O.CS.SC}_2\text{H}_5$ . (265°–270°) (Mylius).

Isoamyl di-thio-carbonic acid

$\text{C}_4\text{H}_9\text{O.CS.SH}$ . Oil, with unpleasant smell.

Salts.— $\text{KA}'$ . Formed from fusel oil,  $\text{KOH}$ , and  $\text{CS}_2$  (Balard, *A. Ch.* [3] 12, 307; Erdmann, *J. pr.* 31, 4; Desains, *A. Ch.* [3] 20, 505; Johnson, *C. J.* 5, 142). Gives a lemon-yellow pp. with  $\text{CuSO}_4$ — $\text{PbA}'$ . Plates. Iodine forms oily  $(\text{C}_4\text{H}_9\text{O.CS})_2\text{S}_2$ .

Di-isoamyl s-di-thio-carbonate  $\text{CO}(\text{SC}_4\text{H}_9)_2$  (281°) (Schmitt a. Glutz).

Cetyl di-thiocarbonate v. vol. i. p. 728.

Isobutyl-tri-thio-carbonic acid  $\text{C}_4\text{H}_9\text{S.CS.H}$ . Formed from  $\text{C}_4\text{H}_9\text{SNa}$  and  $\text{CS}_2$  (Mylius, *B.* 6, 316). The  $\text{Na}$  salt crystallises in yellow needles, v. sol. alcohol and ether.

Isobutyl ether  $(\text{C}_4\text{H}_9\text{S})_2\text{CS}$ . (287°). Got by heating aqueous  $\text{K}_2\text{CS}_2$  with isobutyl iodide. Yellow oil with faint odour.

Di-isoamyl-tri-thiocarbonate  $(\text{C}_4\text{H}_9\text{S})_3\text{CS}$ . (247°). *S.G.* .88 (Husemann, *A.* 126, 297). Oil, with unpleasant smell.

Di-allyl tri-thio-carbonate  $(\text{C}_3\text{H}_5\text{S})_3\text{CS}$ . (170°–175°). *S.G.* .94. Formed from allyl iodide and  $\text{Na}_2\text{CS}_2$  in the cold (Husemann, *A.*

126, 269). Pungent yellow oil, with offensive odour.

**THIOCARBONYL-ACETOACETIC ETHER**  $\text{CS.CAc.CO.Et}$ . [156°–162°]. Formed from thiocarbonyl chloride and acetoacetic ether (Bergreen, *B.* 21, 747). Yellow needles, sl. sol. ether and ligroin.

**THIO-CARBONYL-DI-AMIDO-DI-BENZOIC ACID** v. *m*-AMIDO-BENZOIC ACID.

**THIOCARBONYL-BENZOYL-ACETIC ETHER**  $\text{CS.CBz.CO.Et}$ . [164°]. Formed from  $\text{CSCl}_2$  and benzoylacetate ether (Bergreen, *B.* 21, 351). Yellow needles, sol. alcohol-chloroform.

**THIO-CARBONYL CHLORIDE** v. Sulphochloride of Carbon.

Thio-carbonyl tetrachloride v. PER-CHLOROMETHYL-MERCAPTAN.

**THIO-CARBONYL-ETHYL-O-AMIDO-**

**PHENOL**  $\text{C}_6\text{H}_5\text{N} < \text{O} > \text{CS}$ . [112°]. (above

300°). Formed from ethyl-o-amido-phenol and  $\text{CSCl}_2$  (Seidel, *J. pr.* [2] 42, 449, 457). Insol. water and dilute  $\text{NaOHAq}$ , m. sol. cold alcohol.  $\text{HClAq}$  at 170° forms ethyl-amido-phenol,  $\text{CO}_2$ , and  $\text{H}_2\text{S}$ .  $\text{PCl}_5$  yields  $\text{C}_6\text{H}_5\text{N} < \text{O} > \text{CCl}_3$ .

**THIO-CARBONYL-METHYL-AMIDO-**

**PHENOL**  $\text{C}_6\text{H}_5\text{N} < \text{O} > \text{CS}$ . [128°]. (above

300°). Formed by the action of  $\text{CSCl}_2$  on methyl-o-amido-phenol (Seidel, *J. pr.* [2] 42, 452). Needles, insol. water, sl. sol. cold alcohol.

**THIO-CARBONYL-DI-(β)-NAPHTHYL-**

**THIO-UREA**  $\text{C}_{10}\text{H}_7\text{N} < \text{CS} > \text{S}$ . [152°].

Formed from di-(β)-naphthyl-thio-urea and  $\text{CSCl}_2$  in benzene (Freund a. Wolf, *B.* 25, 1466). Stellate groups of needles, m. sol. hot benzene. Melts at 152° with evolution of gas, forming a solid melting at 224°.

**THIO-CARBONYL-DI-p-TOLYL-THIO-UREA**

$\text{C}_7\text{H}_7\text{N} < \text{CS} > \text{CS}$ . [103°]. Formed from di-p-tyl-thio-urea [172°] and  $\text{CSCl}_2$  in ether (Freund a. Wolf, *B.* 25, 1465). Yellowish needles, v. sol. hot alcohol and ether. Converted by  $\text{HgO}$  into carbonyl-di-tyl-thio-urea [112°].

**THIOCHRONIC ACID**  $\text{C}_6\text{H}_4\text{S.O}_2$ , i.e.

$\text{C}_6(\text{OH})(\text{SO}_2\text{H})(\text{SO}_2\text{H})_2$ . • *Di-ox-y-quinone disulphonic acid*. Formed by boiling thiochronic acid with  $\text{KOH}$ . Deliquescent yellow needles, v. sol. water and alcohol. Reduced by tin and  $\text{HClAq}$  to  $\text{C}_6\text{H}_4\text{S.O}_2$ , which yields  $\text{Na}_2\text{A}'$  2aq and  $\text{KA}'$  2aq, which are re-oxidised in aqueous solution by air to euthiochronates.— $\text{Na}_2\text{A}'$  aq (dried at 150°).— $\text{KA}'$  2aq. Minute lemon-yellow prisms, v. sol. water.— $\text{KA}'$  aq. Small orange-red four-sided prisms.— $\text{Ba}_2\text{A}'$  4aq. Ochre-yellow pp.— $\text{Ag}_2\text{A}'$ : amorphous pp.

(a) **THIO-CINNAMIC ACID**  $\text{C}_6\text{H}_5\text{SO}$  i.e.  $\text{C}_6\text{H}_5\text{CH:CH.CO.SH}$ . Formed from cinnamoyl chloride and  $\text{Pb}(\text{SEt})_2$ , the resulting oily ether

being boiled with alcoholic KSH (Engelhardt, *Z.* [2] 4, 359).—KA'. Crystalline.

(8). **Thio-cinnamic acid**. *Amide*  $C_9H_7S.NH_2$ . [112°]. Formed by passing  $H_2S$  into a solution of cinnamic nitrile in alcoholic  $NH_3$  (Rossum, *Z.* 1866, 362; Krüss, *B.* 17, 1768). Golden plates.

(a). **THIO-CINNAMIC ALDEHYDE** ( $C_9H_7S$ ). [167°]. Formed by passing  $H_2S$  into oil of cinnamon dissolved in alcoholic HCl (Baumann & Fromm, *B.* 24, 1452). Crystalline, v. e. sol. benzene, sl. sol. alcohol.

(8). **Thio-cinnamic aldehyde** ( $C_9H_7S$ ). [213°]. Formed at the same time as the (a)-isomeric. Prisms, v. sl. sol. cold benzene and alcohol.

**Thio-cinnamic orthoaldehyde**. *Phenyl ether*  $C_6H_5.CH:CH.CH(SPh)_2$ . [81°]. Formed by passing dry HCl into a mixture of cinnamic aldehyde and phenyl mercaptan (Baumann, *B.* 18, 885). Needles (from ligroin).

*p*-**Bromo-phenyl ether**.  $CHPh:CH.CH(S.C_6H_4Br)_2$ . [107°]. Needles (from alcohol or ether).

*Glycolyl ether*.  $CHPh:CH.CH(S.CH_2CO_2H)_2$ . [143°]. Formed from cinnamic aldehyde and thioglycolic acid (Bongartz, *B.* 21, 481). Plates (from water). Zinc-dust in alkaline solution converts it into  $CHPh:CH.CH_2S.CH_2CO_2H$  [77°], crystallising from dilute alcohol in plates.

**TRI-THIO-CITRIC ETHER**  $C_9H_7O(CO.SEt)_3$ . Formed from tri-phenyl citrate and NaSEt in presence of ether (Seiffert, *J. pr.* [2] 31, 470). Oil, smelling like mercaptan.

**THIO-COUMARIN**  $C_9H_6$ .  $\begin{array}{c} CH:CH \\ \diagdown \quad \diagup \\ O \quad CS \end{array}$ . [101°].

Formed by heating equal parts of coumarin and  $P_2S_5$  at 120°; the yield is 50 p.c. Also by heating o-coumaric acid with  $P_2S_5$ . Long yellow needles, v. sol. alcohol, ether, and benzene; insol. water. Sublimable. By heating with aqueous alcoholic KOH it is reconverted into coumarin. Unlike coumarin it readily reacts with hydroxylamine and with phenyl-hydrazine (Tiemann, *B.* 19, 1661).

**THIO-CRESOL** v. **TOLYL MERCAPTAN**.

**THIO-CROCONIC ACID**  $C_5H_4O_3S$ , probably  $SC \begin{array}{c} \diagup \quad \diagdown \\ C(OH).CO \\ \diagdown \quad \diagup \\ C(OH).CO \end{array}$ . Formed by saturating a warm solution of potassium croconate treated with 2 mols. of HCl, with  $H_2S$ .—BaA'' 2aq. brownish-yellow amorphous pp., v. sol. dilute HCl, which after some time changes to reddish-brown crystals with violet reflex, invol. dilute HCl (Nietzki & Benkiser, *B.* 19, 299).

**THIO-CUMINIC ACID**. *Amide*  $C_9H_7NS$  i.e.  $C_8H_7.C_6H_4.CS.NH_2$ . Formed by passing  $H_2S$  into a solution of cuminic nitrile in alcoholic  $NH_3$  (Czumpelik, *B.* 2, 185). Needles, v. sol. hot alcohol. Converted in alcoholic solution by iodine into  $C_{20}H_{12}N_2S$  [45°] crystallising in prisms (Wanstrat, *B.* 6, 322).

**THIOCYANDIAMIDINE** v. **GUANYL THIO-UREA**.

**THIOCYANIC ACID** v. **SULPHOCYANIC ACID**.

**THIOCYANO-** v. **SULPHOCYANO-**.

**DI-THIO-CYANURIC ACID**  $Cy_3(SH)_2(OH)aq$ .

*Preparation*.—An alcoholic solution of  $KCy_3$  is mixed with the calculated quantity of HCl, filtered from KCl, and evaporated at 40°. The residue is extracted with strong  $NH_4Aq$  and

$BaCl_2$  is added to the filtrate. The barium salt gradually separates in globular crystals (Klason, *J. pr.* [2] 33, 121). Yield, very small.

*Properties*.—White scales (from hot water). Sol.  $NaOHAq$ . A solution of the potassium salt gives pps. with  $AgNO_3$ ,  $HgCl_2$ , and  $Pb(OAc)_2$ .

*Reactions*.—1. Conc. HCl at 130° gives cyanuric acid and  $H_2S$ .—2. Cold  $KMnO_4Aq$  and hot  $HNO_3Aq$  form cyanuric acid.—3. Iodine forms\* ( $HO-Cy_3$ ) $_2S_4$  as a white crystalline powder.

*Salts*.— $KH_2A'''$ . Silvery mass of microscopic prisms.— $BaHA'''2aq$ .

**Tri-thio-cyanuric acid**  $Cy_3(SH)_3$ . Formed by warming powdered  $C_3N_3Cl_3$  (1 mol.) with conc. aqueous KSH (4 mols.) (Hofmann, *B.* 18, 2196; Klason, *J. pr.* [2] 33, 116). Minute prisms, when ppd. from dilute solutions; amorphous, from conc. solutions. Nearly insol. hot water, alcohol and ether. Not decomposed at 200°. FeCl<sub>3</sub> gives no colour in solutions of the acid, but in conc. solutions of the K salt it gives a white pp. and a yellow solution.

*Reactions*.—1.  $HClAq$  at 130° gives cyanuric acid and  $H_2S$ .—2. Alkaline  $KMnO_4$  at 20° gives cyanuric acid.—3. Warm  $HNO_3$  forms cyanuric acid.—4. At 360° it gives off  $CS_2$  and some  $HCyS$  and leaves nucleus  $C_6H_7N_6$ .

*Salts*.— $K_2A'''3aq$ .— $K_2HA'''6aq$ .— $NaH_2A'''$ . Crystals, v. sol. water.— $BaHA'''3aq$ . Yellow crystals, ppd. by addition of  $BaCl_2$  and  $NH_4Aq$ .— $BaH_2A'''2aq$ . Prisms, m. sol. water.— $SrHA'''5aq$ .— $CaHA'''5aq$ . Prisms, m. sol. water.

*Methyl ether*  $Me_3A'''$ . [189°]. Got by heating methyl sulphocyanide with a few drops of  $HClAq$  at 100° (Hofmann, *B.* 13, 1351; B. 18, 2197, 2755, 2774; 19, 2065). Hexagonal crystals. An alcoholic solution of ethylamine at 100° forms  $Cy_3(NH_2Et)(SMe)_3$  [114°] while at 140° it yields  $Cy_3(NH_2Et)_3SMe$  [84°]. Alcoholic  $NH_3$  forms, in like manner,  $Cy_3(NH_3)(SMe)_3$  and  $Cy_3(NH_3)_3SMe$ .

*Ethyl ether*  $Et_3A'''$ . [27°]. (350°). Formed from  $Cy_3Cl_3$  and NaSEt. Colourless tablets (from  $HOAc$ ) converted by alcoholic  $NH_3$  at 180° into  $Cy_3(NH_3)(SEt)_3$  [112°] (crystallising in trimetric forms; *abcb* = 669:1:391, v. sol. ether), accompanied by  $Cy_3(NH_3)_2(SEt)$  [165°], which is insol. ether (Klason, *J. pr.* [2] 33, 298).

*Amyl ether* ( $C_5H_{11}$ ) $_3A'''$ . Oil. Yields  $Cy_3(NH_3)(SC_5H_{11})_2$  [82°] and  $Cy_3(NH_3)_2SC_5H_{11}$  [178°].

*Phenyl ether*  $Ph_3A'''$ . [97°]. Prisms (from  $HOAc$ ).

*p*-**Tolyl ether** ( $C_7H_7$ ) $_3A'''$ . [114°].

**THIO-DI-ETHYL-ANILINE** v. **TETRA-ETHYL-DI-AMIDO-DI-PHENYL SULPHIDE**.

**THIO-ETHYL-COUMARIN**  $C_9H_6$ .  $\begin{array}{c} CH:CEt \\ \diagdown \quad \diagup \\ O \quad CS \end{array}$ .

[94°]. Formed by heating (a)-ethyl-coumarin with  $P_2S_5$  at 120° (Aldringen, *B.* 24, 5462). Yellowish-red plates, sol. alcohol. May be sublimed.

**THIO-ETHYLENE GLYCOL** v. **ETHYLENE MERCAPTAN**.

**THIO-FORMIC ACID**  $H.CO.SH$  (?) [120°]. Formed by the action of  $H_2S$  on lead formate (Wöhler, *A.* 91, 125; Limpricht, *A.* 97, 361), but not from  $P_2S_5$  and formic acid (Hurst, *A.* 126, 68). Small transparent crystals (from alcohol) with alliaceous odour, insol. water. May be sublimed. According to Nicol (*Pr. Z.* 10, 425) a solution of thioformic acid, got from

$\text{PbA'}$ , and  $\text{H}_2\text{S}$ , rapidly decomposes, yielding formic acid.

**Salts.**— $\text{H.CO.SK}$ . Formed from  $\text{CHCl}_3$  and alcoholic  $\text{K}_2\text{S}$  (Nicol, *T. E.* 29, 531). Needles, sol. water and alcohol, nearly insol. dilute alcohol.  $\text{AgNO}_3$  added to its aqueous solution forms a white pp., turning black on standing.  $\text{HNO}_3$  yields  $\text{S}$  and formic acid.  $\text{MgO}$  also gives formic acid.— $(\text{H.CO.S})_2\text{Pb}$ .

**Anilide**  $\text{H.CS.NHPh}$ . *Thioformanilide*. [137°]. Formed from dry phenyl carbamine and  $\text{H}_2\text{S}$  (Hofmann, *B.* 10, 1095, 1238). Formed also by passing dry  $\text{H}_2\text{S}$  over di-phenyl-formamidine  $\text{NPh:CH.NHPh}$  at 150° (Bernthsen, *A.* 192, 35). Prepared by warming formamidine (5 pts.) with  $\text{P}_2\text{S}_5$  (3 pts.), the yield being 60 p.c. of the theoretical (Hofmann, *B.* 11, 338). Thin plates (from water), partially decomposed on distillation into  $\text{H}_2\text{S}$  and phenyl carbamine. Its solution tastes bitter. Decomposed by hot  $\text{KOH}$  aq into aniline,  $\text{H}_2\text{S}$ , and formic acid. Heated in a sealed tube at 180° it yields  $\text{C}_6\text{H}_5\text{N}_2\text{S}$  [140°] v. sol. alcohol (Nicol, *B.* 15, 211).  $\text{NaOEt}$  and  $\text{EtBr}$  yield oily  $\text{CH}(\text{SEt})_2\text{NPh}$  (c. 235°) (Wallach & Wüsten, *B.* 16, 145).

***o*-Toluide**  $\text{H.CS.NHC}_6\text{H}_4$ , [96°]. Got by heating formyl-toluide with  $\text{P}_2\text{S}_5$  (Senier, *C. J.* 47, 762).

***p*-Toluide**. Yellow needles.

**Xylide**  $\text{HCS.NHC}_6\text{H}_4\text{Me}$ , [105°]. Small needles (from alcohol) (Gudeman, *B.* 21, 2549).

**Thio-orthoformic acid**. *Ethyl ether*  $\text{CH}(\text{SEt})_2$ . Formed by boiling chloroform with aqueous  $\text{NaSEt}$  (Gabriel, *B.* 10, 186; Claesson, *J. pr.* [2] 15, 174). Oil, with nasty smell, partly decomposed on boiling. Oxidised by  $\text{HNO}_3$  to ethane sulphonic acid. Fuming  $\text{HCl}$  aq yields formic acid and mercaptan.

**Benzyl ether**  $\text{CH}(\text{SC}_6\text{H}_5)_2$ , [98°]. Formed from  $\text{NaSC}_6\text{H}_5$  and chloroform (Dennstedt, *B.* 11, 2265). White crystals.

**Phenyl ether**  $\text{CH}(\text{SPh})_2$ , [39-5°]. Tri-metric tables. Oxidised by potassium permanganate to  $\text{PhS.CH}(\text{SO}_2\text{Ph})_2$  [176°] (Laves, *B.* 23, 1416; 25, 347).

**Reference.**—CHLOROFORMIC ACID.

#### THIO-FORMIC ALDEHYDES

**Thio-formic paraldehyde**  $(\text{CH}_2\text{S})_3$ . *Methyl-ene sulphide*. Mol. w. 138. [216°]. V.D. 5.08 (obs.).

**Formation.**—1. By heating  $\text{Na}_2\text{S}$  with methylene iodide (Hugemann, *A.* 126, 293).—2. By reducing  $\text{CS}_2$  with  $\text{Zn}$  and  $\text{HCl}$  aq (Girard, *A.* 100, 806).—3. By the action of  $\text{H}_2\text{S}$  on formic aldehyde or trioxymethylene.

**Preparation.**—By saturating a mixture of formic aldehyde (2 vols.) and conc.  $\text{HCl}$  aq (4 vols.) with  $\text{H}_2\text{S}$  (Baumann, *B.* 23, 67).

**Properties.**—Prisms, smelling like onions. Insol. cold water, sl. sol. alcohol and ether, in sol. benzene and  $\text{CS}_2$ . May be sublimed. Oxidised by  $\text{KMnO}_4$  to a trisulphone and also  $\text{C}_6\text{H}_5\text{S}_2\text{O}$ , crystallising in colourless needles. Forms:  $\text{C}_6\text{H}_5\text{S}_2\text{AgNO}_3$ .— $\text{C}_6\text{H}_5\text{S}_2\text{AgNO}_3$  2aq.— $\text{C}_6\text{H}_5\text{S}_2\text{HgCl}_2$ .— $(\text{C}_6\text{H}_5\text{S})_2\text{PbCl}_2$ .— $(\text{C}_6\text{H}_5\text{S})_2\text{PbCl}_2$  (Hofmann, *B.* 2, 152; 3, 584; Girard, *C. R.* 70, 625).

**Thio-formic orthaldehyde.**

**Ethyl ether**  $\text{CH}_2(\text{SEt})_2$ , (184°) (C.); (180°) (F.). S.G. 2.987. Formed from  $\text{CH}_3\text{I}$  and  $\text{NaSEt}$  (Claesson, *J. pr.* [2] 15, 176). Liquid

with unpleasant smell. Oxidised by  $\text{HNO}_3$  to ethane sulphonic acid.  $\text{KMnO}_4$  and  $\text{H}_2\text{SO}_4$  yield  $\text{CH}_3(\text{SO}_2\text{O})_2\text{H}$  (Fromm, *A.* 253, 155).

**Thio-formic metaldehyde**  $(\text{CH}_2\text{S})_n$ , [176°]. Formed, as a white amorphous substance, on warming an aqueous or alcoholic solution of hexamethylene-amine saturated with  $\text{H}_2\text{S}$  (Wohl, *B.* 19, 2341). Insol. most solvents. Decomposed when heated above its melting-point.

**Di-thio-formic paraldehyde**  $(\text{C}_2\text{H}_4\text{S}_2\text{O})_n$ , aq. *Dithioglyceric aldehyde*, [82°]. (180°-185°). Formed by passing  $\text{H}_2\text{S}$  into a solution obtained by electrolysis of dilute glycerin (Renard, *A. Ch.* [5] 17, 307). Amorphous waxy mass, sol. warm water, insol. alcohol and ether.

(a) **THIO-FURFURALDEHYDE**  $(\text{C}_5\text{H}_4\text{S}_2\text{O})_n$ , [128°]. Formed, together with the (β)-isomeride, by passing  $\text{H}_2\text{S}$  into a solution of furfuraldehyde (10 g.) in alcohol (100 c.c.) and  $\text{HCl}$  aq (20 c.c.) at -5° (Baumann & Fromm, *B.* 24, 3593). Crystals, v. o. sol. alcohol and chloroform, insol. water.

(β) **Thio-furfuraldehyde**  $(\text{C}_5\text{H}_4\text{S}_2\text{O})_n$ , [229°]. Needles, v. sl. sol. alcohol, v. sol. chloroform.

**Thio-furfuraldehyde**  $(\text{C}_5\text{H}_4\text{S}_2\text{O})_n$  ( $n=20$  to 24). Mol. w. (by Raoult's method) 2182. Formed by mixing an alcoholic solution of furfuraldehyde with alcoholic ammonium sulphide (Cahours, *A.* 69, 85; B. & F.). White crystalline powder, softens at 80° and is melted at 91°. Thiofurfuraldehyde is decomposed by warm aniline, yielding furfuraldehyde and  $\text{H}_2\text{S}$  (Schiff, *B.* 19, 2153).

#### THIO-GLYCERIN v. GLYCERIN

##### THIO-GLYCOL v. ETHYLENE MERCAPTAN

#### THIO-GLYCOLLIC ACID $\text{CH}_2(\text{SH})\text{CO}_2\text{H}$ . *Sulphydro-acetic acid*.

**Formation.**—1. By reducing the compound  $\text{ClSO}_2\text{CHCl.COCl}$  with tin and  $\text{HCl}$  aq (Siemens, *B.* 6, 659).—2. By adding  $\text{CH}_3\text{Cl.CO}_2\text{H}$  (1 mol.) to conc.  $\text{KSH}$  aq (2 mols.) (Claesson, *A.* 187, 113).—3. By the action of  $\text{H}_2\text{S}$  on glyoxylic acid in presence of  $\text{Ag}_2\text{O}$  (Böttger, *A.* 198, 215).—4. By boiling thiohydantoin with baryta-water (Andreassch, *B.* 12, 1385).—5. Together with  $\text{HSCy}$ , by the decomposition of rhodanic acid  $\text{C}_2\text{H}_4\text{NS}_2\text{O}$  with baryta-water (Ginsberg & Bondzynski, *B.* 19, 113).

**Properties.**—Oil, miscible with water, alcohol, and ether. Decomposes when quickly heated. Very dilute  $\text{FeCl}_3$  gives a fugitive indigo-blue colour, changed by a few drops of  $\text{NH}_4\text{Ac}$  to dark red and then to violet. Excess of  $\text{FeCl}_3$  oxidises it to di-sulphido-di-acetic acid  $\text{S}_2(\text{CH}_2\text{CO}_2\text{H})_2$ , which is also readily formed by atmospheric oxidation of the alkaline solution. A solution of the K salt added to  $\text{CuSO}_4$  gives a bluish-black pp. reduced by further addition of the K salt to the white cuprous salt  $\text{Cu}_2(\text{S.ClH}_2\text{CO}_2)_2$ .  $\text{HCl}$  passed through a mixture of thioglycollic acid and acetoacetic ether gives rise to crystalline  $\text{CO}_2\text{Et.CH}_2\text{CMe}(\text{S.CH}_2\text{CO}_2\text{H})_2$  [96°] (Bongartz, *B.* 21, 485). Acetyl-propionic acid forms, in like manner,  $\text{CO}_2\text{H.CH}_2\text{CH}_2\text{CMe}(\text{S.CM}_2\text{CO}_2\text{H})_2$  [151°]. Aldehydes react, forming the compound  $\text{CRH}(\text{S.CH}_2\text{CO}_2\text{H})_2$ , compounds which are produced either on standing, on warming, or on treatment with  $\text{ZnCl}_2$  or dry  $\text{HCl}$  (Bongartz, *B.* 19, 1981; 21, 479). Such compounds obtained by using acetyl, benzoic, cinnamic, *o*-oxy-benzoic, and *o*-, *m*-, and *p*-nitro-benzoic aldehydes melt at 108°, 124°, 146°, 149°, 123°, 130°, and 162° respec-

tively. Thioglycollic acid reacts with ketones in presence of  $\text{ZnCl}_2$  or  $\text{HCl}$ , forming acids  $\text{O}(\text{R})(\text{S}(\text{CH}_2\text{CO}_2\text{H})_2)$ ; such compounds obtained from acetone, acetophenone, and benzophenone melt at  $135^\circ$ ,  $139^\circ$ , and  $164^\circ$  respectively.

**Salts.**— $\text{KHA}$  "aq (from water).— $\text{KHA}$ " (from alcohol). Decomposes  $\text{K}_2\text{CO}_3$ , forming  $\text{H}_2(\text{SK})\text{CO}_2\text{K}$ .— $\text{BaA}$  "3aq: crystalline pp.— $\text{BaH}_2\text{A}$ ": gummy.— $\text{CdA}$  "— $\text{Hg}(\text{S}(\text{CH}_2\text{CO}_2\text{H})_2)$ . Needles or flat prisms, v. sol. hot water and alcohol.— $\text{Hg}_2(\text{S}(\text{CH}_2\text{CO}_2)_2)\text{BaH}_2$ . Minute crystals.— $\text{Hg}_2(\text{S}(\text{CH}_2\text{CO}_2)_2)\text{AlH}_2$ .— $\text{Hg}_2\text{MnH}_2\text{A}$  ".— $\text{HgPbA}$  ".— $\text{HgA}$  ".— $\text{PbA}$  ".— $\text{Bi}(\text{HA})$  ". [c.  $33^\circ$ ]. Yellow pp.— $\text{Cu}_2\text{H}_2\text{A}$  ". White pp.— $\text{Cu}_2\text{BaA}$  ".— $\text{Ag}_2\text{A}$  ".— $\text{Ag}_2(\text{NH}_4)\text{A}$  " ( $\text{NO}_3$ ).— $\text{Ag}_2\text{HgA}$  ".

**Ethyl ether**  $\text{EtA}$ . Formed by boiling thioglycollic acid with alcohol and a little  $\text{H}_2\text{SO}_4$  (Claesson, A. 187, 116). Oil with nasty smell. Slowly decomposed by boiling into  $\text{H}_2\text{S}$  and  $\text{S}(\text{CH}_2\text{CO}_2\text{Et})_2$ . Alcoholic  $\text{HgCl}_2$  ppts.  $\text{CHHg}(\text{S}(\text{CH}_2\text{CO}_2\text{Et})_2)$ , converted by excess of the ether into  $\text{Hg}(\text{S}(\text{CH}_2\text{CO}_2\text{Et})_2)$  (Wislicenus, A. 146, 145).

**Ethyl derivative**  $\text{CH}_2(\text{SEt})\text{CO}_2\text{H}$ . Formed by mixing  $\text{CH}_2\text{ClCO}_2\text{Et}$  with  $\text{NaSEt}$  and alcohol (Claesson, B. 8, 120). Liquid, v. sol. alcohol and ether, m. sol. water. Decomposed by heat, but may be distilled with steam.— $\text{KA}$  ".— $\text{BaA}$  ".— $\text{CaA}$  ".— $\text{MgA}$  "3aq.— $\text{ZnA}$  "2aq.— $\text{CdA}$  "aq. [ $85^\circ$ ].— $\text{CoA}$  "2aq. [ $90^\circ$ ].— $\text{NiA}$  "2aq.— $\text{CuA}$  "2aq.— $\text{AgA}$  "aq. Crystalline pp.

**Ethyl ether of the ethyl derivative**  $\text{CH}_2(\text{SEt})\text{CO}_2\text{Et}$ . (188°). S.G. 4 1.0169. Oil. Converted by  $\text{EtI}$  at  $120^\circ$  into crystalline  $\text{CH}_2(\text{SEtI})\text{CO}_2\text{Et}$ .

**Ethyl ether of the isoamyl derivative**  $\text{CH}_2(\text{SC}_4\text{H}_9)\text{CO}_2\text{Et}$ . (230°). S.G. 4 0.9797. Oil.

**Phenyl derivative v. PHENYL-THIO-GLYCOLLIC ACID.**

**Benzyl derivative**  $\text{CH}_2\text{Ph}(\text{SCH}_2\text{CO}_2\text{H})$ . [59°]. Formed from  $\text{CH}_2\text{ClCO}_2\text{H}$  and benzyl mercaptan (Gabriel, B. 12, 1641). Flat tables. Yields  $\text{EtA}$  (275°–290°) and the amide  $\text{CH}_2\text{Ph}(\text{SCH}_2\text{CONH}_2)$  [97°] crystallising in flat plates.

**Phenyl-phenyl derivative**  $\text{C}_6\text{H}_5\text{Ph}(\text{SCH}_2\text{CO}_2\text{H})$ . [170°]. Crystals.

**Amide**  $\text{CH}_2(\text{SH})\text{CONH}_2$ . A product of the passage of  $\text{H}_2\text{S}$  through an alcoholic solution of chloroacetamide containing a little  $\text{NH}_3$  (Schulze, Z. 1865, 73). Groups of small prisms.

**Ethyl derivative of the amide**  $\text{CH}_2(\text{SEt})\text{CONH}_2$  [44°]. Formed from  $\text{CH}_2(\text{SEt})\text{CO}_2\text{Et}$  and ammonia. Thin prisms.

**Reference.**—NITROSO-THIO-GLYCOLLIC ACID.

**THIO-GLYCOLLIC ORTHALDEHYDE.** **Ethyl derivative of the ether**  $\text{CH}_2(\text{SEt})\text{CH}(\text{OEt})$ . (169°). Formed from  $\text{CH}_2\text{ClCH}(\text{OEt})$  and  $\text{NaSEt}$  (Autenrieth, B. 24, 162). Volatile in steam.

**Phenyl derivative of the ethyl ether**  $\text{CH}_2(\text{SPh})\text{CH}(\text{OEt})$ . (273°). Got in like manner.

**THIO-HYDANTOINIC ACID**  $\text{C}_2\text{H}_3\text{N}_2\text{SO}_2$  i.e.  $\text{NH}_2\text{CS}(\text{NH}_2)\text{CH}_2\text{CO}_2\text{H}$  or  $\text{NH}_2\text{C}(\text{NH})\text{S}(\text{CH}_2\text{CO}_2\text{H})$ . Formed by heating sodium chloroacetate in aqueous solution with thio-urea (Maly, A. 189, 380). Crystalline powder, al. sol. water, v. sol. acids and alkalis. Decomposed by heat. Converted into thio-

hydantoin by warming with  $\text{Na}_2\text{CO}_3$  aq or  $\text{HClAq}$ .

**THIOHYDANTOIN**  $\text{C}_2\text{H}_3\text{N}_2\text{SO}$  i.e.

**Formation.**—1. By heating thio-urea with chloro-acetic acid or chloro-acetamide (Volhard, A. 166, 383; Mulder, B. 8, 1264; Maly, A. 163, 133; B. 10, 1853; Claesson, B. 10, 1352).—2. By heating thioglycollic acid (2 mols.) with cyanamide (1 mol.) in aqueous solution (Andreasch, B. 13, 1421; M. 1, 442).

**Preparation.**—Thio-urea (50 g.) dissolved in water (500 c.c.) is mixed with chloro-acetic acid (62 g.) in water (50 c.c.), heated to  $90^\circ$ , cooled, and mixed with the calculated quantity of  $\text{NaOH}$  (Andreasch, M. 8, 414).

**Properties.**—Long needles (from hot water), insol. alcohol and ether. Decomposes about  $200^\circ$ . Since it cannot be desulphurised by  $\text{HgO}$ , Liebermann (A. 207, 132) suggests that it does not contain the group  $\text{CS}$ .

**Reactions.**—1. Chlorine passed into its cooled solution in  $\text{HClAq}$  forms thio-oxy-hydantoin (Kramps, B. 13, 788).—2. Br forms di-bromothio-hydantoin.—3.  $\text{KClO}_3$  and  $\text{HCl}$  yield  $\text{C}_2\text{H}_3\text{KN}_2\text{SO}_3$ , crystallising in monoclinic tables, S.  $1.7$  at  $22^\circ$ ;  $2.3$  at  $100^\circ$ , converted by nitrous acid into  $\text{SO}_2\text{H}(\text{CH}_2\text{CO}_2\text{H})$ , and by baryta-water into sulpho-acetic acid and urea (Andreasch, B. 13, 1423; M. 4, 131).—4. Baryta-water forms thioglycollic acid and dicyandiamide.—5. Boiling  $\text{HClAq}$  forms thio-carbinido-acetic acid.

**Salts.**— $\text{Ag}(\text{C}_2\text{H}_3\text{N}_2\text{SO})$ .— $\text{B}^+\text{H}_2\text{SO}_4$ . Plates.— $\text{B}^+\text{HNO}_3$ .— $\text{B}^+\text{HCl}$ .— $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$  aq. Prisms.— $\text{B}^+\text{H}_2\text{PtCl}_6$ .— $\text{B}^+\text{C}_2\text{H}_3\text{N}_2\text{O}$ . Minute yellow needles.

**References.**—DI-BROMO- and NITROSO-THIOHYDANTOIN.

**DI-THIO-HYDROQUINONE**  $\text{C}_6\text{H}_2(\text{SH})_2$  [98°]. Formed by reducing benzene p-disulphonic chloride with tin and  $\text{HClAq}$  (Körner a. Monsele, G. 6, 142). Formed also from  $(\text{C}_6\text{H}_4(\text{NH}_2))_2\text{S}_2$  by diazotisation, treatment with potassium xanthate, and saponification of the product with alcoholic potash (Leuckart, J. pr. [2] 41, 205). Six-sided plates, slowly oxidised by air.

**THIO-ISATYDE v. ISATYDE.**

**THIO-LACTIC ACID**  $\text{CH}_3\text{CH}(\text{SH})\text{CO}_2\text{H}$ .  **$\alpha$ -Sulphydro-propionic acid.**

**Formation.**—1. From  $\alpha$ -chloro-propionic acid and  $\text{KHS}$  (Schacht, A. 129, 1; Lovén, J. pr. [2] 29, 368).—2. By the action of  $\text{H}_2\text{S}$  on silver  $\alpha$ -chloro-propionate or silver pyruvate (Bottinger, A. 188, 320; B. 9, 404, 804, 1061; 11, 1561; 18, 486).

**Preparation.**—By saturating a solution of pyruvic acid with  $\text{H}_2\text{S}$ , and adding conc.  $\text{HClAq}$  and zinc (Lovén).

**Properties.**—Syrup, miscible with water, alcohol, and ether. May be distilled *in vacuo*. Its odour is unpleasant.  $\text{FeCl}_3$  gives a transient indigo colour, and then oxidises it to sulphido-dipropionic acid.  $\text{CuSO}_4$  gives a violet solution; a smaller quantity of  $\text{CuSO}_4$  ppts. the cuprous salt. Cobalt acetate and air gives a brown colour.

**Salts.**— $\text{BaA}$  (at  $130^\circ$ ). Gummy mass.— $\text{Hg}(\text{S}(\text{CHMe}(\text{CO}_2\text{H}))_2)$ .— $\text{Hg}(\text{S}(\text{CHMe}(\text{CO}_2\text{K}))_2)$  aq.  $\text{Hg}(\text{S}(\text{CHMe}(\text{CO}_2))_2)$  aq.  $\text{AgS}(\text{CHMe}(\text{CO}_2\text{H}))_2$ .

— $\text{Bi}(\text{S.OHMe.CO}_2\text{H})_3$  —  $\text{Pt}(\text{S.OHMe.CO}_2\text{H})_4$  —  $\text{CuS.OHMe.CO}_2\text{H}$ . Yellow pp. —  $\text{PbC}_2\text{H}_3\text{O}_2\text{S}$ .

*Ethyl ether EtA*. Oil. Yields  $\text{CuS.OHMe.CO}_2\text{Et}$  as a yellowish powder.

**THIO-DILACTYLIC ACID** v. SULPHIDO-DIPROPIONIC ACID.

**THIO-MALIC ACID**  $\text{C}_4\text{H}_6\text{SO}_4$ . Formed from bromo-succinic acid and aqueous KSH at  $110^\circ$  (Carius, *A.* 129, 6). Deliquescent mass, oxidised by dilute  $\text{HNO}_3$  to sulpho-succinic acid. —  $\text{BaA}''$ . —  $\text{Ag}_2\text{A}''$ . Bulky pp., readily blackening.

**THIO-MESITOL** v. TRI-METHYL-PHENYL MERCAPTAN.

**THIO-DI-METHYL-ANILINE** v. TETRA-METHYL-DI-AMIDO-DI-PHENYL SULPHIDE.

**THIO-METHYL-COUMARILIC ETHER**

$\text{C}_{12}\text{H}_{12}\text{SO}_2$  i.e.  $\text{C}_6\text{H}_5\text{C}(\text{CMc})=\text{C.CO.SEt}$ . [ $91^\circ$ ]. Formed from methyl-coumarilic ether and  $\text{P}_2\text{S}_5$  (Hantzsch, *B.* 19, 2400). Yellow needles (from alcohol), v. sol. ether.

**THIO-(a)-METHYL-COUMARIN**  $\text{C}_{10}\text{H}_8\text{SO}$  i.e.  $\text{C}_6\text{H}_5\text{C}(\text{CH}_2\text{CMc})=\text{O-CS}$ . [ $122^\circ$ ]. Formed by heating (a)-methyl-coumarin with  $\text{P}_2\text{S}_5$  at  $120^\circ$  (Aldringen, *B.* 24, 3460). Yellow needles, insol. water, v. sol. alcohol. Converted by alcoholic potash into (a)-methyl-coumarin.

**THIO-METHYL-DI-PHENYL-AMINE** v. METHYL-IMIDO-DI-PHENYL SULPHIDE.

**THIO-METHYL-URACIL**  $\text{C}_4\text{H}_4\text{N}_2\text{SO}$  i.e.  $\text{CS}(\text{NH.CMc})=\text{CH}(\text{NH.CO})$  (?). S. 054 at  $21^\circ$ . Formed by the action of alcoholic potash on the needles which separate after some days from a solution of thio-urea (1 mol.) and acetoacetic ether (1 mol.) in alcohol to which a little HCl has been added (Nencki a. Sielber, *J. pr.* [2] 25, 72; List, *A.* 236, 1; Behrend, *B.* 19, 219). Plates, v. sl. sol. ether. Decomposed at  $280^\circ$ .

**Reactions.**—1. The K salt reacts with HI forming  $\text{C}_4\text{H}_4\text{N}_2\text{SOEt}$  [ $145^\circ$ ], and with MeI forming  $\text{C}_4\text{H}_4\text{N}_2\text{SOMe}$  [ $220^\circ$ ], which yields  $\text{C}_4\text{H}_4\text{AgN}_2\text{SO}$ . — 2. *Chloro-acetic ether* forms  $\text{C}_4\text{H}_4\text{N}_2\text{SO}(\text{CH}_2\text{CO}_2\text{Et})$  [ $143^\circ$ ], which yields  $\text{C}_4\text{H}_4\text{N}_2\text{SO}(\text{CH}_2\text{CO}_2\text{H})$  [ $204^\circ$ ]. — 3. Br forms methyl-uracil, and finally di-oxy-methyl-uracil. Cl acts in like manner, forming  $\text{C}_4\text{H}_4\text{Cl}_2\text{N}_2\text{O}_2$ . — 3. On warming with lead hydrate in strongly alkaline solution it is converted into methyl-uracil. Conc.  $\text{HClAq}$  at  $150^\circ$ , conc.  $\text{NH}_4\text{Aq}$  at  $150^\circ$ , and  $\text{Ac}_2\text{O}$  at  $185^\circ$  also form methyl-uracil.

**Salts.** —  $\text{C}_4\text{H}_4\text{AgN}_2\text{SO}$ . —  $\text{C}_4\text{H}_4\text{CuN}_2\text{SO}$ . —  $(\text{C}_4\text{H}_4\text{N}_2\text{SO})_2\text{Hg}$ . —  $\text{C}_4\text{H}_4\text{N}_2\text{NaSO}$  2aq. —  $\text{C}_4\text{H}_4\text{N}_2\text{KSO}$  1aq.

**THIONAMIC ACID.** H. Rose (*I.* 33, 235; 42, 415) found that  $\text{SO}_2$  and  $\text{NH}_3$  combined in equal volumes, when dry  $\text{NH}_3$  was mixed with excess of dry  $\text{SO}_2$ , to form a yellowish white solid, which quickly decomposed in solution, or moist air, giving  $(\text{NH}_4)_2\text{SO}_3$  and ammonium salts of other sulphur oxyacids. Rose concluded that the substance was  $\text{SO}_2\text{NH}_2$  from the fact that it was formed by combining equal volumes of the two gases; if this empirical formula is accepted the compound may be  $\text{SO}_2\text{NH}_2\text{H}$  or  $\text{SO.OH.NH}_2$ . When dry  $\text{SO}_2$  was mixed with excess of dry  $\text{NH}_3$ , Rose found that 1 vol.  $\text{SO}_2$  combined with 2 vols.  $\text{NH}_3$ ; the product—an amorphous, white solid—may be  $\text{SO}_2\text{NH}_2\text{NH}_2$  or  $\text{SO.ONH}_2\text{NH}_2$ .

M. M. P. M.

**THIONAMIDE.** By passing  $\text{NH}_3$  into cooled  $\text{S.Cl}_2$ , Schiff (*A.* 102, 111) obtained a white solid which was decomposed by warm water to  $(\text{NH}_4)_2\text{SO}_4$ . The solid contained  $\text{NH}_4\text{Cl}$ ; Schiff regarded it as a mixture of this salt with  $\text{SO}(\text{NH}_2)_2$ ; he did not attempt to separate the supposed thionamide from  $\text{NH}_4\text{Cl}$ .

M. M. P. M.

(a)-THIO-NAPHTHOIC ACID.

*Amide*  $\text{C}_{10}\text{H}_7\text{CS.NH}_2$ . [ $126^\circ$ ]. Formed from (a)-naphthoic nitrile and alcoholic ammonium sulphide at  $30^\circ$ – $35^\circ$  (Hofmann, *B.* 1, 40; Bamberger, *B.* 21, 54). Crystals, v. sol. alcohol. *Tetrahydride of the amide*

$\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{C}_6\text{H}_4\text{CS.NH}_2$ . Formed by digesting a solution of tetrahydride of (a)-naphthoic nitrile in alcoholic ammonia saturated with  $\text{H}_2\text{S}$  for some days at  $30^\circ$ – $40^\circ$  (Bamberger a. Bordt, *B.* 22, 629). Dark-yellow oil.

(b)-Thio-naphthoic acid. *Amide*

$\text{C}_{10}\text{H}_7\text{CS.NH}_2$ . [ $149^\circ$ ]. Formed from (b)-naphthoic nitrile and ammonium sulphide at  $35^\circ$ – $40^\circ$  (Bamberger a. Bockmann, *B.* 20, 1115). Needles, v. sol. alcohol. Dissolves in hot water, being slowly converted into the nitrile.

**THIO-NAPHTHOL** v. NAPHTHOL MERCAPTAN.

**THIO-DI-NAPHTHYL-AMINE** v. IMIDO-DI-NAPHTHYL SULPHIDE.

**THIONATES.** Salts of the *thionic acids* (q. v., p. 698). Four series of thionates are known; a fifth probably exists:  $\text{M}_2\text{S}_2\text{O}_6$ =dithionates;  $\text{M}_2\text{S}_3\text{O}_6$ =trithionates;  $\text{M}_2\text{S}_4\text{O}_6$ =tetra-thionates;  $\text{M}_2\text{S}_5\text{O}_6$ =pentathionates; and probably  $\text{M}_2\text{S}_6\text{O}_6$ =hexathionates. The thionates are formed by the action of alkalis on the liquid obtained by passing  $\text{H}_2\text{S}$  into saturated  $\text{SO}_2\text{Aq}$ ; also by the oxidation of sulphites, thiosulphates, and mixtures of these, and in other reactions (cf. *Thionic acids*, p. 698). For general qualitative reactions of thionates and thiosulphates v. Debus (*C.* 5, 3, 298).

**DITHIONATES**,  $\text{M}^{II}_2\text{S}_2\text{O}_6$ ,  $\text{M}^{IV}_2\text{S}_2\text{O}_6$ , and  $\text{M}^{VI}_2(\text{S}_2\text{O}_6)_x$  (*Hyposulphates*). The alkali salts are formed by the interaction of a dilute solution of I in  $\text{KIAq}$  and dilute  $\text{NaHSO}_4\text{Aq}$  (Spring a. Bourgeois, *B.* [2] 46, 151; Sokoloff a. Mattscheffski, *B.* 14, 2058); also by the reaction of  $\text{KMnO}_4\text{Aq}$  on thiosulphates in acetic acid solution, or on sulphites or trithionates (Hönig a. Zatzek, *M.* 4, 738; Fordos a. Gélis, *J. Ph.* [3] 36, 113). The Ba salt is formed by passing  $\text{SO}_2$  into water holding  $\text{MnO}_2$  in suspension, filtering, and adding  $\text{BaOAc}$  (for more details v. *DRITHIONIC ACID*, p. 698); most of the other dithionates are obtained by the interaction of  $\text{BaS}_2\text{O}_6\text{Aq}$  and sulphates; several have been prepared by digesting  $\text{H}_2\text{S}_2\text{O}_6\text{Aq}$  with metallic hydroxides. The dithionates are sol. water; the salts of the alkali and alkaline earth metals are not readily decomposed either in solution or as solids; solutions of most of the other salts are decomposed by heat, giving off  $\text{SO}_2$  (v. Klüss, *A.* 246, 179, 284; Geuther, *A.* 226, 232).

Dithionates give off  $\text{SO}_2$  when heated to redness, leaving normal sulphates; thus  $\text{M}_2\text{S}_2\text{O}_6 = \text{SO}_2 + \text{M}_2\text{SO}_4$ ; this reaction is characteristic; so also is the reaction of  $\text{H}_2\text{SO}_4\text{Aq}$  or  $\text{HClAq}$  with boiling solutions of dithionates, whereby  $\text{H}_2\text{SO}_4\text{Aq}$  is formed and  $\text{SO}_2$  is given off, without separation of S.

**Ammonium dithionate**  $(\text{NH}_4)_2\text{S}_2\text{O}_8$ . Obtained by decomposing the Ba salt in solution by  $(\text{NH}_4)_2\text{SO}_4\text{Aq}$ , filtering and crystallising. S.G. 1.704 (Topsoë, *C. C.* 4, 76). Klüss (*A.* 246, 179, 284) gives formula  $2\text{Am}_2\text{S}_2\text{O}_8\text{Aq}$ , and says the salt crystallises in monoclinic needles. Very sol. water; insol. alcohol. Aqueous solution may be boiled without change. Forms double salts with  $\text{AmCl}$  (Fock a. Klüss, *B.* 24, 3017); also with the dithionates of  $\text{Al}$ ,  $\text{Cd}$ ,  $\text{Co}$ ,  $\text{Cu}$ ,  $\text{Fe}$ ,  $\text{Mn}$ ,  $\text{Ni}$ , and  $\text{Zn}$  (K., l.c.).

**Barium dithionate**  $\text{BaS}_2\text{O}_8$ , 2aq. Formed by passing  $\text{SO}_2$  into water at  $c. 40^\circ$  holding coarsely-powdered  $\text{MnO}_2$  in suspension, till the  $\text{MnO}_2$  is dissolved ( $\text{MnO}_2 + \text{SO}_2 + \text{Aq} = \text{MnSO}_4\text{Aq}$ ; and also  $\text{MnO}_2 + 2\text{SO}_2 + \text{Aq} = \text{MnS}_2\text{O}_8\text{Aq}$ ), filtering if necessary, adding  $\text{BaOAc}$  to alkaline reaction ( $\text{MnS}_2\text{O}_8\text{Aq} + \text{BaO.H}_2\text{Aq} = \text{BaS}_2\text{O}_8\text{Aq} + \text{MnO.H}_2$ ), filtering from  $\text{MnO.H}_2$ , evaporating, and recrystallising from water (cf. Stas, *Chem. Propert.* 117). White prisms; S. 24.75 at  $18^\circ$ , 90.9 at  $100^\circ$ , 100.6 at  $102^\circ$  = b.p. of saturated solution; insol. alcohol. The crystals effloresce in air, losing  $2\text{H}_2\text{O}$ ; a hydrate with  $4\text{H}_2\text{O}$  is obtained by slow evaporation (v. Heeren, *P.* 7, 55; Gay-Lussac, *A. Ch.* [2] 10, 312; Baker, *C. N.* 36, 203; cf. Spring a. Bourgeois, *Bl.* [2] 46, 151. For crystalline form v. Senarmont, *J.* 1857, 142; Rammelsberg, *P.* 58, 295; von Lang, *W. A. B.* 45 [2] 27). Schiff (*A.* 105, 239) described double salts with  $\text{MgS}_2\text{O}_8$  and  $\text{Na}_2\text{S}_2\text{O}_8$  (cf. Kraut, *A.* 118, 95); Bodländer (*Chem. Zeit.* 14, 1140) described a double salt with  $\text{Rb}_2\text{S}_2\text{O}_8$ ; and Klüss (*A.* 246, 179, 284) double salts with  $\text{Ag}_2\text{S}_2\text{O}_8$  and  $\text{Ti}_2\text{S}_2\text{O}_8$ .

Many of the other dithionates are prepared from the Ba salt.

**Potassium dithionate**  $\text{K}_2\text{S}_2\text{O}_8$ . Prepared from a solution of the Ba salt by adding an equivalent quantity of  $\text{K}_2\text{SO}_4$  in solution, warming, filtering, and evaporating; also by boiling  $\text{K}_2\text{SO}_4\text{Aq}$  with  $\text{MnO}_2$ , filtering, and separating from  $\text{K}_2\text{SO}_4$  by fractional crystallisation ( $\text{K}_2\text{SO}_4$  is much less sol. water than  $\text{K}_2\text{S}_2\text{O}_8$ ). White, hexagonal crystals; unchanged in air; decrepitate when heated and then gives off  $\text{SO}_2$  and leaves  $\text{K}_2\text{SO}_4$ ; S.G. 2.277 (Topsoë, *Bl.* [2] 19, 246). The crystals rotate the plane of polarisation of light; an aqueous solution is optically inactive (Pape, *P.* 139, 221). S. c. 6 at ordinary temperature, c. 66 at  $100^\circ$ ; insol. alcohol (Heeren, *P.* 7, 55).

**Sodium dithionate**  $\text{Na}_2\text{S}_2\text{O}_8$ , 2aq. Prepared similarly to the K salt. Also formed, according to Bunte (*B.* 7, 646), by heating  $\text{Na.Et.S}_2\text{O}_8$  for some time at  $100^\circ$  ( $\text{Et.S}_2$  distils off). Large, lustrous, rhombic prisms; unchanged in air, S.G. 2.175 at  $11^\circ$  (Baker, *C. N.* 36, 203). S. 47.6 at  $16^\circ$ ; 90.9 at  $100^\circ$ ; insol. alcohol. Solution is slowly reduced by sodium-amalgam to  $\text{Na}_2\text{SO}_3\text{Aq}$  (Spring, *B.* 7, 1161). Kraut (*A.* 117, 97) described a hydrate with  $6\text{H}_2\text{O}$ .

Dithionates of the following metals have also been described (the figures indicate the references):  $\text{Al}$  (1) (3);  $\text{Be}$  (3);  $\text{Bi}$  (3);  $\text{Cd}$  (1) (2) (4);  $\text{Ca}$  (1) (4) (5);  $\text{Cr}$  (3);  $\text{Co}$  (1) (2) (3) (4);  $\text{Cu}$  (3);  $\text{Fe}$  (1) (3) (4);  $\text{Pb}$  (1) (4) (5);  $\text{Li}$  (2) (4);  $\text{Mg}$  (1) (4) (5);  $\text{Mn}$  (4);  $\text{Hg}$  (1) (2) (3);  $\text{Ni}$  (2) (4) (5);  $\text{Rb}$  (6);  $\text{Ag}$  (1) (2) (4) (5);  $\text{Sr}$  (2) (4);  $\text{Ti}$  (3);  $\text{Sn}$  (8);  $\text{U}$  (3);  $\text{Zn}$  (1) (2) (4).

(1) Heeren, *P.* 7, 72, 171; (2) Rammelsberg,

*P.* 58, 298; (3) Klüss, *A.* 246, 179, 284; (4) Topsoë, *C. C.* 4, 76; (5) Baker, *C. N.* 36, 203; (6) Piccard, *J.* pr. 86, 466.

**TRITHIONATES**  $\text{M}'_2\text{S}_3\text{O}_{10}$  and  $\text{M}''\text{S}_3\text{O}_{10}$ . The alkali salts are formed by digesting conc.  $\text{MHSO}_4\text{Aq}$  with  $\text{S}$  at  $50^\circ$ – $60^\circ$  ( $6\text{MHSO}_4\text{Aq} + 2\text{S} = 2\text{M}'_2\text{S}_3\text{O}_{10}\text{Aq} + \text{M}'_2\text{S}_2\text{O}_8\text{Aq} + 3\text{H}_2\text{O}$ ) (Pelouze, *A. Ch.* [3] 70, 85); also by heating dilute  $\text{MHSO}_4\text{Aq}$ , or keeping the solution for a long time in a closed tube (Saint-Pierre, *C. R.* 62, 632); by passing  $\text{SO}_2$  into  $\text{M}'_2\text{S}_2\text{O}_8\text{Aq}$  ( $2\text{M}'_2\text{S}_2\text{O}_8\text{Aq} + 8\text{SO}_2 = 2\text{M}'_2\text{S}_3\text{O}_{10}\text{Aq} + \text{S}$ ); by passing  $\text{SO}_2$  into  $\text{M}'_2\text{SAq}$  (Chancel a. Diacon, *J.* pr. 90, 35; Rathke, *J.* pr. 95, 11); by the interaction of I and a mixture of  $\text{M}'_2\text{SO}_3$  and  $\text{M}'_2\text{S}_2\text{O}_8$  in solution ( $\text{M}'_2\text{SO}_3\text{Aq} + \text{M}'_2\text{S}_2\text{O}_8\text{Aq} + \text{I}_2 = \text{M}'_2\text{S}_3\text{O}_{10}\text{Aq} + 2\text{MIAq}$ ) (Spring, *B.* 7, 1157); by the interaction of boiling water on  $\text{AgKS}_2\text{O}_8$  or  $\text{HgNa}_2(\text{S}_2\text{O}_8)_2$ , whereby  $\text{K}_2\text{S}_3\text{O}_{10}\text{Aq}$  or  $\text{Na}_2\text{S}_3\text{O}_{10}\text{Aq}$  is formed, along with  $\text{Ag}_2\text{S}$  or  $\text{HgS}$  (Spring, l.c.); by reacting on  $\text{M}'_2\text{SO}_3\text{Aq}$  with  $\text{S.Cl}_2$  (Spring, *B.* 6, 1108); by decomposing  $\text{M}'_2\text{S}_2\text{O}_8\text{Aq}$  by a non-oxidising acid, e.g. by  $\text{H}_2\text{SO}_3$  (Spring a. Levy, *Bull. de l'Acad. roy. de Belge*, 42, 108); by heating  $(\text{NH}_4)_2\text{SO}_3$  with  $\text{P.S.}$ , Spring (*B.* 7, 1158) obtained a little  $(\text{NH}_4)_2\text{S}_3\text{O}_{10}$ , along with much  $(\text{NH}_4)_2\text{S}_2\text{O}_8$ , some  $\text{NH}_4$  polysulphides, and P compounds;  $\text{K}_2\text{S}_3\text{O}_{10}$  is also obtained from Wackenroder's solution.

The trithionates are soluble in water; they very readily decompose; heated with water they give off  $\text{SO}_2$ , deposit  $\text{S}$ , and form sulphates in solution. Addition of excess of  $\text{CuSO}_4\text{Aq}$  to solution of a trithionate causes ppn. of  $\text{CuS}$  and evolution of  $\text{SO}_2$  (Spring, *B.* 6, 1108).

SELENOTRITHIONATES  $\text{M}'_2\text{SeS}_3\text{O}_{10}$  are described as *dithio-triselenates* under SELENATES (p. 434).

**Potassium trithionate**  $\text{K}_2\text{S}_3\text{O}_{10}$ . A conc. solution of  $\text{K}_2\text{S}_2\text{O}_8$  is formed by dissolving the salt in 8 pts. water and 1 pt. alcohol till the alcohol separates from the aqueous solution;  $\text{SO}_2$  is passed into this solution at  $25^\circ$ – $30^\circ$ , solid  $\text{K}_2\text{S}_3\text{O}_{10}$  being added from time to time, till the liquid is yellow and smells of  $\text{SO}_2$ ; the crystals that separate are dissolved in water at  $60^\circ$ – $70^\circ$ , the solution is filtered from  $\text{S}$ , mixed with eight times its volume of 84 p.c. alcohol, warmed gently, and allowed to crystallise (Plessy, *A. Ch.* [3] 20, 162; for other methods of preparation v. Langlois, *A. Ch.* [2] 79, 77; Rathke, *J.* 1864, 164; Chancel a. Diacon, *C. R.* 56, 710). White rhombic needles (Baker, *C. N.* 36, 203). Very sol. water, insol. alcohol. Aqueous solution gives  $\text{K}_2\text{SO}_4\text{Aq}$ ,  $\text{SO}_2$ , and  $\text{S}$  when heated. Debus (*C. J.* 53, 313) found that  $\text{K}_2\text{S}_3\text{O}_{10}\text{Aq}$  slowly changes at the ordinary temperature, giving  $\text{K}_2\text{SO}_4\text{Aq}$ ,  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ , and  $\text{K}_2\text{S}_2\text{O}_7\text{Aq}$  without separation of  $\text{S}$ . According to C. a. D. (l.c.),  $\text{K}_2\text{S}_3\text{O}_{10}\text{Aq}$  interacts with  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$  to give only  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ ; with  $\text{H}_2\text{S}$  the products are  $\text{K}_2\text{SO}_4\text{Aq}$ ,  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ , and  $\text{S}$  (Debus, *C. J.* 53, 329). Sodium-amalgam reacts readily, producing  $\text{KNaS}_2\text{O}_8$  and  $\text{KNaSO}_3$  (Spring, *B.* 7, 1161).

The other trithionates that have been isolated are those of Ba (Kessler, *P.* 74, 253); Pb (K., l.c.); Chancel a. Diacon, *C. R.* 56, 710); Na (K., l.c.); Rathke, *J.* pr. 95, 13; Villiers, *C. R.* 106, 1356); and Zn (Fordos a. Gélis, *A. Ch.* [3] 22, 66).

**TETRATHIONATES**  $\text{M}'_4\text{S}_4\text{O}_{12}$  and  $\text{M}''\text{S}_4\text{O}_{12}$ . The alkali salts are formed by trituration  $\text{M}'_2\text{S}_3\text{O}_{10}$  with I, adding a little water and pouring into

alcohol (von Klobukoff, *B.* 18, 1869; Eliasberg, *B.* 19, 322; Fock a. Klüss, *B.* 23, 2429); the Pb salt is formed by the prolonged interaction of I and  $\text{PbS}_2\text{O}_6$ , also by the interaction of  $\text{H}_2\text{SO}_4\text{Aq}$  and a mixture of  $\text{PbS}_2\text{O}_6$  with  $\text{PbO}_2$  (Chancel a. Diacon, *J. pr.* 90, 55); tetrathionates are also formed, according to Spring a. Levy (*Bull. de l'Acad. roy. de Belge*, 424 108), by the interaction, of thiosulphates and ferrous or cuprous salts,  $\text{KMnO}_4\text{Aq}$ , hypochlorites, or  $\text{KClO}_3$  dissolved in  $\text{H}_2\text{SO}_4\text{Aq}$ .  $\text{K}_2\text{S}_2\text{O}_8$  is obtained by neutralising Wackenroder's solution by  $\text{KC}_2\text{H}_3\text{O}_2$  (v. Debus, *Ö. J.* 53, 278; cf. Curtius a. Henkel, *J. pr.* [2] 87, 137). The tetrathionates are o. sol. water, but insol. alcohol; aqueous solutions are generally decomposed on evaporation.

**Potassium tetrathionate**  $\text{K}_2\text{S}_4\text{O}_{10}$ . Formed by adding I, little by little, to conc.  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$  till a permanent reddish-brown colour is produced, dissolving the crystals that separate in warm water, filtering from S, adding alcohol till the pp. that forms is re-dissolved, and allowing to crystallise (Kessler, *P.* 74, 253). Spontaneous decomposition of conc.  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$  gives  $\text{K}_2\text{S}_2\text{O}_8$  and S (Debus, *C. J.* 53, 311). Perfectly dry  $\text{K}_2\text{S}_2\text{O}_8$  can be kept unchanged in a dry atmosphere; but in ordinary air, after a time,  $\text{SO}_2$  is formed; an aqueous solution of  $\text{K}_2\text{S}_2\text{O}_8$  slowly changes to  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ ,  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ ,  $\text{K}_2\text{SO}_4\text{Aq}$ , and  $\text{SO}_2$  (D., l.c.).  $\text{BrAq}$  reacts to form  $\text{H}_2\text{SO}_4\text{Aq}$ , S, and  $\text{KBr}$ ; but if the  $\text{BrAq}$  is added very gradually the S that is formed combines with residual  $\text{K}_2\text{S}_2\text{O}_8$  to form  $\text{K}_2\text{S}_2\text{O}_8$ ; similarly, if a little  $\text{K}_2\text{SO}_4$  is added to  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ , and  $\text{H}_2\text{S}$  is then passed in,  $\text{K}_2\text{SO}_4$  and S are formed, and the S combines with unchanged  $\text{K}_2\text{S}_2\text{O}_8$  to form  $\text{K}_2\text{S}_2\text{O}_8$  (D., l.c. p. 316). Sodium-amalgam forms  $\text{KNaS}_2\text{O}_8\text{Aq}$  (Spring, *B.* 7, 1161).

The other tetrathionates that have been isolated are those of Ba (Lewes, *C. J.* 39, 69; Fordos a. Gélis, *A. Ch.* [3] 22, 66; Curtius a. Henkel, *J. pr.* [2] 37, 137); Cd (Kessler, *P.* 74, 253); Cu (Chancel a. Diacon, *C. R.* 56, 510); Fe (F. a. G.); Pb (K.; C. a. D.); Na (K.; von Klobukoff, *B.* 18, 1869); Sr (K.); and Zn (F. a. G.).

**PENTATHIONATES**  $\text{M}_2\text{S}_5\text{O}_{10}$  and  $\text{M}_2\text{S}_5\text{O}_{11}$ . Wackenroder, in 1845 (*A.* 60, 189), asserted that the liquid formed by passing  $\text{H}_2\text{S}$  into  $\text{SO}_2\text{Aq}$  contained pentathionic acid  $\text{H}_2\text{S}_5\text{O}_{10}$ ; other chemists confirmed his results, and prepared a few salts of the acid (v. Lenoir, *A.* 62, 253; Fordos a. Gélis, *A. Ch.* [3] 22, 66; Kessler, *P.* 74, 257; Ludwig, *Ar. Ph.* [2] 85, 9; Chancel a. Diacon, *C. R.* 56, 710). At a later time the existence of pentathionates was denied, chiefly by Spring (*B.* 12, 2254; 13, 924; 15, 2618), but upheld by Kessler (*B.* 13, 424; v. also Takatatsu a. Smith, *B.* 13, 1976). In 1881 Lewes (*C. J.* 39, 68) seemed to have isolated  $\text{BaS}_5\text{O}_{10}$  and  $\text{K}_2\text{S}_5\text{O}_{10}$ , but Spring failed to confirm his results. Shaw, however (*C. J.* 43, 357), repeated Lewes's experiments, and obtained  $\text{K}_2\text{S}_5\text{O}_{10}$ . In 1888 Debus (*C. J.* 53, 278) made an elaborate investigation of Wackenroder's solution, and prepared  $\text{K}_2\text{S}_5\text{O}_{10}$  therefrom. Curtius a. Henkel (*J. pr.* [2] 87, 187) assert that Wackenroder's solution contains acid tetrathionates, in which the ratio of S to Ba is greater than 4S:Ba, and that these have been mistaken for pentathionates. But Debus's experiments seem to have settled

the dispute in favour of the existence of pentathionates. Ammoniacal  $\text{AgNO}_3\text{Aq}$  gives very distinct brown colouration, followed by a black pp. with pentathionates; this reaction distinguishes them from salts of other S oxyacids (v. Debus, l.c., p. 297).

**Potassium pentathionate**  $2\text{K}_2\text{S}_5\text{O}_{10}$ . 3aq. Debus (*C. J.* 53, 294) prepared this salt from Wackenroder's solution (v. p. 698) by adding 16.66 g.  $\text{KC}_2\text{H}_3\text{O}_2$  (previously fused) to 43 c.c. of the solution of S.G. 1.343; the  $\text{KC}_2\text{H}_3\text{O}_2$  was dissolved in as little water as possible acidulated with a few drops of acetic acid; the solution was placed in a large flat dish in a current of air until the liquid had evaporated; the crystalline residue (weighing 26 g.) was repeatedly pressed between filter-paper, and then dissolved in 50 c.c. water + 1 c.c.  $\text{H}_2\text{SO}_4$  at  $40^\circ$ ; the minute quantity of S that separated (c. .005 g.) was filtered off, and the filtrate was allowed to crystallise in a flat dish. The crystals that separated (18.75 g.) were a mixture of  $\text{K}_2\text{S}_5\text{O}_{10}$  and  $\text{K}_2\text{S}_4\text{O}_{10}$ ; they were dried by placing them on blotting paper, and the crystals of pentathionate were picked out (5.75 g. were obtained), crystallised twice from water acidulated with a little  $\text{H}_2\text{SO}_4\text{Aq}$ , and dried over  $\text{H}_2\text{SO}_4$ . The crystals of pentathionate form four-sided rhombic plates, or six-sided star-like plates; those of tetrathionate form six-sided prisms, with pyramids only on one end, and with the side on which they rest much developed. Lewes (*C. J.* 39, 75) described three salts:  $\text{K}_2\text{S}_5\text{O}_{10}$ ,  $\text{K}_2\text{S}_5\text{O}_{10}\cdot\text{H}_2\text{O}$ , and  $\text{K}_2\text{S}_5\text{O}_{10}\cdot 2\text{H}_2\text{O}$ ; Debus's salt was  $2\text{K}_2\text{S}_5\text{O}_{10}\cdot 3\text{H}_2\text{O}$ . According to Fock a. Klüss (*B.* 23, 2428), this is the only salt that exists (cf. D., l.c., p. 297). The salt can also be obtained by passing  $\text{H}_2\text{S}$  into  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$  acidulated with  $\text{H}_2\text{SO}_4\text{Aq}$  (D., l.c., p. 315).

Crystals of  $2\text{K}_2\text{S}_5\text{O}_{10}\cdot 3\text{H}_2\text{O}$  begin to decompose, when kept in a stoppered bottle, after a month or so, giving eventually a yellow, pulpy mass of  $\text{K}_2\text{S}_2\text{O}_8$ , S, and water; the decomposition is caused by water in the interstices of the crystals. By powdering finely, washing with dilute alcohol, and placing over  $\text{H}_2\text{SO}_4$ , Debus (l.c. p. 295) kept the salt unchanged for two or three years.  $2\text{K}_2\text{S}_5\text{O}_{10}\cdot 3\text{H}_2\text{O}$  dissolves in c. 2 parts water, forming a clear, neutral solution, which soon decomposes with separation of S and formation of  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$  (D., l.c., p. 311); addition of a drop of dilute  $\text{KOH Aq}$  to the solution causes separation of S (p. 291);  $\text{H}_2\text{S}$  ppt. much S, and  $\text{K}_2\text{S}_2\text{O}_8$  and  $\text{K}_2\text{S}_2\text{O}_8$  are formed in the solution (p. 328);  $\text{SO}_2$  produces  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$  and  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$  (p. 332); the salt is insoluble in alcohol.

**Barium pentathionate**  $\text{BaS}_5\text{O}_{10}$ . 3aq; obtained by Lewes (*C. J.* 39, 68) by partially neutralising Wackenroder's solution by  $\text{BaOAq}$ , crystallising over  $\text{H}_2\text{SO}_4$ , pouring off from  $\text{BaS}_5\text{O}_{10}$ , and again crystallising.

**Copper pentathionate**  $\text{CuS}_5\text{O}_{10}$ . 4aq; obtained by Debus (l.c., p. 300) in blue, prismatic crystals, by adding  $\text{Cu}(\text{C}_2\text{H}_3\text{O}_2)_2\text{Aq}$  to Wackenroder's solution and allowing to evaporate. Debus probably obtained *zinc pentathionate*, but not in a pure state (l.c., p. 299).

**HEXATHIONATES**. By adding  $\text{KC}_2\text{H}_3\text{O}_2\text{Aq}$  to the mother-liquor from  $\text{K}_2\text{S}_2\text{O}_8$  and  $\text{K}_2\text{S}_5\text{O}_{10}$  (v. *supra*), evaporating in a current of air, dis-

solving in water with a little  $\text{H}_2\text{SO}_4\text{Aq}$ , allowing to evaporate in portions, and collecting the crystals separately, Debus (*C. J.* 53, 301) obtained a salt in which the ratio of S to O was almost 6S:8O, as required by *potassium hexathionate*.

#### THIONEAL v. TETRA-PHENYL-THIOPHENE.

**THIONIC ACIDS.** The acids  $\text{H}_2\text{S}_x\text{O}_y$ , where  $x=2, 3, 4, 5$ , and probably 6, are generally called thionic acids, and are distinguished as *di*-, *tri*-, &c., thionic acid. The acids are known only in aqueous solutions; most of these solutions readily oxidise to  $\text{H}_2\text{SO}_4\text{Aq}$ . Dithionic acid is produced by the action of certain oxidisers on  $\text{H}_2\text{SO}_4\text{Aq}$ ; dithionates are formed by oxidising sulphites and thiosulphates; trithionates are formed when mixtures of sulphites and thiosulphates are oxidised, also when  $\text{SO}_2\text{Aq}$  interacts with alkali thiosulphates; tetrathionates result by the action of certain oxidisers on thiosulphates. These processes may be represented diagrammatically as follows (the actual reactions are much more complex):

- (1)  $2\text{H}_2\text{SO}_4\text{Aq} + \text{O} = \text{H}_2\text{S}_2\text{O}_8\text{Aq} + \text{H}_2\text{O}$ ;
- (2)  $2\text{M}_2\text{SO}_3\text{Aq} + \text{O} = \text{M}_2\text{S}_2\text{O}_8\text{Aq} + \text{M}_2\text{O}$ ;
- $\text{M}_2\text{S}_2\text{O}_8\text{Aq} + 3\text{O} = \text{M}_2\text{S}_4\text{O}_{10}\text{Aq}$ ;
- (3)  $\text{M}_2\text{SO}_3\text{Aq} + \text{M}_2\text{S}_2\text{O}_3\text{Aq} + \text{O} = \text{M}_2\text{S}_3\text{O}_9\text{Aq} + \text{M}_2\text{O}$ ;
- $2\text{M}_2\text{S}_2\text{O}_3\text{Aq} + 3\text{SO}_2\text{Aq} = 2\text{M}_2\text{S}_4\text{O}_{10}\text{Aq} + \text{S}$ ;
- (4)  $2\text{M}_2\text{S}_2\text{O}_3\text{Aq} + \text{O} = \text{M}_2\text{S}_4\text{O}_{10}\text{Aq} + \text{M}_2\text{O}$ .

After passing  $\text{H}_2\text{S}$  for a long time into nearly saturated  $\text{H}_2\text{SO}_4\text{Aq}$ , the solution contains  $\text{H}_2\text{S}_2\text{O}_8$ , much  $\text{H}_2\text{S}_2\text{O}_8$ ,  $\text{H}_2\text{S}_3\text{O}_9$ , and probably  $\text{H}_2\text{S}_4\text{O}_{10}$ , along with  $\text{H}_2\text{SO}_4$ , dissolved colloidal S, and a little S in suspension. This solution is known as *Wackenroder's solution* (Wackenroder, *A.* 60, 180 [1845]). It has been examined by many chemists; a very thorough investigation was made by Debus in 1888 (*C. J.* 53, 278; where references will be found to other memoirs). The solution examined by Debus was prepared by passing a slow current of  $\text{H}_2\text{S}$  into 480 c.c. nearly saturated  $\text{SO}_2\text{Aq}$  at a little above  $0^\circ$  for two hours, keeping in a stoppered bottle for forty-eight hours at the ordinary temperature, passing in  $\text{H}_2\text{S}$  for two hours, after forty-eight hours again passing in  $\text{H}_2\text{S}$ , and repeating these treatments until the liquid no longer smelled of  $\text{SO}_2$  after standing for a couple of hours at the ordinary temperature (about two weeks were required before the action was completed). The liquid thus obtained contains a large quantity of S, partly as a hard brittle solid, partly as a soft and gummy mass, and partly in suspension in minute particles which pass through filter paper; the liquid remains milky after filtration, and does not become clear on standing for two or three weeks (regarding the variety of S in solution, v. SULPHUR, *Allotropic forms* of, p. 608). Debus (*l.c.*, p. 348) thinks that the product of the direct interaction of  $\text{SO}_2\text{Aq}$  and  $\text{H}_2\text{SAq}$  is  $\text{H}_2\text{S}_2\text{O}_8$  ( $3\text{SO}_2\text{Aq} + \text{H}_2\text{SAq} = \text{H}_2\text{S}_2\text{O}_8\text{Aq}$ ); that part of this  $\text{H}_2\text{S}_2\text{O}_8$  reacts with excess of  $\text{SO}_2\text{Aq}$  to form  $\text{H}_2\text{S}_3\text{O}_9\text{Aq}$  and  $\text{H}_2\text{S}_4\text{O}_{10}\text{Aq}$  ( $? \text{H}_2\text{S}_2\text{O}_8\text{Aq} + \text{H}_2\text{SO}_4\text{Aq} = \text{H}_2\text{S}_3\text{O}_9\text{Aq} + \text{H}_2\text{S}_4\text{O}_{10}\text{Aq}$ ), and that part of the  $\text{H}_2\text{S}_2\text{O}_8\text{Aq}$  reacting with  $\text{H}_2\text{SO}_4\text{Aq}$  forms  $\text{H}_2\text{S}_2\text{O}_8\text{Aq}$  ( $? \text{H}_2\text{S}_2\text{O}_8\text{Aq} + \text{H}_2\text{SO}_4\text{Aq} = \text{H}_2\text{S}_2\text{O}_8\text{Aq} + \text{H}_2\text{SO}_4\text{Aq}$ ) (*D.*, *l.c.*, p. 333); that the  $\text{H}_2\text{S}$  reacts with  $\text{H}_2\text{S}_2\text{O}_8\text{Aq}$  to form  $\text{H}_2\text{O}$  and S, part of the S combining, as it is formed, with  $\text{H}_2\text{S}_2\text{O}_8\text{Aq}$  to form  $\text{H}_2\text{S}_3\text{O}_9\text{Aq}$ ,  $\text{H}_2\text{S}_4\text{O}_{10}\text{Aq}$  and  $\text{H}_2\text{S}_5\text{O}_{11}\text{Aq}$ , and part

remaining in solution as colloidal S. If  $\text{H}_2\text{S}$  is passed into Wackenroder's solution, more  $\text{H}_2\text{S}_2\text{O}_8$  is formed; and if the passage of  $\text{H}_2\text{S}$  is continued until all reaction ceases the thionic acids are decomposed, and the final products are S and  $\text{H}_2\text{O}$ , so that the equation  $\text{SO}_2\text{Aq} + 2\text{H}_2\text{SAq} = 3\text{S} + 2\text{H}_2\text{O}$  correctly represents the interaction of  $\text{SO}_2\text{Aq}$  with  $\text{H}_2\text{SAq}$  so far as the final products are concerned (*v. D.*, *l.c.*, p. 351).

Solutions of the thionic acids more or less rapidly decompose, the final products being  $\text{H}_2\text{SO}_4\text{Aq}$ ,  $\text{SO}_2\text{Aq}$ , and S; oxidisers such as Cl or  $\text{HNO}_3\text{Aq}$ —in some cases air is sufficient—convert them into  $\text{H}_2\text{SO}_4\text{Aq}$ ; reducers, such as Na amalgam, produce  $\text{H}_2\text{S}_2\text{O}_8\text{Aq}$ , sometimes also  $\text{H}_2\text{SO}_4\text{Aq}$ , and in some cases  $\text{H}_2\text{SAq}$ . None of the acids has been isolated apart from water; salts of all are known (*v. THIONATES*, p. 695). The acids are all dibasic.

Regarding the constitution of the thionic acids v. Mendeleeff, *B.* 3, 870; Michaelis, *A.* 170, 31; Spring, *D.* 6, 1108; Debus, *C. J.* 53, 351.

**DITHIONIC ACID  $\text{H}_2\text{S}_2\text{O}_8\text{Aq}$ .** (*Hyposulphuric acid*.) A solution of this acid is formed by suspending coarsely-powdered  $\text{MnO}_2$  in water, and passing in  $\text{SO}_2$  while the liquid is kept at  $c. 0^\circ$ ; filtering, adding  $\text{BaO}$  to alkaline reaction, and filtering from  $\text{BaSO}_4$  and  $\text{MnO}_2\text{H}_2$ ; evaporating, crystallising out  $\text{BaS}_2\text{O}_8$ , 2aq, and decomposing this salt in solution by the equivalent quantity of  $\text{H}_2\text{SO}_4\text{Aq}$  filtering from  $\text{BaSO}_4$ , and evaporating *in vacuo* till a liquid of S.G. 1.347 is obtained ( $\text{MnO}_2 + 2\text{SO}_2\text{Aq} = \text{MnS}_2\text{O}_8\text{Aq}$ ;  $\text{MnO}_2 + \text{SO}_2\text{Aq} = \text{MnSO}_4\text{Aq}$ ) (Spring, *A.* Bourgeois, *Bl.* [2] 46, 151). If evaporation is continued beyond this concentration,  $\text{H}_2\text{SO}_4\text{Aq}$  and  $\text{SO}_2$  are formed; the same decomposition occurs when  $\text{H}_2\text{S}_2\text{O}_8\text{Aq}$  is evaporated by heat.  $\text{H}_2\text{S}_2\text{O}_8\text{Aq}$  is reduced by Zn and  $\text{HClAq}$  to  $\text{H}_2\text{SO}_4\text{Aq}$  at  $0^\circ$  (Otto, *A.* 147, 187); it is oxidised to  $\text{H}_2\text{SO}_4\text{Aq}$  by Cl,  $\text{HNO}_3$ ,  $\text{KClO}_3$  and  $\text{HCl}$  &c.; it slowly oxidises in air (*cf. DITHIONATES*, p. 695). Thomsen (*Th.* 2, 259) gives the following heats of formation of  $\text{H}_2\text{S}_2\text{O}_8\text{Aq}$ :— $[\text{S}^\circ\text{O}_2\text{Aq}] = 211,080$ ;  $[2\text{SO}_2^\circ\text{O}_2\text{Aq}] = 68,920$ ;  $[2\text{SO}_2^\circ\text{Aq}, \text{O}] = 53,520$ ; for the heat of oxidation of  $\text{H}_2\text{S}_2\text{O}_8\text{Aq}$  to  $\text{H}_2\text{SO}_4\text{Aq}$  he gives  $[\text{S}_2\text{O}_8\text{Aq} + \text{O} = 2\text{SO}_4\text{Aq}] [\text{S}^\circ\text{O}_2\text{Aq}, \text{O}] = 79,740$ .

**TRITHIONIC ACID  $\text{H}_2\text{S}_3\text{O}_9\text{Aq}$ .** A dilute solution of this acid is formed by decomposing  $\text{K}_2\text{S}_3\text{O}_9\text{Aq}$  by the equivalent quantity of  $\text{HClO}_4\text{Aq}$  or  $\text{H}_2\text{SiF}_6\text{Aq}$ , and filtering from  $\text{KClO}_4$  or  $\text{K}_2\text{SiF}_6$  (Langlois, *C. R.* 10, 461; 62, 812; Kessler, *P.* 74, 250). The dilute solution cannot be evaporated, even *in vacuo*, without partial decomposition, with formation of  $\text{SO}_2$  and S; when heated it rapidly changes to  $\text{H}_2\text{SO}_4\text{Aq}$ ,  $\text{SO}_2$ , and S. The dilute solution is colourless and odourless, and has a sour and bitter taste (*cf. TRITHIONATES*, p. 696). The K salt, from which the acid solution is obtained, may be prepared by dissolving  $\text{K}_2\text{S}_3\text{O}_9$  in water containing one-eighth part of alcohol, adding the salt till the alcohol separates from the aqueous solution, passing in  $\text{SO}_2$ , with addition from time to time of a little  $\text{K}_2\text{S}_3\text{O}_9$ , temperature being kept at  $25^\circ\text{--}30^\circ$ , till the liquid is yellow and smells of  $\text{SO}_2$ , setting aside till crystals separate, and re-crystallising from warm water (filtering from separated S) (Plessey, *A. Ch.* [3] 11, 182).

**TETRAATHIONIC ACID**  $\text{H}_2\text{S}_4\text{O}_6\text{Aq}$ .  $\text{PbS}_2\text{O}_6\text{Aq}$  is decomposed by the equivalent quantity of  $\text{H}_2\text{SO}_4\text{Aq}$  (not by  $\text{H}_2\text{S}$ , which reacts with  $\text{H}_2\text{S}_4\text{O}_6$ ), and the filtrate from  $\text{PbSO}_4$  is concentrated on the water-bath, and then *in vacuo* over  $\text{H}_2\text{SO}_4$  (Fordos a. Gélis, *C. R.* 115, 920).  $\text{PbS}_2\text{O}_6$  may be prepared by pouring a solution of 2 pts.  $\text{Na}_2\text{S}_2\text{O}_8 \cdot 5\text{H}_2\text{O}$  in much warm water into a dilute warm solution of 8 pts. lead acetate, and thoroughly washing the ppt.  $\text{PbS}_2\text{O}_6$  with warm water, adding water enough to partially dissolve the  $\text{PbS}_2\text{O}_6$ , then adding 1 pt. I, and letting stand for some days, with frequent shaking, filtering from  $\text{PbI}_2$ , evaporating and crystallising ( $2\text{PbS}_2\text{O}_6 + 2\text{I} + \text{Aq} = \text{PbS}_2\text{O}_6\text{Aq} + \text{PbI}_2$ ).

$\text{H}_2\text{S}_4\text{O}_6\text{Aq}$  is colourless and odourless; it has a sour taste. Dilute  $\text{H}_2\text{S}_4\text{O}_6\text{Aq}$  may be boiled without change, but the conc. solution decomposes to  $\text{H}_2\text{SO}_4\text{Aq}$ ,  $\text{SO}_2$ , and S. Dilute  $\text{HClAq}$  or  $\text{H}_2\text{SO}_4\text{Aq}$  does not interact with cold  $\text{H}_2\text{S}_4\text{O}_6\text{Aq}$ ; on warming  $\text{H}_2\text{S}$  is given off;  $\text{HNO}_3\text{Aq}$  or Cl rapidly oxidises  $\text{H}_2\text{S}_4\text{O}_6\text{Aq}$  to  $\text{H}_2\text{SO}_4\text{Aq}$  (*cf.* TETRAATHIONATES, p. 696). Thomsen (*Th.* 2, 262) gives the following data for I.E.:— $[\text{S}_2\text{O}_3^-\text{Aq}] = 192,430$ ;  $[\text{S}_2\text{O}_3^-\text{S}_2\text{O}_6\text{Aq}] = 50,270$ ;  $[\text{S}_2\text{O}_3^-\text{Aq}, \text{S}_2\text{O}_6] = 34,870$ ;  $[\text{S}_2\text{O}_3^-\text{Aq}, \text{O}] = 53,490$ .

**PENTATHIONIC ACID**  $\text{H}_2\text{S}_5\text{O}_6\text{Aq}$ , and **HEXATHIONIC ACID**  $\text{H}_2\text{S}_6\text{O}_6\text{Aq}$ . These acids very probably exist in *Wackher's solution* (*v. supra*, p. 698), as salts of  $\text{H}_2\text{S}_5\text{O}_6$ , and probably also of  $\text{H}_2\text{S}_6\text{O}_6$ , have been obtained from that solution; solutions of the acids have not been isolated (*v.* PENTATHIONATES, p. 697, and HEXATHIONATES, p. 697).

M. M. P. M.

**THIONINE**. The group  $\text{S} \begin{smallmatrix} \text{C}_6\text{H}_5 \\ \text{C}_6\text{H}_4(\text{NH}_2)\text{N} \end{smallmatrix} \text{NH}$  *i.e.*  $\text{C}_6\text{H}_4(\text{NH}_2) \begin{smallmatrix} \text{S} \\ \text{N} \end{smallmatrix} \text{C}_6\text{H}_4\text{NH}_2$  (Bernthsen a. Goske, *B.* 20, 931).

**THIONOL**  $\text{C}_6\text{H}_4\text{NSO}_2$ , *i.e.*  $\text{S} \begin{smallmatrix} \text{C}_6\text{H}_5 \\ \text{C}_6\text{H}_4(\text{OH})\text{N} \end{smallmatrix} \text{O}$ . Formed by heating imido-di-phenyl sulphide with dilute  $\text{H}_2\text{SO}_4$  at  $150^\circ\text{--}160^\circ$  (Bernthsen, *A.* 230, 188). Brownish-red powder, which acquires green lustre on rubbing. Insol. cold water, sol. acids and alkalis, forming a violet solution. Yields di-oxy-imido-diphenyl sulphide (*q. v.*) on reduction.— $\text{B}'\text{H}_2\text{SO}_4$ . Green needles.— $\text{B}'\text{BaO}$  (dried at  $100^\circ$ ). Plates with green lustre.— $\text{B}'\text{Ag}_2\text{O}$  (dried at  $100^\circ$ ). Brown amorphous pp.

**THIONOLINE** *v.* OXY-AMIDO-IMIDO-DIPHENYL SULPHIDE.

**THIONURIC ACID**  $\text{C}_6\text{H}_4\text{N}_2\text{SO}_4$ , *i.e.*  $\text{CO} \begin{smallmatrix} \text{NH.CO} \\ \text{NH.CO} \end{smallmatrix} \text{CH.NH.SO}_2\text{H}$ . Formed by the simultaneous action of  $\text{NH}_3$  and  $\text{SO}_2$  on alloxan in aqueous solution (Liebig a. Wöhler, *A.* 26, 268, 314, 331). Formed also by warming nitrosobarbituric acid with ammonium sulphite (Baeyer, *A.* 127, 210). Crystalline mass of needles, *v. sol.* water. Decomposed by boiling water into uranil and  $\text{H}_2\text{SO}_4$ . Reduces ammoniacal  $\text{AgNO}_3$  to a mirror.— $(\text{NH}_4)_2\text{A}''\text{aq}$ . Four-sided tables, *sl. sol.* cold water. At  $200^\circ$  it yields  $(\text{NH}_4)_2\text{SO}_4$  and xanthanine (Finck, *A.* 182, 298).— $(\text{NH}_4)\text{HA}''$ . White needles.— $\text{CaA}''$ . Prisms.— $\text{PbA}''\text{aq}$ .

**THIONYL-*m*-AMIDO-BENZOIC ACID**  $\text{SO}_2\text{N.C}_6\text{H}_4\text{CO}_2\text{H}$ .

*Methyl ether*  $\text{MeA}'$ . [ $57^\circ$ ]. ( $212^\circ$  at 100 mm.). Formed from methyl *m*-amido-benzoate

and  $\text{SOCl}_2$  (Michaelis, *A.* 274, 250). Yellow crystalline mass, *v. sol.* ether and benzene.

*Ethyl ether*  $\text{EtA}'$ . Oil.

**THIONYL-DIAMIDO-DI-PHENYL-ETHYLENE**  $\text{C}_6\text{H}_4(\text{C}_6\text{H}_4\text{N}_2\text{SO})_2$ . [ $202^\circ$ ]. Formed from di-amido-stilbene and  $\text{SOCl}_2$  (Michaelis, *A.* 274, 265). Red needles, *m. sol.* benzene and  $\text{CHCl}_3$ .

**THIONYL-AMIDO-PHENOL**. *Ethyl derivative*  $\text{C}_6\text{H}_4(\text{OEt})(\text{N}_2\text{SO})$ . [ $32^\circ$ ]. ( $220^\circ$  at 200 mm.). Formed from *p*-amido-phenetol and  $\text{SOCl}_2$  (Michaelis, *A.* 274, 246). Light-yellow needles, *v. sol.* ether. Slowly decomposed by water.

**THIONYL-AMYLAMINE**  $\text{SO}_2\text{NC}_5\text{H}_{11}$ . ( $87^\circ$  at 60 mm.). Formed from amylamine ( $103^\circ$ ) in ether and  $\text{SOCl}_2$  (Michaelis, *A.* 274, 191). Oil, decomposed by water.

**THIONYL-ANILINE**  $\text{C}_6\text{H}_5\text{N}_2\text{SO}$ . ( $200^\circ$ ). S.G. 1.236. Formed from aniline in benzene solution and  $\text{SOCl}_2$  (Michaelis, *B.* 23, 3480; 24, 745). Liquid with peculiar odour, *sol.* alcohol. Converted by alkalis into aniline and sulphite. Chlorine forms tri-chloro-aniline [ $78^\circ$ ]. Conc.  $\text{HClAq}$  also forms aniline and  $\text{SO}_2$ . The compound  $\text{C}_6\text{H}_4\text{Br}_2\text{N}_2\text{SO}$  [ $75^\circ$ ] is formed from tri-bromo-aniline in benzene and  $\text{SOCl}_2$ . The compounds  $[1;2]\text{C}_6\text{H}_4\text{Cl}_2\text{N}_2\text{SO}$  [ $-8^\circ$ ],  $[1;3]\text{C}_6\text{H}_4\text{Cl}_2\text{N}_2\text{SO}$  ( $233^\circ$ ) and  $[1;4]\text{C}_6\text{H}_4\text{Cl}_2\text{N}_2\text{SO}$  [ $36^\circ$ ] ( $237^\circ$ ) are formed in like manner. *o*-, *m*-, and *p*-Thionyl-bromo-anilines melt at  $4^\circ$ ,  $32^\circ$ , and  $61^\circ$  respectively (Michaelis, *A.* 274, 221). Thionyl-tetra-bromo-aniline melts at  $78^\circ$ . Thionyl-*p*-iodo-aniline [ $64^\circ$ ] and  $[4;2;1]\text{C}_6\text{H}_3\text{I}_2\text{N}_2\text{SO}$  [ $74^\circ$ ] are also crystalline.

*Reference*.—NITRO-THIONYL-ANILINE.

**THIONYL BROMIDE**  $\text{SOBr}_2$ , *v.* SULPHUR OXYBROMIDES, p. 617.

**THIONYL-ISOBUTYLAMINE**  $\text{C}_4\text{H}_9\text{NSO}$ , *i.e.*  $\text{CHMe}_2\text{CH}_2\text{N}_2\text{SO}$ . ( $116^\circ$ ). Formed from  $\text{SOCl}_2$  and isobutylamine in ether (Michaelis, *A.* 274, 191). Liquid, with pleasant smell.

**THIONYL CHLORIDE**  $\text{SOCl}_2$ , *v.* SULPHUR OXYCHLORIDES, p. 617.

**THIONYL-CUMIDINE**  $\text{C}_6\text{H}_4\text{Pr.N}_2\text{SO}$ . ( $158^\circ$ ). Got from  $\text{SOCl}_2$  and the cumidine obtained from isopropyl-benzene by nitration and reduction (Michaelis, *A.* 274, 239). Oil, not decomposed by boiling water.

Thionyl-*p*-cumidine  $\text{C}_6\text{H}_4\text{Me}_2\text{N}_2\text{SO}$ . [ $-10^\circ$ ]. ( $246^\circ$ ). Oil, *v. sol.* alcohol and ether.

**THIONYL-ETHYLAMINE**  $\text{EtN}_2\text{SO}$ . ( $78^\circ$ ). Formed by adding  $\text{SOCl}_2$  to an ethereal solution of ethylamine cooled below  $0^\circ$  (Michaelis, *B.* 24, 756).

**THIONYL-MESIDINE**  $\text{C}_6\text{H}_4\text{Me}_2\text{N}_2\text{SO}$ . [ $-11^\circ$ ]. ( $241^\circ$ ). S.G. 1.4121. Volatile with steam (Michaelis, *A.* 274, 240).

**THIONYL-METHYLAMINE**  $\text{MeN}_2\text{SO}$ . ( $59^\circ$ ). Liquid (Michaelis, *A.* 274, 187).

**THIONYL-METHYL-ANILINE**  $\text{SO}(\text{C}_6\text{H}_4\text{NHMe})_2$ . [ $154^\circ$ ]. Formed from  $\text{SOCl}_2$  and methyl-aniline in ethereal solution in presence of  $\text{AlCl}_3$  (Michaelis a. Godehaux, *B.* 23, 3019). Colourless needles, *v. sol.* alcohol. Yields a nitrosamine  $\text{SO}(\text{C}_6\text{H}_4\text{NMeNO})_2$ . [ $171^\circ$ ].

**THIONYL-( $\alpha$ )-NAPHTHYLAMINE**  $\text{C}_{10}\text{H}_7\text{N}_2\text{SO}$ . [ $33^\circ$ ]. ( $226^\circ$  at 100 mm.). Formed from ( $\alpha$ )-naphthylamine in benzene and  $\text{SOCl}_2$  (Michaelis, *A.* 274, 259). Reddish yellow needles, slowly converted by water into naphthylamine sulphite.

**Thionyl-( $\beta$ )-naphthylamine** [58°]. Needles. The thionyl derivative of bromo-( $\beta$ )-naphthylamine [68°] melts at 118°.

**THIONYL-*o*-NITRO-ANILINE**  $C_6H_4N_2SO_2$ , i.e.  $C_6H_4(NO_2)N:SO$ . [62°], the *m*-compound melts at 63°, while the *p*-isomeride melts at 70° (Michaelis, A. 274, 225).

**THIONYL-NITRO-MESIDINE**  $C_6H_4N_2SO_2$ , i.e.  $C_6H_4(NO_2)N:SO$ . [77°]. Got from nitro-mesidine [74°] (Michaelis, A. 274, 241). Light yellow needles, v. s. sol. benzene.

**Thionyl-di-nitro-mesidine**. [127°]. Formed from di-nitro-mesidine [193°].

**THIONYL-NITRO-NAPHTHYLAMINE**  $C_{10}H_6(NO_2)N:SO$ . Nitro-naphthylamines [191°] and [119°] yield thionyl derivatives melting at 89° and 135° respectively (Michaelis, A. 274, 258).

**THIONYL-NITRO-TOLUIDINE**  $C_7H_7N_2SO_2$ , i.e.  $C_7H_7Me(NO_2)N:SO$ . The compounds from (2,1,4)-nitro-toluidine [75°] and (3,1,4)-nitro-toluidine [114°] melt at 44° and 39° respectively (Michaelis, A. 274, 232).

**DI-THIONYL-PHENYLENE-DIAMINE**  $C_6H_4(N:SO)_2$ . The *m*- and *p*-compounds melt at 44° and 116° respectively (Michaelis, A. 274, 261).

**THIONYL-PHENYLETHYL-AMINE**  $PhCH_2CH_2N:SO$ . (172° at 25 mm.). Liquid, decomposed by water into  $SO_2$  and base.  $SO_2$  passed into its ethereal solution forms amorphous  $PhCH_2CH_2NH:SO_2H$ , whence benzoic aldehyde yields  $PhCH_2CH_2N(SO_2H)CHPh.OH$  [114°] (Michaelis, B. 26, 2167).

**THIONYL-PHENYL-HYDRAZINE** v. Action of  $SOCl_2$  on PHENYL-HYDRAZINE.

**THIONYL-PHENYL-PROPYLAMINE**  $CH_3PhCH_2CH_2N:SO$ . Formed from phenyl-propylamine hydrochloride and  $SOCl_2$  (Michaelis a. Jacobi, B. 26, 2161).  $SO_2$  passed into its ethereal solution forms the amorphous compound  $NH(SO_2H)C_6H_4Ph$ , which reacts with benzoic aldehyde forming  $SO_2H.N(CHPh.OH)C_6H_4Ph$  [106°].

**THIONYL-PROPYLAMINE**  $PrN:SO$ . (104°). Smells like bleaching-powder (Michaelis, A. 274, 190).

**THIONYL-TOLUIDINE**  $C_7H_7Me.N:SO$ . Formed from toluidine and  $SOCl_2$ . The *o*-compound is liquid (184° at 100 mm.). The *m*-compound is liquid (220°). The *p*-isomeride [7°] (c. 224°) may be crystallised by cooling (Michaelis a. Herz, B. 23, 8482; 24, 758; A. 274, 231). The thionyl derivatives of (3,1,4)- and (5,1,2)-bromo-toluidines melt at 47° and 50° respectively.

**THIO-ORCIN**  $C_6H_4Me(SH)_2$ . [35°]. Formed by reducing  $C_6H_4Me(SO_2Cl)_2$  with tin and  $HClAq$  (Gabriel, B. 12, 1640).— $PbO.H_2S$ .

**THIONYL-XYLIDINE**  $C_8H_8Me.N:SO$ . The (1,2,4)-compound [−9°] (131° at 20 mm.), (1,3,4)-compound (238°), and (1,4,2)-isomeride [−8°] (119° *in vacuo*) are all oily (Michaelis, A. 274, 287). Thionyl-fluoro-xylylidine (144° at 45 mm.) is also an oil.

**THIO-OXALIC ACID**. *Ethylether*  $C_2H_4SO_2$ , i.e.  $CO_2Et.CO_2SEt$ . (217° cor.). S.G. 2 1.145. Formed by the action of  $Cl.CO.CO_2Et$  on mercaptan (Morley a. Saint, C. J. 43, 400). Colourless liquid with faint odour like garlic. Decomposed by  $KOHAq$  into mercaptan, alcohol, and oxalate. Alcoholic  $KOH$  (1 mol.) forms  $EtSH$  and  $CO_2Et.CO_2K$ . Water slowly decomposes it, forming oxalic acid, alcohol, and mer-

captan. Dry  $NH_3$  forms mercaptan and  $CO_2Et.CONH_2$ .

( $\beta$ )-Thio-oxalic acid  $NH_2.CS.CO_2H$ . The salt  $C_2H_3KNSO_3$  is formed by the action of cold conc.  $KOHAq$  on the ethers. It crystallises in needles, v. sol. water and decomposed by evaporating. The free acid is unstable.

*Amide of the methyl ether*.  $NH_2.CS.CO_2Me$ . [86°]. Formed by passing dry  $H_2S$  into  $Cy.CO_2Me$  (Weddige, J. pr. [2] 7, 79; 9, 133; 10, 193). Light-yellow crystals, sol. water, alcohol, and ether.

*Amide of the ethylether*  $NH_2.CS.CO_2Et$ . Mol. w. 133. [64°]. Formed in like manner. Lemon-yellow crystals. Re-converted by boiling with alcohol and  $Pb(OH)_2$  into cyanofornic ether. Methylamine and ethylamine form the crystalline compounds  $CO(NHMe).CS.NH_2$  and  $CO(NHEt).CS.NH_2$  respectively.

*Amide of the isobutyl ether*  $NH_2.CS.CO_2C_4H_9$ . [58°]. Lemon-yellow crystals, sl. sol. water.

*Di-amide*  $CO(NH_2).CS.NH_2$ . Formed from  $CO_2Et.CS.NH_2$  and alcoholic ammonia (Weddige, J. pr. [2] 9, 137). Lemon-yellow needles (from alcohol), sl. sol. water.

*Di-thio-oxalic acid*. *Amide*  $CS(NH_2).CS(NH_2)$ . *Hydrogen rubecide*. Mol. w. 120. Formed, together with yellow  $Cy.CS.NH_2$ , by combination of cyanogen with  $H_2S$  (Wöhler, P. 3, 177; Vöckel, A. 38, 315). Formed also by passing cyanogen into an alcoholic solution of  $NaSH$  and ppg. by  $HCl$  (Wollner, J. pr. [2] 29, 129; Ephraim, B. 22, 2305). Prepared by passing  $H_2S$  into an ammoniacal solution of  $CuSO_4$ , which has been decolourised by  $KCy$  (Formánček, B. 22, 2655). Small yellowish-red crystals, sl. sol. water, sol. alcohol and ether. Dilute  $KOHAq$  forms oxalic acid, conc.  $KOHAq$  forms  $KCy$  and  $KCyS$ . Boiling  $HClAq$  forms oxalic acid.  $MeI$  and  $MeOH$  at 150° form  $SMe.I$ . Alcoholic hydroxylamine hydrochloride (2 mols.) forms  $C_6(NH_2)_2(NOH)_2$  and  $H_2S$ . Benzoic aldehyde, acting on a boiling solution, forms a compound [209°] which is apparently

$CHPh<\overset{S}{N}>C.C<\overset{S}{N}>CHPh$  (Ephraim, B. 24,

1027).— $PbC_2H_4N_2S_2$ : orange pp. (Wallach, B. 13, 528). Yields  $PbS$  on boiling with water.

*Anilide*  $CS(NHPh).CS(NHPh)$ . [133°]. Formed from oxanilide by successive treatment with  $PCl_5$  and  $H_2S$  (Wallach, B. 13, 527). Golden plates.

*Di-methyl-di-amide*  $CS(NHMe).CS(NHMe)$ . [140°]. Formed from thiocyanic acid, alcohol, and methylamine (Wallach, A. 262, 360). Yellow crystals, sl. sol. alcohol. Converted by  $NaOEt$  and propyl chloride into  $C(NMe)(SC_2H_5).C(NMe)(SC_2H_5)$  (170°–175°).

*Di-ethyl-di-amide*  $CS(NHEt).CS(NHEt)$ . [58°]. Formed in like manner. Yellowish-red crystals, insol. water. Converted by  $NaOEt$  and  $EtI$  into  $C(NEt)(SEt).C(NEt)(SEt)$  (126°–129°).

*Di-amyl-di-amide*  $CS(NHC_4H_9).CS(NHC_4H_9)$ . [60°]. Formed from thiocyanic acid, alcohol, and amylamine (Wallach, A. 262, 362). Red prisms.

*Di-benzyl-diamide*  $CS(NHC_6H_5).CS(NHC_6H_5)$ . [115°]. Formed

from thiocyanic acid, alcohol, and benzylamine. Yellowish-red crystals, al. sol. warm alcohol.

**Hexa-thio-ortho-oxalic acid.** *Ethyl ether*  $C_2(SEt)_4$ . Formed from  $C_2Cl_4$  and  $NaSEt$  (Claesson, *J. pr.* [2] 15, 212). Heavy oil.

**THIO-OLY- v. SULPHYDRO-**

**THIO-PARABANIC ACID.** *Methyl derivative v. METHYL-THIO-PARABANIC ACID.*

*Allyl derivative*  $C_6H_4N_2SO_2$ , i.e.

$CS \begin{smallmatrix} \text{NH} \cdot \text{CO} \\ \text{N}(C_2H_5) \end{smallmatrix} > CO$ . *Oxalyl- thio- sinamine.*

[90°]. Formed by warming the dicyanide of allyl-thio-urea with dilute  $H_2SO_4$  (Maly, *Z.* 1869, 260). Lemon-yellow needles, m. sol. cold water.

**THIOPHENE**  $C_4H_4S$  i.e.  $S \begin{smallmatrix} \text{CH} \cdot \text{CH} \\ \text{CH} \cdot \text{CH} \end{smallmatrix}$  (84° cor.). V.D. 3.0 (calc. 2.9). S.G.  $\approx$  1.062;  $\frac{d}{4}$  1.0884;  $\frac{d}{15}$  1.0705 (R. Schiff, *B.* 18, 1601). S.V. 84.9.  $R_D$  41.4 (Nasini a. Scala, *G.* 17, 70). H.C.p. 670,900 (Berthelot a. Matignon, *C. R.* 111, 10; *Bl.* [3] 4, 252). H.F. -14900. *Critical temperature* 317° (Pawlewski, *B.* 21, 2141). *Critical pressure* 47.7 atmospheres. Occurs in coal-tar benzene to the extent of about .5 p.c. (V. Meyer, *B.* 16, 1471).

**Formation.**—1. In small quantity by passing acetylene through boiling sulphur (V. Meyer a. Sandmeyer, *B.* 16, 2176).—2. By heating succinic anhydride with  $P_2S_5$ .—3. By heating sodium succinate with  $P_2S_5$ , the yield being 50 p.c. of the theoretical amount (Volhard a. Erdmann, *B.* 18, 454). It is not formed by heating *s*-di-bromo-succinic acid with  $P_2S_5$  or  $P_2S_3$  (Ossipoff, *J. R.* 20, 215).—4. By heating erythrite with  $P_2S_5$  (Paul a. Tafel, *B.* 18, 688).—5. From its (a)-carboxylic acid, which is obtained by heating mucic acid with  $BaS$  (Paul a. Tafel, *B.* 18, 456).—6. In small quantities by passing  $Et_2S$  through a red-hot tube (Meyer, *B.* 18, 217).—7. In small quantities by passing ethylene, coal-gas, or ligroin-vapour over heated iron pyrites.—8. In small quantities by heating  $P_2S_5$  with crotonic acid, with *n*-butyric acid, with paraldehyde, or with ether (Meyer).

**Isolation.**—20 pts. commercial 'pure' benzene is shaken for four hours with 1 pt. of  $H_2SO_4$ . The acid is diluted with two or three times its weight of water and treated at once with steam. Nearly pure thiophene passes over. Yield, about 3½ p.c. by volume of the  $H_2SO_4$ , used (Schulze, *B.* 18, 497).

**Properties.**—Liquid with faint odour, not decomposed below 335°. Not solid at -20°. Greatly resembles benzene. Oxidised by  $HNO_3$  with great violence. On shaking with isatin and  $H_2SO_4$ , it yields a blue colouring matter (indophenine). Not affected by boiling with sodium. Benzene that contains thiophene gives a bright-blue colour to  $H_2SO_4$  containing nitrous acid. Thiophene (10 g.) shaken with alcohol (100 g.), cold saturated  $HgCl_2$  solution (1,000 g.), and  $NaOAc$  (70 g.) dissolved in water (130 g.) forms a white pp. containing  $C_4H_4(HgCl)S$ , which crystallises from alcohol in white plates [188°], and  $C_4H_4(HgCl)_2S$ , a white powder, insol. alcohol (Volhard, *A.* 267, 172). The compound  $C_4H_4(HgCl)S$  is converted by  $AcCl$  into a thienyl methyl ketone and by  $I$  into di-iodo-thiophene. Thiophene combines with  $CHPh$ , and with di-bromo-di-( $\beta$ )-naphthyl oxide (Liebermann, *B.* 26, 853).

**Reactions.**—1. *Chloral* and  $H_2SO_4$  yield  $CCl_2 \cdot CH(C_2H_5)_2$ .—2.  $BzCl$  and  $AlCl_3$  form thienyl phenyl ketone.—3. *Phenyl-glyoxylic acid* and  $H_2SO_4$  form  $C_{12}H_8NSO_2$ , which dissolves in chloroform with crimson, and in  $H_2SO_4$  with purple colour.—4.  $Cl$  and  $Br$  yield chloro- and bromo- derivatives.—5.  $H_2SO_4$  forms a brown solution containing a sulphonic acid, and slowly decomposes the thiophene, forming  $H_2S$ ,  $SO_2$ , and an amorphous pp.—6.  $H_2SO_4$  and  $KNO_3$  form a compound called 'nitroso-dithiophene'

$HO \cdot N \begin{smallmatrix} \text{C}_2\text{H}_5 \\ \text{C}_2\text{H}_5 \end{smallmatrix} > O$  (?), ppd. by water as a dark

insoluble powder (Liebermann, *B.* 20, 8281).—7. Passed with  $PCl_5$  through a red-hot tube it forms  $C_4H_3S \cdot PCl_2$  (218°) which is decomposed by water into  $C_4H_3S \cdot PO(OH)_2$  [70°] and is converted by  $Cl$  into  $C_4H_3S \cdot PCl_4$ , which is converted by  $SO_2$  into  $C_4H_3S \cdot POCl_2$  (259°) and by water into  $C_4H_3S \cdot PO(OH)_2$  [169°] (Sachs, *B.* 25, 1514).—8. *Diazobenzene chloride* and  $AlCl_3$  forms ( $\beta$ )-phenyl-thiophene [57°] (Mühlau a. Berger, *B.* 26, 2001).

**References.**—AMIDO-, BROMO-, DI-BROMO-DI-NITRO-CHLORO-, TRI-CHLORO-NITRO-, IODO-, IODONITRO-, and NITRO- THIOPHENE.

#### THIOPHENE (a)-CARBOXYLIC ACID

$C_4H_3SO_2$  i.e.  $S \begin{smallmatrix} \text{CH} \text{---} \text{CH} \\ \text{C}(CO_2H) \cdot \text{CH} \end{smallmatrix}$  Thiophene 'a'.

*carboxylic acid.* [126.5°]. (260° cor.). I.H.F. 85,400. H.C.p. 591,900 (Stohmann, *J. pr.* [2] 43, 12). Formed by adding sodium-amalgam to a mixture of  $Cl \cdot CO_2Et$  with (a)-iodothiophene, with di-iodo-thiophene, or with di-bromo-thiophene (Nahsen, *B.* 17, 2192; 18, 2304; Ronz, *B.* 18, 2306). Formed also by heating mucic acid with  $BaS$  for 6 hours at 205°, the yield being 12 p.c. of the theoretical (Paul a. Tafel, *B.* 18, 456). Obtained by oxidation of (a)-ethyl-thiophene (Schleicher, *B.* 18, 3017), of (a)-propyl-thiophene (Ruffi, *B.* 20, 1740), of thienyl methyl ketone (Peter, *B.* 17, 2645; 18, 542), and of thienyl ethyl ketone (Ernst, *B.* 20, 518) with alkaline  $KMnO_4$ .

**Properties.**—Slender white needles (from water) or long flat needles (by sublimation), v. sol. hot water, sl. sol. cold, v. e. sol. alcohol and ether, m. sol. chloroform, sl. sol. ligroin. Gives a blue colour on warming with isatin and  $H_2SO_4$  (indophenine reaction). Yields thiophene on distilling with lime. Yields a di-bromo-derivative [211°].

**Salts.**— $BaA'$ , 2aq. Small crystals. S. 22.19 at 14.5°.— $CaA'_2$ , 3aq. S. 18.5 at 18.5°.— $ZnA'_2$  (dried). S. 14 at 15°.— $PbA'_2$  (dried) .5 at 18.5°.— $AgA'$ : plates or needles. S. .195 at 11°.

*Ethyl ether*  $EtA'$ . (218° cor.). S.G. 1.115. Liquid, smelling like benzoic ether.

*Chloride*  $C_4H_3S \cdot COCl$ . (190° uncor.). Liquid, smelling like benzoyl chloride.

*Amide*  $C_4H_3S \cdot CONH_2$ . [174°] (Meyer, *A.* 236, 210). Prisms, m. sol. ether. Phenyl thiocarbimide forms  $C_4H_3S \cdot CO \cdot NH \cdot CO \cdot NHPh$ . [206°]

*Anilide*  $C_4H_3S \cdot CONHPh$ . [140°]. Formed by the action of phenyl cyanate on thiophene in presence of  $AlCl_3$  (Leuchart a. Schmidt, *B.* 18, 2340). Iridescent plates.

*Amidoxim*  $C_4H_3S \cdot C(NO) \cdot NH_2$ . [92°]. Formed by the action of hydroxylamine on the

nitrile (Meyer, *A.* 236, 213). Long prisms (from benzene).

**Nitrile** (192°) (D.); (200° cor.) (Peter, *B.* 18, 548). Formed by distilling thienyl-glyoxylic acid with aqueous hydroxylamine (Douglas, *B.* 25, 1311).

**Tetrahydride**  $S \begin{smallmatrix} \text{CH}(\text{CO}_2\text{H})\text{CH}_2 \\ \text{CH}_2 \end{smallmatrix}$  [51°].

H.F. 114,900. H.C.p. 700,400. Formed by reducing the acid, in alkaline solution, with sodium-amalgam (Ernst, *B.* 19, 3278; 20, 518). Plates or needles (from ligroin), v. e. sol. water and alcohol, v. sol. ether. Volatile with steam. Much decomposed on distillation. Reduces ammoniacal  $\text{AgNO}_3$ . Salts.— $\text{CaA}'$ , 3aq. Crystalline, sol. water.— $\text{AgA}'$ . M. sol. water. **Methyl ether**  $\text{MeA}'$ . (c. 206°). **Ethyl ether**  $\text{EtA}'$ . Liquid.

**Thiophene ( $\beta$ )-carboxylic acid**

$S \begin{smallmatrix} \text{CH}:\text{CH} \\ \text{CH}:\text{C}\cdot\text{CO}_2\text{H} \end{smallmatrix}$  ( $\gamma$ )-Thiophenic acid. [136°].

S. 44 at 17°. Formed by the action of alkaline  $\text{KMnO}_4$  on ( $\beta$ )-methyl-thiophene (Muhkert, *B.* 18, 3003) or ( $\beta$ )-ethyl-thiophene, the yield being about 8 p.c. (Damsky, *B.* 19, 3284). Needles (from water), sol. ether, volatile with steam. Gives the indophenine reaction.— $\text{CaA}'$ , 3aq. S. (of  $\text{CaA}'$ ) 7-92 at 14.5°.— $\text{BaA}'$ , (dried). S. 11-54 at 17°.— $\text{AgA}'$ . Needles or plates, v. sl. sol. Aq. **Amide**  $\text{C}_4\text{H}_5\text{S}\cdot\text{CONH}_2$ . [178°]. Converted by phenyl cyanate into  $\text{C}_4\text{H}_5\text{S}\cdot\text{CO}\cdot\text{NH}\cdot\text{CO}\cdot\text{NHPh}$ . [206°].

**Thiophene ' $\alpha$ '-carboxylic acid**. [118°]. (268° cor.). This is a mixture of the ( $\alpha$ )- and ( $\beta$ )-acids. It is got by saponifying the mixed nitrile which is formed by distilling a mixture of potassium thiophene ( $\alpha$ ) and ( $\beta$ ) sulphonates with  $\text{KCy}$  (V. Meyer, *B.* 16, 2174; 18, 2315; Bonz, *B.* 18, 2308). Formed also by oxidising a mixture of ( $\alpha$ )-methyl-thiophene (2 pts.) and ( $\beta$ )-methyl-thiophene (3 pts.) and by slow evaporation of an aqueous solution of the mixed thiophene carboxylic acids in the cold (Fgli, *B.* 18, 548; V. Meyer, *B.* 19, 2891; *A.* 236, 221). Volatile with steam. Can be separated into the ( $\alpha$ )- and ( $\beta$ )-acids by crystallisation.

**Thiophene dicarboxylic acid**

$S \begin{smallmatrix} \text{CH} \text{---} \text{CH} \\ \text{C}(\text{CO}_2\text{H})\text{:C}(\text{CO}_2\text{H}) \end{smallmatrix}$  [270°]. Formed by oxidising the corresponding di-methyl-thiophene with alkaline  $\text{KMnO}_4$  (Grünwald, *B.* 20, 2586). Formed also by oxidising ( $\beta$ )-methyl-thienyl methyl ketone (Gerlach, *A.* 267, 153). Long needles (from water), v. e. sol. ether. Not volatile with steam. Resorcin at 200° forms a fluorescein which exhibits yellowish-green fluorescence in alkaline solution.— $\text{PbA}''$ .— $\text{BaA}''$ . Crystals, sl. sol. cold water.— $\text{AgA}''$ . White pp. **Methyl ether**  $\text{MeA}''$ . [59-5°]. Plates.

**Thiophene dicarboxylic acid**

$S \begin{smallmatrix} \text{C}(\text{CO}_2\text{H})\text{:CH} \\ \text{C}(\text{CO}_2\text{H})\text{:CH} \end{smallmatrix}$

**Formation**.—1. By oxidation by alkaline  $\text{KMnO}_4$  of di-methyl-thiophene from coal tar (Messinger, *B.* 18, 567), from ( $\alpha$ )-ethyl-thienyl methyl ketone, from ( $\alpha$ )-ethyl-thiophene ( $\alpha$ )-carboxylic acid (Schleicher, *B.* 18, 3020), from methyl-thienyl methyl ketone (Demuth, *B.* 18, 3025), and from ( $\alpha$ )-methyl-thiophene carboxylic acid (Levi, *B.* 19, 656).—2. By saponifying its nitrile, which may be got by fusing potassium

thiophene disulphonate with  $\text{KCy}$  (Jaekel, *B.* 19, 191).—3. By saponifying its ether which is got by the action of sodium-amalgam on a mixture of di-bromo-thiophene and  $\text{ClCO}_2\text{Et}$  (Bonz, *B.* 18, 2306).

**Properties**.—Crystalline powder, v. sl. sol. cold water, sol. ether. Not melted at 300°. Does not give the fluorescein reaction.

**Salts**.— $\text{BaA}''$  aq. Crystalline, v. sl. sol. cold water.— $\text{CaA}''$  3aq.— $\text{AgA}''$ : white pp.

**Methyl ether**  $\text{MeA}''$ . [145°] (J.); [147°] (S.); [151°] (D.). White needles from alcohol.

**Ethyl ether**  $\text{EtA}''$ . [47°] (J.); [52°] (S.). Long needles (from alcohol).

**Nitrile**  $\text{C}_4\text{H}_3\text{SCy}$ . [92°]. Crystals.

**Tetrahydride**  $S \begin{smallmatrix} \text{CH}(\text{CO}_2\text{H})\text{CH}_2 \\ \text{CH}(\text{CO}_2\text{H})\text{CH}_2 \end{smallmatrix}$  [163°

cor.]. Formed by reducing the acid in alkaline solution by sodium-amalgam (Ernst, *B.* 19, 3275). Plates, v. sol. water, sol. ether. Reduces hot ammoniacal  $\text{AgNO}_3$ . Hot conc.  $\text{H}_2\text{SO}_4$  evolves  $\text{CO}$  (1 mol.).— $\text{BaA}''$ : scales.— $\text{AgA}''$ : white powder.— $\text{MeA}''$ . Oil.

**Thiophene dicarboxylic acid**

$S \begin{smallmatrix} \text{CH} \text{---} \text{C}\cdot\text{CO}_2\text{H} \\ \text{C}(\text{CO}_2\text{H})\text{:CH} \end{smallmatrix}$ . Formed by oxidation of the corresponding di-methyl-thiophene by alkaline  $\text{KMnO}_4$  (Zelinsky, *B.* 20, 2022). Needles, sl. sol. cold water. Decomposes and partially sublimes at 280°, v. sol. hot water.— $\text{AgA}''$ .

**Methyl ether**  $\text{MeA}''$ . [121°]. Plates.

**Ethyl ether**  $\text{EtA}''$ . [36°].

**Thiophene tri-carboxylic acid**  $\text{C}_3\text{SH}(\text{CO}_2\text{H})_3$ . Formed by oxidation of di-methyl-thienyl methyl ketone with  $\text{KMnO}_4$  (Messinger, *B.* 18, 2302).

**Methyl ether**  $\text{MeA}'''$ . [118°] Plates, v. sol. alcohol and ether.

**References**.—Bromo- and Iodo- THIOPHENE CARBOXYLIC ACID AND NITRO-THIOPHENIC ACID.

**THIOPHENE GREEN**  $\text{C}_8\text{H}_5\text{N}_2\text{S}$ . The leucobase  $\text{C}_8\text{SH}_5\text{Cl}(\text{OH})(\text{C}_6\text{H}_4\text{NMe}_2)_2$  is got by heating thiophenic aldehyde with di-methyl aniline,  $\text{ZnCl}_2$ , and a little alcohol at 100° (Levi, *B.* 20, 513). It crystallises in needles [93°], and is readily oxidised to thiophene green  $\text{C}_8\text{H}_5\text{N}_2\text{S}(\text{OH})(\text{C}_6\text{H}_4\text{NMe}_2)_2$ , which is an oil and forms the salts  $(\text{C}_8\text{H}_5\text{N}_2\text{S})\cdot\text{ZnCl}_2\cdot 2\text{aq}$ ,  $\text{B}^+\text{H}_2\text{SO}_4$ ,  $\text{B}^+\text{H}_2\text{C}_2\text{O}_4\cdot 2\text{aq}$ , and  $\text{B}^+\text{C}_2\text{H}_3\text{N}_4\cdot \text{NO}_3$ , crystallising in scales with coppery lustre.

**Leuco-thiophene green** v. **THIOPHENE-DIAMIDO-DI-PHENYL-THIENYL-METHANE**.

**THIOPHENE ( $\alpha$ )-SULPHINIC ACID**

$\text{C}_4\text{H}_5\text{S}\cdot\text{SO}_2\text{H}$ . [67°]. Formed by the action of zinc-dust on an alcoholic solution of thiophene sulphonic chloride (Weitz, *B.* 17, 800). Needles, v. sol. water, alcohol, and ether. Gives the indophenine reaction.— $\text{BaA}'$ , 2aq. White plates, v. sol. water.— $\text{ZnA}'$ , 3aq.— $\text{AgA}'$ . Crystalline pp.

**THIOPHENE ' $\alpha$ '-SULPHONIC ACID**

$\text{C}_4\text{H}_5\text{S}\cdot\text{SO}_3\text{H}$ . Formed by shaking thiophene (20 g.) dissolved in ligroin (2,000 c.c.) with  $\text{H}_2\text{SO}_4$  (300 c.c.) for 2 hours (V. Meyer & Kreis, *B.* 16, 2172; Biedermann, *B.* 19, 1615). Deliquescent mass. Yields thiophene on distillation. It is doubtless a mixture of the ( $\alpha$ ) and ( $\beta$ ) acids.— $\text{NaA}'$  aq.— $\text{BaA}'$ , 3aq.— $\text{CaA}'$ .— $\text{PbA}'$  aq. Very soluble powder.— $\text{AgA}'$  3aq. Plates (Weitz, *B.* 17, 796).

**Ethyl ether**  $\text{EtA}'$ . Oil.

**Chloride**  $\text{C}_4\text{H}_5\text{S}\cdot\text{SO}_2\text{Cl}$  [28°]. (above 200°). Oil or colourless crystals.

**Amide**  $C_6H_4S.CONH_2$ . [142°] (Langer, B. 17, 1568). Needles (from water).—

$C_6H_4S.CO.NHAc$ . Pearly scales.

**Amide**  $C_6H_4S.CONHPh$ . [96°].

Thiophene ( $\beta$ )-sulphonic acid

$\begin{matrix} CH_3CH \\ | \\ S < CH_2C_6H_4SO_3H \end{matrix}$  Formed by the action of sodium-amalgam on di-bromo-thiophene ( $\beta$ )-sulphonic acid, which is got by sulphonation of di-bromo-thiophene (Langer, B. 17, 1567; 18, 553). Obtained in like manner from iodo-thiophene sulphonic acid, and from tri-bromo-thiophene sulphonic acid (Rosenberg, B. 18, 1776). Crystalline solid, v. sol. water. Gives a blue colour with isatin and  $H_2SO_4$ .— $BaA'$ .

**Chloride**  $C_6H_4S.SO_2Cl_2$ . [43°]. Plates, v. sol. ether, insol. ligroin.

**Amide**  $C_6H_4S.SO_2NH_2$ . [148°]. Tables.

Thiophene disulphonic acid  $C_6H_4S(SO_3H)_2$ . Formed by reduction of di-bromo-thiophene ' $\beta$ '-di-sulphonic acid by sodium-amalgam (Langer, B. 18, 554, 1114; Rosenberg, B. 18, 3030). Crystalline, v. sol. water.— $BaA''$  2/3 aq.

**Chloride**  $C_6H_4S(SO_2Cl)_2$ . [149°]. Scales.

**Amide**  $C_6H_4S(SO_2NH_2)_2$ . [c. 280°]. Needles.

Thiophene disulphonic acid  $C_6H_4S(SO_3H)_2$ . Formed by reducing iodo-thiophene ( $\alpha\beta$ )-disulphonic acid with sodium-amalgam (Langer, B. 18, 560).

**Amide**  $C_6H_4S(SO_2NH_2)_2$ . [142°]. Plates. Gives the indophenine reaction.

Thiophene disulphonic acid  $C_6H_4S(SO_3H)_2$ . Formed from lead thiophene sulphonate and fuming  $H_2SO_4$  (Jaekel, B. 19, 185, 1066). Crystalline, v. sol. water and alcohol.— $K.A''$  aq; prisms, v. sol. water.— $Na.A''$  3 aq. Needles, v. sol. water.— $BaA'$  3 aq. Flat prisms, sl. sol. water.— $CuA'$  4 aq. Blue needles.— $Ag_2A'$ .

**Chloride**  $C_6H_4S(SO_2Cl)_2$ . [77-5°]. Needles (from ether).

**Amide**  $C_6H_4S(SO_2NH_2)_2$ . [211-5].

**References**.—Di-bromo-, Iodo- and Nitro-thiophene sulphonic acid.

**THIOPHENIC ACID** v. THIOPHENE CARBOXYLIC ACID.

**THIOPHENIC ALDEHYDE**  $C_6H_4S.CHIO$ . [198° cor.]. S.G. 21.1-21.5. Formed by distilling ( $\alpha$ )-thienyl-glyoxylic acid (Biedermann, B. 19, 637, 1853). Formed also by the action of  $HI_2S$  on  $CHCl_2$ — $\begin{matrix} CH_2CH \\ | \\ CO.CO \end{matrix}$  (Hantzsch, B. 22, 2838).

Oil, smelling like benzoic aldehyde. Oxidised by air to thiophene ( $\alpha$ )-carboxylic acid.

**Oxim**  $C_6H_4S.CH(NOH)$ . Thiophene synal-doxim. [128°]. Needles (from ether). Converted by  $NaOHAq$  into thiophene carboxylic nitrile (Hantzsch, B. 24, 47). Yields an acetyl-derivative [75°-80°].  $NaOMe$  and  $MeI$  in  $MeOH$  yield  $C_6H_4S.CH<N^Me$  [120°], crystallising in

tables; converted by dilute  $H_2SO_4$  into the aldehyde and ( $\beta$ )-methyl-hydroxylamine (Gold-schmidt a. Zanoli, B. 25, 2588). Phenyl cyanate in ether forms  $C_6H_4S.CH.NO.CO.NHPh$  [70°], crystallising in needles.

**Oxim**  $C_6H_4S.CH^2NOH$ . Thiophene anti-aldoxim. Formed by the action of hydroxyl-amine hydrochloride,  $NaOHAq$  and  $Na_2CO_3$  on the aldehyde (Goldschmidt a. Zanoli, B. 25, 2590). Converted by phenyl cyanate into  $C_6H_4S.CH.NO.CO.NHPh$  [144°], whence  $NaOH$

forms  $C_6H_4S.CH.N.NHPh$  [46°]. o-Tolyl cyanate forms  $C_6H_4S.CH.NO.CO.NH.C_6H_4$  [60°].

**Phenyl hydrazide**  $C_6H_4S.CH.N.NHPh$ . [134-5°]. Needles (from alcohol).

**THIOPHENIC IMIDO-ETHYL ETHER**

$C_6H_4S.C(OEt).NH$ . The salt  $BHCl$  is formed by the action of dry  $HCl$  on the nitrile of thiophene carboxylic acid (Douglas, B. 25, 1312). It is crystalline, and is converted by hydroxyl-amine into  $C_6H_4S.C(OEt).NOH$  [67°].

**THIOPHENINE** is AMIDO-THIOPHENINE.

**THIOPHENOL** v. PHENYL MERCAPTAN.

**THIOPHENURIC ACID**  $C_6H_4S.NSO_2$ . [172°]. Excreted in the urine of rabbits after injection of sodium thiophene ( $\alpha$ )-carboxylic acid (Jaffé a. Levi, B. 21, 3458). Prisms, resembling hippuric acid (from water), v. sl. sol. ether, v. sol. alcohol. Split up by boiling baryta-water into glycecoll and thiophene ( $\alpha$ )-carboxylic acid.— $BaA'$ , 2 aq. Needles, v. sol. water.— $CaA'$ , 2 aq.— $AgA'$ .

**THIO-PHENYL-ACETIC ACID**. **Amide**  $C_6H_4S.CH_2.CN.NH_2$ . [98°]. Formed by heating phenyl-acetamide (3 pts.) with  $P_2S_5$  (2 pts.), and also by allowing a solution of phenyl-acetonitrile in alcoholic ammonium sulphide to stand for some days (Berthsen, B. 11, 503; A. 184, 292). Trimetric crystals (from alcohol), decomposed on distillation into  $H_2S$  and  $C_6H_4S.CH_2.CN$ .

**Reactions**.—1. Boiling  $NH_4Aq$  forms phenyl-acetamide. —2.  $HgO$  forms phenyl-acetonitrile. —3.  $Zn$  and  $HClAq$  form phenyl-ethyl-amine (Colombo a. Spica, B. 8, 821). —4. Benzoic aldehyde forms oily  $C_{10}H_7N_2S(?)$ . —5. Sodium-amalgam forms  $Ph.CH_2.CN.NH_2$ , and a compound  $C_{10}H_7NS$ , [108°]. —6. Iodine added to a hot alcoholic solution forms  $C_{10}H_7N_2S$  [42°]. —7.  $MeI$  forms  $(CH_3Ph.C(NH).SMe)HI$  [139°], which gives rise to  $(C_6H_4S.NS)H.PtCl_4$ . —8.  $EtI$  forms  $(C_6H_4S.NS)HI$  [116°], which is v. a. sol. water, and yields, on treatment with  $NaOHAq$ , the free base  $CH_3Ph.C(NH).SMe$ , which is an oil that quickly decomposes into mercaptan and phenyl-acetonitrile. The salts  $(C_6H_4S.NS)HCl$  [c. 120°],  $B'_2H_2PtCl_4$  (below 130°), and  $B'HI$  are crystalline. —9. Aniline forms the compound  $CH_3Ph.C(NH_2).NPh$ .

**THIO-PHENYL-ALLOPHANIC ACID** v. PHENYL-THIO-ALLOPHANIC ACID.

**THIO-DI-PHENYL-AMINE** v. IMIDO-DI-PHENYL SULPHIDE.

**THIO-PHENYL-CARBAMIC ACID** v. PHENYL-THIO-CARBAMIC ACID.

**THIO-DI-PHENYL KETONE** v. THIO-BENZOPHENONE.

**THIO-IX-PHENYL-METHYL-AMINE** v. METHYL-IMIDO-DI-PHENYL SULPHIDE.

**DI-THIO-PHTHALIC ACID**  $C_6H_4(CO.SH)_2$ . The salt  $K_2A'$  is formed by dissolving  $KSH$  (2 mols.) in an alcoholic solution of phenyl phthalate (1 mol.). The free acid splits up at once into  $H_2S$  and thiophthalic anhydride (Schreder, B. 7, 706).

(a) Di-thio-isophthalic acid. The  $K$  salt, formed by the action of  $KSH$  on phenyl isophthalate, crystallises in yellow needles.

**Ethyl ether**  $Et.A'$ . Formed by adding water to the hydrochloride of  $C_6H_4(C(NH).SEt)_2$  (Luckenbach, B. 17, 1435). Small needles.

( $\beta$ ) Di-thio-isophthalic acid. **Amide**  $C_6H_4(CSNH_2)_2$ . [200°]. Formed by heating isophthalic nitrile with alcoholic ammonium

sulphide (L.). Needles, sol. hot alcohol. Reconverted into the nitrile by lead acetate. Boiling KOH aq forms isophthalic acid.

**THIO-PHTHALIC ANHYDRIDE**  $C_6H_4SO_2$ , *i.e.*  $C_6H_4 \begin{smallmatrix} \text{CO} \\ \diagup \diagdown \\ \text{CO} \end{smallmatrix} S$ . [114°]. (284°). Formed by the action of KSH on phthalyl chloride, or on phenyl phthalate (Graebe a. Zschöcke, *B.* 17, 1175). Formed also by the action of  $As_2S_3$  on phthalyl chloride (Rayman, *Bl.* [2] 47, 898). Plates, v. sol. hot alcohol, ether, and chloroform, sl. sol. water. Volatile with steam. Sol. alkalis and converted by long, boiling with alkalis into phthalic acid. Ammonia forms phthalimide. Resorcin and  $H_2SO_4$  give a thiofluorescein, the alkaline solution of which is deep red with green fluorescence.

**THIO-PHTHALIDE**  $C_6H_4 \begin{smallmatrix} \text{CO} \\ \diagup \diagdown \\ \text{CO} \end{smallmatrix} S$ . [57°].

Formed by heating  $C_6H_4Cy.CH_2.SCy$  with conc. HCl aq for 5 hours at 180° (Day a. Gabriel, *B.* 23, 2480). Thin needles (from dilute alcohol).

**THIO-PHTHALIMIDINE**  $C_6H_4NH$ , *i.e.*

$C_6H_4 \begin{smallmatrix} \text{C(NH)} \\ \diagup \diagdown \\ \text{CH}_2 \end{smallmatrix} S$  or  $C_6H_4Cy.CH_2.SH$ . [62°]. Formed by warming *o*-cyano-benzyl sulphocyanide with  $H_2SO_4$  at 65° (Day a. Gabriel, *B.* 23, 2481). Formed also by adding KSH aq to *o*-cyano-benzyl chloride in alcohol. Needles, which darken in air, v. sol. alcohol and ether. Boiling NaOH aq forms thiophthalide. KSH added to its alcoholic solution forms  $C_6H_4N_2S_2$ , crystallising from nitrobenzene in needles with green lustre. —  $B'HCl$ . Needles. —  $B'H.PCl_2$ . Orange-yellow prisms. —  $B'HI$ . Needles. — *Picrate*: slender needles.

**THIOPHTHENE**  $C_6H_4S_2$ , *i.e.*  $\begin{smallmatrix} \text{CH} - \text{C} - \text{CH} \\ \diagup \quad \diagdown \\ \text{CH.S.C.S.CH} \end{smallmatrix}$

(225° cor.). Formed by distilling citric acid (1 pt.) with  $P_2S_5$  (2 pts.), adding NaOH aq, and distilling with steam (Biedermann a. Jacobson, *B.* 19, 2444). Oil, not solid at -10°. Gives the indophenine reaction. —  $B'C_6H_5N_2O$ . [133°]. Yellow needles, v. sol. alcohol and benzene.

*Reference.*—TETRA-BROMO-THIOPHTHENE.

**THIOPHYLLINE**  $C_8H_8N_2O_2$ . [264°]. Occurs, in small quantity, in extract of tea (Kossel, *B.* 21, 2164). Crystals (containing aq), more sol. water and alcohol than theobromine, v. sol.  $NH_4Aq$ . Forms salts with acids. On evaporation with chlorine-water it leaves a scarlet residue, turned violet by  $NH_4Aq$ . —  $C_6H_4AgN_2O_2$ . Amorphous, converted by  $MeI$  into caffeine  $C_8H_{10}N_4O_2$  [229°].

(a) **THIO-PROPIONIC ACID**  $C_3H_5OS$ .

*Methyl ether*  $CH_3.CH_2.CO.SMe$ . (120°). V.D. 51.23. Formed from propionyl chloride, and lead mercaptide in the cold (Obermeyer, *B.* 20, 2922).

(b) Thio-propionic acid  $Et.CO.S.OH$ . The salt  $NaA$  aq formed by boiling propionitrile with alcoholic ammonium sulphide is crystalline (Dupré, *Bl.* [2] 29, 304).

*Amide*  $EtC(NH).SH$ . [42°]. Formed by heating propionamide (5 mols.) with  $P_2S_5$  (1 mol.) in benzene for a short time (Hubacher, *A.* 259, 229). Yellowish plates, v. e. sol. benzene.

**THIO-ISOPROPYL-COUMARIN**  $C_{12}H_{12}SO$ , *i.e.*

$C_6H_4 \begin{smallmatrix} \text{CH} : \text{C} (C_3H_7) \\ \diagup \quad \diagdown \\ \text{O} - \text{CS} \end{smallmatrix}$ . [81°]. Formed by heating isopropyl-coumarin with  $P_2S_5$  at 120° (Aldringen,

*B.* 24, 3463). Reddish-yellow needles, sol. hot alcohol, sl. sol. ether.

**THIO-PRUSSIAC ACIDS.** By heating ammonium sulphocyanide there is formed, besides thio-urea, dithiodiprussic acid  $C_4H_4N_4S_2$ , a yellowish-white powder, sl. sol. hot water; thiodiprussic acid  $C_4H_4N_4S$ , amorphous, m. sol. hot water; and ammonium dithiotriprussiate  $C_4H_4N_4S_3$ , which crystallises from water. The first acid gives no colour with  $FeCl_3$ , the two other bodies give a red colour. The lead salts of these acids dissolve in hot water.

**THIOTETRAPYRIDINE**, so called,  $C_{16}H_{16}N_4S$  (?). [155°]. Formed by heating nicotine (1 pt.) with sulphur (6 pts.) at 150° till the mass is chrome-green (Cahours a. Etard, *Bl.* [2] 34, 452). Yellow prisms (from alcohol). —  $B'2HCl$ . —  $B'HHgCl_2$ . —  $B'HI.PCl_2$ , yellow amorphous pp.

**THIO-PYROCATECHIN** v. OXY-PHENYL MERCAPTAN.

**THIO-PYROMUCIC ACID.** *Amide*  $C_6H_4O.CS.NH_2$ . [127°]. Formed by passing  $H_2S$  into a solution of furfuronitrile in alcohol-ether (Douglas, *B.* 25, 1314). Yellowish crystals, sl. sol. cold water, v. sol. alcohol.

**THIO-PYRUVIC ACID.** The compound  $(C_2H_3O_2S)C_2H_3O_2$  [87°] separates as a powder when  $HS$  is passed into pyruvic acid (Böttinger, *A.* 188, 325). It is v. e. sol. water and is converted by boiling HIAq into  $CH_3.CH(SH).CO.H$ . Boiling water forms  $HS$  and thiopyruvic acid.

**DI-THIO-RESORCIN**  $C_6H_4(SH)_2$ . Mol. w. 142. [27°]. (243°). Formed by reducing the sulphochloride  $C_6H_4(SO_2Cl)_2$  with tin and HCl aq (Patschke, *J. pr.* [2] 2, 418, Körner, *G.* 6, 140). Crystals, smelling like some geraniums.  $Pb(OAc)_2$  added to its alcoholic solution ppts. orange  $C_6H_4S_2Pb$ , whence  $MeI$  forms  $C_6H_4(SMe)_2$  (278°) (Obermeyer, *B.* 20, 2927).

**THIO-RUFIC ACID**  $C_6H_4S_2O_4$ . Formed by the action of  $CS_2$  on a mixture of  $NaOEt$  and acetoacetic ether (Norton a. Oppenheim, *B.* 10, 701). Pearly orange scales, nearly insol. water. —  $NaA$ : brick-red needles. —  $CaA_2$ : red needles.

**THIO SALICYLIC ACID** v. OXY-THIO-RENZOIC ACID.

**THIOBINAMINE** v. ALLYL-THIO-UREA.

**THIO-SUCCINIC ACID.** *Anhydride*  $C_4H_2 \begin{smallmatrix} \text{CO} \\ \diagup \diagdown \\ \text{CS} \end{smallmatrix} O$ . 'Sulphosuccinyl'. [31°]. (225°).

Formed by adding succinyl chloride dissolved in benzene or  $CS_2$  to an aqueous solution of  $Na_2S$ . Got also by distilling succinic acid (100 g.) with  $P_2S_5$  (100 g.) (Auger, *A. Ch.* [6] 22, 333). White crystals. Its aqueous solution gives off  $H_2S$  on heating. Phenylhydrazine forms  $CO_2H.C_6H_5.C(SH).N.NHPh$  [120°] and  $C_2H_5 \begin{smallmatrix} \text{CO} \\ \diagup \diagdown \\ \text{C} (N_2H_5Ph) \end{smallmatrix} O$  [216°], which on

distillation changes to succinyl-phenylhydrazine [155°]. Phenylhydrazine also produces  $C_6H_4(CO.N_2H_5Ph)_2$  [219°] (Zanetti, *C. C.* 1889, 668). Sodium-amalgam forms  $C_6H_4NaSO_3$ , converted by phenylhydrazine acetate into  $CO_2H.C_6H_4.CH.N_2H_5Ph$  [c. 175°].

**Di-thio-succinic acid**  $C_4H_4(CO.SH)_2$ . The salt  $KA'$ , got by boiling succinyl-phenol with KSH in alcohol, crystallises in minute needles, v. sol. water, alcohol, and ether (Weselsky, *B.* 2, 618). Its aqueous solution is decomposed by spontaneous evaporation. *Acids*

split it up into  $H_2S$  and thiosuccinic anhydride (v. *supra*).

**Ethyl ether**  $C_2H_5(CO.SEt)_2$ . (271°). Formed from di-phenyl succinate (42 g.) and sodium mercaptide (30 g.) in dry ether in the cold (Seiffert, *J. pr.* [2] 81, 469). Oil, smelling of garlic.

**THIO-SUCCINURIC ACID**  $C_4H_4N_2SO_4$ . [211°]. Formed by heating succinic anhydride with thio-urea at 140° (Pike, *B. 6*, 1105). Yellowish powder, insol. alcohol and ether, sl. sol. water and HOAc. Decomposed by alkalis into thio-urea and succinic acid.

**(a) - DI - THIO - TEREPHTHALIC ACID**  $C_8H_4S_2O_4$ , i.e.  $C_6H_4(CO.SH)_2$ . Formed by the action of alcoholic KSH on di-phenyl terephthalate (Schreder, *B. 7*, 708). Amorphous, v. sl. sol. alcohol.

**(b) - Di - thio - terephthalic acid. Amide**  $C_8H_4(CS.NH_2)_2$ . [263°]. Formed by heating terephthalic nitrile with alcoholic ammonium sulphide (Luckenbach, *B. 17*, 1430). Yellow amorphous powder, insol. alcohol. Boiling with lead acetate reproduces the nitrile.

**THIOSULPHATES.** Salts of the hypothetical thiosulphuric acid  $H_2S_2O_4$ . These salts were called *hyposulphites* before the isolation of the true hyposulphites ( $M_2S_2O_4$ , p. 592).  $Na_2S_2O_4 \cdot 5aq$  is still, however, commonly known as sodium hyposulphite. Thiosulphates are formed by boiling normal alkali sulphites in solution with S; ( $M_2SO_3.Aq + S = M_2S_2O_4.Aq$ ); caustic alkali solutions and milk of lime also give thiosulphates by boiling with S. Thiosulphates are produced by the action of air,  $SO_2$ , or  $K_2Cr_2O_7.Aq$  on the alkali and alkaline earth polysulphides in solution ( $M_2S_3.Aq + 3O = M_2S_2O_4.Aq + 3S$ ;  $2M_2S_3.Aq + 3SO_2.Aq = 2M_2S_2O_4.Aq + 9S$ ;  $2M_2S_3.Aq + 4M.CrO_3.Aq + H_2O = 5M_2S_2O_4.Aq + 4Cr_2O_3 + 2MOH.Aq$  (Döpping, *A. 46*, 172). Spring (*B. 7*, 1157) by heating  $(NH_4)_2SO_3$  with  $P_2S_5$  got a large quantity of  $(NH_4)_2S_2O_4$ , along with  $(NH_4)_2S_2$ , and also some  $(NH_4)_2S_3O_4$ , and P compounds; and by the interaction of  $H_2S$  and  $SO_2.NH_3.ONH_2$  he obtained  $(NH_4)_2S_2O_4$ . A little  $H_2S_2O_4.Aq$  is said to be formed by the interaction of steam and molten S (Myers, *A. 129*, 351).

The alkali salts, also the Ca and Sr salts, are readily soluble in water; many of the others are insoluble or only slightly soluble; the insoluble salts are often obtained from solutions of the alkali salts by double decomposition. Thiosulphates are decomposed by heating strongly; alkali salts leave a mixture of sulphate and sulphide; other salts also give off  $H_2S$  and S. Aqueous solutions of thiosulphates evolve  $H_2S$  when boiled, forming sulphates, or sulphides if the metal of the thiosulphate is ppd. by  $H_2S$ .

Aqueous solutions of thiosulphates are decomposed by dilute mineral acids, with separation of S and evolution of  $SO_2$ . Salts of the acid used are formed, and  $H_2S_2O_4.Aq$ , which then decomposes to  $H_2SO_4.Aq$  and S. This reaction has been studied by several chemists (v. Berthelot, *C. R.* 108, 971; Vanbel, *B. 22*, 1686, 2703; Vortmann, *B. 22*, 2307; Fousserau, *C. R.* 104, 1842). Colefax (*C. J.* 61, 176) in 1892 examined the interaction of  $Na_2S_2O_4.Aq$  and acids; he found that when the products of the change are not removed the interaction stops before all the

$H_2S_2O_4.Aq$  is decomposed. C. determined the effects on the velocity and the limit of the reaction of concentration, increasing the relative mass of the acid used, the nature of the acid, temperature, and the presence of  $SO_2$  in the solution before acidification (reference to older memoirs are given by C.).

Thiosulphates are converted into tetrathionates by the action of I; oxidisers such as  $HNO_3$ ,  $KClO_4$ , and  $HClO_4$ , and  $KMnO_4.Aq$  produce sulphates. According to Hänig a. Zatzek (*M. 4*, 738),  $KMnO_4$  in solution in acetic acid produces dithionates.

For the general qualitative reactions of thiosulphates compared with those of thionates v. Debuss (*C. J.* 53, 298).

**SELENOTHIOSULPHATES**  $M_2SeSO_4$  are described as **Thioselenates**, under **SELENATES** (p. 434).

**Constitution of thiosulphates.** The formula  $SO_2.OM.SM$  is generally adopted for the normal thiosulphates of monovalent metals (Odling, *C. N.* 29, 153; cf. Schorlemmer, *C. J.* [2] 7, 254; Williamson, *C. J.* [2] 7, 259). Some chemists, considering the resemblances between thiosulphates and sulphites, have suggested the

formula  $SO \begin{matrix} \diagup OM \\ \diagdown OSM \end{matrix}$  (v. Blomstrand, *Die Chemie*

*der Jetztzeit* [Hoidelberg, 1869], 258; Buchanan, *B. 3*, 485; Michaelis, *G. O.* [5th ed.] 1, 745). The formation of thiosulphates by boiling sulphites with S is readily represented by either formula, according as sulphites are regarded as  $SO_2.OM.M$  or  $SO.O.M.OM$ . As the balance of evidence is in favour of the formula  $SO_2.OM.M$ , it is likely that the salts formed by adding S to the sulphites are  $SO_2.OM.SM$ . The production of  $(NH_4)_2S_2O_4$  by the interaction of  $(NH_4)_2SO_3$  and  $P_2S_5$  (Spring, *B. 7*, 1158) also confirms the formula  $SO_2.OM.SM$ , inasmuch as a thiosulphate is produced in this reaction from a sulphate ( $SO_2.ONH_2.ONH_2$ , giving  $SO_2.ONH_2.SNH_2$ ). Spring's synthesis of  $H_2S_2O_4$  from  $SO_2$  and  $H_2S$ —for the actual reaction carried out, viz. formation of  $(NH_4)_2S_2O_4$  by first combining  $SO_2$  and  $NH_3$ , and then interacting with  $H_2S$ , is equivalent to the synthesis of  $H_2S_2O_4$  (v. S., *loc.*)—is also in keeping with the formula  $SO_2.OM.SM$ . By warming  $EtBr$  with  $Na_2S_2O_4.Aq$ , Bunte (*B. 7*, 646) obtained the salt  $EtNaS_2O_4$ . This salt is decomposed by dilute acids giving  $EtSH$  and  $SO_2.OH.ONa$ ; when heated it gives off  $Et_2S_2$  and  $SO_2$ , leaving  $Na_2SO_3$ . These reactions indicate that  $EtNaS_2O_4$  is  $SO_2.Na.EtS$ ; hence the formula of  $Na_2S_2O_4$  is probably  $SO_2.Na.NaS$ . One of the Na atoms in  $Na_2S_2O_4$  is then probably in direct union with an atom of S; and as  $EtNaS_2O_4$  easily gives  $SO_2.OH.ONa$ , along with  $EtSH$ , it is likely that the formula of this salt is  $SO_2.ONa.SEt$ , and hence that the formula for  $Na_2S_2O_4$  is  $SO_2.ONa.SNa$ . The formula  $SO_2.OH.SH$  makes possible the existence of two isomeric salts  $MM'S_2O_4$ , viz.  $SO_2.OM.SM'$  and  $SO_2.OM'.SM$ ; two such salts are known where  $M = Na$  and  $M' = K$ . (v. **POTASSIUM THIOSULPHATE**, p. 706).

**Ammonium thiosulphate**  $(NH_4)_2S_2O_4$ . Obtained by the interaction of  $(NH_4)_2CO_3$  and  $CaS_2O_4.Aq$ , filtering and evaporating (Rammelsberg, *P. 66*, 298); white, rhombic, deliquescent leaflets, crystallising with  $xH_2O$ . Fock a. Klüss (*B. 22*, 3009; 23, 534) obtained the anhydrous

salt by reacting on  $\text{SO}_2\text{Aq}$  with  $(\text{NH}_4)_2\text{S}_2$ , evaporating at a low temperature and finally over  $\text{H}_2\text{SO}_4$ , and thoroughly drying between filter paper (*cf.* Arppe, *A.* 95, 118). The anhydrous salt is not deliquescent (*F. a. K.*). *Double salts* are described by *F. a. K. (l.c.)*; also *B.* 23, 1753: (1) with  $\text{CdS}_2\text{O}_3$ ; (2) with  $\text{MgS}_2\text{O}_3$ ; (3) with  $\text{K}_2\text{S}_2\text{O}_3$ , the salt obtained was  $\text{SO}_2\text{OK.SNH}_4$ . *F. a. K.* could not obtain  $\text{SO}_2\text{ONH}_4\text{SK}$ ; (4) with  $\text{Cu}_2\text{S}_2\text{O}_3$  and  $\text{Cu}_2\text{I}_2$ , also with  $\text{Cu}_2\text{I}_2$  and  $\text{NH}_4\text{I}$  (*Brun. C. R.* 114, 667); (5) with  $\text{PbS}_2\text{O}_3$  (*Rammelsberg, P.* 56, 308); (6) with  $\text{HgS}_2\text{O}_3$  (*R., l.c.*).

**Barium thiosulphate**  $\text{BaS}_2\text{O}_3\text{aq}$ . A white pp. obtained by mixing  $\text{Ba}(\text{C}_2\text{H}_3\text{O}_2)_2\text{aq}$  and  $\text{Na}_2\text{S}_2\text{O}_3\text{aq}$ , and completing ppn. by alcohol; loses all water at  $170^\circ$ , at red heat gives  $\text{BaS}$ ,  $\text{BaSO}_3$ ,  $\text{BaSO}_4$ , and *S* (*H. Rose, P.* 21, 437; *Rammelsberg, P.* 56, 295).

*Double salts.* (1) With  $\text{CdS}_2\text{O}_3$  (*Fock a. Klüss, B.* 23, 1753); (2) with  $\text{Cu}_2\text{S}_2\text{O}_3$  (*Cohen, C. J.* 51, 38); (3) with  $\text{PbS}_2\text{O}_3$  (*Rammelsberg, P.* 56, 308).

**Cadmium thiosulphate**  $\text{CdS}_2\text{O}_3\text{aq}$  (*F. a. K., B.* 23, 534); *double salts* with (1)  $\text{Na}_2\text{S}_2\text{O}_3$ , (2)  $\text{K}_2\text{S}_2\text{O}_3$ , (3)  $\text{SrS}_2\text{O}_3$  (*F. a. K., B.* 23, 1753; *Vortmann a. Padberg, B.* 22, 2637).

**Calcium thiosulphate**  $\text{CaS}_2\text{O}_3\text{aq}$ . Formed by mixing hot conc. solutions of  $\text{CaCl}_2$  and  $\text{Na}_2\text{S}_2\text{O}_3$ , evaporating under  $60^\circ$ , separating  $\text{NaCl}$ , which crystallises first, and allowing to cool (*Kessler, P.* 74, 282). Also obtained by heating  $\text{CaSO}_3$  and *S* with water, or by boiling milk of lime with *S*, passing in  $\text{SO}_2$ , and crystallising below  $00^\circ$  (*Herschel, N. Ed. P. J.* 1, 8, 296; 2, 154). Forms large, clear, six-sided, triclinic prisms, that effloresce in air at  $40^\circ$ ; *S.* 100 at  $3^\circ$  (*H., l.c.*). Conc. solution gives  $\text{CaSO}_3$  and *S* by heating above  $60^\circ$ . *Rammelsberg, P.* 56, 308) describes a *double salt* with  $\text{PbS}_2\text{O}_3$ .

**Cobalt thiosulphate**  $\text{CoS}_2\text{O}_3\text{aq}$  (*Rammelsberg, P.* 56, 308; *Fock a. Klüss, B.* 23, 3310). A *double salt* with  $\text{Na}_2\text{S}_2\text{O}_3$  is described by *Vortmann a. Padberg (B.* 22, 2637).

**Copper thiosulphates.** According to von Hauer (*W. A. B.* 13, 443) an *acid cuprous salt*  $\text{Cu}_2\text{H}_2(\text{S}_2\text{O}_3)_2$  is obtained, in microscopic, golden-yellow needles, by adding conc.  $\text{CuSO}_4\text{aq}$  to  $\text{Na}_2\text{S}_2\text{O}_3\text{aq}$  till the liquid is deep yellow, and gently warming, washing the pp. with water and alcohol, and drying over  $\text{H}_2\text{SO}_4$ . *Double salts* of  $\text{Cu}_2\text{S}_2\text{O}_3$ : (1) with  $\text{BaS}_2\text{O}_3$  (*Cohen, C. J.* 51, 38); (2) with  $\text{K}_2\text{S}_2\text{O}_3$  (*C., l.c.*; *Rammelsberg, P.* 56, 321); (3) with  $\text{Ag}_2\text{S}_2\text{O}_3$  (*C., l.c.*); (4) with  $\text{Na}_2\text{S}_2\text{O}_3$  (*Lenz, A.* 40, 99; *Siewert, J.* 1866, 257; *Kessel, B.* 10, 1677, 2000; *Schütte, J. pr.* 70, 249; *Vortmann, M.* 9, 165).

**Iron thiosulphate.** The *ferrous salt*  $\text{FeS}_2\text{O}_3\text{aq}$  was obtained by *Vortmann a. Padberg (B.* 22, 2637) by rubbing  $\text{BaS}_2\text{O}_3$  with conc.  $\text{FeSO}_4\text{aq}$  (the salts being present in the ratio of equal numbers of molecules), filtering from  $\text{BaSO}_4$ , adding a mixture of alcohol and ether, and allowing the green, oily liquid that separated to stand for some days. Small green crystals; very sol. water; solution is decomposed by boiling, with separation of  $\text{FeS}$ . A *double salt* with  $\text{Na}_2\text{S}_2\text{O}_3$  is described by *V. a. P. (l.c.)*. For accounts of former attempts to prepare pure ferrous thiosulphate *v. Fordos a. Gélis (J. Ph. [3] 4, 833)*; *Berthelot (A. Ch.*

*[5] 2, 58)*; *Vogel (J. pr.* 8, 102); *Koene (P.* 63, 245, 431); *Rammelsberg (P.* 56, 306).

No *ferric thiosulphate* has been isolated. **Lead thiosulphate**  $\text{PbS}_2\text{O}_3$ . Obtained by adding  $\text{Na}_2\text{S}_2\text{O}_3\text{aq}$  to  $\text{Pb}(\text{NO}_3)_2\text{aq}$ , or  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2\text{aq}$ , and washing the pp. with cold water. A white solid; very sol. water; sol. solutions of alkali thiosulphates (*v. Pape, J.* 1864, 57; *Letts, C. J.* [2] 8, 424). For reaction with  $\text{PCl}_5$ —giving  $\text{PbCl}_2$ ,  $\text{HCl}$ ,  $\text{SO}_2$ ,  $\text{SOCl}_2$ ,  $\text{POCl}_3$ , and probably  $\text{PSCl}_3$ —*v. Buchanan (B.* 8, 486). *Rammelsberg (P.* 56, 308) has described *double salts* with the thiosulphates of  $\text{NH}_4$ , *Ba*, *Ca*, *K* (*v. also Spring, B.* 7, 1157), and *Na* (*v. also Vortmann a. Padberg, B.* 22, 2637).

**Lithium thiosulphate**  $\text{Li}_2\text{S}_2\text{O}_3\text{aq}$  (*v. Fock a. Klüss, B.* 22, 3096).

**Magnesium thiosulphate**  $\text{MgS}_2\text{O}_3\text{aq}$ . By passing  $\text{SO}_2$  into  $\text{MgSAq}$  till colourless, boiling  $\text{MgSO}_3$  in  $\text{SO}_2\text{aq}$  with *S*, or adding  $\text{BaS}_2\text{O}_3\text{aq}$  to  $\text{MgSO}_4\text{aq}$  and filtering, a solution is obtained which on evaporation at a low temperature gives small, white, prismatic crystals of this salt. Loses  $3\text{H}_2\text{O}$  at  $170^\circ$ , and gives off  $\text{SO}_2$  and *S* at red heat, leaving  $\text{MgSO}_3$  and  $\text{MgO}$  (*Herschel, N. Ed. P. J.* 1, 8, 296; 2, 154; *Rammelsberg, P.* 56, 303; *Fock a. Klüss, B.* 22, 3310). *Double salts* (1) with  $(\text{NH}_4)_2\text{S}_2\text{O}_3$ , (2) with  $\text{K}_2\text{S}_2\text{O}_3$ , are described by *R. (l.c.)*; *v. also Kessler, P.* 74, 256; also *F. a. K., B.* 23, 534).

**Manganese thiosulphate**  $\text{MnS}_2\text{O}_3\text{aq}$ . Formed similarly to  $\text{FeS}_2\text{O}_3\text{aq}$  (*Vortmann a. Padberg, B.* 22, 2637). A *double salt* with  $\text{Na}_2\text{S}_2\text{O}_3$  is described by *V. a. P. (l.c.)*.

**Mercury thiosulphates.** Neither the mercurous nor the mercuric salt has been isolated. Addition of a thiosulphate to solution of a mercurous salt ppts.  $\text{Hg}_2\text{S}$ ; with a mercuric salt, a compound of  $\text{HgS}$  with the mercuric salt employed is said to be formed (*Rammelsberg, P.* 56, 314). *Double salts* of *mercurous thiosulphate* with (1)  $(\text{NH}_4)_2\text{S}_2\text{O}_3$ , (2)  $\text{Cu}_2\text{S}_2\text{O}_3$ , (3)  $\text{Na}_2\text{S}_2\text{O}_3$ , are described by *Rammelsberg (l.c.)*; and a *double salt* of *mercuric thiosulphate* with  $\text{K}_2\text{S}_2\text{O}_3$  by *Vortmann a. Padberg (B.* 24, 1351).

**Nickel thiosulphate**  $\text{NiS}_2\text{O}_3\text{aq}$  (*Rammelsberg, P.* 56, 309; *Fock a. Klüss, B.* 22, 3310). For a *double salt* with  $\text{Na}_2\text{S}_2\text{O}_3$  *v. Vortmann a. Padberg (B.* 22, 2637).

**Platinum thiosulphate.** Not isolated; but *Schottländer (A.* 140, 200) describes a *double salt*  $\text{PtS}_2\text{O}_3\text{aq}$   $\cdot 3\text{Na}_2\text{S}_2\text{O}_3\text{aq}$ .

**Potassium thiosulphate**  $\text{K}_2\text{S}_2\text{O}_3$ . Obtained by boiling conc.  $\text{K}_2\text{SO}_4$  with excess of *S*; or by adding hot  $\text{K}_2\text{Cr}_2\text{O}_7\text{aq}$  to hot  $\text{K}_2\text{S}_2\text{O}_3\text{aq}$ , little by little, waiting after each addition till the separated  $\text{Cr}_2\text{O}_3$  is pure green in colour ( $2\text{K}_2\text{S}_2\text{O}_3\text{aq} + 4\text{K}_2\text{Cr}_2\text{O}_7\text{aq} + \text{H}_2\text{O}$

$= 5\text{K}_2\text{S}_2\text{O}_3\text{aq} + 2\text{KOHaq} + 4\text{Cr}_2\text{O}_3$ ); (*Döpping, A.* 46, 172; *Kessler, P.* 74, 274). In either case the filtered solution is evaporated to the crystallising point, and the crystals of  $\text{K}_2\text{S}_2\text{O}_3 \cdot x\text{H}_2\text{O}$  are heated to *c.*  $180^\circ$ . By evaporating at  $30^\circ$ , thin, four-sided, deliquescent prisms are obtained of the *hydrated salt*  $8\text{K}_2\text{S}_2\text{O}_3 \cdot \text{H}_2\text{O}$  (*Rammelsberg, P.* 56, 296; *Kessler, l.c.*; *Fock a. Klüss, B.* 22, 3096). This hydrate is very sol. water, but insol. alcohol; it loses all water at *c.*  $180^\circ$ ; heated more strongly it decomposes to  $\text{K}_2\text{S}$  and  $\text{K}_2\text{SO}_4$  (*R., l.c.*). Other hydrates are described by *D. a. P., l.c.* (*v. also Plessy, A. Ch.*

[B] 11, 182; F. a. K., *l.c.*). The final products of the action of  $\text{SO}_2$  on  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$  are  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ ,  $\text{K}_2\text{S}_2\text{O}_7\text{Aq}$ , and  $\text{K}_2\text{S}_2\text{O}_3\text{Aq}$  (Debus, *C. J.* 53, 343).

**Double salts.**—(1) with  $(\text{NH}_4)_2\text{S}_2\text{O}_8$  (Fock a. Klüss, *B.* 23, 534); the salt obtained was  $\text{SO}_2\text{OK.SNH}_4$ , the isomeric salt  $\text{SO}_2\text{ONH}_4\text{.SK}$  could not be isolated; (2) with  $\text{Bi}_2(\text{S}_2\text{O}_8)_3$  (Carnot, *C. R.* 83, 338); (3) with  $\text{CdS}_2\text{O}_8$  (F. a. K., *B.* 23, 534); (4) with  $\text{Cu}_2\text{S}_2\text{O}_8$  (Cohen, *O. J.* 51, 38); (5) with  $\text{HgCy}_2$  (F. a. K., *B.* 24, 1351); (6) with  $\text{HgS}_2\text{O}_8$  (F. a. K., *l.c.*); (7) with  $\text{PbS}_2\text{O}_8$  (Rammelsberg, *P.* 56, 308; Spring, *B.* 7, 1157); (8) with  $\text{Ag}_2\text{S}_2\text{O}_8$  (Cohen, *C. J.* 51, 38; Schwicker, *B.* 22, 1728, describes  $\text{KAgS}_2\text{O}_8\text{.NH}_3$ ). (9) With  $\text{Na}_2\text{S}_2\text{O}_8$  two salts are obtained: (i.)  $\text{SO}_2\text{OK.NaS}_2\text{O}_8$  2aq, by the interaction of  $\text{Am}_2\text{S}_2\text{O}_8$  and  $\text{NaKS}_2\text{O}_8$  2aq; (ii.)  $\text{SO}_2\text{SK.ONa}$  2aq, by the interaction of  $\text{Am}_2\text{S}_2\text{O}_8$  and  $\text{KNaSO}_3$  (v. SULPHITES, p. 587); the first salt melts at  $c. 57^\circ$  and has  $S. = 213.7$  at  $15^\circ$ , heated with  $\text{EtBr}$  it gives  $\text{SO}_2\text{OK.SET}$ ; the second salt melts at  $c. 62^\circ$  and has  $S. = 105.3$  at  $15^\circ$ , heated with  $\text{EtBr}$  it gives  $\text{SO}_2\text{ONa.SET}$  (Schwicker, *B.* 22, 1728).

**Silver thiosulphate  $\text{Ag}_2\text{S}_2\text{O}_8$ .** This salt has probably not been isolated pure. On adding dilute  $\text{AgNO}_3\text{Aq}$  to  $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$  a white pp. is formed, and is dissolved on shaking; addition of more  $\text{AgNO}_3\text{Aq}$  produces a greyish, flocculent pp., which is a mixture of  $\text{Ag}_2\text{S}_2\text{O}_8$  and  $\text{Ag}_2\text{S}$ . By treating this pp. with  $\text{NH}_4\text{Aq}$ , filtering from  $\text{Ag}_2\text{S}$ , exactly neutralising the filtrate by  $\text{HNO}_3\text{Aq}$ , and quickly drying the white flocculent pp. that formed between filter paper, Herschel (*N. Ed. P. J.* 1, 26, 398; 2, 154) obtained fairly pure  $\text{Ag}_2\text{S}_2\text{O}_8$ . A white powder; slightly soluble water; solution has a sweet taste; decomposes readily to  $\text{Ag}_2\text{S}$  and  $\text{H}_2\text{SO}_4\text{Aq}$ .

**Double salts.**  $\text{Ag}_2\text{O}$  and  $\text{Ag}$  salts generally dissolve readily in solutions of alkali thiosulphates, forming double salts, either of the form  $2\text{AgMS}_2\text{O}_8\text{.aq}$ , or of the form  $\text{Ag}_2\text{M}(\text{S}_2\text{O}_8)_2\text{.2aq}$  (Herschel, *l.c.*). (1) With  $(\text{NH}_4)_2\text{S}_2\text{O}_8$ ; by adding excess of  $\text{AgCl}$  to  $(\text{NH}_4)_2\text{S}_2\text{O}_8\text{Aq}$ , and washing the white crystalline pp.,  $2\text{Ag}(\text{NH}_4)_2\text{S}_2\text{O}_8\text{.aq}$  is obtained. Using less  $\text{AgCl}$  and ppg. the solution by alcohol produces  $\text{Ag}(\text{NH}_4)_2(\text{S}_2\text{O}_8)_2\text{.2aq}$  (H., *l.c.*). (2) With  $\text{Na}_2\text{S}_2\text{O}_8$ ; addition of  $\text{AgNO}_3\text{Aq}$ , drop by drop, with constant shaking, to  $\text{Na}_2\text{S}_2\text{O}_8\text{Aq}$ , till a permanent pp. begins to form, followed by addition of alcohol, ppts.  $\text{Ag}_2\text{Na}_4(\text{S}_2\text{O}_8)_2\text{.2aq}$ ; the salt is washed with alcohol, and dried *in vacuo* (Lenz, *A.* 40, 94); when the mother-liquor from this salt is allowed to evaporate  $2\text{AgNaS}_2\text{O}_8\text{.aq}$  is deposited (Herschel, *l.c.*; cf. Lenz, *l.c.*). The second of these salts is much less soluble in water than the first; it dissolves in  $\text{Na}_2\text{S}_2\text{O}_8\text{Aq}$ , with formation of  $\text{Ag}_2\text{Na}_4(\text{S}_2\text{O}_8)_2\text{.2aq}$ . Both salts are decomposed by boiling their aqueous solutions, with formation of  $\text{Ag}_2\text{S}$ . (3) With  $\text{K}_2\text{S}_2\text{O}_8$ ; two salts are known similar to the sodium salts. Schwicker (*B.* 22, 1738) describes the compound  $\text{AgKS}_2\text{O}_8\text{.NH}_3$ . Herschel (*l.c.*) obtained double salts with  $\text{CaS}_2\text{O}_8$  and with  $\text{SrS}_2\text{O}_8$ .

**Sodium thiosulphate  $\text{Na}_2\text{S}_2\text{O}_8$  5aq.**

**Formation.**—1. By boiling  $\text{Na}_2\text{SO}_3\text{Aq}$  with  $\text{S}$ .—2. By passing  $\text{SO}_2$  into solution of sodium polysulphides.—3. By the action of  $\text{SO}_2$  on *soda waste* suspended in water, whereby  $\text{CaS}_2\text{O}_8\text{Aq}$  is formed; followed by addition of  $\text{Na}_2\text{SO}_3$ , filtration from  $\text{CaSO}_4$ , and evaporation.

**Preparation.**— $\text{Na}_2\text{S}_2\text{O}_8$  2aq is dissolved in a little water, the solution is boiled with flowers of sulphur for a considerable time, and filtered; the clear, colourless liquid is evaporated to the crystallising point, and the crystals that separate are purified by recrystallisation from water.

**Properties.**—Large, white, monoclinic prisms; S.G. 1.736 at  $10^\circ$  (Kopp, *J.* 8, 45; cf. Schiff, *J.* 12, 41; Smith, *Am. J. Pharm.* 53, 148). Melts at  $45^\circ$  in the water of crystallisation (Kopp, *J.* 8, 45); at  $48.5^\circ$  (Tilden, *C. J.* 45, 268). The crystals are dehydrated by keeping *in vacuo* over  $\text{H}_2\text{SO}_4$ , or by heating to  $100^\circ$ . S. 49.75 at  $0^\circ$ , 69.44 at  $20^\circ$ , 101.16 at  $40^\circ$ , 192.3 at  $60^\circ$  (Kremers, *P.* 99, 50). An aqueous solution of the salt is easily supersaturated; thus Schiff (*A.* 113, 350) dissolved 171 parts  $\text{Na}_2\text{S}_2\text{O}_8$  5aq ( $= 108.9$  parts  $\text{Na}_2\text{S}_2\text{O}_8$ ) in 100 parts water at  $19.1^\circ$ , and Kremers obtained a solution of 217.4 parts  $\text{Na}_2\text{S}_2\text{O}_8$  in 100 parts water at the ordinary temperature. According to Baumhauer (*J. pr.* 104, 148), a supersaturated solution may be cooled to  $-10^\circ$  without crystallising; addition of a crystal of the salt causes rapid crystallisation, with the evolution of much heat (cf. Parmentier a. Amat, *C. R.* 98, 735). Solution of  $\text{Na}_2\text{S}_2\text{O}_8$  5aq in water is accompanied by the disappearance of much heat; Madorff (*B.* 2, 68) says that 110 parts  $\text{Na}_2\text{S}_2\text{O}_8$  5aq dissolving in 100 parts water lower the temperature from  $10.7^\circ$  to  $-8^\circ$ , i.e. through  $18.7^\circ$ . Schiff (*A.* 113, 350) gives the following data for S.G. and composition of aqueous solutions of  $\text{Na}_2\text{S}_2\text{O}_8$  5aq:—

S.G. of sol.	P.p. $\text{Na}_2\text{S}_2\text{O}_8$ 5aq	P.p. $\text{Na}_2\text{S}_2\text{O}_8$	S.G. of sol.	P.p. $\text{Na}_2\text{S}_2\text{O}_8$ 5aq	P.p. $\text{Na}_2\text{S}_2\text{O}_8$

$\text{Na}_2\text{S}_2\text{O}_8$  5aq is insol. alcohol.

\* According to Jochem (*O. C.* 1885, 642), a trihydrated salt  $\text{Na}_2\text{S}_2\text{O}_8$  8aq is obtained by adding alcohol to a saturated solution of the ordinary salt, removing the oily liquid that separates, and adding to it 98 p.c. alcohol. According to Parmentier a. Amat (*C. R.* 98, 785),  $\text{Na}_2\text{S}_2\text{O}_8$  5aq is obtained crystallised in needles, melting at  $c. 82^\circ$ , by placing a supersaturated

solution of the ordinary salt in a freezing mixture in a closed vessel.

**Reactions.**—1. Heat decomposes  $\text{Na}_2\text{S}_2\text{O}_3$ ; the change begins at  $c. 220^\circ$  with separation of S, at  $c. 400^\circ$   $\text{Na}_2\text{SO}_3$  and  $\text{Na}_2\text{S}$  are formed, and at a higher temperature more S is given off, and  $\text{Na}_2\text{SO}_3$  and  $\text{Na}_2\text{S}$  remain.—2.  $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$  interacts with iodine in KIAq to form  $\text{NaIAq}$  and  $\text{Na}_2\text{S}_2\text{O}_4\text{Aq}$ ; according to Villiers (*C. R.* 108, 402) some  $\text{Na}_2\text{S}_2\text{O}_3$  is also formed. With a mixture of  $\text{Na}_2\text{SO}_3$  and  $\text{Na}_2\text{S}_2\text{O}_3$  in solution I produces  $\text{NaIAq}$ ,  $\text{Na}_2\text{SO}_4\text{Aq}$  and  $\text{Na}_2\text{S}_2\text{O}_4\text{Aq}$  (Colefax, *C. J.* 61, 198, 1083).—3.  $\text{Na}_2\text{S}_2\text{O}_3$  is oxidised by potassium permanganate solution; in alkaline solutions the oxidation is complete to  $\text{Na}_2\text{SO}_4\text{Aq}$  according to Hönig a. Zatzek (*M. J.* 4, 738); Glaser (*M. J.* 6, 329) says that the oxidation is also complete in neutral solutions; Luokow (*Fr.* 32, 53) represents the oxidation, on boiling, either in neutral, acid, or alkaline solution as producing  $\text{Na}_2\text{SO}_3$  and  $\text{Na}_2\text{S}_2\text{O}_3$ .—4. Acids interact with  $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$ , forming Na salts of the acids, and  $\text{H}_2\text{S}_2\text{O}_3\text{Aq}$ , which then decomposes to  $\text{H}_2\text{SO}_4\text{Aq}$  and S; when the products are not removed from the solution the reaction stops before all the  $\text{H}_2\text{S}_2\text{O}_3$  is decomposed (Colefax, *C. J.* 61, 176; and v. beginning of article THIOSULPHATES, p. 705).

**Combinations.**—1. With water (v. *supra*, Properties).—2. With various thiosulphates to form double salts. Double salts with  $\text{CdS}_2\text{O}_3$ ,  $\text{CoS}_2\text{O}_3$ ,  $\text{FeS}_2\text{O}_3$ ,  $\text{PbS}_2\text{O}_3$ ,  $\text{MnS}_2\text{O}_3$ ,  $\text{NiS}_2\text{O}_3$ ,  $\text{TiS}_2\text{O}_3$ , and  $\text{ZnS}_2\text{O}_3$  are described by Vortmann a. Padberg (*B. Z.* 22, 2637); Fock a. Klüss (*B. Z.* 23, 1763) also describe that with  $\text{CdS}_2\text{O}_3$ . Rammelsberg (*P.* 56, 308) prepared salts with  $\text{PbS}_2\text{O}_3$  and  $\text{Hg}_2\text{S}_2\text{O}_3$ . For a double salt with  $\text{Hg}_2\text{S}_2\text{O}_3$  v. Schwicker (*B. Z.* 22, 1728). For the double salts with  $\text{K}_2\text{S}_2\text{O}_3$  v. POTASSIUM THIOSULPHATE, double salts, No. (9) (p. 707), and for those with  $\text{Ag}_2\text{S}_2\text{O}_3$  v. SILVER THIOSULPHATE, double salts, No. (2) (p. 707). Schotländer (*A.* 140, 200) describes a double salt  $3\text{Na}_2\text{S}_2\text{O}_3 \cdot \text{PtS}_2\text{O}_3 \cdot 10\text{aq}$ .

Strontium thiosulphate  $\text{SrS}_2\text{O}_3$ , 6aq. Prepared like the Ba salt (Herschel, *N. Ed. P. J.* 1, 26, 398; 2, 154; Kessler, *P.* 74, 274). Fock a. Klüss (*B. Z.* 22, 8310) describe a salt  $\text{SrS}_2\text{O}_3$ , aq.

Thallium thiosulphate  $\text{TlS}_2\text{O}_3$ . A white, crystalline pp., formed by adding  $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$  to fairly conc.  $\text{TlOHAq}$  (Crookes, *C. J.* 17, 136; Heberling, *A.* 184, 11). For a double salt with  $\text{Na}_2\text{S}_2\text{O}_3$  v. Werther (*J. pr.* 92, 180); Vortmann a. Padberg (*B. Z.* 22, 2637); also Jochum (*C. C.* 1885, 642).

Zinc thiosulphate  $\text{ZnS}_2\text{O}_3$ . Prepared by double decomposition from  $\text{ZnSO}_4\text{Aq}$  and  $\text{BaS}_2\text{O}_3\text{Aq}$  (v. Rammelsberg, *P.* 56, 295; Fordos a. Gélis, *J. pr.* 29, 291). For a compound with  $\text{NH}_3$  v. B. (*l.c.*). For a double salt with  $\text{Na}_2\text{S}_2\text{O}_3$  v. Vortmann a. Padberg (*B. Z.* 22, 2637).

M. M. P. M.

**THIOSULPHURIC ACID**  $\text{H}_2\text{S}_2\text{O}_3\text{Aq}$ . This acid almost certainly exists in the liquid obtained by adding a dilute weak acid to dilute  $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$ ; the acid and salt being mixed in equivalent quantities; the  $\text{H}_2\text{S}_2\text{O}_3\text{Aq}$  soon begins to decompose to  $\text{H}_2\text{SO}_4\text{Aq}$  and S. Landolt (*B.* 16, 2958) has made an extensive investigation into the conditions and time of existence of  $\text{H}_2\text{S}_2\text{O}_3$  in solution. Thomsen (*Th.* 2, 256) gives the thermal data;  $[\text{SO}^+\text{Aq.S}] = -9310$ ;  $[\text{SO}^+\text{S.Aq}] = -1610$ .

For the salts of  $\text{H}_2\text{S}_2\text{O}_3$  v. THIOSULPHATES, M. M. P. M.

**THIOTOLENE** v. Methyl-thiophene.

**THIO-*o*-TOLUIC ACID.** *Amide*  $\text{C}_6\text{H}_4\text{Me.CS.NH}_2$ . [88°]. Formed from *o*-toluic nitrile (Gabriel a. Heymann, *B.* 24, 786).

**Thio-*p*-toluic acid.** *Amide*. [168°]. Formed by passing  $\text{H}_2\text{S}$  into an alcoholic solution of *p*-toluic nitrile (Paterao a. Spica, *B.* 8, 441). Yellowish needles. Zinc and  $\text{HClAq}$  yield  $\text{C}_6\text{H}_4\text{Me.CH}_2\text{NH}_2$ .

**THIO-TOLUIDINE** v. DI-AMIDO-DI-TOLYL SULPHIDE.

**THIO-*p*-TOLYL-DI-PHENYL-DI-GUANIDINES** v. DI-PHENYL-DI-GUANIDO-DI-TOLYL SULPHIDE and DI-PHENYL-DI-CARBIMIDO-TETRA-AMIDO-TETRA-TOLYL DISULPHIDE.

**THIO-TOLYL-DI-PHENYL-THIO-UREA** v. DI-PHENYL-DI-THIOURAMIDO-DI-TOLYL SULPHIDE.

**THIO-URAMIDO-BARBITURIC ACID**

$\text{C}_6\text{H}_4\text{N}_2\text{SO}_3$ , i.e.  $\text{NH}_2\text{C}(\text{NH})_2\text{S.CH} < \begin{smallmatrix} \text{CO.NH} \\ \text{CO.NH} \end{smallmatrix} > \text{CO}$ .

Formed by the action of thio-urea on an aqueous solution of chloro-, bromo-, or di-bromo-barbituric acid (Mulder, *B.* 12, 2309; Trzcinski, *B.* 16, 1057). Formed also by heating alloxan with thio-urea and alcoholic  $\text{SO}_2$  at  $100^\circ$  (Nencki, *B.* 4, 722; 5, 451). Slender needles, insol. water, sol. hot  $\text{HClAq}$ . Converted by boiling  $\text{KOHaq}$  into thio-dialuric acid  $\text{C}_6\text{H}_4\text{N}_2\text{SO}_3$ , 14aq (?) which yields  $\text{KA}^+\text{aq}$ .  $\text{H}_2\text{SO}_4$  ( $\frac{1}{2}$  pt.) at  $150^\circ$ – $160^\circ$  forms uro-sulphinic acid  $\text{C}_6\text{H}_4\text{N}_2\text{SO}_2$ .

**THIO-URAMIDO-BENZENE *p*-SULPHONIC ACID.** The salt  $\text{NH}_2\text{CS.NH.C}_6\text{H}_4\text{SO}_3\text{K}$ , formed by heating potassium sulphocyanide with amido-benzene *p*-sulphonic acid at  $140^\circ$ , crystallises from dilute alcohol in aggregates of thin needles (Pellizzari, *A.* 248, 156).

***m*-THIO-URAMIDO-BENZOIC ACID**

$\text{NH}_2\text{CS.NH.C}_6\text{H}_4\text{CO}_2\text{H}$ . [187°]. Formed from *m*-amido-benzoic acid and potassium sulphocyanide (Arzruni, *B.* 4, 406). Formed also by allowing a solution of *m*-cyanamido-benzoic acid in colourless ammonium sulphide to stand for 24 hours (Traube, *B.* 15, 2118). Needles. Converted by ammoniacal  $\text{AgNO}_3$  into *m*-uramido-benzoic acid. Not coloured by  $\text{FeCl}_3$ .

***p*-THIO-URAMIDO-BENZYL-THIO-UREA**

$\text{NH}_2\text{CS.NH.C}_6\text{H}_4\text{CH}_2\text{NH.CS.NH}_2$ . *p-*o*-di-thio-uramido-toluene*. [176°]. Formed by heating *p*-amido-benzyl-amine hydrochloride (1 mol.) with potassium sulphocyanide (2 mols.) in aqueous solution (Amsel a. Hofmann, *B.* 19, 1289). White needles.

**THIO-URAMIDO-BUTYRIC ACID.** *Anhydride*

$\text{NH}_2\text{C} < \begin{smallmatrix} \text{S} \\ \text{NH.CO} \end{smallmatrix} < \text{CH}_2\text{C} < \begin{smallmatrix} \text{S} \\ \text{NH.CO} \end{smallmatrix}$ . [200°]. Formed from  $\alpha$ -bromo-*n*-butyric acid and thio-urea (Andreasch, *M.* 8, 419). Needles, v. sol. hot water.

**Thio-uramido-iso-butyric acid.** *Anhydride*

$\text{O}_2\text{H}_2\text{N.SO}$  i.e.  $\text{NH}_2\text{C} < \begin{smallmatrix} \text{S} \\ \text{NH.CO} \end{smallmatrix} < \text{CH}_2\text{C} < \begin{smallmatrix} \text{S} \\ \text{NH.CO} \end{smallmatrix}$ . [242°]. Formed from bromo-iso-butyric acid and thio-urea (Andreasch, *M.* 8, 410). Plates, sl. sol. water. Oxidised by  $\text{HCl}$  and  $\text{KClO}_4$  to urea and  $\alpha$ -sulpho-iso-butyric acid.

***o*-THIO-URAMIDO-CINNAMIC ACID**

$\text{NH}_2\text{CS.NH.C}_6\text{H}_4\text{CH}:\text{CH.CO}_2\text{H}$ . [286°–289°]. Got by heating the sulphocyanide of *o*-amido-cinnamic acid  $\text{C}_6\text{H}_3(\text{NH}_2\text{HSCy})\text{CH}:\text{CH.CO}_2\text{H}$

[164°] at 116° (Rothschild, B. 23, 3342). V. sol. hot HOAc and  $\text{NH}_4\text{Aq}$ .

**$\alpha$ -Thio- $\psi$ -uramido-cinnamic acid**  $\text{C}_{11}\text{H}_{12}\text{N}_2\text{SO}_4$ , i.e.  $\text{NH}_2\text{C}(\text{NH}_2)\cdot\text{S}\cdot\text{C}(\text{CO}_2\text{H})\cdot\text{CHPh}$ . Formed from benzoic aldehyde, thiodydantoin, and  $\text{NaOHAq}$  (Andreasch, M. 8, 421). Needles (from alcohol), decomposed by alkalis.

**$\beta$ -Thio- $\psi$ -uramido-propionic acid**  $\text{NH}_2\text{C}(\text{NH}_2)\cdot\text{S}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$ . Formed by heating  $\beta$ -iodo-propionic acid with thio-urea and water and a little  $\text{NaOH}$  (Andreasch, M. 6, 831). Small pyramids (containing 2aq), sl. sol. cold water and cold alcohol. Decomposed by baryta into cyanamide and  $\text{CH}_3(\text{SH})\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$ .  $\text{KClO}_4$  and  $\text{HCl}$  yield  $\beta$ -sulpho-propionic acid.

**$\alpha$ , $\psi$ -Di-thio-uramido-toluene** v. Thio-uramido-benzyl-thio-urea.

**Di- $p$ -thio-uramido-di-tolyl- $\alpha$ -sulphide**  $[\text{2:1:4}] \text{S}(\text{C}_6\text{H}_4\text{Me}\cdot\text{NH}\cdot\text{CS}\cdot\text{NH}_2)_2$ . Thio- $p$ -tolyl-di-thiurea. [121°]. Formed by evaporating to dryness an aqueous solution of di- $p$ -amido-di-tolyl sulphide, hydrochloride and ammonium sulphocyanide (Truhlar, B. 20, 669). White amorphous powder. Sol. alcohol and benzene, sl. sol. ether.

**Thio-urea**  $\text{CSN}_2\text{H}_4$ , i.e.  $\text{CS}(\text{NH}_2)_2$  or  $\text{HS}\cdot\text{C}(\text{NH}_2)\cdot\text{NH}_2$ . Mol. w. 76. [170°]. S. 9 in the cold (Volhard, J. pr. [2] 9, 13).

**Formation**.—1. By heating dry ammonium sulphocyanide for two hours at 170°, cooling to 100°, adding an equal weight of water at 80°, filtering, and allowing to crystallise (Emerson Reynolds, C. J. 22, 1; Claus, A. 179, 113; Smolka, A. Friedreich, M. 10, 90).—2. By the action of tin and  $\text{HCl}$ , or of  $\text{HI}$ , on persulphocyanic acid  $\text{C}_2\text{H}_2\text{N}_2\text{S}_2$  (Glutz, A. 154, 39).—3. By passing dry  $\text{H}_2\text{S}$  into an ethereal solution of cyanamide (Baumann, B. 6, 1375).—4. By allowing a solution of cyanamide, mixed with yellow ammonium sulphide, to stand for a day (Baumann, B. 8, 26).—5. From cyanamide and thioacetic acid.—6. Together with urea by the action of ammonia on  $\text{COS}$  (Berthelot, C. R. 94, 1069).

**Properties**.—Silky trimetric needles, melting at 170°. After one fusion it melts at 149° (Prätorius, J. pr. [2] 21, 141). V. sol. water, nearly insol. alcohol and ether. Tastes bitter, not coloured by  $\text{FeCl}_3$ . According to Armstrong (C. J. Proc. 8, 2), the molecule of thio-urea is  $\text{C}_2\text{S}_2\text{N}_4\text{H}_4$ .

**Reactions**.—1. Water at 140° forms ammonium sulphocyanide. Alcohol at 100° acts in like manner (Haller, Bl. [2] 45, 706).—2. An alcoholic solution of nitrous ether quickly converts it into ammonium sulphocyanide.—3. Prolonged heating at 170° also converts it into ammonium sulphocyanide. At 180° it slowly forms guanidine sulphocyanide and ammonium tri-thio-carbonate. Nitrous acid gives off nitrogen.—4.  $\text{KOH}$  at 100° slowly forms  $\text{NH}_3$ ,  $\text{KSH}$ ,  $\text{K}_2\text{CO}_3$ , and a little  $\text{KCyS}$ . Alcoholic potash acts in like manner (Haller, C. R. 102, 974).  $\text{H}_2\text{SO}_4$  and  $\text{HCl}$  act in the same way.—5. Aqueous  $\text{KMnO}_4$  forms urea and other products (Maly, M. 11, 277).—6. Oxidising agents (e.g.  $\text{H}_2\text{O}_2$ ,  $\text{K}_2\text{Cr}_2\text{O}_7$ ,  $\text{KNO}_3$ ,  $\text{KMnO}_4$ , and iodine) form  $\text{S}_2\text{C}(\text{NH}_2)_2\cdot\text{NH}_2$ , which has an insoluble nitrate (Storch, M. 11, 452).—7. Ammoniacal  $\text{AgNO}_3$  forms urea and  $\text{Ag}_2\text{S}$ .—8.  $\text{H}_2\text{O}$ , added to a cold aqueous solution, produces cyanamide.

$\text{PbO}$  acts in like manner. At 100° the product is dicyandiamide (Hofmann, B. 2, 605).—9. Acetoacetic ether reacts forming an ether  $\text{C}_2\text{H}_5\text{N}_2\text{SO}(\text{OEt})$ , which on saponification yields  $\text{CS} < \begin{smallmatrix} \text{NH}\cdot\text{CMe} \\ \text{NH}\cdot\text{CO} \end{smallmatrix} > \text{CH}$ , v. sl. sol. water (Behrend, B. 19, 219).—10.  $\text{CCl}_4\cdot\text{COCl}$  forms  $\text{C}_2\text{H}_5\text{Cl}_2\text{N}_2\text{SO}_4$ , crystallising in slender needles, m. sol. alcohol, sl. sol. water, v. sl. sol. ether; converted by  $\text{Br}$  into  $\text{CCl}_4\cdot\text{SO}_2\cdot\text{Br}$  (McGowan, C. J. 49, 191; 51, 669; J. pr. [2] 36, 220).  $\text{CCl}_4\cdot\text{SO}_2\cdot\text{Cl}$  added to an alcoholic solution of thio-urea forms the chloride  $\text{Cl}\cdot\text{CSN}_2\text{H}_4$ , which is ppd. on adding ether, while the filtrate contains the compound  $(\text{CSN}_2\text{H}_4)_2(\text{CCl}_4\cdot\text{SO}_2)$  [125°], which is more sol. alcohol than water, and gives with  $\text{Br}$  a pp. of  $\text{CCl}_4\cdot\text{SO}_2\cdot\text{Br}$ .—11.  $\text{CCl}_4\cdot\text{SO}_2\cdot\text{NH}_3$  in alcohol forms flat prisms of  $(\text{CSN}_2\text{H}_4)_2\text{CCl}_4\cdot\text{SO}_2\cdot\text{H}$  [139°], m. sol. water and ether, v. sl. alcohol, converted by  $\text{Br}$  into  $\text{CCl}_4\cdot\text{SO}_2\cdot\text{Br}$  (McGowan, C. J. 51, 667; J. pr. [2] 36, 219).—12. Chloro-acetone forms  $(\text{NH}_2\cdot\text{CS}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{CH}_3)_2\text{HCl}$  [126°] (Fawcett, B. 21, 402).—13.  $\text{ClCO}_2\text{Et}$  forms  $(\text{NH}_2\cdot\text{CS}\cdot\text{NH}\cdot\text{CO}_2\text{Et})_2\text{HCl}$  [117°].—14.  $\text{CH}_3\text{Cl}\cdot\text{OH}$  gives  $\text{C}_2\text{H}_5\text{N}_2\text{S}_2$ , a white amorphous powder, insol. water, nearly insol. all usual menstrua, reconverted into thio-urea by  $\text{HClAq}$  (von Hemmelmayr, M. 12, 89).—15. Di-bromo-succinic acid forms fumaric acid on heating (Nencki, A. Sieber, J. pr. [2] 25, 74).—16. A hot conc. solution of di-bromo-pyruvic acid forms 'sulphuvinuric acid'  $\text{C}_2\text{H}_2\text{N}_2\text{SO}_4$ , which crystallises with 2aq, reduces Fehling's solution to  $\text{Cu}_2\text{O}$  in the cold, and to a copper mirror on warming, and yields the salts  $\text{CaA}^+$ ,  $\text{MgA}^+$ ,  $\text{ZnA}^+$ ,  $\text{HA}^+\text{HCl}$ ,  $\text{HA}^+\text{HBr}$ , and  $\text{HA}^+\text{HNO}_3$  (N. a. S.).—17. Bromo-pyruvic ether forms amido-thiazole carboxylic ether  $\text{S} < \begin{smallmatrix} \text{CH} \\ \text{C}(\text{NH}_2) \end{smallmatrix} > \text{CO}_2\text{Et}$  [173°] (Steude, A. 261, 30).

18. Bromo-acetoacetic ether gives  $\mu$ -amido-thiazyl-acetic ether  $\text{S} < \begin{smallmatrix} \text{CH} \\ \text{C}(\text{NH}_2) \end{smallmatrix} > \text{C}\cdot\text{CH}_2\cdot\text{CO}_2\text{Et}$ .

[94°], which yields an acid [c. 130°], split up on fusion into  $\text{CO}_2$  and amido-methyl-thiazole (Steude).  $\alpha$ -Chloro-acetoacetic ether forms  $\text{C}_2\text{NSMe}(\text{NH}_2)\cdot\text{CO}_2\text{Et}$  [175°] (Züroher, A. 250, 281).—19. Thio-urea heated with an alcoholic solution of chloro-acetic acid and phenyl-hydrazine forms  $\text{C}_2\text{H}_2\text{N}_2\text{SO}$  [176°] (Probst, J. pr. [2] 45, 416).—20. Fusion with (8)-iodopropionic acid and a little water forms  $\text{C}_2\text{H}_2\text{N}_2\text{SO}_4$  [176°], which crystallises from water in needles (containing 2aq), sl. sol. alcohol, insol. ether (Andreasch, M. 6, 832).—21. Di-chloro-acetic acid forms thiodydantoin.  $\alpha$ -Bromo-propionic acid forms methyl-thiodydantoin (206° uncor.) (Dixon, C. J. 63, 815).—22. Aldehyde heated in a sealed tube with thio-urea forms  $\text{CSN}_2\text{H}_4(\text{CHMe})$ , which is sl. sol. ether and cold alcohol, and is decomposed by hot water (Reynolds, C. N. 24, 87).—23. Succinic anhydride at 140° forms  $\text{C}_2\text{H}_2\text{N}_2\text{SO}$  [211°].—24. Citraconic anhydride at 130° forms  $\text{C}_2\text{H}_2\text{N}_2\text{SO}_4$  [223°] (Pike, B. 6, 1104).—25. Acetyl-acetone and a small quantity of  $\text{HClAq}$  form  $\text{CH}_3(\text{CMe}:\text{N}\cdot\text{CS}\cdot\text{NH}_2)_2\text{HCl}$  [219°]. In presence of excess of  $\text{HCl}$  the product is  $\text{CH}_2 < \begin{smallmatrix} \text{CMe}:\text{N} \\ \text{CMe}:\text{N} \end{smallmatrix} > \text{CS}$  [210°] (Evans, J. pr. [2] 48, 503).

**Salts**.— $\text{B}^+\text{HNO}_3$ . Crystalline. —  $\text{B}^+\text{HCl}$ . Formed from the stannous double chloride and

**H<sub>2</sub>S.** Crystalline.—B'HI. Tables.—B'NH<sub>4</sub>Cl. [164°]. Felted crystalline mass (Reynolds, *C. J.* 59, 385).—B'NH<sub>4</sub>I. [186°].—B'H<sub>2</sub>PtCl<sub>6</sub>. Yellow prisms, v. sol. water and alcohol. Can be dried at 100°.—B'HPTCl<sub>6</sub>. Got when saturated solutions of thio-urea and PtCl<sub>6</sub> are mixed. Dark-red prisms, insol. water, alcohol and ether.—B'AuCl<sub>3</sub>. Yellow monoclinic crystals, got by adding AuCl<sub>3</sub> to a saturated solution of thio-urea.—B'TiSO<sub>4</sub>.—B'<sub>2</sub>CuSO<sub>4</sub>. White silky needles. Got by mixing conc. solutions of thio-urea and CuSO<sub>4</sub>.—B'<sub>2</sub>Cu<sub>2</sub>(SO<sub>4</sub>)<sub>2</sub> aq.—B'<sub>2</sub>CuCl<sub>2</sub>. Colourless dimetric crystals, sol. water, but ppd. by HCl and KCl. Alkaline in reaction. Attacked by H<sub>2</sub>S with difficulty. Does not absorb CO (Rathke, *B.* 17, 301).—B'<sub>2</sub>CuCl<sub>2</sub> aq. Ppd. by adding CuCl<sub>2</sub> aq. to aqueous thio-urea (Rathke, *B.* 14, 1779; 17, 301). Minute needles, insol. water.—B'<sub>2</sub>CuCl<sub>2</sub>. Flat needles. Formed by mixing the two preceding salts into which it is decomposed by water.—B'<sub>4</sub>HgO.—B'(HgO)<sub>2</sub> 3aq. Ppd. by adding neutral Hg(NO<sub>3</sub>)<sub>2</sub> to a dilute solution of thio-urea (Emerson Reynolds, *A.* 150, 235; Kurnakoff, *B.* 24, 3956). Crystalline. Loses thio-urea on washing with water.—B'<sub>2</sub>HgCl<sub>2</sub>: large crystals, v. sol. water.—B'<sub>2</sub>HgCl<sub>2</sub>: minute needles, nearly insol. water (Claus, *B.* 9, 227).—B'HgI<sub>2</sub> (Maly, *B.* 9, 173).—B'HgCyS. Needles, decomposed by heat into dicyandiamide, H<sub>2</sub>Cy, and HgS (Nencki, *B.* 6, 598).—B'<sub>2</sub>PbCl<sub>2</sub>: needles (Claus, *A.* 179, 135).—B'<sub>2</sub>Pb(CyS)<sub>2</sub>.—B'<sub>2</sub>SnCl<sub>2</sub>.—B'<sub>2</sub>ZnCl<sub>2</sub>: spherical groups of prisms (from water).—B'<sub>2</sub>CdSO<sub>4</sub>.—B'<sub>2</sub>SiBr<sub>2</sub> (Emerson Reynolds, *C. J.* 51, 202).—B'<sub>2</sub>Ag<sub>2</sub>O 4aq. Crystalline.—B'<sub>2</sub>AgNO<sub>3</sub> (K.).—B'<sub>2</sub>AgNO<sub>3</sub>. [141°]. Silky crystals, sol. hot alcohol (Emerson Reynolds, *C. J.* 61, 249).—B'<sub>2</sub>AgCl. [171°]. Needles, m. sol. hot alcohol.—B'<sub>2</sub>AgBr. [121°].—B'<sub>2</sub>AgI.—B'<sub>2</sub>AgCy. [126°].—B'<sub>2</sub>Ag<sub>2</sub>C<sub>2</sub>O<sub>4</sub>: needles.

**Chloride** (CSN<sub>2</sub>H<sub>4</sub>)<sub>2</sub>Cl<sub>2</sub>. Formed by passing Cl into a conc. alcoholic solution of thio-urea (Claus, *A.* 179, 139). Formed also by the action of CCl<sub>4</sub>, SO<sub>2</sub>Cl<sub>2</sub> and of ICl, ICl<sub>3</sub> or POCl<sub>3</sub> on thio-urea (M'Gowan, *C. J.* 49, 191; *J. pr.* [2] 83, 188). Small needles, v. sol. water, m. sol. alcohol, insol. ether. Decomposed by alkalis, yielding cyanamide. Alcoholic KI removes chlorine, setting thio-urea free. Dilute HNO<sub>3</sub> forms crystals of (CSN<sub>2</sub>H<sub>4</sub>)<sub>2</sub>(NO<sub>3</sub>)<sub>2</sub>, which is sl. sol. water, insol. alcohol and ether.

**Bromide** (CSN<sub>2</sub>H<sub>4</sub>)<sub>2</sub>Br<sub>2</sub>. Formed by adding Br to an alcoholic or cold aqueous solution of thio-urea; in aqueous solution excess of Br produces urea (Claus, *A.* 179, 138; M'Gowan, *C. J.* 51, 878; *J. pr.* [2] 36, 216). Crystals. Its aqueous solution deposits S when heated. Sodium-amalgam reproduces thio-urea.

**Iodide** (CSN<sub>2</sub>H<sub>4</sub>)<sub>2</sub>I<sub>2</sub>. Formed from thio-urea, I, and alcohol (M'Gowan, *J. pr.* [2] 83, 192). Prisms.

**Methylo-iodide** (CSN<sub>2</sub>H<sub>4</sub>)MeI. [117°]. Formed slowly by combination of thio-urea with MeI in the cold (Bernthsen, A. Klinger, *B.* 11: 498). Prisms, v. sol. water and alcohol. AgCl gives the chloride, which forms the platino-chloride (B'MeCl)<sub>2</sub>PtCl<sub>4</sub> aq.

**Ethylo-chloride** B'EtCl. Crystals.

**Ethylo-bromide** (CSN<sub>2</sub>H<sub>4</sub>)EtBr. Hexagonal plates (Claus, A. Siegfried, *A.* 179, 145). Decomposes at 100°.

**Ethylo-iodides** (CSN<sub>2</sub>H<sub>4</sub>)EtI. Crystal-

line. Gives with moist Ag<sub>2</sub>O a base. Boiling aqueous alkalis liberate mercaptan.—B'Et<sub>2</sub>PtCl<sub>6</sub> (dried at 100°). Tables.—B'<sub>2</sub>EtI. Needles (from alcohol) (Claus, *B.* 8, 41).

**Benzyl-chloride** (CSN<sub>2</sub>H<sub>4</sub>)C<sub>6</sub>H<sub>5</sub>Cl. [168°]. Formed from benzyl chloride and thio-urea. Yields unstable benzyl-thio-urea CSN<sub>2</sub>H<sub>4</sub>C<sub>6</sub>H<sub>5</sub> [72°], which decomposes at 100° into dicyandiamide and benzyl mercaptan (Bernthsen, A. Klinger, *B.* 12, 574).—(CSN<sub>2</sub>H<sub>4</sub>C<sub>6</sub>H<sub>5</sub>Cl)<sub>2</sub>PtCl<sub>4</sub>.

**Compound with oxalic ether** (CSN<sub>2</sub>H<sub>4</sub>)<sub>2</sub>Et<sub>2</sub>C<sub>2</sub>O<sub>4</sub>. [150°]. Monoclinic crystals (Nencki, *B.* 7, 780). Decomposed by hot water.

**Compounds with amines** (CSN<sub>2</sub>H<sub>4</sub>)<sub>2</sub>NMeI<sub>2</sub>Br. [138°]. Formed from methylamine hydrobromide and thio-urea in alcohol (Reynolds, *C. J.* 59, 392). Felted crystals.—(CSN<sub>2</sub>H<sub>4</sub>)<sub>2</sub>NEt<sub>2</sub>H<sub>2</sub>Br. [134°]. Formed by boiling thio-urea together with diethylamine hydro-bromide and absolute alcohol.—(CSN<sub>2</sub>H<sub>4</sub>)<sub>2</sub>NEt<sub>2</sub>HBr.—(CSN<sub>2</sub>H<sub>4</sub>)<sub>2</sub>NEtI [135°]. Prisms.—(CSN<sub>2</sub>H<sub>4</sub>)<sub>2</sub>NEt<sub>2</sub>Br [160°]. Rectangular prisms (Reynolds, *C. J.* 59, 388).

**Acetyl derivative** CSN<sub>2</sub>H<sub>4</sub>Ac. Mol. w. 118. [165°]. Formed by heating thio-urea with Ac<sub>2</sub>O (Nencki, *B.* 6, 598). Formed also from thio-acetic acid and cyanamide (Prätorius, *J. pr.* [2] 21, 147). Prisms (from hot water), v. sol. alcohol, m. sol. ether.—B'H<sub>2</sub>PtCl<sub>6</sub>. Crystalline.

**Propionyl derivative** (Freitag, *J. pr.* [2] 20, 381).

**Benzoyl derivative** CSN<sub>2</sub>H<sub>4</sub>Bz. [170°]. Formed by warming thio-urea (2 mols.) with BzCl (1 mol.) (Pike, *B.* 6, 755). Got also from benzoyl sulphocyanide and NH<sub>4</sub>Aq (Miguel, *B.* [2] 25, 252). Needles (from alcohol); sl. sol. cold water. Tastes bitter.

**o-Oxy-benzoyl derivative** NH<sub>4</sub>CS.NH.CO.C<sub>6</sub>H<sub>4</sub>.OH. [182°]. S. (boiling alcohol) 7. Formed from salicyl thiocarbimide and aqueous NH<sub>3</sub> (Miguel, *A. Ch.* [5] 11, 304).

**THIO-ψ-URIC ACID** v. THIO-URAMIDO-BARBITURIC ACID.

**THIO-VALERIC ALDEHYDE** C<sub>4</sub>H<sub>7</sub>S. (115°). Formed, together with C<sub>4</sub>H<sub>7</sub>S<sub>2</sub> [95°], by heating isovaleric aldehyde (23 pts.) with S (9 pts.) in sealed tubes at 250° for eight hours (Barbaglia, *G.* [1] 95; *B.* 17, 2654). Oil with penetrating odour like onions, sol. alcohol and ether. Does not combine with NaHSO<sub>3</sub>.

**Isomeride** C<sub>4</sub>H<sub>7</sub>S<sub>2</sub>. [69°]. V.D. (H=1) 50.76. Formed by passing H<sub>2</sub>S into a dilute aqueous solution of isovaleric aldehyde. Fibrous crystals (from ether), insol. water.

**THIOXENE** v. DI-METHYL-THIOPHENE.

**THIOXYLENOL** v. XYLIL MERCAPTAN.

**THIOXYL METHYL KETONE** v. DI-METHYL-TRIENYL METHYL KETONE.

**THORIUM** Th. (*Thorinum*.) At. w. 232. Mol. w. unknown. The m.p. of Th has not been determined; it is certainly very high (Nilson, *B.* 15, 2541). S.G. 11.1 at 17° (N., l.c., p. 2543). S.H. -02787 (N., *B.* 16, 161). Crystallises in regular octahedral and hexagonal forms, isomorphous with Si (Brögger, *Z.* K. 7, 442; cf. Nilson, *B.* 15, 2546; 16, 162 note). S.V.S. 20.9.

**Historical.**—In 1818 Berzelius announced the discovery of the oxide of a new element in a rare Norwegian mineral; to the metal of this oxide he gave the name thorium (from

the Scandinavian god *Thor*). A few years later Berzelius found that the substance he had supposed to be a new earth was really yttrium phosphate. In 1828, however, Berzelius isolated a new earth from another Norwegian mineral; he named the new earth *thoria*, and the mineral from which it had been prepared he called *thorite* (P. 16, 385). In 1851 Bergemann discovered a new metal and called it *donarium*; but this metal was shown to be identical with the thorium of Berzelius by Damour (C. R. 34, 685), Berlin (P. 87, 608), and Bergemann himself (P. 85, 558). In 1862 Bahr supposed he had found a new metal, which he called *wasium*, but soon afterwards he recognised that the metal was identical with thorium (P. 119, 572; 132, 227). The metal thorium was isolated by Berzelius in 1828 (P. 16, 385); it was also obtained by Chydenius in 1861 (Bl. [2] 1, 130); and in a state of greater purity by Nilson in 1882 (B. 15, 2537).

**Occurrence.**—Compounds of Th have been found only in very small quantities in a few localities. *Thorite* from Lövön in Norway contains c. 69 p.c. ThO<sub>2</sub> according to Berzelius; an orange-coloured variety of this mineral, *orangite*, was found by Bergemann to contain 74 p.c. ThO<sub>2</sub>; Nilson (B. 15, 2519) found from 50 to 59 p.c. ThO<sub>2</sub> in different specimens of *thorite*. Small quantities of ThO<sub>2</sub> have been found in specimens of *pyrochlore*, *monazite*, *samaraskite*, *cucenite*, *gadolinite*, and *orthite*. Several minerals containing Th have been discovered by Hidden a. Mackintosh in North Carolina and Colorado; one of these is a silicophosphate of Th, another a silicate of Th and Y, another a silicate of Th and U, and another is a uranate of Th, Pb, and Y (Am. S. [3] 36, 461; 38, 474).

**Formation.**—1. By reducing ThCl<sub>4</sub> or 2ThCl<sub>4</sub>.KCl, by heating with K (Berzelius, P. 16, 385).—2. By reducing fused ThCl<sub>4</sub> or 2ThCl<sub>4</sub>.KCl, by means of Na (Chydenius, Bl. [2] 1, 130; 6, 433; Nilson, B. 15, 2537).

**Preparation.**—Powdered *thorite* is evaporated with HClAq to dryness; the residue is heated to render silica insoluble, and treated with water; the solution is filtered and ppd. by H<sub>2</sub>S; the filtrate from PbS is ppd. by NH<sub>4</sub>Aq, and the pp. of crude ThO<sub>2</sub>.xH<sub>2</sub>O is thoroughly washed and dissolved in HClAq; Th(C<sub>2</sub>O<sub>4</sub>)<sub>2</sub> is ppd. from this solution by H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>Aq, and the pp., after being thoroughly washed with boiling water, is decomposed by heating; the crude ThO<sub>2</sub> thus obtained is converted into Th(SO<sub>4</sub>)<sub>2</sub> by treatment in a Pt basin with conc. H<sub>2</sub>SO<sub>4</sub> after being thoroughly moistened with water. The impure Th(SO<sub>4</sub>)<sub>2</sub> thus obtained is freed from acid and water by heating, and is dissolved in as little ice-cold water as possible (c. 5 parts are required), and the solution is heated to c. 20° when Th(SO<sub>4</sub>)<sub>2</sub>.9H<sub>2</sub>O ppts. The Th(SO<sub>4</sub>)<sub>2</sub>.9H<sub>2</sub>O is dehydrated by heating; the Th(SO<sub>4</sub>)<sub>2</sub> is dissolved in the minimum quantity of ice-cold water and the solution is heated to c. 20°; the crystals of Th(SO<sub>4</sub>)<sub>2</sub>.9H<sub>2</sub>O that separate are dehydrated, dissolved in ice-cold water, and the hydrated sulphate is ppd. by heating to 20°. This treatment is repeated a few times, when pure Th(SO<sub>4</sub>)<sub>2</sub>.9H<sub>2</sub>O is obtained. This method of purifying crude sulphate of Th, which is given by Nilson (B. 15, 2521), depends on the great differences between the solubilities in water of

Th(SO<sub>4</sub>)<sub>2</sub> and Th(SO<sub>4</sub>)<sub>2</sub>.9H<sub>2</sub>O; the former, when pure, is soluble in 20·6 parts water at 0°, the latter requires 88 parts water at 0°, and much more at 20°, for solution. The sulphates of the metals present in the crude Th(SO<sub>4</sub>)<sub>2</sub> prepared as described are much more soluble in water at 20° than Th(SO<sub>4</sub>)<sub>2</sub>.9H<sub>2</sub>O. For other methods of preparing salts of Th from *thorite* v. Berzelius (l.c.), Chydenius (l.c.), Delafontaine (Ar. Sc. [2] 18, 343), and Cleve (Bl. [2] 21, 115).

To prepare Th from pure Th(SO<sub>4</sub>)<sub>2</sub>, Nilson (B. 15, 2538) dissolved the salt in water, ppd. by KOHAq and boiled, washed the ThO<sub>2</sub>.xH<sub>2</sub>O thoroughly, dissolved in HClAq and reppd. by KOHAq (to remove all traces of H<sub>2</sub>SO<sub>4</sub>); he thoroughly washed the pp. by decantation, dissolved it in HClAq, added KCl, in the ratio 2ThCl<sub>4</sub>:KCl, evaporated to dryness in a Pt basin, and dried the residue by warming over a flame, stirring constantly, and then powdering and heating again. The dry double salt of ThCl<sub>4</sub> and KCl was heated to redness in a stream of dry HCl (prepared from conc. H<sub>2</sub>SO<sub>4</sub> and sublimed NII<sub>2</sub>Cl), HCl was removed by a stream of H, and some of the salt was transferred to a cylinder of wrought iron (fitted with a lid which screwed on), in which a layer of dry NaCl had been placed; pieces of sodium were arranged over the Th-K salt in the cylinder, on these was placed another layer of the Th-K salt, and the cylinder was thus nearly filled with alternate layers of Na and the double salt; the contents of the cylinder were pressed together by a piston which fitted into the cylinder, sufficient dry NaCl was added to fill the cylinder, the lid was screwed on, and the apparatus was heated to full redness for about fifteen minutes; after cooling, the contents of the apparatus were treated with cold water, whereby chlorides were dissolved and the excess of sodium was converted into NaOH and dissolved (the action is apt to be explosive); the thorium was washed with water, then with alcohol, and finally with ether, and dried at 100°.

The yield of thorium by this method is almost equal to that calculated from the equation. For a detailed description of the iron cylinder used for reduction v. Nilson a. Pettersson, W. 4, 554 (on the preparation of Be).

**Properties.**—Prepared as described, Th forms a greyish-white, glistening powder; the powder consists of small, thin, six-sided, crystalline leaflets; the larger crystals are as white and lustrous as silver, the smaller are grey and less lustrous. The crystals are somewhat brittle. S.G. at 17° 11·1 to 11·23; the latter number referring to the well-crystallised metal (Nilson, B. 15, 2543; 16, 160). S.H. (0° to 100°) -0·2787, hence at heat = 6·4 (N., B. 16, 161). Crystallises in combinations of regular octahedra and hexahedra; isomorphous with Si (N., l.c., and note, p. 162). S.V.S. 20·9. The emission-spectrum of Th has been mapped by Thalén (*Détermin. des Longueurs d'Onde des Raies Métalliques* [Upsala, 1868]); the most marked lines are three in the indigo; 4393, 4382, and 4281. Soret (Ar. Sc. [2] 68, 69; [3] 4, 94) found that ThCl<sub>4</sub>Aq cuts off almost the whole of the ultra-violet part of the spectrum.

Th is unchanged in air up to 100°-120°; when heated to a higher temperature it burns to ThO<sub>2</sub> with production of much white light. Th

is readily oxidised by heating in O; on this account some of the metal is oxidised in the process of preparation if the lid of the cylinder does not fit tightly. Nilson's experiments (*B.* 15, 2541) show that Th does not melt at the full heat of a wind-furnace. Th does not react with water; it combines directly with Cl, Br, I and S. The metal is slowly acted on by  $\text{H}_2\text{SO}_4$  or  $\text{HNO}_3$ , rapidly by  $\text{HClAq}$  or *aqua regia*; alkali solutions do not seem to react.

The at. w. of Th has been determined: (1) by analysing  $\text{Th}(\text{SO}_4)_2$  and hydrates of this salt (Berzelius, *P.* 16, 898 [1829]; Ohnidenius, *P.* 119, 43 [1861]; Delafontaine, *Ar. Sc.* 18, 343 [1863]; Hermann, *J. pr.* 93, 114 [1864]; Cleve, *Bl.* [2] 21, 116 [1874]; Nilson, *B.* 15, 2527 [1882]; Krüss a. Nilson, *B.* 20, 1665 [1887]); (2) by analyses of the double Th-K sulphate (Berzelius, *l.c.*); (3) by analyses of the acetate, oxalate, and formate of Th (Ohnidenius, *l.c.*); (4) by determining S.H. of Th (Nilson, *B.* 16, 153 [1883]); (5) by finding V.D. of  $\text{ThCl}_4$  (Krüss a. Nilson, *B.* 20, 1665 [1887]). The mol. w. of Th is not known.

Th is distinctly metallic in its chemical relations; the only oxide that has been isolated with certainty,  $\text{ThO}_2$ , is basic, forming salts  $\text{ThX}_2$  ( $\text{X} = \text{SO}_4, 2\text{NO}_3$ , &c.). There are indications of the existence of a higher oxide ( $\text{Th}_2\text{O}_3$ ). Thorium forms the last member of the even-series family of Group IV. in the periodic classification of the elements. The members of this family are C, Ti, Zr, Ce, —, Th. The four elements Ti, Zr, Ce, and Th closely resemble one another in their chemical properties; they are also similar to the odd-series family of Group IV., namely, Si, Ge, Sn, —, Pb. For a general account of Group IV. (and more especially of C and Si) v. CARBON GROUP OF ELEMENTS (vol. i. p. 682); for a description of the even-series family (Ti, Zr, Ce, Th) v. TITANIUM GROUP OF ELEMENTS (this vol. p. 749); and for the odd-series family (Ge, Sn, Pb; Si being described in vol. i. p. 652) v. TIN GROUP OF ELEMENTS (this vol. p. 735).

The atom of thorium is tetravalent in the gaseous molecule  $\text{ThCl}_4$ .

**Reactions and Combinations** (Nilson, *B.* 15, 2541).—1. Heated in air, oxidation begins at c.  $120^\circ$ , and at much below red heat the metal burns brilliantly to  $\text{ThO}_2$ .—2. Heated in a stream of oxygen, the metal burns to  $\text{ThO}_2$ , with the production of dazzling white light.—3. Th burns to  $\text{ThX}$ , when heated in chlorine, in bromine vapour, or in vapour of iodine.—4. When heated with sulphur part of the S volatilises, and when the temperature is above the b.p. of S combination occurs with production of much light,  $\text{ThS}$ , being formed.—5. According to Troost (*C. R.* 116, 1227). Th combines with carbon, when  $\text{ThO}_2$  is mixed with C and heated in  $\text{CO}_2$  in the electric arc (v. Carbide, *infra*).—6. Water does not react with Th at any temperature, so far as experiments have been tried. Nilson (*l.c.*) gives no details, but says 'Thorium is not changed by water under any conditions'.—7. Sulphuric acid reacts slowly with Th; when dilute, the acid evolves  $\text{H}_2$ ; when conc. and hot,  $\text{SO}_2$  is given off.—8. The action of nitric acid is slight; the dilute warm acid acts very gradually; conc. acid is almost without action.—9. Hydrochloric acid rapidly dissolves Th, forming  $\text{ThCl}_4$ , and giving off  $\text{H}_2$ ; the action

is most complete with conc. acid.—10. *Aqua regia* dissolves Th easily.—11. Alkaline solutions seem not to react with Th.

**Detection and Estimation.**—Salts of Th are colourless when the acid is colourless. Alkalis, and also  $(\text{NH}_4)_2\text{SAq}$ , ppt. gelatinous, white  $\text{ThO}_2 \cdot 2\text{H}_2\text{O}$ , insoluble in excess of the precipitant; alkali carbonates form a white pp. soluble in excess; solution in  $(\text{NH}_4)_2\text{CO}_3\text{Aq}$  becomes turbid at  $60^\circ$ , but goes clear on cooling; saturation of a solution of a salt of Th with  $\text{K}_2\text{SO}_4$  forms white  $\text{Th}(\text{SO}_4)_2 \cdot \text{K}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$ , insoluble in  $\text{K}_2\text{SO}_4\text{Aq}$ , but soluble in water;  $\text{KFeCl}_4\text{Aq}$  ppt. white  $\text{ThFeCl}_4$ ; oxalic acid and alkali oxalates ppt. white amorphous  $\text{Th}(\text{C}_2\text{O}_4)_2$ , insoluble in dilute acids, soluble in solutions of alkali oxalates or  $\text{NH}_4\text{C}_2\text{H}_3\text{O}_2$ , especially on warming.

Th is generally estimated by ppn. as  $\text{ThO}_2 \cdot 2\text{H}_2\text{O}$  or  $\text{Th}(\text{C}_2\text{O}_4)_2$ , and subsequent conversion into  $\text{ThO}_2$  by heating.

Thorium, bromide of. The gummy, white mass obtained by Berzelius (*P.* 16, 385), by evaporating a solution of  $\text{ThO}_2 \cdot 2\text{H}_2\text{O}$  in  $\text{HBrAq}$ , was probably  $\text{ThBr}_4$ . The hydrated salt  $\text{ThBr}_4 \cdot 10\text{aq}$  seems to have been obtained, from  $\text{ThO}_2 \cdot 2\text{aq}$ , by Jannasch, Locke, a. Lesinsky (*Zeit. f. anorg. Chemie*, 5, 283).

Thorium, carbide of. By heating an intimate mixture of  $\text{ThO}_2$  and C in the electric arc, in an atmosphere of  $\text{CO}_2$ , Troost (*C. R.* 116, 1227) obtained a hard, brittle solid, containing from 8.2 to 9.5 p.c. C, and therefore approximating to the formula  $\text{ThC}_2$  (which requires 9.38 p.c. O). S.G. 10.15 at  $15^\circ$ ; scratches glass slightly; decomposes cold water, giving off  $\text{H}_2$  and strongly smelling hydrocarbons; gradually decomposes in moist air; burns rapidly and brilliantly when heated to redness.

Thorium, chloride of,  $\text{ThCl}_4$ . Mol. w. 378.5. V.D. 172.2 at  $1050^\circ$ – $1270^\circ$  (Krüss a. Nilson, *B.* 20, 1671). This compound is formed by heating a mixture of  $\text{ThO}_2$  and C in a stream of dry Cl; the  $\text{ThCl}_4$  sublimes in white needles. Krüss a. Nilson (*B.* 20, 1675) prepared pure  $\text{ThCl}_4$  by heating Th to incipient redness in a stream of dry, air-free  $\text{HCl}$ ; then raising the temperature to full redness, in order to sublime a little  $\text{FeCl}_3$ , formed from the iron in the thorium used; and finally subliming the  $\text{ThCl}_4$  at an incipient white heat. (For details of the apparatus used v. Nilson a. Pettersson, *J. pr.* [2] 33, 1 [on preparation of  $\text{BeCl}_2$ ]).

$\text{ThCl}_4$  crystallises in lustrous, white needles; moderately hygroscopic, but remains some hours in the air before deliquescing (K. a. N., *l.c.*). Does not volatilise at c.  $420^\circ$  (Ohnidenius, *P.* 119, 43). The V.D. found by K. a. N. at temperatures from  $1050^\circ$  to  $1270^\circ$  shows that the formula  $\text{ThCl}_4$  is molecular. K. a. N. got the value 142 for V.D. at  $1400^\circ$ , showing that dissociation had begun. Troost (*C. R.* 101, 860) obtained values for V.D. of  $\text{ThCl}_4$  at c.  $950^\circ$  considerably lower than those of K. a. N. It is likely that his specimen was not pure, or that the apparatus used contained traces of O sufficient to cause decomposition to  $\text{ThO}_2$  and Cl (K. a. N., *l.c.*, p. 1674).

Hydrated thorium chloride  $\text{ThCl}_4 \cdot 8\text{H}_2\text{O}$  was obtained by Cleve in thin, white prisms, by concentrating a solution of  $\text{ThO}_2 \cdot 2\text{H}_2\text{O}$  in  $\text{HClAq}$ .

allowing to crystallise, and drying over  $H_2SO_4$  (*Bl.* [2] 21, 116).

**Double salts.**— $ThCl_4$  combines with *potassium chloride* to form  $2ThCl_4 \cdot KCl \cdot 18H_2O$ ; obtained by mixing very conc. solutions of the constituents. Forms small, white crystals; v. sol. water, also sol. alcohol; dehydrated by heating in  $HCl$  (Cleve, *Bl.* [2] 21, 116). By heating a dry mixture of  $ThCl_4$  and  $NH_4Cl$  in  $HCl$ , Chydenius (*Bl.* [2] 1, 130; 6, 433) obtained a compound with *ammonium chloride*, which, when crystallised from water *in vacuo*, had the composition  $ThCl_4 \cdot 8NH_4Cl \cdot 8H_2O$ ; loses  $6H_2O$  at  $100^\circ$ . Cleve (*l.c.*) prepared a compound with *platinic chloride*  $ThCl_4 \cdot PtCl_4 \cdot 12H_2O$ ; and Nilson (*l.c.*) a compound with *platinous chloride*  $2ThCl_4 \cdot 3PtCl_4 \cdot 24H_2O$ .

**Thorium, ferrocyanide of.**  $ThFeCy_4 \cdot 4H_2O$ . A white powder; prepared by adding  $K_4FeCy_6$  aq. to solution of a salt of  $Th$  (Cleve, *Bl.* [2] 21, 116).

**Thorium, fluoride of.**  $ThF_4 \cdot 4H_2O$ . Obtained by adding  $HFAq$  to  $ThCl_4$  aq.; the gelatinous pp. becomes powdery after a time (Chydenius, *Bl.* [2] 1, 130; 6, 433). Loses  $H_2O$  at  $100^\circ$ , and  $2H_2O$  at  $140^\circ$ – $200^\circ$ ; heated to redness gives  $ThO_2$  and  $HF$ . Berzelius (*P.* 16, 385) obtained a heavy white powder by heating  $ThO_2 \cdot 2H_2O$  with  $HFAq$ . Combines with *potassium fluoride*; Chydenius (*l.c.*) obtained two salts, (1)  $ThF_4 \cdot KF$  by mixing  $ThCl_4$  aq. with  $KHF_4$  aq., (2)  $ThF_4 \cdot 2KF \cdot 4H_2O$  by boiling  $ThO_2 \cdot 2H_2O$  with conc.  $KHF_4$  aq. and  $HFAq$ . The isolation of a third salt,  $7ThF_4 \cdot 8KF \cdot 6H_2O$ , is doubtful.

**Thorium, hydride of.** By heating  $ThO_2$  with excess of  $Mg$  powder, in a stream of  $H$ , Winkler (*B.* 24, 885) obtained a grey powder, which gave off  $H$  with dilute  $HCl$  aq. and burnt when heated in  $O$ . Analyses of this powder gave 72.86 p.c.  $Th$ , .50 p.c.  $H$ , 17.57 p.c.  $Mg$ , and 9.07 p.c.  $O$ . Supposing the  $ThO_2$ ,  $Mg$ , and  $H$  interacted in accordance with the equation  $ThO_2 + 2Mg + 2H = ThH_2 + 2MgO$ , then, from the quantities of  $ThO_2$  and  $Mg$  used, the product would give on analysis 73.77 p.c.  $Th$ , .63 p.c.  $H$ , 15.45 p.c.  $Mg$ , and 10.15 p.c.  $O$ . From these data Winkler concluded that a hydride,  $ThH_2$ , was formed in the reaction.

**Thorium, hydroxides of, v. OXIDES AND HYDRATED OXIDES (*infra*).**

**Thorium, iodide of.** The white gummy mass, crystallising after a time, obtained by Chydenius (*Bl.* [2] 1, 130; 6, 433) by evaporating a solution of  $ThO_2 \cdot 2H_2O$  in  $HIAq$ , was probably  $ThI_4$ . The substance goes brown in the light.

**Thorium, nitride of.** By heating  $ThO_2$  or  $ThCl_4$  in  $NH_3$ , also by heating  $ThCl_4$  and  $NH_4Cl$  in  $HCl$ , Chydenius (*l.c.*) obtained a small quantity of what he supposed to be either a nitride of  $Th$  or a compound of the metal with  $N$  and  $H$ .

**Thorium, oxides and hydrated oxides of.** Besides the oxide  $ThO_2$ , a peroxide, probably  $Th_2O_4$ , is said to exist.

**THORIUM DIOXIDE  $ThO_2$ .** (*Thoria*.) Mol. w. not known. Obtained by ppg. a salt of  $Th$  by alkali,  $(NH_4)_2SAq$ , or  $KCNAq$ , drying, and strongly heating; also by decomposing  $Th(C_2O_4)_2$  by heat. A fine, white powder. S.G. 10.22 at  $17^\circ$  (Nilson, *B.* 15, 2536). S.V.S. 25.87. S.H. (40 to  $100^\circ$ ) .0548 (N. a. Pettersson, *B.* 12, 1459).

By heating  $ThO_2$  with borax in a porcelain oven, Nordenskjöld obtained the oxide in microscopic crystals isomorphous with  $SnO_2$  and  $ZrO_2$  (*P.* 150, 219).  $ThO_2$  has not been fused; it is not reduced by heating with  $C$ , but when mixed with  $C$  and heated in  $Cl$  the chloride  $ThCl_4$  is obtained.  $ThO_2$  does not react with molten alkalis. It is scarcely acted on by acids; warm conc.  $H_2SO_4$ , however, converts it into  $Th(SO_4)_2$ .

**HYDRATES OF THORIUM DIOXIDE.** The *dihydrate*  $ThO_2 \cdot 2H_2O$  ( $\frac{1}{2} ThO_2 \cdot H_2O$ , *thorium hydroxide*) is obtained by ppg. a solution of a salt of  $Th$  by an alkali,  $(NH_4)_2SAq$ , or  $KCNAq$ , washing, and drying at  $100^\circ$ . It forms a hard, white solid.  $ThO_2 \cdot 2H_2O$  combines with  $CO_2$  in the air; it dissolves in acids, forming salts  $ThX_4$ , where  $X = SO_4, 2NO_3$ , &c. Another hydrate,  $4ThO_2 \cdot H_2O$  ( $= Th_4O_{10}(OH)_2$ , *thorium metahydroxide*) is obtained, according to Cleve (*Bl.* [2] 21, 116), by heating  $ThO_2$  (obtained by decomposition of  $Th(C_2O_4)_2$ ) with excess of  $HNO_3$  aq. or  $HCl$  aq. at  $100^\circ$  till the acid is driven off, adding water, and then ppg. the opalescent solution so obtained by  $NH_4$  aq., washing, and drying at  $100^\circ$ . This hydrate is said to be insoluble in dilute acids.

**THORIUM PEROXIDE  $Th_2O_4$ .** An oxide with this composition is said to be produced by adding  $H_2O_2$  aq. and  $NH_4$  aq. to a solution of a salt of  $Th$  (Cleve, *Bl.* [2] 43, 53; Lecoq de Boisbaudran, *C. R.* 100, 605).

**Thorium, oxysulphide of.** By strongly heating  $ThO_2$ , obtained from  $ThO_2 \cdot 2H_2O$ , in  $CS_2$  vapour, Chydenius (*Bl.* [2] 1, 130; 6, 433) obtained a solid substance to which he gave the formula  $2ThO_2 \cdot ThS_2 = Th_3O_5S_2$ . According to Krüss a. Volk (*Zeit. f. anorg. Chemie*, 5, 75; 6, 40), the compound obtained by heating  $ThO_2$  in  $CS_2$  is  $ThOS$ , and the same compound is formed by heating  $2ThCl_4 \cdot KCl$  in  $HS_2$ .

**Thorium, phosphide of.** By heating  $Th$  in vapour of  $P$ , Berzelius (*P.* 16, 385) obtained a dark grey, metal-like, lustrous solid, which was changed to  $Th$  phosphate by heating in air.

**Thorium, platino-cyanide of.**  $Th(PtCy_6)_2 \cdot 16H_2O$ . Yellow-green, orthorhombic prisms (Cleve, *Bl.* [2] 21, 116).

**Thorium, salts of.** All the normal compounds which have been isolated by replacing  $H$  of acids by  $Th$  belong to the class  $ThX_4$ , where  $X = 2NO_3, 2IO_3, SO_4, \frac{1}{2}P_2O_5$ , &c.; basic salts also exist. The chief salts of oxyacids are *borate*, *carbonate*, *chlorate*, *chromate*, *iodate* and *periodate*, *molybdate*, *nitrate*, *oxalate*, *phosphates*, *selenate* and *selenites*, *silicates*, *sulphate* and *sulphite*, and *tartrate*.

**Thorium, silicofluoride of.** By treating  $ThO_2 \cdot 2H_2O$  with  $H_2SiF_6$  aq., Cleve (*Bl.* [2] 21, 116) obtained a semi-transparent, crystalline solid, probably  $Th(SiF_6)_2$ ; insol. in excess of  $H_2SiF_6$ ; over  $H_2SO_4$  gave off  $HF$  and  $SiF_4$ .

**Thorium, sulphide of.**  $ThS_2$ . Obtained by heating  $Th$  with  $S$ ; excess of  $S$  sublimes, and when the temperature passes the b.p. of  $S$  the elements combine with evolution of heat and light (Nilson, *B.* 15, 2542; cf. Berzelius, *P.* 16, 385). Also formed by heating  $ThO_2$  obtained from  $Th(C_2O_4)_2$  to white heat in vapour of  $CS_2$  (Chydenius, *Bl.* [2] 1, 130; 6, 433); but, according to Krüss a. Volk (*l.c.*), the compound thus formed is  $ThOS$ . A black powder. Burns when heated in air, giving off  $SO_2$  and leaving

**ThO<sub>2</sub>.** Not acted on by HClAq or HNO<sub>3</sub>Aq; *aqua regia* dissolves the compound, forming Th(SO<sub>4</sub>)<sub>2</sub>. Molten KOH forms K<sub>2</sub>S and ThO<sub>2</sub>; heating in Cl<sub>2</sub> produces ThCl<sub>4</sub>.

**Thorium, sulphocyanide of.** The salt [Th(SCy)<sub>3</sub>] is obtained, as a viscous mass, by evaporating a solution of ThO<sub>2</sub>·2H<sub>2</sub>O in HSCNAq. A solution of the compound gives a pp. with HgCy<sub>2</sub>, said to be Th(OH)<sub>3</sub>SCy·HgCy<sub>2</sub>·H<sub>2</sub>O; and the filtrate is said to give crystals of Th(OH)(SCy)<sub>3</sub>·3HgCy<sub>2</sub>·12H<sub>2</sub>O (Cleve, *Bl.* [2] 21, 116). M. M. P. M.

**THUJIGENIN** C<sub>11</sub>H<sub>12</sub>O<sub>10</sub> or C<sub>22</sub>H<sub>24</sub>O<sub>10</sub>. Occurs in small quantity in *Fronde Thujæ*, the green parts of *Thuja occidentalis* (Rochleder a. Kawalier, *Sitz.* W. 29, 10). Minute needles, v. sl. sol. water, sol. alcohol. NH<sub>3</sub> colours its alcoholic solution green. AcCl forms resinous C<sub>11</sub>H<sub>11</sub>AcO<sub>2</sub>.

**THUJIN** C<sub>22</sub>H<sub>24</sub>O<sub>12</sub>. Occurs in the green branches of *Thuja occidentalis* (Rochleder a. Kawalier, *Sitz.* W. 29, 10). Minute lemon-yellow four-sided tables, sol. alcohol. Tastes bitter. Its alcoholic solution is coloured yellow by alkalis, is turned reddish-brown by air, gives a yellow pp. with lead acetate, and gives a dark-green colour with FeCl<sub>3</sub>. Reduces ammoniacal AgNO<sub>3</sub>. Boiling dilute H<sub>2</sub>SO<sub>4</sub> turns it first green, then yellow, and splits it up into sugar and thujetin. Boiling baryta-water hydrolyses it in like manner.

**Thujetin** C<sub>22</sub>H<sub>24</sub>O<sub>10</sub>. Yellow solid, nearly insol. water, sol. alcohol and ether. Not altered by dilute HCl or H<sub>2</sub>SO<sub>4</sub>. Its alcoholic solution is turned a splendid bluish-green colour by NH<sub>3</sub>Aq. Gives, in alcoholic solution, a red pp. with lead acetate, and a black colour with FeCl<sub>3</sub>. Boiling baryta-water converts it into thujetic acid C<sub>22</sub>H<sub>22</sub>O<sub>12</sub>, which crystallises in minute lemon-yellow needles, sol. alcohol and ppd. by water.

\*(*S*)-**THUJOL** is **TANACETONE**.

**THUJONE** C<sub>10</sub>H<sub>16</sub>O. (212°). S.G. 22·9265. Occurs, together with the terpene C<sub>10</sub>H<sub>16</sub>, and levorotatory fenchone, in the essential oil of thuja obtained by distilling the ends of the branches and the leaves of *Thuja occidentalis* with water (Schweizer, *A.* 61, 398; Jahns, *Ar. Ph.* 221, 748; Wallach, *A.* 272, 109). Yields an oxim.

**Reactions.**—1. When heated with ammonium formate it yields a formyl derivative which on saponification gives rise to 'thujoneamine' C<sub>10</sub>H<sub>17</sub>NH<sub>2</sub> (199°), which forms the salts B'H<sub>2</sub>PtCl<sub>4</sub> and B'HCl. Thujone-amine hydrochloride decomposes on distillation into NH<sub>3</sub>Cl and thujene C<sub>10</sub>H<sub>16</sub> (c. 173°), S.G. 22·84. —2. KMnO<sub>4</sub> forms two 'thujaketonic acids.' —3. Br forms C<sub>10</sub>H<sub>14</sub>Br<sub>2</sub>O [122°] (Wallach, *A.* 275, 179).

(a)-**Thujaketonic acid** C<sub>10</sub>H<sub>14</sub>O<sub>2</sub>, i.e. CH<sub>3</sub>·CO·C<sub>6</sub>H<sub>11</sub>·CO<sub>2</sub>H. [76°]. S. c. 2·5 at 100°. Transparent plates. Yields an oxim [c. 186°].

(*S*)-**Thujaketonic acid** C<sub>10</sub>H<sub>14</sub>(CO·CH<sub>3</sub>)·CO<sub>2</sub>H. [79°]. S. 1·43 at 100°. Small matted needles. On distillation it yields methyl heptyl ketone (186°) S.G. 22·854, which gives  $\psi$ -cumene dihydride C<sub>6</sub>H<sub>10</sub>, on heating with ZnCl<sub>2</sub> at 100° (Wallach, *A.* 275, 166). Forms an oxim [106°] which crystallises in needles.—AgA': v. sl. sol. cold water.

**THULIUM.** This name was given by Cleve in 1879 to the metal of a new earth which he announced to be present in specimens of *gadolinite* (C. R. 89, 478). The name thulium was derived from *Thule*, the old name for Scandinavia. The presence of the new earth was more or less confirmed by the work of Nilson (*B.* 13, 1433), and of Soret (C. R. 89, 251). In 1880 Cleve said he had isolated *thulia*, and described it as a white earth, giving an emission spectrum characterised by two bright lines 5896 and 5306, and forming solutions of salts which showed two absorption bands 6840 and 4645. To this earth Cleve assigned the formula Tm<sub>2</sub>O<sub>3</sub>, and he determined the maximum value of the atomic weight of the supposed element to be Tm = 170·7. In 1888 Krüss a. Nilson declared that thulium consists of two distinct elements (B. 21, 1681).

The absolute homogeneity of thulia has been by no means established (v. METALS, RARE, vol. iii. p. 245). M. M. P. M.

**THYME OIL.** The essential oil from garden thyme, *Thymus vulgaris*, contains levorotatory thymene C<sub>10</sub>H<sub>16</sub> (160°–165°), thymol C<sub>10</sub>H<sub>14</sub>O and a little cymene (Lallemand, *A.* 102, 119; *A. Ch.* [3] 49, 155). The oil from wild thyme, *Thymus serpyllum*, contains cymene, thymol, carvacrol, and a phenol coloured violet by FeCl<sub>3</sub> (Jahns, *Ar. Ph.* [3] 16, 277; Febre, *C. R.* 92, 1290; Buri, *Ar. Ph.* [3] 12, 485).

**THYMO-ACRYLIC ACID** v. OXY-CYMYL-ACRYLIC ACID.

**THYMOHYDROQUINONE** v. HYDROTHYMOQUINONE.

**THYMOL** C<sub>10</sub>H<sub>14</sub>O i.e. C<sub>6</sub>H<sub>4</sub>MePr.OH [5:2:1]. Mol. w. 150. V.D. 75·3 (calc. 75) (Eykmann, *B.* 22, 2757). [49·5°] (Reissert, *B.* 23, 2242). (232°). S.G. 9·9941. O.E. (0°–10°)·00085. S. 3. S.V. 188·9 (Pinetta, *A.* 243, 46); 189·3 (Ramsay).  $R_D = 76·66$  (Nasini a. Bernheimer, *G.* 16, 93). H.F.p. (liquid) 69,250; (solid)–8768. Occurs in essential oil of thyme (Doveri, *A.* 64, 374; Lallemand, *A. Ch.* [3] 49, 148; *A.* 102, 119), of horsemint, *Monarda punctata* (Arppe, *A.* 58, 42), of *Ptychotis ajowan* (Stenhouse a. Haines, *A.* 98, 307; H. Müller, *B.* 2, 130) of *Monarda Didyma*, of *Anni Copticum* (Buri, *Ar. Ph.* [3] 12, 485), and in the oil from wild thyme (Jahns, *B.* 15, 819).

**Formation.**—By boiling diazo-*n*-cymene with water (Widmar, *B.* 15, 170; 19, 245).

**Preparation.**—By extracting oil of thyme with NaOHaq. ppg. by HCl, and recrystallising from HOAc.

**Properties.**—Plates (from alcohol), v. sol. alcohol, ether, and HOAc, v. sl. sol. water. Has a slight odour of thyme and a peppery taste. When solid it is slightly heavier than water, when liquid it is lighter. Not ppd. by adding water to its alcoholic solution. Not dissolved by NH<sub>3</sub>Aq, but absorbs NH<sub>3</sub>, becoming liquid, but re-solidifying after the NH<sub>3</sub> has escaped. Sol. KOHAq. FeCl<sub>3</sub> does not colour its aqueous solution. Bromine-water only gives a milkiness. An aqueous solution (1 vol.) warmed first with HOAc ( $\frac{1}{2}$  vol.) and then with H<sub>2</sub>SO<sub>4</sub> (1 vol.) is coloured reddish-violet, the solution showing two absorption bands at E and D (Wolff, *Fr.* 22, 96). KOHAq followed by I in KI gives on warming a fugitive red tint (Itallie, *Fr.* 29, 205).

**Estimation:** Messinger, *B.* 23, 2754.

**Reactions.**—1. Decomposed by distilling with  $P_2O_5$  into propylene and *m*-cresol.—2.  $P_2S_5$  yields cymene (Fittica, B. 6, 938; A. 172, 805).  
3. Oxidised by chromic acid to thymoquinone.—4.  $POCl_3$  yields chloro-cymene.—5. *Potash-fusion* yields several oxy-acids (Barth, B. 11, 567, 1571).—6. *Iodine* and *potash* yield a red amorphous pp. [110°] converted by heat or by boiling water into a yellow body [165°] (Messinger a. Vortmann, B. 22, 2316).—7. Boiling  $POCl_3$  (1 mol.) acting on thymol (1 mol.) forms liquid  $C_{10}H_{12}O.POCl_2$  (280°–285°) which is converted by water into liquid  $C_{10}H_{12}O.PO(OH)_2$ , which yields  $BaA''$  4aq and is decomposed by heat into thymol and  $HPO_3$  (Discaizo, G. 15, 279).—8. Boiling  $POCl_3$  acting on thymol (2 mols.) forms  $(C_{10}H_{12}O)_2POCl$  (330°–340° at 320 mm.), a liquid which is converted by water into  $(C_{10}H_{12}O)_2PO.OH$ , which is insol. water and yields  $NaA'$  [74°] (Kreysler, B. 18, 1705) and  $BaA'$  5aq. S. 197 at 21°.—9.  $PCl_5$  (1 mol.) acting on thymol (4 mols.) forms  $(C_{10}H_{12}O)_4PO$  [59°] crystallising from alcohol in prisms (K. a. L.).—10.  $SiCl_4$  forms  $Si(OC_{10}H_{11})_4$  (48°) (450°) crystallising from  $CHCl_3$  in prisms (Hertkorn, B. 18, 1693).—11.  $Cl.CO.NH_2$  reacts forming  $C_6H_5MePr.CO.CO.NH.CO.NH$ . [190°] (Gattermann, A. 244, 44).—12.  $C_6H_5(NMe_2)(NH_2)$  [1:4] forms indothymol  $C_6H_5(NMe_2)_2N < \underset{O}{C}$  [69°] crystallising in needles, insol. water and alkalis, forming a blue solution in alcohol, a violet in ether, and a green in  $HIOAc$ .  $HClAc$  decomposes indothymol into thymoquinone, dimethyl-aniline, and  $NH_3$  (Bayraz, Bl. [3] 7, 97).  
13. *Chloral* forms  $C_{10}H_{12}OC.HClO$  [130°–134°] (Mazzara, G. 13, 272).—14. *Chloral*, conc.  $H_2SO_4$ , and  $HOAc$  yield  $CCl_3.CHI(C_6H_{11}.OH)_2$  (Jäger, B. 7, 1197).—15. Dilute  $H_2SO_4$  gradually added to a mixture of benzoic aldehyde (1 mol.) and thymol (2 mols.) forms  $C_6H_5.CHI(C_6H_{11}.OH)_2$  [146°] which is sol. alkalis and yields a diacetyl derivative [126°] (Lussanoff, B. 22, 1943).—16.  $COCl_2$  passed into an aqueous solution of  $C_{10}H_{12}ONa$  forms di-thymyl carbonate  $(C_{10}H_{12}O)_2CO$  which crystallises from alcohol in needles [48°] (above 360°) and yields *o*-oxybenzoic acid when heated with  $NaOPh$  at 180° (Richter, J. pr. [2] 27, 505). According to Bender (B. 19, 2268), di-thymyl carbonate, prepared by heating thymyl ethyl carbonate at 800°, melts at 60°.  $COCl_2$  also forms, as a by-product,  $C_{10}H_{12}O.COCl$ , which is converted by ammonia into  $C_{10}H_{12}O.CO.NH_2$  [181°].—17.  $Cl.CO_2Et$  acting in the cold upon  $C_{10}H_{12}ONa$  forms  $C_{10}H_{12}O.CO.OEt$  (c. 261°), an oil which yields *o*-oxybenzoic acid,  $PhOEt$ , and thymol when heated with  $NaOPh$  (Richter).—18. Treatment with  $ClCH_2.CO.H$  and  $NaOHaq$  produces  $C_{10}H_{12}O.CH_2.CO.H$  [148°] which yields  $BaA'$ , 2aq.  $PhA'$ ,  $AgA'$ , oily  $EtA'$  (290°), and an amide [97°] (Saarbach, J. pr. [3] 21, 159; Spica, G. 10, 342).  
19. *o*-Chloropropionic acid and  $KOHaq$  yield  $C_{10}H_{12}O.CHMe.CO_2H$  [48°] (Seighilone, G. 12, 50).—20. Thymol (10 g.) mixed with  $H_2SO_4$  (70 g.) containing nitrous acid gives thymol-chroin  $C_{10}H_{12}N_2O_4$ , a dark-violet amorphous body which dissolves in alcohol, ether,  $CHCl_3$ , and benzene, forming red solutions with pale-green fluorescence. Alkalis turn its alcoholic solutions blue. Sublimes at 140°, giving off violet vapours.

Yields brown amorphous  $C_{10}H_{12}As_2N_2O_4$  (Brunner a. Chuit, B. 21, 252; cf. Liebermann, B. 7, 1100).—21. By heating with ammonium-zinc chloride it is converted into thymylamine  $C_{10}H_{12}NH_2$  and di-thymylamine  $(C_{10}H_{12})_2NH$ .—22. *Cyanuric chloride* converts sodium thymol into  $(C_{10}H_{12})_2C_3N_3O_4$  [151°] a yellow crystalline powder, insol. water, sl. sol. alcohol (Otto, B. 20, 2239).—23. Aqueous  $KOH$  and  $K_2S_2O_8$  form  $C_{10}H_{12}O.SO_3.OK$ , which crystallises from alcohol in slender silky threads (Heymann a. Königs, B. 19, 3307). It is oxidised by alkaline  $KMnO_4$  to oxyeumic acid  $C_6H_5Pr(OH).CO_2H$  [4:3:1].  
**Salts.**— $C_{10}H_{12}ONa$ . Crystalline. Its aqueous solution is ppd. by  $HgCl_2$  and  $AgNO_3$ .— $C_{10}H_{12}O.Hg.HgNO_2$ .— $C_{10}H_{12}O.Hg.HgOAc$  (Merck, G. P. 48539; Pharm. Zeit. 1889, 625).— $(C_{10}H_{12}O)_2.Hg.O$  (Lallemand).— $(C_{10}H_{12}O)_2Al$ . Decomposed by heat into propylene and  $(C_6H_5Me.O)_2Al$ , the *m*-cresylate then splitting up into alumina, *m*-cresol, di-*m*-tolyl oxide, and a body  $C_{10}H_{12}O$  [200°] S. (alcohol) 17 at 20°; 1 at 78°; S. (benzene) 93 at 21°; S.G. 805; V.D. 208.8, crystallising in pearly plates (Gladstone a. Tribe, C. J. 39, 9; 41, 11).

**Acetyl derivative**  $C_{10}H_{12}OAc$ . (245°). S.G. 1.009.

**Benzoyl derivative**  $C_{10}H_{12}OBz$ . [82°]. I.F. 90,480 (Stohmann, J. pr. [2] 36, 9).

**Methyl ether**  $C_{10}H_{12}OMe$ . (216° cor.). S.G. 9531. C.E. (0°–10°) 00083. S.V. 214.3 (Pinette, A. 243, 47). I.F.p. 61,429 [ $C_{10}$ , 94,000;  $H_2O$ , 69,000] (Stohmann, J. pr. [2] 35, 26). Formed from thymol,  $KOH$ , and  $MeI$  (Engelhardt a. Latschinoff, Z. [2] 5, 43).

**Ethyl ether**  $C_{10}H_{12}OEt$ . (227°) (Pinette; cf. Jungfleisch, Bl. [2] 4, 17). S.G. 9534. C.E. (0°–10°) 00089. S.V. 240. I.F.p. 68,853 (Stohmann). Yields the ethyl derivative of oxyterephthalic acid on oxidation (Paterno a. Canzoneri, G. 9, 460). Decomposes at 360°–400° into thymol and ethylene (Bamberger, B. 19, 1820).

**Propyl ether**  $C_{10}H_{12}OPr$ . (243°). S.G. 9276. C.E. (0°–10°) 00088. S.V. 265.5.

**Butyl ether**  $C_{10}H_{12}OC_4H_9$ . (258°). S.G. 9230. C.E. (0°–10°) 00085. S.V. 289.2.

**Isoamyl ether**  $C_{10}H_{12}OC_5H_{11}$ . (238°–243°) (E. a. L.). Oil.

**Heptyl ether**  $C_{10}H_{12}OC_7H_{15}$ . (307°). S.G. 9097. C.E. (0°–10°) 00082. S.V. 368.7.

**Octyl ether**  $C_{10}H_{12}OC_8H_{17}$ . (320°). S.G. 9026. C.E. (0°–10°) 00075. S.V. 395.6 (Pinette).

**Ethylene ether**  $(C_{10}H_{12}O)_2$ . [99°]. Plates (from ether) (Paterno, G. 5, 13).

**Nitroso-thymol v. Ozim of Thymoquinone.**

**Dithymol v. Di-oxy-di-cymyl.**

**References.**—Amido-, Bromo-amido-, Bromo-nitro-, Tri-chloro-, Iodo-, Iodo-amido-, and Nitro-thymol.

**DI-THYMOL-ETHANE v. DI-OXY-DI-CYMYL-ETHANE.**

**THYMOL DICARBOXYLIC ALDEHYDE**  $C_{10}H_{12}O$ , i.e.  $C_6HMePr(OH)(CHO)$ . [80°]. Formed as a by-product in the preparation of thymotic acid by the action of chloroform and  $NaOH$  on thymol (Kobek, B. 16, 2104). Needles. Gives a red colour with  $FeCl_3$ .

**THYMOL (a)-SULPHONIC ACID**  $C_6HMePr(OH).SO_3H$ . [92°] (Stebbins, Am. 8, 111). Formed from thymol by the action of

$\text{H}_2\text{SO}_4$  or  $\text{ClSO}_3\text{H}$  at  $50^\circ$  (Engelhardt a. Latschinoff, Z. 1869, 44; 1871, 261). Pearly plates (containing aq), v. e. sol. water.  $\text{FeCl}_3$  colours neutral solutions dark-violet. Yields thymoquinone on oxidation.

**Salts.**— $\text{KA}'_2$  2aq. Efflorescent tables, v. e. sol. water.— $\text{NaA}'_2$  2aq.  $[\text{NH}_4\text{A}']_2$  2aq.  $[\text{LiA}']_2$  2aq.  $[\text{BaA}']_2$  4aq. Prisms, decomposing at  $100^\circ$ .— $\text{PbA}'_2$  4aq.

**Benzoyl derivative**  $\text{C}_{10}\text{H}_{12}(\text{OBz})\text{SO}_3\text{H}$ .— $\text{KA}'_2$  2aq.— $\text{CaA}'_2$  4aq.— $\text{BaA}'_2$  5aq.— $\text{PbA}'_2$  5aq.

**Ethyl derivative**  $\text{C}_{10}\text{H}_{12}(\text{OEt})\text{SO}_3\text{H}$ . Formed from the K salt, KOH, and EtI.— $\text{KA}'_2$ . Thin plates.— $\text{BaA}'_2$  3aq. Plates, sl. sol. hot aq.

**Isoamyl derivative**  $\text{C}_{10}\text{H}_{12}(\text{OC}_4\text{H}_9)\text{SO}_3\text{H}$ .— $\text{KA}'_2$ . Needles, v. sol. water.— $\text{BaA}'_2$  3aq.

**Thymol ( $\beta$ )-sulphonic acid**  $\text{C}_{10}\text{H}_{12}(\text{OH})\text{SO}_3\text{H}$ . Formed in small quantity by the action of  $\text{H}_2\text{SO}_4$  on thymol.— $\text{KA}'_2$  aq. Plates, sl. sol. cold water. Coloured violet-blue by  $\text{FeCl}_3$ .

**Thymol ( $\gamma$ )-sulphonic acid**  $\text{C}_{10}\text{H}_{12}(\text{OH})\text{SO}_3\text{H}$ . Formed by heating thymol with fuming  $\text{H}_2\text{SO}_4$  at  $100^\circ$  (E. a. L.).— $\text{KA}'_2$  aq. Granular, v. sol. water.— $\text{BaA}'_2$  3aq. Tufts of needles, more soluble than the ( $\alpha$ )-isomeride. Not decomposed at  $120^\circ$ .

**Benzoyl derivative**  $\text{C}_{10}\text{H}_{12}(\text{OBz})\text{SO}_3\text{H}$ .— $\text{KA}'_2$  3aq. Flat needles, sl. sol. cold water.

**Ethyl derivative**  $\text{C}_{10}\text{H}_{12}(\text{OEt})\text{SO}_3\text{H}$ .— $\text{KA}'_2$ . Flat needles.— $\text{BaA}'_2$  3aq. Six-sided tables.

**Thymol-sulphonic acid**

**Ethyl derivative**  $\text{C}_{10}\text{H}_{12}\text{MePr}(\text{OEt})\text{SO}_3\text{H}$  [1:4:3:6]. Formed by boiling diazo-cymene-sulphonic acid with absolute alcohol.— $\text{BaA}'_2$  3aq; white plates, sol. hot water, sl. sol. cold (Widman, B. 19, 247).

**Thymol sulphonic acid. Methyl derivative**  $\text{C}_{10}\text{H}_{12}(\text{OMe})\text{SO}_3\text{H}$ . Formed, together with an isomeride, by sulphonation of the methyl ether of thymol (E. a. L.; Paterno a. Pisati, B. 8, 440).— $\text{KA}'_2$  large tables.— $\text{BaA}'_2$  3aq. Nodules, y. sol. hot water. S. 3:94 at  $26^\circ$ .

**Thymol disulphonic acid**  $\text{C}_{10}\text{H}_{10}(\text{OH})(\text{SO}_3\text{H})_2$ . Formed by sulphonating thymol.— $\text{KA}''$  1½aq. Efflorescent needles (from alcohol), v. e. sol. water.

**References.**—AMIDO-, BROMO-, and IODO-THYMOL SULPHONIC ACID.

**THYMOQUINONE**  $\text{C}_{10}\text{H}_{12}\text{O}_2$  i.e.  $\text{C}_6\text{H}_4\text{MePrO}_2$  [2:5:4:1]. Mol. w. 164.  $[\alpha]_D^{25} + 1.45$  (232°). Formed by oxidation of thymol (Lallemand, J. 1854, 592), of the methyl ether of thymol (Paterno, B. 8, 440), of cymenol (Carstanjen, J. pr. [2] 3, 53; 15, 410), of di-ox-di-cymyl-ethane (Steiner, B. 11, 289), of carvacrol p-sulphonic acid (Claus, J. pr. [2] 39, 356), and of amido-thymol (Andersen, J. pr. [2] 23, 172; Armstrong, B. 10, 297; Liebermann a. Ilinski, B. 18, 8194). Yellow crystals, with pungent odour, v. sl. sol. water, v. sol. alcohol and ether. Reduced by  $\text{SO}_2$  to hydrothymoquinone.  $\text{K}_2\text{SO}_5$  at  $60^\circ$  forms crystalline  $\text{C}_{10}\text{H}_{12}\text{O}_5\text{K}$ . Phenyl cyanate forms  $\text{C}_{10}\text{H}_{12}\text{O}_2\text{N}:\text{O}:\text{CO}:\text{NHPh}$  [132°], crystallising in large yellow needles (Goldschmidt a. Strauss, B. 22, 3106).

**Oxim**  $\text{C}_6\text{H}_4\text{MePr}(\text{NOH})$  or  $\text{C}_6\text{H}_4\text{MePr}(\text{OH})(\text{NO})$ . **Nitroso-thymol** [163°]. Formed by the action of nitrous acid on thymol (R. Schiff, B. 8, 1500; Widmann, B. 15, 170; Liebermann, B. 18, 8194). Formed also by the action of hydroxylamine hydrochloride on

thymoquinone (Goldschmidt a. Schmid, B. 17, 2081). Slender, monoclinic needles,  $\alpha:\beta:\gamma = 1.987:1.18941:1$ ;  $\beta = 94^\circ 57'$  (Panebianco, G. 10, 79); sl. sol. hot water. Its alkaline solution is red. Oxidised by alkaline  $\text{K}_2\text{FeO}_4$  to nitro-thymol. Reduced by tin and HCl to amido-thymol (Liebermann, B. 10, 77). Does not react with  $\text{SO}_2$  (Schmidt, J. pr. [2] 44, 521). Fuming HCl forms di-chloro-thymoquinone and chloro-amido-thymol (Sutkowski, B. 19, 2315). KOH and  $\text{BzCl}$  form  $\text{C}_{10}\text{H}_{12}\text{O}(\text{NOBz})$  [110°]. Hydroxylamine (8 mols.) in strongly alkaline solution forms, in 48 hours, a white substance which, if ppd. by HOAc, immediately dissolved in dilute NaOH, treated with an equal weight of a phenol, and exposed to the air, gives a deep-blue colour or pp. turned red by acids (Kehrmann a. Mesinger, B. 23, 2818, 3557).

**Di-oxim**  $\text{C}_{10}\text{H}_{12}\text{N}_2\text{O}_2$  i.e.  $\text{C}_{10}\text{H}_{12}(\text{NOH})_2$ . Formed by boiling an alcoholic solution of nitroso-thymol (1 mol.) with hydroxylamine hydrochloride (2 mols.) and partially neutralising with alkali from time to time. Yellowish-white granules, decomposing at  $235^\circ$  without melting. Insol. water and  $\text{NH}_4\text{Aq}$ , sol. KOHAq.

**Chlorimide**  $\text{C}_6\text{H}_4\text{MePr}(\text{O})\text{NCl}$ . Formed

by adding a solution of bleaching powder to a cold acidified solution of the hydrochloride of p-amido-thymol (Andersen, J. pr. [2] 23, 169). Pungent oil, volatilising even at  $15^\circ$ . Decomposes at  $160^\circ$ – $170^\circ$ . Volatile with steam. Decomposed by conc. HClAq into chloro-amido-thymol and mono- and di-chloro-thymoquinone. Conc. HBrAq behaves in a precisely similar way. Alcohol at  $140^\circ$  converts the chlorimide into thymoquinone. Conc. aqueous  $\text{SO}_2$  reduces it in a few days to hydro-thymoquinone. Reduced by tin and HCl to p-amido-thymol, considerable quantities of hydrothymoquinone being formed at the same time.

**Polymeride** [201°]. Formed by the action of daylight on thymoquinone (Armstrong, B. 10, 297; Liebermann, B. 10, 2177; 18, 8193). Silky yellow needles (from alcohol), insol. ether. Changes to thymoquinone on distillation. Not attacked by  $\text{SO}_2$  at  $180^\circ$ , but reduced by HI and P, or in alcoholic solution, by Zn and HClAq to hydrothymoquinone.

**Phenyl hydrazide** [249°]. Insol. benzene.

**Oxim**  $\text{C}_{10}\text{H}_{12}\text{NO}_2$ . [263°]. Crystalline, insol. water. Reduced by tin and HCl to amido-hydrothymoquinone.

**Dioxim**  $(\text{C}_{10}\text{H}_{12}\text{N}_2\text{O}_2)_2$ . [c.  $290^\circ$ ]. Powder. May be reduced to di-amido-cymene.

**References.**—DI-AMIDO-, BROMO-, CHLORO-, IODO-, and OXY-THYMOQUINONE.

**o-THYMOTIC ACID**  $\text{C}_{10}\text{H}_{12}\text{O}_4$  i.e.  $\text{C}_6\text{H}_4\text{Me}(\text{C}_6\text{H}_4)(\text{OH})\text{CO}_2\text{H}$  [6:3:2:1]. Mol. w. 194.  $[\alpha]_D^{25} + 1.23$ . Formed by the action of  $\text{CO}_2$  upon heated sodium-thymol (Kolbe a. Lautemann, A. 115, 205; Kobek, B. 16, 2101). Silky crystals, v. sol. alcohol, ether, and benzene, almost insol. cold water. Volatile with steam. Gives a deep-blue colour with  $\text{FeCl}_3$ . Yields thymol when distilled with baryta. PCl, acting on the Na salt forms thymotide  $\text{C}_{10}\text{H}_{12}\text{O}_4$  [187°], which is reconverted into thymotic acid by potash fusion (Naqdet, Bl. 4, 92).

**p-Thymotic acid**  $\text{C}_{10}\text{H}_{12}\text{O}_4$  i.e.  $\text{C}_6\text{H}_4\text{Me}(\text{C}_6\text{H}_4)(\text{OH})\text{CO}_2\text{H}$  [6:3:4:1].

[187°]

Formed by heating thymol with aqueous NaOH and  $\text{CCl}_4$  (Kobek). White plates, v. sol. alcohol, ether, and benzene, insol. cold water. Not coloured by  $\text{FeCl}_3$ .

*Methyl derivative*

$\text{C}_6\text{H}_5\text{Me}(\text{C}_6\text{H}_5)(\text{OMe})\text{CO}_2\text{H}$ . [187°]. Silky needles (from dilute alcohol).— $\text{AgA}'$ : pp.

*p-THYMOTIC ALCOHOL*  $\text{C}_{11}\text{H}_{14}\text{O}$ , i.e.

$\text{C}_6\text{H}_5\text{Me}(\text{C}_6\text{H}_5)(\text{OH})\text{CH}_2\text{OH}$ . [120°–130°]. Formed by reducing thymotic aldehyde with sodium-amalgam (Kobek, B. 16, 2093). Amorphous powder, v. sol. alcohol and ether, insol. water.

*p-THYMOTIC ALDEHYDE*  $\text{C}_{11}\text{H}_{12}\text{O}$ , i.e.

$\text{C}_6\text{H}_5\text{Me}(\text{C}_6\text{H}_5)(\text{OH})\text{CHO}$ . [133°]. Formed, together with  $\text{C}_6\text{H}_5\text{Me}(\text{C}_6\text{H}_5)(\text{OH})(\text{CHO})_2$  [6:3:4:5:1] [80°], by heating thymol with chloroform and  $\text{NaOH}$  (Kobek, B. 16, 2096). Silky needles, v. sol. alcohol, sl. sol. hot water. On heating with aniline it yields the compound  $\text{C}_6\text{H}_5\text{Me}(\text{C}_6\text{H}_5)(\text{OH})\text{CH}_2\text{NPh}$  [142°] crystallising in yellow needles.

*Methyl derivative*

$\text{C}_6\text{H}_5\text{Me}(\text{C}_6\text{H}_5)(\text{OMe})\text{CHO}$ . (278°). Formed by methylation of the aldehyde. Oil, yielding an anilide  $\text{C}_6\text{H}_5\text{Me}(\text{C}_6\text{H}_5)(\text{OMe})\text{CH}_2\text{NPh}$  [80°] crystallising in transparent tables.

**THYMYLAMINE**  $\text{C}_{11}\text{H}_{13}\text{NH}_2$ . (230°). Formed, together with di-thymylamine, by heating thymol with ammoniacal  $\text{ZnBr}_2$  or  $\text{ZnCl}_2$  and  $\text{NH}_4\text{Br}$  or  $\text{NH}_4\text{Cl}$  at 350°–360°, the yield being 25 p.c. (Lloyd, B. 20, 1260). Colourless oil.— $\text{B}'_2\text{H}_3\text{PtCl}_4$ : yellow needles.

*Acetyl derivative*  $\text{C}_{16}\text{H}_{19}\text{NaO}$ . [112°].

*Isomeride v. CARVACRYLAMINE.*

Di-thymyl-amine  $(\text{C}_6\text{H}_5)_2\text{NH}$ . (340°–345°). Formed as above, the yield being 25 p.c. Oil. Its solution in  $\text{P}_2\text{SO}_5$  is coloured blue by nitrites or nitrates.— $\text{B}'_2\text{H}_3\text{PtCl}_4$ .

*Acetyl derivative*  $(\text{C}_{16}\text{H}_{19})_2\text{NaO}$ . [78°].

**THYMYL CYANURIC ACID** v. **CYANIC ACID**.

**THYMYL MERCAPTAN**  $\text{C}_{10}\text{H}_{13}\text{SH}$ . *Thio-thymol*. (231°). S.G. .989. Formed by heating thymol with  $\text{P}_2\text{S}_5$  (Fittica, A. 172, 325; Bechler, J. pr. [2] 8, 167). Liquid with pungent odour. Oxidised by  $\text{HNO}_3$  to sulpho-toluic acid.— $\text{Hg}(\text{SC}_6\text{H}_5)_2$ . Greenish rhombohedra [78°].— $\text{PbA}'_2$ : golden needles (from alcohol).

**THYMYL PHOSPHATE**  $(\text{C}_6\text{H}_5)_3\text{PO}_4$ . [90°]. Formed by heating thymol with  $\text{POCl}_3$ , the yield being 75 p.c. of the theoretical amount (Kreysler, B. 18, 1706). Colourless needles.

**THYMYL SILICATE**  $(\text{C}_6\text{H}_5)_3\text{SiO}_2$ . [48° (c. 450°)]. Formed by heating thymol with  $\text{SiCl}_4$ , the yield being 70 p.c. of the theoretical amount (Hertkorn, B. 18, 1692).

**TIGLIC ACID**  $\text{C}_8\text{H}_{14}\text{O}_2$ , i.e.  $\text{CH}_3\text{CH}_2\text{CH}(\text{OMe})\text{CO}_2\text{H}$ . *Methyl-crotonic acid*. Mol. w. 100. [65°].

(199° i.v.) (Kopp, A. 195, 84). Occurs as a glyceryl ether in croton oil (Geuther a. Fröhlich, Z. 1870, 549; Schmidt a. Berendes, A. 191, 94; B. 10, 835; Ar. Ph. [8] 13, 213), and as isocamyl ether in Roman oil of chamomile (Köbig, A. 195, 101).

*Formation*.—1. By the action of heat or of conc.  $\text{H}_2\text{SO}_4$  on angelic acid (Demarcay, B. 9, 1933).—2. By reducing the dibromide of angelic acid with sodium-amalgam (Schmidt, A. 208, 253).—3. From  $\text{C}_6\text{H}_5\text{Me}(\text{OH})\text{CO}_2\text{Et}$  (derived from oxalic ether,  $\text{EtI}$ ,  $\text{MeI}$ , and  $\text{Zn}$ ) by treatment with  $\text{PbCl}_2$  and saponification of the product

(Frankland a. Duppa, A. 186, 9).—4. By distilling  $\text{CH}_3\text{CH}(\text{OH})\text{CHMeCO}_2\text{H}$  (Rohrbeck, A. 188, 235), or by heating it with  $\text{HIAq}$  (Rücker, A. 201, 61).—5. By reducing methyl-acetoacetic ether with sodium-amalgam and heating the resulting  $\text{CH}_3\text{CH}(\text{OH})\text{CHMeCO}_2\text{H}$  at 200° (Wielicenus, A. 250, 243).—6. By heating veratrine with alcoholid potash (Wright a. Luff, C. J. 33, 347).—7. By heating veratrine with conc.  $\text{HClAq}$  (Ahrens, B. 23, 2704).

*Properties*.—Triclinic plates, v. sol. hot water, alcohol, and ether. Smells like benzoic acid. Volatile with steam. Not attacked by sodium-amalgam. Forms with isovaleric acid the double salts  $\text{CaA}'(\text{C}_8\text{H}_{14}\text{O}_2)_4\text{aq}$  and  $\text{AgA}'\text{C}_8\text{H}_{14}\text{O}_2$ .

*Reactions*.—1. Yields acetic aldehyde and acid on oxidation with  $\text{KMnO}_4$  (Beilstein a. Wiegand, B. 17, 2261; Kondakoff, J. R. 20, 523).—2. *Potash-fusion* gives propionic and acetic acids.—3. Fuming  $\text{HI}$  forms an iodo-valeric acid [87°] (Schmidt, B. 12, 252).—4.  $\text{HI}$  and  $\text{P}$  yield  $\text{C}_6\text{H}_5\text{MeHCO}_2\text{H}$ .—5. Bromine forms  $\text{C}_6\text{H}_5\text{Br}_2\text{O}$  [88°] (Pückert, A. 250, 240; Wielicenus, A. 272, 21; 271, 99).—6.  $\text{HIOCl}$  forms a mixture of  $\text{CH}_3\text{CH}(\text{OH})\text{COClMe}$  [112°] and  $\text{CH}_3\text{CHClCO}_2\text{Me}(\text{OH})\text{CO}_2\text{H}$  [76°] (Melikoff, B. [2] 47, 166).

*Salts*.— $\text{KA}'$ .— $\text{CaA}'$ , 3aq. S. (of  $\text{CaA}'$ ) 6:4 at 17°.— $\text{BaA}'$ , 4aq. S. (of  $\text{BaA}'$ ) 18:5 at 16°.— $\text{AgA}'$ .

*Ethyl ether*  $\text{EtA}'$ . (155°). S.G. 2.942.

*Isocamyl ether*  $\text{C}_8\text{H}_{17}\text{A}'$ . (205°).

*Reference*.—Chloro-tiglic acid.

**TIGLIC ALDEHYDE**  $\text{C}_{11}\text{H}_{18}\text{O}$ . *Guaioi*. (118°). V.D. 2.92. Formed by distillation of gum guaiacum (Deville, C. R. 17, 1143; 19, 134; Vöckel, A. 89, 346; Herzog, M. 8, 118). Formed also by heating acetic aldehyde (1 mol.) with propionic aldehyde (1 mol.) and aqueous (28 p.c.)  $\text{NaOAc}$  for 30 hours at 100° (Lieben a. Zeisel, M. 7, 63). Pungent oil, miscible with alcohol and ether. Oxidised by air to tiglic acid. Alkaline sodium nitroprusside gives a violet-red colour destroyed by  $\text{HOAc}$  (Von Bitto, A. 267, 376).  $\text{Br}$  forms di-bromo-valeric aldehyde. Iron and dilute (50 p.c.) acetic acid reduce it to valeric aldehyde (91°), an inactive amyl alcohol  $\text{CHMeEtCH}_2\text{OH}$  (129°) and tiglic alcohol  $\text{C}_8\text{H}_{16}\text{O}$  (c. 130°). Reacts with phenyl-hydrazine, and combines with  $\text{NaHSO}_4$ .  $\text{CrO}_3$  forms acetic acid (Gilm, A. 106, 379). Aqueous  $\text{SO}_3$  at 0° forms oxy-pentane disulphonic acid (Haymann, M. 9, 1055).

**TIGLYL ALCOHOL** v. **PENTENYL ALCOHOL**.

**TIN** Sn. At. w. 118.8 (v. *infra*). Mol. w. not known with certainty (v. *infra*). Melts at 231.68° (Callendar a. Griffiths, C. N. 63, 1); for other data, giving m.p. from 220° to 235°, v. Carnelley's *Melting and Boiling-point Tables* (2, 12). Boils between the m.p.s of  $\text{Ni}$  and  $\text{Fe}$ , i.e. between 1450° and 1600° (Carnelley a. Williams, C. J. 35, 566). S.G. c. 7.3 (determinations vary from c. 7.0 to c. 7.5) (v. Clarke's *Table of Specific Gravities* [2nd ed.] 6). The so-called allotropic variety of tin seems to have S.G. from 5.8 to 6.1 (v. Schertel, J. pr. [2] 19, 822). S.H. (0°–100°) .0559; so-called allotropic tin has S.H. .0546 (0°–100°) (Bunsen, P. 141, 1); S.H. liquid tin (250°–350°) = .0687 (Person, A. Ch. [8] 24, 129). C.E. (linear, 0°–100°) .00002296 (Matthiessen,

Pr. 15, 220; v. also Kopp, A. 81, 1; Fizeau, C. R. 68, 1125). T.C. 15.2 (Ag=100) (Wiedemann, P. M. [4] 19, 243). E.C. (Hg at 0°-1) at 15° = 8.823 (Kirchoff a. Hausemann, W. 13, 406); at 0° = 8.726, at 100° = 6.091 (Lorenz, W. 13, 422). Heat of fusion (for 1 kilo. tin) = 14,352 (Person, A. Ch. [8] 24, 129). For spectrum of tin v. Thalén (A. Ch. [4] 18, 237); Sale. (U. J. [2] 9, 1147); also Hartley a. Adeney (T. 1884 [i.] 118).

**Historical.**—Tin was known long before the Christian era. Pliny distinguished *plumbum album* or *candidum* from *plumbum nigrum*; in the fourth century A.D. the former of these substances began to be called *stannum*, from which word the symbol Sn is derived.

**Occurrence.**—Tin has been found in Siberia and in South Australia. *Tinstone* or *cassiterite*, consisting essentially of  $\text{SnO}_2$ , is found in considerable quantities, both in veins and in alluvial deposits, in many parts of the world. *Tin pyrites*, containing  $\text{SnS}_2$  with  $\text{Cu}_2\text{S}$ ,  $\text{FeS}$ , and  $\text{ZnS}$ , is found in small quantities in various tin veins. Small quantities of  $\text{SnO}_2$  occur in various *lithi-micas* (Sandberger, J. M. 1878, 201, 657). According to Lockyer (Pr. 27, 279), there are indications of the occurrence of tin in the sun.

**Formation.**—1. By ppn. from solution of  $\text{SnCl}_4$  in  $\text{HClAq}$  by tin; or by tin and iron simultaneously, with a little  $\text{Fe}_2\text{O}_3$ , to neutralise excess of acid (Schultze, B. 23, 974).—2. By electrolysis of  $\text{SnCl}_4$  in dilute  $\text{HClAq}$ .—3. By reduction of  $\text{SnO}_2$  by heating with C.

**Preparation.**—Tinstone is cleansed by agitation with water; it is then sorted, stamped or rolled to a certain fineness, and washed. The washed ore is calcined in reverberatory calciners to remove sulphur from the sulphides of Fe that are present in most tin ores; the calcined ore is exposed to the air for some days to insure the oxidation of any sulphides that remain in the ore to sulphates, and it is then washed in water, whereby sulphates of Fe, Cu, &c., dissolve and the tin oxide sinks to the bottom of the vessels. The tin oxide is then separated into lighter and heavier parts by agitation with water; the heavier parts are mixed with charcoal or anthracite, some lime or fluorspar is added as a flux, and the mixture is smelted in a reverberatory furnace. The product of the smelting is purified by melting, when the tin runs off, leaving the less fusible foreign metals behind; this purified tin is again melted, the molten mass is stirred with billets of green wood for some hours, and is then allowed to partially solidify by cooling, when the metal separates into different strata, which are ladled into moulds: the upper stratum is the purest and the undermost is the least pure. Sometimes the smelting is conducted in a blast furnace. For details v. TIN in DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 834.

Commercial tin generally contains small quantities of As, Cu, Fe, and Pb, and occasionally traces of Sb, Bi, Mn, Mo, W, and Zn. To prepare pure tin, the purest commercial metal is granulated and dissolved in conc.  $\text{HClAq}$ ; a little water is very slowly poured into the liquid so as to form two layers, and a plate of tin is placed in the liquid so that part of it is in the upper (less conc.) and part in the under (more conc.) layer. A slight electric current is thus produced,

and crystals of pure tin are deposited on the plate (Hiller, A. 85, 253).

Pure tin was prepared by Bongartz a. Classen (B. 21, 2903) by heating the purest commercial tin (Banca tin) in dry Cl and so forming  $\text{SnCl}_4$ , distilling fractionally, and collecting that which passed over at 120°, adding to the  $\text{SnCl}_4$  about four times its volume of water, and then crystallised  $\text{Na}_2\text{S}$  until the pp. of  $\text{SnS}$ , that formed was dissolved, then adding  $\text{NaOHAq}$  about equal to half the quantity of  $\text{Na}_2\text{S}$  used, allowing to stand for some days, drawing off the clear, almost perfectly colourless liquid into a Ptbasin, and passing an electric current through this alkaline liquid, washing the ppd. tin with water, then with absolute alcohol, and drying at 100°. The current was arranged so that it produced c. 2 to 3 c.c. detonating gas per minute from water; c. 2 to 3 g. tin were obtained in 24 hours.

**Properties.**—Pure tin is a silver-white metal; the commercial metal generally has a slightly yellowish tinge. It is unchanged in pure air; but it tarnishes in the air of large towns from formation of a film of sulphide. Tin is one of the least tenacious metals; a wire 1.6 mm. diameter breaks with a weight of c. 14 kilos. Tin may be hammered into plates c. .0254 mm. thick; the malleability varies much with temperature, at 200° the metal is so brittle that it crumbles when hammered. Tin readily crystallises; by fusing, allowing to cool partially, and pouring out the still fluid metal, fair-sized crystals are obtained. Crystals are formed by depositing tin by electrolysis. Stolba (J. 1873, 282) covers the outside of a Pt basin, all except a small portion, with wax, places the unwaxed surface of the basin on a plate of amalgamated zinc in a larger porcelain basin, fills the Pt basin with a dilute and not very acid solution of  $\text{SnCl}_4$ , and the porcelain basin with water containing c.  $\frac{1}{2}$  part of  $\text{HClAq}$ ; crystals of tin deposit on the bottom of the Pt basin. The forms of the crystals of tin are probably rhombic and quadratic (von Foullon, J. M. 1885 (11) Ref. 266). According to Frankenheim (P. 40, 456), the crystals belong to the regular system; Miller (B. J. 24, 133) obtained quadratic prisms by separating tin by electrolysis. If a piece of tin is brushed over with warm, dilute *aqua regia*, or with a mixture of warm dilute  $\text{H}_2\text{SO}_4$  and  $\text{HNO}_3$ , the surface becomes covered with a fretwork of crystals, from the facets of which light is unequally reflected, and the surface appears like watered silk. When a bar of tin is bent a crackling sound may be heard due to the crystals in the inner parts of the bar breaking against one another. When warmed, tin has a characteristic smell.

By exposure for some time to a very low temperature (c. -89°) tin crumbles to a grey powder (v. Fritzsche, B. 2, 112, 540); S.G. c. 5.8 to 6.1 (v. Schertel, J. pr. [3] 19, 822). Tin which had been kept for 300 to 400 years was found by Schertel (i.e.) to have become reddish-grey, and so brittle that it was crushed by pressure between the finger-nails; by immersion in boiling water the metal became more coherent and lighter in colour, and the S.G. increased to 7.3 (cf. Oudemanna, P. M. [5] 4, 470).

Tin remains lustrous in pure air at the ordinary temperature, and also in water; &

greyish-white film of  $\text{SnO}_2$  forms on the surface of tin kept molten in the air; when heated to whiteness in air the metal burns brightly to  $\text{SnO}_2$ . Tin dissolves in  $\text{HClAq}$ , forming  $\text{SnCl}_2$  solution; dilute  $\text{H}_2\text{SO}_4\text{Aq}$  has only a slight action, conc. hot  $\text{H}_2\text{SO}_4$  produces  $\text{SnSO}_4$  and  $\text{SO}_2$ ; dilute  $\text{HNO}_3\text{Aq}$  dissolves tin, with formation of  $\text{Sn(NO}_3)_2\text{Aq}$  and  $\text{NH}_4\text{NO}_3\text{Aq}$ , conc.  $\text{HNO}_3$  transforms the metal into  $\text{SnO}_2$ . Tin dissolves in hot conc.  $\text{NaOHaq}$ , forming  $\text{Na}_2\text{SnO}_3$  solution and giving off  $\text{H}_2$ .

When haloid compounds of tin are volatilised in a stream of  $\text{H}_2$  and the gas is ignited, the flame shows two cones; the inner cone is blue with  $\text{SnCl}_2$ , green with  $\text{SnBr}_2$ , and yellow with  $\text{SnI}_2$ , and gives a continuous spectrum; the outer cone is carmine-red, and gives a spectrum with two characteristic lines (Salet, *C. J.* [2] 9, 1147).

Tin is metallic physically, and in most of its chemical relations. The oxide  $\text{SnO}_2$  interacts towards several acids as a basic oxide, forming salts  $\text{SnX}_2$  ( $\text{X} = \text{SO}_3$ , &c.); but with conc.  $\text{KOHaq}$  or  $\text{NaOHaq}$  this oxide reacts as an acidic oxide, forming salts  $\text{M}_2\text{SnO}_3$ . Tin is the third member of the odd-series family of Group IV. in the periodic classification of the elements; it is closely allied to  $\text{Ge}$  and  $\text{Pb}$ , and less closely to  $\text{Si}$ ; it shows very marked analogies with  $\text{Ti}$ ,  $\text{Zr}$ ,  $\text{Ce}$ , and  $\text{Th}$ , which (with  $\text{C}$ ) form the even-series family of Group IV. For details of the chemical relations of tin *v.* **TIN GROUP OF ELEMENTS**, this vol. p. 735.

The atom of tin is divalent in the gaseous molecule  $\text{SnCl}_2$ , and tetravalent in the gaseous molecule  $\text{SnCl}_4$ .

*Supposed allotropic form of tin.* The grey brittle powder formed by the action of great cold on tin, and also found in some very old specimens of the metal, is sometimes regarded as an allotropic variety of tin (*v. supra*). All the specimens of tin, however, which have been observed to undergo this change have contained small quantities of impurities; until the change has been effected with pure tin, and has been proved to occur without any change of mass, the existence of an allotropic variety of tin cannot be said to be established. According to von Fournell (*J. M.* 1885 [1] *Ref.* 266) there are three varieties of tin: (1) rhombic, S.G. 6.52 to 6.56; (2) quadrate, S.G. 7.196; (3) grey brittle tin, S.G. 5.781 to 5.809.

*Atomic weight of tin.* The at. w. has been determined (1) by oxidising  $\text{Sn}$  to  $\text{SnO}_2$  by  $\text{HNO}_3$  (Gay-Lussac, *A. Ch.* [2] 80, 163 [1812]; Berzelius, *P.* 8, 184 [1812]; Mulder, *A.* 72, 212 [1849]; Vlaanderen, *B. J.* 1858, 183 [1858]; Dumas, *A. Ch.* [3] 55, 134 [1859]; van der Plaats, *C. R.* 100, 52 [1885]; Bongartz a. Classen, *B.* 21, 2900 [1888]); (2) by ppg.  $\text{Cl}$  from  $\text{SnCl}_2$  by  $\text{AgNO}_3\text{Aq}$  (Dumas, *A. Ch.* [3] 55, 156 [1859]); (3) by electrolysis  $\text{SnCl}_2 \cdot 2\text{NH}_4\text{Cl}$  and  $\text{SnCl}_2 \cdot 2\text{KCl}$  (B. a. C., *L.c.* [1888]); (4) by electrolysis  $\text{SnBr}_2$  (B. a. C., *L.c.*); (5) by reducing  $\text{SnO}_2$  in  $\text{H}_2$  (v. d. P., *L.c.* [1885]); (6) by determining S.H. of  $\text{Sn}$  (Bunsen, *P.* 141, 1 [1870]); (7) by determining V.D. of, and analysing,  $\text{SnCl}_2$  and  $\text{SnCl}_4$ . The older determinations gave values from 115.9 to 117.8. The results of the determinations of B. a. C. are summarised by them (*L.c.*, p. 2909) as follows:—

Number of experiments	Method	At. weight	Diff. between min. and max. found
11	oxidation of $\text{Sn}$ to $\text{SnO}_2$	118.7606	.459
10	electrolysis of $\text{SnCl}_2 \cdot 2\text{NH}_4\text{Cl}$	118.8093	.228
10	electrolysis of $\text{SnCl}_2 \cdot 2\text{KCl}$	118.7975	.163
10	electrolysis of $\text{SnBr}_2$	118.7309	.144

B. a. C. regard the second and third methods as the most trustworthy; in the oxidation of  $\text{Sn}$  to  $\text{SnO}_2$ , the  $\text{Pt}$  vessel was also slightly acted on, and there was the possibility of a very small loss in dissolving  $\text{SnBr}_2$  in the last method. The mean of the results obtained by the electrolysis of the two double chlorides is 118.8 ( $\text{O} = 15.96$ ).

*Molecular weight of tin.* As the V.D. of tin has not been determined the molecular weight is not known. Ramsay determined the depression of the vapour pressure of  $\text{Hg}$  caused by dissolving tin therein; assuming that equal volumes of dilute solutions contain equal numbers of molecules of the dissolved bodies, and that the mol. w. of liquid  $\text{Hg}$  is 200, the results obtained by R. gave the mol. w. of tin as 117.4 in one experiment and 149.5\* in another.

*Reactions and Combinations.*—1. When tin is heated in air or oxygen, a film is formed on the surface, containing both  $\text{SnO}$  and  $\text{SnO}_2$ ; when heated to whiteness tin burns brightly, forming  $\text{SnO}$  (v. Emich, *M.* 14, 345).—2. Heated in chlorine, bromine, or iodine, the compounds  $\text{SnX}_2$  and  $\text{SnX}_4$  are formed, according to whether there is excess of tin or halogen.—3. Tin combines with sulphur, and with selenium, to form  $\text{SnS}$  and  $\text{SnSe}$ , when heated with these elements.—4. Tin probably combines with phosphorus when heated in vapour of that element.—5. Tin forms alloys with many metals (v. **TIN, ALLOYS** or, p. 720).—6. Water is decomposed by tin at a full red heat with formation of  $\text{SnO}$  and  $\text{H}_2$ .—7. *Sulphydic acid* has a slight action on tin, in moist air, forming a film of  $\text{SnS}$ .—8. *Hydrochloric acid* dissolves the metal, forming solution of  $\text{SnCl}_2$  and giving off  $\text{H}_2$ ; the reaction proceeds more rapidly with warm conc.  $\text{HClAq}$ .—9. *Pure conc. nitric acid*, S.G. c. 1.55, has no action on tin. When the acid is diluted the products of the reaction vary with the concentration and the temperature; according to Walker (*C. J.* 63, 845), both  $\text{Sn(NO}_3)_2$  and  $\text{Sn(NO}_3)_4$  are formed, the quantity of  $\text{Sn(NO}_3)_2$  increasing as concentration increases at a fixed temperature; with very dilute acid an increase of temperature causes only a slight increase in the quantity of the stannic salt, but the effect of temperature is very marked with more conc. acid; the proportion of stannous to stannic salt formed is only slightly affected by changing the relative masses of tin and acid; when a fairly conc. solution of tin in  $\text{HNO}_3\text{Aq}$  is heated, hydrated stannic nitrates, varying in composition, are deposited (v. also Montemartini, *G.* 22, 384, 397, 426; abstract in *C. J.* 62, 1402; v. also Hay, *C. N.* 23, 298; Scott, *C. N.* 23, 823). *Pure*

**HNO<sub>3</sub>**, diluted sufficiently to start the reaction produces chiefly  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$  (v. *Hydrated stannic oxide*, under **TIN OXIDES AND HYDRATED OXIDES**, p. 725). When tin dissolves "in **HNO<sub>3</sub>**, **NH<sub>4</sub>NO<sub>3</sub>** is formed; the gases evolved are **NO**, **N<sub>2</sub>O**, and **N** (v. Ackworth a. Armstrong, *C. J.* 82, 84).—10. A mixture of **nitric and sulphuric acids**, or **nitric and hydrochloric acids**, produces **NH<sub>4</sub>OH** along with **NH<sub>3</sub>** (Divers, *C. J.* 43, 443; D. a. Shimidzu, *C. J.* 47, 597; cf. **Hydroxylamine**, vol. ii. p. 734). With certain proportions of **HNO<sub>3</sub>** and **H<sub>2</sub>SO<sub>4</sub>**, Bassett (*C. N.* 53, 172) obtained **Sn(NO<sub>3</sub>)<sub>2</sub>** in solution, and almost pure **N<sub>2</sub>O**.—11. Dilute sulphuric acid reacts slowly when warmed with tin, forming **SnSO<sub>4</sub>**, if the tin is kept in excess, and chiefly **Sn(SO<sub>3</sub>)<sub>2</sub>**, if the acid is in excess, and giving off **H<sub>2</sub>**. *Conc. sulphuric acid* reacts to form **SnSO<sub>4</sub>**, or **Sn(SO<sub>3</sub>)<sub>2</sub>**, according to the proportion of tin to acid, and evolves **H<sub>2</sub>S** or **SO<sub>2</sub>**, or both, according to the concentration of the acid and the temperature; with pure hot **H<sub>2</sub>SO<sub>4</sub>**, **SO<sub>2</sub>** is given off, and **S** separates (v. Calvert a. Johnson, *C. J.* [2] 4, 435; also Pattison Muir a. Robbs, *C. N.* 45, 69).—12. *Aqua regia* dissolves tin, forming **SnCl<sub>4</sub>**.—13. Tin reacts with *mercuric chloride and bromide*, when heated with these compounds, forming **SnCl<sub>2</sub>**, or **SnBr<sub>2</sub>**, and **Hg**.—14. With *sulphurous chloride*, **SnCl<sub>2</sub>** is formed, with production of much heat (Wöhler, *A.* 73, 374).—15. Tin dissolves in warm conc. *caustic potash*, or *soda*, solution, forming **M<sub>2</sub>SnO<sub>3</sub>** and giving off **H<sub>2</sub>**.—16. Fusion with *nitre* forms **K<sub>2</sub>SnO<sub>3</sub>**.

**Detection and Estimation.**—**H<sub>2</sub>S** ppts. dark brown **SnS** from slightly acidified solutions of stannous salts; the ppt. is soluble in warm yellow ammonium sulphide, forming **(NH<sub>4</sub>)<sub>2</sub>Sn<sub>2</sub>Aq**, from which acids ppt. yellow **SnS<sub>2</sub>**. **AuCl<sub>3</sub>** produces a purple ppt. a compound of **Sn**, **Au**, and **O** (v. *Purple of Cassius*, under **TIN OXIDES AND HYDRATED OXIDES**, p. 727). **H<sub>2</sub>S** ppts. yellow **SnS<sub>2</sub>** from acidified solutions of stannic salts; the ppt. dissolves in warm yellow ammonium sulphide, and acids re-ppt. **SnS<sub>2</sub>** from this solution. Tin is generally estimated as **SnO<sub>2</sub>**.

**Tin, alloys of.** Tin forms alloys with many metals. For a general account of the properties of different classes of tin alloys, v. **DICTIONARY OF APPLIED CHEMISTRY**, vol. iii. p. 837. For alloys of tin with *antimony*, v. Karmarsch (*D. P. J.* 123, 267); Kestner (*Kast. Archiv*, 19, 424); Johnson (*Chem. Gazette*, 1855, 110); Chaudet (*A. Ch.* [2] 3, 376); with *bismuth and lead*, and with *bismuth, cadmium and lead*, v. vol. i. p. 511; with *cadmium*, v. vol. i. p. 655; with *cadmium and gold*, v. Heycock a. Neville (*C. J.* 59, 936); with *copper*, v. vol. ii. p. 251 (also **DICTIONARY OF APPLIED CHEMISTRY**, vol. iii. p. 688); with *copper and lead*, v. vol. iii. p. 125 (also French, *S. C. I.* 8, 86); with *iridium, platinum, and rhodium*, v. Deville a. Debray (*C. R.* 81, 889); with *iron*, v. vol. iii. p. 53 (also Headen, *Am. S.* [3] 44, 464); with *gold*, v. Laurie (*P. M.* [5] 88, 94); with *lead*, v. vol. iii. p. 125; with *lead and zinc*, v. vol. iii. p. 125 (also Wright a. Thompson, *Pr.* 45, 461; 48, 25); with *mercury*, v. *infra*; with *platinum*, v. vol. iv. p. 288; with *silver*, v. W. a. T. (*Pr.* 48, 25); with *sodium*, v. Bailey (*C. N.* 65, 18). Tin alloys with *zinc* in all proportions; the alloys are harder than tin, but softer than zinc; they are less

malleable than tin. Many varieties of bronzes are alloys of tin with *zinc and copper* (v. Rudberg, *P.* 18, 240). *Amalgams of tin* are readily formed by immersing tin in **Hg**; the action is more rapid if the **Hg** is warmed (v. Böttger, *J. pr.* 1, 805; Joule, *Chem. Gazette*, 1850, 339, also *C. J.* 16, 384; Kupffer, *A. Ch.* [2] 40, 293).

**Tin, bromides of.** Tin combines with **Br** to form two compounds, **SnBr<sub>2</sub>**, and **SnBr<sub>4</sub>**. The V.D. of the latter has been determined, and the formula **SnBr<sub>4</sub>** is molecular; from the analogy of the chlorides it is probable that the formula **SnBr<sub>2</sub>** is molecular also. Watts a. Bell (*C. J.* 33, 442) obtained both **SnBr<sub>2</sub>**, and **SnBr<sub>4</sub>**, by heating **SnO<sub>2</sub>** in **Br** vapour mixed with **CO**.

**STANNOUS BROMIDE SnBr<sub>2</sub>.** (*Dibromide of tin*.) Obtained by Balard (*A. Ch.* [2] 32, 337); more fully examined by Rayman a. Preis (*A.* 223, 323). Prepared by heating tin in **HBr** gas, allowing the oily liquid so obtained to cool, dissolving the crystals that form in dilute **HBrAq**, and purifying the solid that separates by distilling it in a stream of **N**. A crystalline, slightly yellow, transparent solid; melts at 215° to a transparent liquid, which solidifies at 215°. S.G. 5.117 at 17°. Carnelley a. Williams (*C. J.* 35, 563) say that **SnBr<sub>2</sub>** boils between 617° and 634°. Partly decomposed by water, with separation of an oxybromide of tin (R. a. P., *l.c.*). By crystallising a solution of tin in warm conc. **HBrAq**, R. a. P. (*l.c.*) obtained the *hydrate* **SnBr<sub>2</sub> · xH<sub>2</sub>O** (x = 1 or 2), in colourless needles. By cooling a mixture of **NH<sub>4</sub>Cl** and solution of tin in warm conc. **HBrAq**, the compound **SnBr<sub>2</sub> · 2NH<sub>4</sub>Cl · H<sub>2</sub>O** was obtained in large rhombic, porcelain-like crystals (R. a. P., *l.c.*).

**STANNIC BROMIDE SnBr<sub>4</sub>.** (*Tetrabromide of tin*.) Mol. w. 437.8. Melts at 30° (Carnelley a. O'Shea, *C. J.* 33, 55), at 33° (Rayman a. Preis, *A.* 223, 323). Boils at c. 201° (C. a. O'S., *l.c.*), at 203.3° (R. a. P., *l.c.*). S.G. 3.349 (R. a. P., *l.c.*). V.D. at 228°–260° = 227–230 (C. a. O'S., *l.c.*). Prepared by passing vapour of **Br** over melted tin in a tube shaped thus 

the tin being at *b* and the **Br** at *a*. The tin burns in the **Br** vapour; the product is distilled backwards and forwards from *b* to *c* until the distillate is quite colourless. On cooling the liquid solidifies to colourless crystals of **SnBr<sub>4</sub>** (C. a. O'S., *l.c.*). R. a. P. (*l.c.*) prepared **SnBr<sub>4</sub>** by heating tin with **Br**, and crystallising from **SnCl<sub>4</sub>** or **SnBr<sub>4</sub>Cl**. **SnBr<sub>4</sub>** forms white crystals, which are slowly decomposed in the air; according to R. a. P. (*l.c.*) the crystals deliquesce to a clear liquid, which when placed over **H<sub>2</sub>SO<sub>4</sub>** deposits crystals of the *hydrate* **SnBr<sub>4</sub> · 4H<sub>2</sub>O**. **SnBr<sub>4</sub>** is soluble in cold water; after some hours **SnO<sub>2</sub> · xH<sub>2</sub>O** is deposited; boiling hastens this change; addition of **HNO<sub>3</sub>** to hot **SnBr<sub>4</sub>** ppts. all the tin as **SnO<sub>2</sub> · xH<sub>2</sub>O**, with evolution of a little **Br** (C. a. O'S., *l.c.*). R. a. P. (*l.c.*) found that **SnBr<sub>4</sub>** absorbs **NH<sub>3</sub>**; on heating some **NH<sub>3</sub>** was given off, and a yellow sublimate of **SnBr<sub>2</sub> · 2NH<sub>3</sub>** was obtained. According to Nickles (*C. R.* 51, 869), **SnBr<sub>4</sub>** combines with *ether* to form **SnBr<sub>4</sub> · Et<sub>2</sub>O**.

**Stannibromhydric acid H<sub>2</sub>SnBr<sub>2</sub> · xH<sub>2</sub>O.** (*Bromostannic acid. Hydróbromostannic acid*.) This compound was obtained by Seubert (*B.* 20, 194) by adding 74.1 parts **HBrAq** (50 p.c. **HBr**)

to 100 parts  $\text{SnBr}_2$  (i.e. in the ratio  $2\text{HBr}:\text{SnBr}_2$ ). A yellow liquid was formed which solidified after a time to a mass of yellow, needle-shaped crystals; the small quantity of mother-liquor was removed by melting and allowing to solidify partially. It is doubtful whether the acid crystallises with 7 or  $9\text{H}_2\text{O}$ . The acid forms amber-yellow needles, probably trichlinic; it is very deliquescent; fumes in air, giving off  $\text{HBr}$ . By adding  $\text{Na}_2\text{CO}_3$  to  $\text{H}_2\text{SnBr}_4\text{Aq}$ , and allowing to evaporate, Seubert (*l.c.*) obtained sodium stannibromide,  $\text{Na}_2\text{SnBr}_6 \cdot 6\text{H}_2\text{O}$ , in yellow needles. Several other stannibromides are described by Rayman a. Preis (A. 223, 323); their composition is  $\text{MSnBr}_x \cdot x\text{H}_2\text{O}$ , where  $\text{M} = (\text{NH}_4)_2, \text{Ba}, \text{Ca}, \text{Fe}, \text{Mg}, \text{Mn}, \text{Ni}, \text{Na}, \text{Sr}$ , and  $x$  is 6, 8, or 10.

**Tin, bromochlorides of.** Rayman a. Preis (A. 223, 323) obtained a compound to which they gave the formula  $\text{SnBr}_2\text{Cl}$  by heating tin in  $\text{Br}$  that contained some  $\text{Cl}$ , and repeatedly distilling. The compound is a liquid boiling between  $181^\circ$  and  $190^\circ$ . It dissolves  $\text{SnBr}_2$ , which crystallises out unchanged. By adding  $\text{Br}$  to excess of  $\text{SnCl}_2$ , Ladenburg (A. Suppl. 8, 60) obtained indications of the formation of bromochlorides, probably  $\text{SnBr}_2\text{Cl}$  and  $\text{SnBr}_3\text{Cl}$ .

**Tin, chlorides of.** Tin and  $\text{Cl}$  combine to form two compounds,  $\text{SnCl}_2$  and  $\text{SnCl}_4$ . Both formulae are molecular.

**Stannous chloride**  $\text{SnCl}_2$ . (*Dichloride of tin. Tin-salt.*) Mol. w. 189.54; perhaps 379.08 ( $= \text{Sn}_2\text{Cl}_4$ ) in the liquid state (*v. infra*). Melts at  $249.3^\circ$  (Carnelley a. Williams, C. J. 35, 63). Boils between  $617^\circ$  and  $628^\circ$  (C. a. W., *l.c.*); at  $606^\circ$  (Biltz a. Meyer, Z. P. C. 2, 184). V.D. *v. infra*. I.F. ( $\text{SnCl}_2$ ) = 80,790; ( $\text{SnCl}_2\text{Aq}$ ) = 81,140; ( $\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$ ) = 86,520 (Th. 3, 327).

**Preparation.**—1. By heating a mixture of equal parts tin filings and  $\text{HgCl}_2$ ;  $\text{Hg}$  sublimes and leaves  $\text{SnCl}_2$ .—2. By heating tin in  $\text{HCl}$  gas.—3. By dissolving tin in warm, fairly conc.  $\text{HClAq}$ , evaporating to the crystallising point, drying the crystals of  $\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$  that separate, heating them in a capacious crucible so long as gases are given off, pouring the liquid into a small crucible, pounding when cold, and distilling from a retort; the first portions of the distillate are said to be pure  $\text{SnCl}_2$  (Capitaine, J. P. 25, 552).

**Properties.**—A semi-transparent, white solid; melts at c.  $250^\circ$  and boils at incipient redness (*v. supra*). Heated to bright redness, out of air, some  $\text{SnCl}_2$  is given off, then  $\text{SnCl}_4$ . Heated in air gives  $\text{SnCl}_2$  and  $\text{SnO}_2$ .  $\text{SnCl}_2$  dissolves in a little water; the solution is decomposed by much dilution, with separation of a hydrated oxychloride  $\text{SnCl}_2 \cdot \text{SnO} \cdot 2\text{H}_2\text{O}$ . According to Michael a. Kraft (A. Ch. [3] 41, 471), 1,000 c.c. saturated  $\text{SnCl}_2\text{Aq}$  contains, at  $15^\circ$ , 1,333 g.  $\text{SnCl}_2$  and 494 g. water, and the S.G. is 1.827. Gerlach (D. P. J. 186, 131) gives the following data for a solution of the hydrate  $\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$ :

P.c.	S.G.	P.c.	S.G.
$\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$	of solution	$\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$	of solution

VOL. IV.

An aqueous solution of  $\text{SnCl}_2$ , generally becomes turbid from ppn. of  $\text{Sn}_2\text{OCl}_2$ ; digestion with tin and a little  $\text{HClAq}$  dissolves the pp.; addition of tartaric acid, or  $\text{NH}_4\text{Cl}$ , stops the solution from becoming turbid, the former by dissolving the oxychloride, the latter by forming a double salt  $\text{SnCl}_2 \cdot 2\text{NH}_4\text{Cl}$ , which is very soluble in water.

Mallet (G. J. 35, 524) obtained a semi-transparent, jelly-like solid from an aqueous solution of  $\text{SnCl}_2$ , which had stood in a loosely closed bottle for a year & two; the solid dried to a substance like gum arabic; it reddened litmus; the composition of the substance was  $\text{SnO}_2 \cdot \text{HCl}$ . Mallet writes the formula as  $\text{SnO} \cdot \text{OH} \cdot \text{Cl}$ , and suggests the name *chlor-stannic acid*.

**Molecular weight of stannous chloride.** The V.D. of the gas obtained by heating  $\text{SnCl}_2$  has been determined repeatedly. The following table presents the results:—

Calculated for $\text{SnCl}_2$	Calculated for $\text{Sn}_2\text{Cl}_4$	Temp., and Observers
94.7	189.4	
	103.7 ? temp.	Rieth, P. 3, 668 [1870].

	123.7	" 675° Biltz
	122.9	" 699° Meyer, Z.
	119.5	" 760° P. C. 2, 184
	111.4	" 790° [1888].
	102.7	" 1113°

From their determinations, Biltz a. Meyer concluded that molecules of the composition  $\text{Sn}_2\text{Cl}_4$  do not exist in the gaseous state, and that the mol. w. of the gas comes to a constant value, corresponding with the formula  $\text{SnCl}_2$ , only at a temperature very much above the b.p. of the liquid ( $\text{SnCl}_2$  boils at  $606^\circ$ ). In some of the earlier determinations at c.  $800^\circ$  partial decomposition occurred, with production of  $\text{Cl}$ . The results, taken as a whole, seem to be explained by assuming that the molecules of the liquid, near to the b.p., have the composition  $\text{Sn}_2\text{Cl}_4$ , that some of these are dissociated to  $2\text{SnCl}_2$  at c.  $30^\circ$  above the b.p., and that this process of dissociation continues slowly, and is not completed at even  $500^\circ$  above the b.p.

**Reactions.**—1. Heated strongly in air,  $\text{SnCl}_2$  is given off, and  $\text{SnO}_2$  remains. Heated to its b.p. in a retort,  $\text{SnCl}_2$  and  $\text{SnCl}_4$  distil, and the oxychloride  $\text{Sn}_2\text{OCl}_2$  remains (Capitaine, J. Ph. 25, 552).—2. When sulphur is added to molten  $\text{SnCl}_2$ , the products are  $\text{SnCl}_2$  and  $\text{SnS}$ ; with selenium the products are  $\text{SnCl}_2$  and  $\text{SnSe}$  (Schneider, P. 127, 624).—3. Many salts are reduced by  $\text{SnCl}_2\text{Aq}$ , either to lower salts or to metals. Au, Hg, and Ag are ppd. from solutions of their salts; ferric and manganic salts are reduced to ferrous and manganous salts;  $\text{CuCl}_2\text{Aq}$  to  $\text{Cu}_2\text{Cl}_2$ .—4. The higher oxides of Bi, Cr, Pb, Mo, W, &c., are reduced to the lower oxides of these metals.—5. Arsenious oxide is reduced to As by a considerable excess of  $\text{SnCl}_2\text{Aq}$ .—6. According to Böttger (Polytech. Notizbl. 35, 96), a mixture of 2 pts.  $\text{SnCl}_2$  rubbed with 1 pt.

**potassium chlorate** gets hot, and produces an oxychloride of tin,  $\text{KClO}_4$ , oxide of chlorine, and  $\text{H}_2\text{O}$ . For reactions with water *v. supra*, *Properties*; also *infra*, *Combinations*, No. 1.

**Combinations.**—1. With water to form the hydrate  $\text{SnCl}_4 \cdot 2\text{H}_2\text{O}$ . This compound is prepared by dissolving tin in warm conc.  $\text{HClAq}$  and evaporating to the crystallising point, in contact with tin to prevent formation of  $\text{SnCl}_2$ .  $\text{SnCl}_4 \cdot 2\text{H}_2\text{O}$ , commonly known by the name of *tin-salt*, forms large white, monoclinic crystals (Marignac, *J.* 1856, 394); melts at c.  $37.7^\circ$ ; S.G.  $2.71$  at  $15.5^\circ$  (solid),  $2.588$  at  $37.7^\circ$  (liquid) (Penny, *C. J.* 4, 239). H.F.  $[\text{SnCl}_4 \cdot 2\text{H}_2\text{O}] = 86,520$  (*Th.* 3, 327). When gradually heated to  $100^\circ$ , most of the water is removed; when rapidly heated,  $\text{H}_2\text{O}$  and  $\text{HCl}$  are given off and  $\text{Sn}_2\text{OCl}_2$  remains, which gives off  $\text{SnCl}_2$  when more strongly heated.  $\text{SnCl}_4 \cdot 2\text{H}_2\text{O}$  decomposes slowly on exposure to the air, forming  $\text{Sn}_2\text{OCl}_2$  and  $\text{SnCl}_2$ .—2. With ammonia, forming  $\text{SnCl}_4 \cdot \text{NH}_3$ .—3. According to Engel (*C. R.* 106, 1398), a compound of  $\text{SnCl}_2$  with hydrogen chloride is formed by passing  $\text{HCl}$  gas over  $\text{SnCl}_4 \cdot 2\text{H}_2\text{O}$  at  $0^\circ$ ; the liquid thus formed solidifies at  $27^\circ$ , forming crystals of  $\text{SnCl}_2 \cdot \text{HCl} \cdot 3\text{H}_2\text{O}$ , which melt at  $40^\circ$ .—4. With chlorides of the alkali and alkaline earth metals, to form  $\text{MCl}_2 \cdot \text{SnCl}_4 \cdot x\text{H}_2\text{O}$ , where  $\text{M} = (\text{NH}_4)_2, \text{K}, \text{Ba}$ , or  $\text{Sr}$  (*v. Marignac, C. R.* 55, 650; Rammelsberg, *Kristall. Chemie*, 211; Richardson, *Am.* 14, 89). Poggiale (*C. R.* 20, 1180) described a salt  $\text{SnCl}_4 \cdot 4\text{NH}_4\text{Cl} \cdot 3\text{H}_2\text{O}$ . Richardson (*l.c.*) obtained  $\text{SnCl}_4 \cdot \text{KCl} \cdot \text{H}_2\text{O}$  as well as  $\text{SnCl}_4 \cdot 2\text{KCl} \cdot 2\text{H}_2\text{O}$ . These double salts are perhaps best regarded as *stannochlorides*, derived from the acid  $\text{HSnCl}_4$  (*v. Combinations*, No. 3) and the hypothetical acid  $\text{H}_2\text{SnCl}_4$ .

**STANNIC CHLORIDE**  $\text{SnCl}_4$ . (*Tetrachloride of tin*.) Mol. w. 260.28. Boils at  $113.9^\circ$  at 760 mm. (Thorpe, *C. J.* 37, 373); at  $114.1^\circ$  at 760 mm. (Young, *C. J.* 59, 912). Solidifies at  $-33^\circ$  (Besson, *C. R.* 109, 940). S.G.  $2.27875$ ;  $1.97813$  at b.p. (Thorpe, *l.c.*). V.D. 133.1 at  $124^\circ$  (Dumas, *A. Ch.* [2] 33, 385). S.H.  $1402$  ( $10^\circ$ – $15^\circ$ ) (Regnault, *A. Ch.* [3] 9, 332). Heat of vapourisation = 30,530 (gram-units for 1 kilo.) (Andrews, *C. J.* 1, 27). H.F.  $[\text{SnCl}_4] = 127,250$ ;  $[\text{SnCl}_4 \cdot \text{Aq}] = 157,170$ ;  $[\text{SnCl}_4 \cdot \text{Cl}] = 46,460$ ;  $[\text{SnCl}_4 \cdot \text{Aq} \cdot \text{Cl}] = 76,030$  (*Th.* 3, 327). C.E. (cubical,  $0^\circ$ – $100^\circ$ )  $0.0130244$  (Thorpe, *l.c.*). S.V.  $131.07$  (Thorpe, *l.c.*; for S.V. from  $0^\circ$  to  $280^\circ$  *v. Young, C. J.* 59, 933, 935). For vapour pressures from  $-10^\circ$  to  $319^\circ$  *v. Young (l.c., p. 927)*. Critical temperature =  $818.7^\circ$ ; critical pressure = 28080 mm. (*Y., l.c., p. 928*).

**Formation.**—1. By heating tin in excess, of  $\text{Cl}$ .—2. By heating 1 pt. tin filings intimately mixed with 4 or 5 pts.  $\text{HgCl}_2$ .—3. By heating a mixture of  $\text{Sn}(\text{SO}_4)_2$  and  $\text{NaCl}$ .—4. By passing vapour of  $\text{CCl}_4$  over heated  $\text{SnO}_2$  (Watts & Bell, *C. J.* 33, 442).—5. By adding fuming sulphuric acid to tin, and then passing in  $\text{HCl}$  gas and distilling (Heumann & Köchlin, *B.* 15, 416).

**Preparation.**—Dry  $\text{Cl}$  is led over tin filings heated in a retort connected with a dry flask, which is kept cold; the distillate is distilled from tin filings, and then repeatedly redistilled in a current of dry  $\text{CO}_2$ . A solution of  $\text{SnCl}_4$  is obtained by passing  $\text{Cl}$  into  $\text{SnCl}_4 \cdot \text{Aq}$  until no pp. is produced with  $\text{HgCl}_2 \cdot \text{Aq}$ , or by dis-

solving tin in dilute  $\text{HClAq}$  containing a little  $\text{HNO}_3$ .

**Properties.**—A thin, mobile, colourless, fuming, very corrosive liquid. Solidifies at  $-83^\circ$  to small white crystals (Besson, *C. R.* 109, 940).  $\text{SnCl}_4$  dissolves crystalline  $\text{S}$ , also  $\text{P}$ ,  $\text{I}$ ,  $\text{Br}$ ,  $\text{CS}_2$ , &c. (Girardin, *C. R.* 51, 1057).  $\text{SnCl}_4$  does not conduct electricity, even at its b.p.; addition of absolute alcohol forms crystals, probably  $(\text{SnCl}_4 \cdot 5\text{EtOH})$ , which conduct when dissolved; ether behaves similarly to alcohol (Coldridge, *P. M.* [5] 29, 383, 480).  $\text{SnCl}_4$  withdraws moisture from the air, probably forming  $\text{SnCl}_4 \cdot 3\text{H}_2\text{O}$  (*v. infra*, *Hydrates of stannic chloride*).  $\text{SnCl}_4$  dissolves in water, with production of heat  $[\text{SnCl}_4 \cdot \text{Aq}] = 29,920$  (*Th.* 3, 327), and considerable contraction of volume (*v. also Reactions*, No. 1). Gerlach (*D. P. J.* 178, 49) gives the following table:—

Pctge. $\text{SnCl}_4$	S.G. $\text{SnCl}_4 \cdot \text{Aq}$	Vol. of 100 pts. by wt. of solution; vol. of 100 pts. water = 100	Vol. of mixture of $\text{SnCl}_4$ and water; vol. of sum of constituents = 100
0	1.000	100.00	100.00
10	1.082	92.42	97.82
20	1.174	85.18	95.76
30	1.279	78.19	93.73
40	1.404	71.12	91.42
50	1.556	64.26	88.78
60	1.743	57.37	85.81
70	1.973	50.68	82.63
100	2.234	44.76	100.00

**Hydrates of stannic chloride.**—Various hydrates have been isolated: (1)  $\text{SnCl}_4 \cdot 3\text{H}_2\text{O}$ , by exposing  $\text{SnCl}_4$  to air (Casselmänn, *A.* 83, 272); also by adding 18 pts. water to 260 pts.  $\text{SnCl}_4$ , when  $\frac{2}{3}$  of the  $\text{SnCl}_4$  remains unchanged, and  $\frac{1}{3}$  forms the hydrate, which sinks in the excess of  $\text{SnCl}_4$  (Gerlach, *D. P. J.* 178, 49); also by dissolving 260 pts.  $\text{SnCl}_4$  in 54 pts. water, and letting the solution cool to  $60^\circ$  (*G., l.c.*); (2)  $\text{SnCl}_4 \cdot 2\text{H}_2\text{O}$ , by keeping the trihydrate in *vacuo* (Scheurer-Kestner, *C. R.* 50, 50); also by drying the pentahydrate over  $\text{H}_2\text{SO}_4$  (Lewy, *A. Ch.* [3] 16, 303); (3)  $\text{SnCl}_4 \cdot 5\text{H}_2\text{O}$ , by dissolving  $\text{SnCl}_4$  completely in water and evaporating (*G., l.c.; L., l.c.*); (4)  $\text{SnCl}_4 \cdot 8\text{H}_2\text{O}$ , by strongly cooling dilute  $\text{SnCl}_4 \cdot \text{Aq}$  (*G., l.c.*); (5)  $\text{SnCl}_4 \cdot 9\text{H}_2\text{O}$ , obtained by Nöllner (*Z.* [2] 1, 445) by treating  $\text{SnCl}_4 \cdot \text{Aq}$  with *aqua regia*, and exposing the solution to a winter temperature. Gerlach (*l.c.*) gives a table (*v. next page*), showing the S.G. and percentage composition of solutions of the pentahydrate.

**Reactions.**—1. With water:  $\text{SnCl}_4$  dissolves in water (*v. supra*) with production of much heat. Vignon (*C. R.* 108, 1049; 109, 372) found that  $\text{H}_2\text{SnO}_4$  ppd. from freshly prepared  $\text{SnCl}_4 \cdot \text{Aq}$ , from  $\text{SnCl}_4 \cdot \text{Aq}$  after keeping, and from  $\text{SnCl}_4 \cdot \text{Aq}$  after heating, showed markedly different heats of neutralisation by potash. He concluded that  $\text{SnCl}_4 \cdot \text{Aq}$  contains  $\text{HClAq}$  and  $\text{H}_2\text{SnO}_4 \cdot \text{Aq}$ , and that the  $\text{H}_2\text{SnO}_4$  in solution gradually polymerises. Dilute  $\text{SnCl}_4 \cdot \text{Aq}$  gradually decomposes, giving  $\text{HClAq}$  and  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$  (Casselmänn, *A.* 83, 272). Heating in a sealed tube with a little water is said to give  $\text{SnO}_2$ .—2. With conc. nitric acid  $\text{SnCl}_4$  forms  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ .—3. Dry hydrogen sulphide forms white crystals of  $\text{SnCl}_4 \cdot 6\text{H}_2\text{S}$ , which gives off  $\text{H}_2\text{S}$  and  $\text{HCl}$  when heated, and

leaves SnS<sub>2</sub> (Coldridge, *P. M.* [5] 29, 333, 480).—4. SnCl<sub>2</sub> dissolves *stannous oxide*, forming SnCl<sub>2</sub> and a solution of SnO<sub>2</sub>.H<sub>2</sub>O in excess of SnCl<sub>2</sub> (Scheurer-Kestner, *C. R.* 50, 50).

**Combinations.**—1. With *hydrogen chloride*. By passing dry HCl over SnCl<sub>2</sub>.5H<sub>2</sub>O, then saturating the liquid so formed with dry HCl at 28°, and cooling to 0°, Engel (*C. R.* 103, 213) obtained white crystalline leaflets of the compound SnCl<sub>2</sub>.2HCl.6H<sub>2</sub>O, melting at c. 20°, and giving off HCl when more strongly heated. The same compound was prepared by Seubert (*B. Z.* 79, 793) by adding to SnCl<sub>2</sub> such a quantity of conc. HClAq that the ratio of water in the acid was to the SnCl<sub>2</sub> as 6H<sub>2</sub>O:SnCl<sub>2</sub> (100 pts. SnCl<sub>2</sub> require 62.15 pts. of 33 p.c. HClAq), and after a little passing in c. 8 pts. dry HCl; the whole then solidified to a crystalline mass, melting at 19.2°. This

compound is best called *stannichlorhydric acid*; it has also been called *chlorostannic acid* (Mallet gave the name *chlor-stannic acid* to SnO.OH.Cl, v. STANNOUS CHLORIDE, *Properties*, p. 721), and *hydrochlorostannic acid*. Chassevant (*A. Ch.* [6] 39, 5) has described a compound SnCl<sub>2</sub>.HCl.3H<sub>2</sub>O.—2. With several *metallic chlorides*. The double salts of SnCl<sub>2</sub> and alkali and alkaline earth chlorides have the composition MSnCl<sub>2</sub>.xH<sub>2</sub>O, where M = (NH<sub>4</sub>)<sub>2</sub>, K, Na, Ba, Ca, Mg, or Sr; these salts are best named *stannichlorides* (for details, v. HOLLEY, A. 39, 101; LEWY, *J. pr.* 37, 479; Rammelsberg, *Krystall. chemie*; Wittstein, *R. P.* 64, 74; Topsoe, *W. A. B.* 69 [2] 261; Morel, *C. C.* 1891 [1] 492; Chassevant, *A. Ch.* [6] 30, 6). Cleve (*Bl.* [2] 31, 195) obtained double salts of the form xSnCl<sub>2</sub>.2MCl.xH<sub>2</sub>O, where M = Co, Bi, La, or Y, x = 2 and 5, and s had large values (from 18 to 45).—3. With certain *non-metallic chlorides*; the compound SnCl<sub>2</sub>.2SnCl<sub>4</sub> is said to be obtained by the interaction of Cl and SnS (H. Rose, *P.* 44, 320; Casselmann, *P.* 42, 517); the compound SnCl<sub>2</sub>.PCl<sub>5</sub> was obtained by Casselmann (*l.c.*) by heating a mixture of SnCl<sub>2</sub>.2SnCl<sub>4</sub> and PCl<sub>5</sub> in a stream of HCl.—4. With certain *nonmetallic oxychlorides*: (1) SnCl<sub>2</sub>.POCl<sub>3</sub> formed by the reaction of POCl<sub>3</sub> and SnCl<sub>2</sub> (Casselmann, *A.* 91, 248; 98, 213); (2) SnCl<sub>2</sub>.2SeOCl<sub>2</sub> by combining the constituent compounds (Weber, *B. B.* 1865, 154); (3) SnCl<sub>2</sub>.2NOCl by passing the dry vapour from *aqua regia* over SnCl<sub>2</sub> (Hampe, *A.* 126, 43), also by subliming SnCl<sub>2</sub>.N<sub>2</sub>O<sub>2</sub> formed by the action of N<sub>2</sub>O and NO<sub>2</sub> on SnCl<sub>2</sub> (Weber a. Hampe, *P.* 118, 471).—5. With *hydrogen sulphide* to form SnCl<sub>2</sub>.5H<sub>2</sub>S; decomposed by heating to SnS<sub>2</sub>, H<sub>2</sub>S, and HCl (Coldridge, *P. M.* [5] 29, 383).—6. With *hydrogen cyanide*, to form crystals that are decomposed in moist air (Klein, *A.* 74, 85).—7. With *ammonia*, to form SnCl<sub>2</sub>.2NH<sub>3</sub> according to H. Rose (*P.* 24, 163), to form SnCl<sub>2</sub>.4NH<sub>3</sub> according to Grouvelle a. Persoz (*A. Ch.* [2] 44, 322).—8. With *phosphorus trihydride*, to form 3SnCl<sub>2</sub>.2PH<sub>3</sub> (H. Rose, *P.* 24, 159); heated to 100° in CO<sub>2</sub> there are formed HCl and Sn<sub>2</sub>P<sub>2</sub>Cl<sub>6</sub> according to Mahu (*J. Z.* 5, 160).—9. With certain *nonmetallic oxides*: (1) with SO<sub>2</sub> to form a solid (? composition) (H. Rose, *P.* 44, 320); (2) with NO a compound is formed, according to Kuhlmann (*A.* 39, 319), but no action occurs according to Hampe (*A.* 126, 43); (3) with N<sub>2</sub>O<sub>2</sub> to form SnCl<sub>2</sub>.N<sub>2</sub>O<sub>2</sub>, produced by passing NO<sub>2</sub> and N<sub>2</sub>O over SnCl<sub>2</sub> (Hampe, *l.c.*).—10. With *ethyl alcohol*, to form SnCl<sub>2</sub>.5EtOH (Coldridge, *P. M.* [5] 29, 383, 480).—11. With *anhydrous alcohol*, to form SnCl<sub>2</sub>.2C<sub>2</sub>H<sub>5</sub>(OH) (Bauer a. Klein, *Z.* [2] 4, 370).—12. With *ether*, to form SnCl<sub>2</sub>.2Et<sub>2</sub>O (Coldridge, *l.c.*).—13. With various *nitriles*, forming crystallisable compounds (Lewy, *C. R.* 21, 371).

Tin, chlorobromides of; v. TIN BROMOCHLORIDES, p. 721.

Tin, chloro-iodide of; v. TIN IODOCHLORIDE, p. 724.

Tin, chlorosulphide of; v. TIN THIOCHLORIDE, p. 733.

Tin, ferriocyanides of; v. vol. ii. p. 340.

Tin, ferrocyanides of; v. vol. ii. p. 337.

Tin, fluorides of. Only one fluoride, SnF<sub>4</sub>, has been isolated; double salts of stannic fluoride (SnF<sub>4</sub>) are known.

**STANNOUS FLUORIDE**  $\text{SnF}_2$ . (*Diffuoride of tin*.) Formed, in small opaque, lustrous, prisms, by dissolving  $\text{SnO} \cdot x\text{H}_2\text{O}$  in HFAq, and evaporating; heated in air it forms the oxyfluoride  $\text{SnOF}_2$  ( $= \text{SnF}_2 \cdot \text{SnO}_2$ ) (Marignac, *Ann. M.* [5] 15, 221; Fremy, *A. Ch.* [3] 47, 37). By dissolving freshly pptd.  $\text{SnO} \cdot x\text{H}_2\text{O}$  in solutions of alkali fluorides acidified by HFAq, Wagner (*B.* 19, 896) obtained *stannofluorides* of the form  $x\text{SnF}_2 \cdot 2\text{MF} \cdot y\text{H}_2\text{O}$ , where  $x=1$  and 3,  $y=1$  and 2, and M was  $\text{NH}_4$ , K, and Na.

**STANNIC FLUORIDE.** This compound has not been isolated; a solution of  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$  in HFAq coagulates when heated, but does not yield any definite compound; when evaporated in air HF is given off, and an oxyfluoride,  $\text{SnOF}_2$ , is deposited (Marignac, *l.c.*).

**Stannifluorides.** A series of these salts,  $\text{MSnF}_2 \cdot x\text{H}_2\text{O}$ , where M = one atom of a divalent metal or two atoms of a monovalent metal, has been obtained by Marignac (*Ann. M.* [5] 15, 221). The salts are isomorphous with the corresponding silicofluorides and titanifluorides; they are generally obtained by saturating the stannates with HFAq and evaporating, some are formed by double decomposition from the Pb or Ag salt. The following salts have been obtained:  $\text{MSnF}_2 \cdot x\text{H}_2\text{O}$ ; M =  $\text{NH}_4$ , Ba, Cd  $x=6$ , Ca  $x=2$ , Cu  $x=4$ , Pb  $x=3$ , Li  $x=2$ , Mg  $x=6$ , Mn  $x=6$ , Ni  $x=6$ , K  $x=1$ , Ag  $x=4$ , Na, Sr  $x=2$ , Zn  $x=6$ .

**Tin, haloid compounds of.** Tin and the halogens combine to form two series of compounds,  $\text{SnX}_2$  and  $\text{SnX}_4$  ( $\text{SnF}_4$  has not been isolated). The V.D.s of  $\text{SnCl}_2$ ,  $\text{SnCl}_4$ , and  $\text{SnBr}_4$  have been determined; it is probable that the simplest formula in every case is molecular. One or two compounds of the forms  $\text{SnXX}'$  and  $\text{SnXX}'_2$  are known, where X and X' are different halogens. A few oxyhaloid compounds are known, and probably also one or two thiohaloid compounds. The compounds  $\text{SnBr}_2$  and  $\text{SnCl}_2$  combine with HBr and HCl respectively, forming acids  $\text{H}_2\text{SnBr}_4$  and  $\text{H}_2\text{SnCl}_4$ , from which series of salts, stannibromides and stannichlorides, are derived; stannifluorides are also known. An acid  $\text{HSnCl}_3$  has also been isolated, and a few stannochlorides— $\text{M}'\text{SnCl}_2$  and  $\text{M}'_2\text{SnCl}_4$ —are known, as also some stannoidides.

**Tin, hydrosulphide of.** The compound  $\text{SnS}_2\text{H}_2$ , which has probably been isolated, may be called hydrosulphide of tin (*v.* Tin, thioacids and salts *op.*, p. 733).

**Tin, hydroxides of, v. Tin oxides and hydrated oxides**, p. 725; also **Tin, oxyacids and salts**, p. 727.

**Tin, hydroxyl chloride of**,  $\text{SnO} \cdot \text{OH} \cdot \text{Cl}$ , *v. Chlor-stannic acid*, under **STANNOUS CHLORIDE**, *Properties*, p. 721.

**Tin, iodides of.** Two compounds are formed by combining tin and I; they correspond in composition with the two bromides and the two chlorides. The V.D.s of the iodides have not been determined, but the simplest formulae are probably molecular.

**STANNOUS IODIDE**  $\text{SnI}_2$ . (*Di-iodide of tin*.) Formula probably molecular.

**Preparation.**—1. Tin and I are heated together in the ratio  $\text{Sn}:\text{I}$  (1 pt. tin to 2-14 pts. I); the brown crystalline solid so formed (a mixture of  $\text{SnI}_2$  and  $\text{SnI}_4$ ) is mixed with tin

filings and heated, when orange-red  $\text{SnI}_2$ , sublimes, and  $\text{SnI}_4$  remains as a red crystalline solid mixed with particles of tin, which are easily separated (Henry, *T.* 1845, 363).—2. Conc.  $\text{KIAq}$  is added to warm conc.  $\text{SnCl}_2\text{Aq}$ ; the yellow crystalline pp. is dried and melted, out of contact with air, and a red crystalline mass of  $\text{SnI}_2$  is formed on cooling (Boullay, *A. Ch.* [2] 34, 372).—3. Tin foil is heated for some hours with fairly conc.  $\text{HIAq}$  in a sealed tube at  $120^\circ$ – $150^\circ$  (Wöhler a. Dönhaupt, *A.* 86, 374);  $\text{SnI}_2$  separates, on cooling, in shining yellow-red prisms.

**Properties and Reactions.**—A red, crystalline solid. Melts at  $316^\circ$  (Carnelley a. Williams, *C. J.* 35, 564). Slightly soluble in cold, more soluble in hot, water, without decomposition (Boullay, *l.c.*). According to Personne (*C. R.* 54, 216),  $\text{SnI}_2$  is decomposed by a large quantity of water, forming  $\text{HIAq}$  and several oxyiodides (*q. v.*).  $\text{SnI}_2$  is soluble in  $\text{SnCl}_2\text{Aq}$ . When heated out of contact with air,  $\text{SnI}_2$  melts without decomposition, but when heated in the air it is decomposed to an oxyiodide, which remains in the vessel, and  $\text{SnI}_4$ , which sublimes.

**Combinations.**—1. With **stannous chloride** to form  $\text{SnI}_2 \cdot \text{SnCl}_2$  (*v. Iodochloride, infra*).—2. With **stannous oxide** to form several oxyiodides (*q. v.*).—3. With **ammonia**, probably forming  $\text{SnI}_2 \cdot 2\text{NH}_3$  (Rammelsberg, *P.* 48, 169).—4. With **alkali iodides** and with **iodides of the alkaline earth metals** to form **stanno-iodides**; these salts have the composition  $\text{M} \cdot \text{SnI}_2 \cdot x\text{H}_2\text{O}$  and  $\text{M}'\text{SnI}_2 \cdot x\text{H}_2\text{O}$ , corresponding with the stannochlorides (*v. STANNOUS CHLORIDE, Combinations*, p. 722); M =  $\text{NH}_4$ , K, Na, also  $\frac{1}{2}\text{Ba}$  and  $\frac{1}{2}\text{Sr}$ . The stanno-iodides are formed by mixing solutions of the constituent salts, or by adding  $\text{SnCl}_2\text{Aq}$  to excess of the alkaline iodide in solution; the salts must be crystallised from alcohol, as they are decomposed by water, forming stannous oxyiodides (*v. Boullay, l.c.*; Personne, *l.c.*).

**STANNIC IODIDE**  $\text{SnI}_4$ . (*Tetra-iodide of tin*.) Formula probably molecular. This compound is probably formed by heating tin with 4-2 pts. I, and subliming from the product (Henry, *T.* 1845, 363). Schneider (*P.* 127, 624) recommends to add 6 pts.  $\text{CS}_2$  to 1 pt. tin filings, and then to add gradually, cooling frequently, 4 pts. I, and to allow the yellow liquid to evaporate.

$\text{SnI}_4$  crystallises in orange-red octahedra; melts at  $146^\circ$ , sublimes at  $180^\circ$ , and boils at  $295^\circ$  (Personne, *C. R.* 54, 216). S.G. 4.696 at  $11^\circ$  (Bödeker, *Die Beziehungen zwischen Dichten u. Zusammensetzung bei festen u. liquiden Stoffen* [Leipzig, 1860]). Solubility in  $\text{CS}_2$  at  $15^\circ$  = 145 (Schneider, *l.c.*); it is also soluble in  $\text{CHCl}_3$ ,  $\text{EtOH}$ ,  $\text{Et}_2\text{O}$ , and  $\text{C}_2\text{H}_5$ . Decomposed by water to  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$  and  $\text{HIAq}$ . Combines with ammonia to form  $\text{SnI}_4 \cdot x\text{NH}_3$ , where  $x=3, 4$ , and 6 (Personne, *l.c.*), also = 8 (Rammelsberg, *P.* 48, 169).  $\text{SnI}_4$  is said not to combine with alkali iodides.

**Tin, iodochloride of**,  $\text{SnI} \cdot \text{Cl}$  ( $= \text{SnI}_2 \cdot \text{SnCl}_2$ ). According to Henry (*T.* 1845, 363) the addition of I to conc.  $\text{SnCl}_2\text{Aq}$  causes ppn. of  $\text{SnI}_2$ , and on evaporating the mother-liquor (which contains  $\text{SnCl}_2$ ,  $\text{SnCl}_4$ , and  $\text{SnI}_4$ ) straw-yellow crystals are deposited that have the composition  $\text{SnI}_2 \cdot \text{SnCl}_2$ . The crystals are decomposed by water, with separation of  $\text{SnI}_2$ .

**Tin, iodosulphide of, v. TIN TRIO-IODIDE, p. 733.**

**Tin, oxides and hydrated oxides of.** Two oxides have been isolated,  $\text{SnO}$  and  $\text{SnO}_2$ ; various compounds of these oxides with  $\text{H}_2\text{O}$  seem to exist, but their composition readily undergoes change with variation of temperature. Both oxides interact with acids to form corresponding salts,  $\text{SnX}_2$  and  $\text{SnX}_4$ , where  $\text{X} = \text{NO}_3$ ,  $\frac{1}{2}\text{SO}_4$ ,  $\frac{1}{2}\text{PO}_4$ , &c. Some of the hydrates of  $\text{SnO}_2$  also react as weak acids, especially  $\text{SnO}_2 \cdot \text{H}_2\text{O}$  ( $= \text{H}_2\text{SnO}_3$ ), from which is derived a series of *stannates*  $\text{MSnO}_3$ ,  $\text{M} = \text{Na}$ ,  $\text{Ca}$ ,  $\text{Pb}$ , &c.; and  $x\text{SnO}_2 \cdot x\text{H}_2\text{O}$  ( $= x\text{H}_2\text{SnO}_3$ ),  $x$  probably  $= 5$ , from which is a series of *metastannates*,  $x\text{MSnO}_3$  is derived. Stannic and metastannic acids and salts derived from them are described under the heading **TIN OXYACIDS AND SALTS AND DERIVATIVES THEREOF** (p. 727). The oxides  $\text{SnO}$  and  $\text{SnO}_2$  are described in this section of the article **TIN**, and a brief account is also given of the experiments on the hydrates of these oxides other than stannic and metastannic acids.

When tin is strongly heated in air or oxygen a film forms on the surface consisting of  $\text{SnO}$  and  $\text{SnO}_2$ ; at a full red heat, or incipient white heat, tin burns to  $\text{SnO}_2$ . According to Vignon (*C. R.* 107, 734), tin ppd. by zinc from neutral  $\text{SnCl}_4\text{Aq}$  or  $\text{SnCl}_4\text{Aq}$  oxidises easily in air; after being exposed to the air for some days it contains from 20 to 33 p.c.  $\text{SnO}$ . Emich (*M.* 14, 345) found that the surface of tin that was kept molten in the air became covered with crystalline nodules of  $\text{SnO}_2$ .

**STANNOUS OXIDE  $\text{SnO}$ . (Protoxide of tin.)**  
Mol. w. not known.

**Formation.**—1. By heating finely-divided tin in the air; the metal becomes covered with a film of  $\text{SnO}$  (Vignon, *C. R.* 108, 96). Also by exposing tin ppd. by zinc from  $\text{SnCl}_4\text{Aq}$  or  $\text{SnCl}_4\text{Aq}$  to the air at ordinary temperatures (V., *C. R.* 107, 734).—2. By dehydrating  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$  ppd. from  $\text{SnCl}_4\text{Aq}$  by alkali carbonates, either by heating in a stream of  $\text{CO}_2$ , or by boiling with water containing a little  $\text{KOH}$ .—3. By dissolving  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$  in cold  $\text{KOH}$ aq, and allowing the solution to stand in the air (Ditte, *A. Ch.* [5] 27, 145).—4. By heating  $\text{SnC}_2\text{O}_4$  in a tube of hard glass without free access of air (Liebig, *A.* 95, 116).—5. By ppg. a stannous salt by  $\text{KCN}$ aq, and boiling the pp. for some days with  $\text{KCN}$ aq (Varenne, *C. R.* 89, 360).

**Preparation.**— $\text{SnCl}_4\text{Aq}$  is ppd. by  $\text{Na}_2\text{CO}_3\text{Aq}$ , the white pp. of  $\text{SnO}_2 \cdot \text{H}_2\text{O}$  is thoroughly washed with cold water, and is then boiled with water containing a little  $\text{KOH}$ aq or  $\text{NaOH}$ aq (less than sufficient to dissolve the pp.), when the  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$  is gradually dehydrated, and small black, lustrous crystals of  $\text{SnO}$  are obtained (Fremy, *A. Ch.* [3] 12, 460).—2. Tin is dissolved in warm  $\text{HCl}$ aq, the solution is evaporated, in contact with tin, until it solidifies to  $\text{SnCl}_2$  on cooling; 7 parts, or rather more,  $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$  are then added for each part of  $\text{SnCl}_2$  in the basin, and the liquid thus formed is heated with constant stirring until it becomes black, and is then allowed to cool; the brownish-black powder,  $\text{SnO}$ , thus obtained is thoroughly washed with cold water, and dried at  $100^\circ$  (Sandall, *J. pr.* 14, 254).—3. A solution of  $\text{SnCl}_2$  is ppd. by a slight excess of  $\text{KOH}$ aq in the cold, the pp. is

thoroughly washed and dissolved in cold  $\text{KOH}$ aq (c. 1 part  $\text{KOH}$  in 10 parts  $\text{H}_2\text{O}$ ); the solution, which should be saturated with  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ , is allowed to stand in the air, when  $\text{SnO}$  is gradually ppd. as small, blue-black, shining crystals (Ditte, *A. Ch.* [5] 27, 145).

**Properties and Reactions.**—Prepared by any of the methods described above,  $\text{SnO}$  forms small, black, lustrous, regular crystals (for crystalline form v. Nordenskjöld, *P.* 114, 612). S.G. 6.1 (N., *l.c.*); 6.6 at  $0^\circ$  (Betzeli; Ditte, *A. Ch.* [5] 27, 145).

According to Fremy (*A. Ch.* [3] 12, 460), another modification of  $\text{SnO}$  is obtained by heating the black crystals (prepared by the first process given above) to  $258^\circ$ ; the crystals are said to swell up and change into soft, olive-green laminae, without any change in weight.

By evaporating very dilute  $\text{NH}_4\text{Cl}$ aq, holding  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$  in suspension, until  $\text{NH}_4\text{Cl}$  began to crystallise, Fremy (*A. Ch.* [3] 12, 460) obtained a cinnabar-red powder, which he took to be a third form of  $\text{SnO}$ . Retf. (*A.* 60, 214) obtained red, crystalline  $\text{SnO}$  by digesting  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$  at  $56^\circ$ , with a solution of  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$  in acetic acid; the solution containing a little free acetic acid, and having S.G. 1.06.

For the S.G. and appearance of  $\text{SnO}$  prepared in various ways v. also Ditte (*l.c.*).

$\text{SnO}$  is unchanged in air at ordinary temperatures. According to Ditte (*A. Ch.* [5] 27, 145),  $\text{SnO}$  that separates from an alkaline solution is unchanged at  $300^\circ$ – $310^\circ$ ; when heated to redness it is partly decomposed to  $\text{Sn}$  and  $\text{SnO}_2$ , which combines with unchanged  $\text{SnO}$  to give  $2\text{SnO} \cdot \text{SnO}_2$ .  $\text{SnO}$  is readily converted into  $\text{SnO}_2$  by heating with oxidising agents; the change is effected by heating to  $500^\circ$  in  $\text{NO}$  (Sabatier a. Senderens, *C. R.* 114, 1129).  $\text{SnO}$  dissolves in acids to form stannous salts,  $\text{SnX}_2$ ,  $\text{X} = \text{NO}_3$ ,  $\frac{1}{2}\text{SO}_4$ ,  $\frac{1}{2}\text{PO}_4$ , &c.; it is not acted on by  $\text{NH}_4\text{Aq}$ ; boiled with fairly conc.  $\text{KOH}$ aq or  $\text{NaOH}$ aq it gives a solution of an alkali stannate ( $\text{M}_2\text{SnO}_3$ ) and tin; heated in  $\text{Cl}$  forms  $\text{SnCl}_2$  and  $\text{SnO}_2$ ; mixed with  $\text{S}$  and strongly heated,  $\text{SnS}_2$  and  $\text{SO}_2$  are produced;  $\text{SnO}$  is reduced to tin by heating to redness in  $\text{H}$  or with  $\text{C}$ .

**HYDRATED STANNOUS OXIDE.** The white pp. formed by adding an alkali carbonate to solution of a stannous salt, washing with air-free cold water, and drying at a temperature not above  $80^\circ$ , is said to have the composition  $2\text{SnO} \cdot \text{H}_2\text{O} = \text{Sn}_2\text{O}(\text{OH})_2$ . According to Ditte (*A. Ch.* [5] 27, 145) the pp. formed by adding  $\text{KOH}$ aq or  $\text{NaOH}$ aq to  $\text{SnCl}_4\text{Aq}$ , washing thoroughly, and drying *in vacuo* at  $14^\circ$  is  $\text{Sn}_2\text{O} \cdot 2\text{H}_2\text{O}$  ( $= \text{Sn}_2\text{O}_3 \cdot \text{H}_2\text{O}$ ). Stannous hydroxide is a yellowish white amorphous powder. It is dehydrated, to  $\text{SnO}$ , by heating in  $\text{CO}_2$ ; also by the action of boiling water containing a little  $\text{KOH}$ , or a trace of  $\text{HCl}$ , or acetic acid— $\text{HNO}_3\text{Aq}$  and  $\text{H}_2\text{SO}_4\text{Aq}$  form stannous salts; also by boiling with  $\text{NH}_4\text{Cl}$ aq (Ditte, *l.c.*). The hydroxide is gradually oxidised by exposure to air to  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ . Boiled with conc.  $\text{KOH}$ aq it gives  $\text{K}_2\text{SnO}_3\text{Aq}$  and tin. Many metallic salts are reduced, to lower salts or to the metals, by the action of  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$  (for details of the interaction with  $\text{CuO}$  in presence of alkali v. Lonsen, *J. pr.* 89, 90).

**STANNIC OXIDE  $\text{SnO}_2$ . (Dioxide of tin.)** Mol.

wt. unknown; probably at least  $\text{Sn}_{10}\text{O}_{20}$  (v. Carnelley a. Walker, *C. J.* 53, 92).

**Occurrence.**—*Tinstone* is more or less pure  $\text{SnO}_2$ ; the percentage of the oxide varies from c. 85 to c. 99, the other constituents are generally  $\text{SiO}_2$ , and oxides of Al, Fe, and Mn. *Tinstone* crystallises in quadratic forms. Crystalline  $\text{SnO}_2$  has been found in the fused slag from a furnace used for casting gun-metal (Abel, *C. J.* 10, 119).

**Formation.**—1. By exposing molten tin to the action of the air (Emich, *M.* 14, 345).—2. By heating to c.  $600^\circ$   $\text{SnO}_2 \cdot x\text{H}_2\text{O}$  formed by the interaction of tin and  $\text{HNO}_3$  aq. or of alkalis and stannic salts, or of alkali stannates and dilute acids.—3. By strongly heating  $\text{SnO}$  or  $\text{SnO} \cdot x\text{H}_2\text{O}$ .—4. By passing a mixture of vapour of  $\text{SnCl}_4$  and steam through a red-hot tube.—5. By heating  $\text{SnC}_2\text{O}_4$  in small quantities, in contact with the air (Vogel, *C. C.* 1855, 413).—6. By passing a little  $\text{CO}_2$  into a dilute solution of an alkali stannate (Ditte, *A. Ch.* [6] 30, 282).

**Preparation.**—A. Crystalline stannic oxide.—1. Molten tin is kept in contact with the air until the surface becomes covered with crystalline nodules of  $\text{SnO}_2$  (Emich, *M.* 14, 345). 2. A stream of  $\text{CO}_2$  is passed through  $\text{SnCl}_4$ , and then through a red-hot porcelain tube through which a current of steam is passed at the same time (Daubrée, *C. R.* 29, 227).—3. Amorphous  $\text{SnO}_2$  is strongly heated in a rapid current of dry  $\text{HCl}$  (Deville, *C. R.* 53, 161).—4.  $\text{SnC}_2\text{O}_4$  is strongly heated, in small quantities at a time, in an open porcelain or silver dish (Vogel, *C. C.* 1855, 413).

B. Amorphous stannic oxide.—5. The hydrated stannic oxide obtained by ppg. a stannic salt by an alkali, decomposing an alkali stannate solution by dilute acid, or by treating tin with  $\text{HNO}_3$  aq. is thoroughly washed and dried, and then heated to c.  $630^\circ$ , at which temperature dehydration is complete (Carnelley a. Walker, *C. J.* 53, 83).

**Properties.**—Crystalline stannic oxide is a hard, lustrous, white solid. It is dimorphous. Prepared by heating the amorphous oxide in  $\text{HCl}$  gas,  $\text{SnO}_2$  crystallises in quadratic forms isomorphous with *tinstone* and *anatase* ( $\text{TiO}_2$ ) (Daubrée, *C. R.* 29, 227); prepared by decomposing vapour of  $\text{SnCl}_4$  by steam, it crystallises in trimetric prisms isomorphous with *brookite* ( $\text{TiO}_2$ ). S.G. of crystalline  $\text{SnO}_2 = 6.7$  to  $6.85$  (Playfair a. Joule, *C. J.* 1, 137; Mallet, *J.* 3, 705; Bergemann, *J.* 10, 661; Daubrée, *C. R.* 29, 227). The crystals obtained by long continued heating molten tin in air had S.G. 7.0096 at  $4^\circ$  (Emich, *M.* 14, 345). Crystalline  $\text{SnO}_2$  is hard enough to scratch glass. The amorphous oxide has S.G. 6.6 to 6.9 (P. a. J., l.c.; Herapath, *P. M.* 64, 321; Boullay, *A. Ch.* [2] 43, 266). It is a hard, yellowish-white powder.  $\text{SnO}_2$  has not been fused. It is not acted on by acids (but v. *Reactions*, No. 6). Fusion with  $\text{KOH}$  or  $\text{NaOH}$  forms  $\text{M}_2\text{SnO}_3$ , which dissolves in water. The product of fusion with  $\text{KHSO}_4$  dissolves in water, but addition of more water ppts. all the tin as  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ .

Mallet (*C. J.* 85, 524) obtained a compound  $\text{SnO} \cdot \text{HCl}$ , to which he gave the formula  $\text{SnO} \cdot \text{OH} \cdot \text{Cl}$ , and the name *chlor-stannic acid*, by keeping  $\text{SnCl}_4$  for a year or two in a loosely closed bottle.

**Reactions.**—1. Fusion with sulphur produces  $\text{SnS}_2$  and  $\text{SO}_2$ .—2. When strongly heated in chlorine  $\text{SnCl}_4$  is formed.—3.  $\text{SnO}_2$  is reduced to tin by heating to a high temperature in hydrogen, or with potassium, sodium, or carbon, or in carbonic oxide.—4. Fusion with caustic potash or caustic soda forms alkali stannate ( $\text{M}_2\text{SnO}_3$ ), which dissolves in water.—5. Heating with phosphorus trichloride to  $160^\circ$  forms  $\text{SnCl}_2$ ,  $\text{SnCl}_4$ , and  $\text{P}_2\text{O}_5$  (Michaelis, *J. Z.* 6, 239; 7, 110).—6. According to Ditte (*C. R.* 104, 172),  $\text{SnO}_2$  dissolves very slowly in hot sulphuric acid (1 acid to 8 water), and on concentrating till not more than 3 or 4 vols. water are present to 1 vol.  $\text{H}_2\text{SO}_4$ , crystals of  $\text{SnO}_2 \cdot 2\text{H}_2\text{SO}_4$  separate.

HYDRATED STANNIC OXIDE. Carnelley a. Walker (*C. J.* 53, 60, 68, 83) examined the dehydrating action of heat on  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ , obtained by decomposing  $\text{Na}_2\text{SnO}_3$  aq. by cold dilute  $\text{HCl}$  aq. and drying the pp. in the air for five months. The pp. lost less and less weight for each increase of c.  $10^\circ$  from  $50^\circ$  to c.  $110^\circ$ , at which temperature rather less water was present than corresponded with the formula  $\text{SnO}_2 \cdot \text{H}_2\text{O}$ , the loss of weight for each rise of  $10^\circ$  was then approximately constant up to c.  $360^\circ$ , at which temperature the composition was nearly that required by the formula  $3\text{SnO}_2 \cdot \text{H}_2\text{O}$ ; at a little above  $360^\circ$  the solid changed colour from brown to pale yellow, and at the same time lost weight at a rate nearly three times as great as during the previous rise of  $100^\circ$ ; after changing colour the solid had the composition  $7\text{SnO}_2 \cdot 2\text{H}_2\text{O}$ ; the loss of weight, per  $10^\circ$  increase, then decreased very much for the next  $30^\circ$  or  $40^\circ$ , and after that dehydration continued irregularly until at  $630^\circ$ – $635^\circ$  the oxide  $\text{SnO}_2$  remained. From these results, considered with results obtained by the same method for other hydrated oxides, C. a. W. concluded that probably a large number of hydrates of  $\text{SnO}_2$  exists, but that none of these is stable through more than a very small range of temperature. The results of J. van Bemmelen (*B.* 13, 1466) on the dehydration by heat of stannic hydrates, obtained by oxidising tin by  $\text{HNO}_3$  aq. and by decomposing  $\text{SnCl}_4$  aq. by  $\text{CaCO}_3$ , and on the rehydration of the products obtained by heat, by placing them in air more or less saturated with moisture, at different temperatures, show that the quantity of water of hydration varies with variations in temperature, in the molecular states of the solids, and in the moistness of the surrounding air. Not only does the quantity of water of hydration vary with variations in the molecular state of the hydrates, but the firmness or looseness wherewith the water is held also varies much as the molecular condition varies. According to J. van B. the loosely held water is given up in dry air; and when the product is placed in moist air water is taken up until a state of equilibrium is attained wherein as many molecules of water are taken up as are lost in the unit of time.

The following compositions have been given to different hydrates of  $\text{SnO}_2$ .

1. *Hydrates obtained by decomposing soluble stannates by dilute acids:* (1)  $8\text{SnO}_2 \cdot 7\text{H}_2\text{O}$ , by drying in a stream of dry air (Fremy, *A. Ch.* [8] 12, 462); (2)  $\text{SnO}_2 \cdot 2\text{H}_2\text{O}$ , by drying in the air at the ordinary temperature (Weber, *P.* 122, 358); (3)  $\text{SnO}_2 \cdot \text{H}_2\text{O}$ , by drying *in vacuo* (Fremy,

(*l.c.*); (4)  $8\text{SnO}_2 \cdot 2\text{H}_2\text{O}$ , by drying at  $140^\circ$  (Freymy, *l.c.*); to these should probably be added (5)  $78\text{SnO}_2 \cdot 2\text{H}_2\text{O}$ , by drying at c.  $365^\circ$  (Carnelley & Walker, *l.c.*).

II. *Hydrates obtained by oxidising tin by  $\text{HNO}_3$  aq.*: (6)  $58\text{SnO}_2 \cdot 10\text{H}_2\text{O}$ , by drying at the ordinary temperature (Freymy, *l.c.*); (7)  $58\text{SnO}_2 \cdot 5\text{H}_2\text{O}$ , by drying at the ordinary temperature (Thomson, *Ann. Phil.* 1817, 149), by drying over  $\text{H}_2\text{SO}_4$  (Weber, *l.c.*), by drying *in vacuo*, or at  $100^\circ$  (Freymy, *l.c.*); (8)  $58\text{SnO}_2 \cdot 4\text{H}_2\text{O}$ , by drying at  $130^\circ$  (Freymy, *l.c.*); (9)  $58\text{SnO}_2 \cdot 3\text{H}_2\text{O}$ , by drying at  $160^\circ$  (Freymy, *l.c.*); (10)  $2\text{SnO}_2 \cdot \text{H}_2\text{O}$ , by drying at  $55^\circ$  (Thomson, *l.c.*).

The hydrates obtained by decomposing stannates by dilute acids, or by ppg. stannic salts by  $\text{CaCO}_3$  or  $\text{BaCO}_3$ , differ in properties from the hydrates obtained by oxidising tin by  $\text{HNO}_3$  aq.; the former are generally distinguished as *stannic hydrates*, and the latter as *metastannic hydrates*. The stannic hydrates, dried in air, form hard, semi-transparent lumps, like gum arabic; soluble in the stronger acids, forming stannic salts  $\text{SnX}_4$ , where  $\text{X} = \text{NO}_3, \frac{1}{2}\text{SO}_4$ , &c.; soluble in alkali solutions, forming stannates  $\text{M}_2\text{SnO}_3$  (*v. Stannates*, under TIN OXYACIDS, AND SALTS AND DERIVATIVES THEREOF, *infra*). Metastannic hydrates are white solids (? crystalline) that do not dissolve in  $\text{HNO}_3$  aq. or  $\text{H}_2\text{SO}_4$  aq. (*v. infra*). These hydrates interact with  $\text{HCl}$  aq., and the product is soluble in water but insoluble in conc.  $\text{HCl}$  aq.; according to Weber (*P.* 122, 358), the solution gives  $\text{SnCl}_4 \cdot 3\text{SnO}_2 \cdot 5\text{H}_2\text{O}$ , when evaporated over  $\text{H}_2\text{SO}_4$ ; by prolonged boiling, with fresh additions of water, all the tin in the solution is ppg. as metastannic hydrate (Freymy, *A. Ch.* [3] 12, 463; 23, 393). Metastannic hydrates dissolve in  $\text{KOH}$  aq. and  $\text{NaOH}$  aq., forming metastannates  $\text{M}_2\text{H}_2\text{SnO}_3$  (*v. Metastannates*, under TIN OXYACIDS, AND SALTS AND DERIVATIVES THEREOF, p. 730).

According to Ditte (*C. R.* 104, 172), both stannic and metastannic hydrates dissolve in warm  $\text{H}_2\text{SO}_4$  aq. (1 part acid and 8 parts water), and on concentrating till not more than 3 to 4 vols. water are present to 1 vol.  $\text{H}_2\text{SO}_4$ , the solution deposits white crystals of  $\text{SnO}_2 \cdot 2\text{H}_2\text{SO}_4$ ; these crystals are very deliquescent; they are decomposed by water; if so much water is added that not more than 43 g.  $\text{H}_2\text{SO}_4$  are present in 1,000 c.c. of the liquid, a pp. of  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$  is formed. By dissolving stannic or metastannic hydrate in warm  $\text{H}_2\text{SeO}_4$  aq., and concentrating, D. (*l.c.*) obtained crystals of  $\text{SnO}_2 \cdot 2\text{H}_2\text{SeO}_4$ .

For further details of reactions of stannic and metastannic hydrates *v. TIN OXYACIDS, AND SALTS AND DERIVATIVES THEREOF (infra)*.

OXIDES OF TIN OTHER THAN STANNOUS AND STANNIC OXIDES. Oxides which are most simply regarded as  $x\text{SnO}_2 \cdot y\text{SnO}$  seem to exist.

According to Fuchs (*J. pr.* 5, 318), a greyish-white, slimy solid, having the composition  $\text{SnO} \cdot \text{SnO}_2 (= \text{Sn}_2\text{O}_3)$ , is obtained by diffusing freshly ppg.  $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$  in  $\text{SnCl}_4$  aq. free from acid, and boiling

$(2\text{SnCl}_4 \text{ aq.} + \text{Fe}_2\text{O}_3 = \text{SnO} \cdot \text{SnO}_2 + 2\text{FeCl}_4 \text{ aq.})$ . This oxide is said to dissolve completely in  $\text{NH}_3$  aq., and also in  $\text{HCl}$  aq.

By digesting  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$  ppg. by alkali from  $\text{SnCl}_4$  aq., with  $\text{SnCl}_4$  aq. Schiff (*A.* 120, 53) obtained an orange-yellow solid, to which he gave

the composition  $\text{SnO} \cdot 6\text{SnO}_2 \cdot 5\text{H}_2\text{O}$ ; by digesting  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ , formed by oxidising tin with  $\text{HNO}_3$  aq., with  $\text{SnCl}_4$  aq. Schiff (*l.c.*) obtained a yellow powder, said by him to be  $\text{SnO} \cdot 6\text{SnO}_2 \cdot 9\text{H}_2\text{O}$ , or when dried at  $85^\circ$  to be  $\text{SnO} \cdot 6\text{SnO}_2 \cdot 4\text{H}_2\text{O}$  (*v. also Tschermak, C. C.* 1862, 305).

PURPLE OF CASSIUS. A purple-coloured solid is obtained by adding solution of a stannous salt to dilute  $\text{AuCl}_3$  aq.; this solid has been examined by many chemists, who have generally assigned to it formulæ which represent it as a compound of  $\text{SnO}_2$ , sometimes of  $\text{SnO} \cdot \text{SnO}_2$ , and  $\text{AuO}$ . According to the most recent investigations the composition varies according to the conditions of preparation, and all that can be said with certainty is that the purple solid is a compound of tin, gold, and oxygen (*v. Buisson, J. Ph.* 16, 629; Bohlen, *Ar. Ph.* 57, 277; Capaun, *J. pr.* 22, 153; Fuchs, *J. pr.* 5, 318; Wächter, *A.* 68, 116; Fignier, *Ph. C.* 1844, 724; Debray, *C. R.* 100, 1035; Müller, *J. pr.* [2] 30, 252; and, for a bibliography (to 1866), Fischer, *D. P. J.* 182, 39).

Tin oxyacids, and salts and derivatives thereof. Some of the hydrates of  $\text{SnO}_2$  interact with alkalis to produce salts wherein tin forms part of the acidic radicle; compounds are also known the acidic radicles whereof contain tin in combination with other negative elements besides oxygen, or tin in combination with both metallic and nonmetallic elements.

The reactions of the hydrates of  $\text{SnO}_2$  ppg. from solutions of stannates by dilute cold acids, or ppg. from stannic salts by alkalis, are distinctly different from the reactions of the hydrates of  $\text{SnO}_2$  obtained by oxidising tin by  $\text{HNO}_3$  aq., or by ppg. by dilute acids from solutions of another class of salts which have the same composition as stannates, except that they always contain H and O in the ratio  $2\text{H}:\text{O}$  in addition to the constituents of stannates. It is therefore usual to distinguish the acidic hydrates of  $\text{SnO}_2$  as *stannic* and *metastannic acids*; to the former is given the composition  $\text{H}_2\text{SnO}_3 (= \text{SnO}_2 \cdot \text{H}_2\text{O})$ , and to the latter the composition  $\text{H}_2\text{Sn}_2\text{O}_5 (= 5\text{SnO}_2 \cdot 5\text{H}_2\text{O})$ . Neither of these formulæ is to be regarded as more than an attempt to connect the differences in the chemical behaviour of two compounds having identical percentage compositions (if the  $\text{H}_2\text{O}$  in one class is omitted) with differences in the complexities of their interacting atomic aggregates; the molecular weight of neither compound is known. It is, indeed, doubtful whether a compound with the composition  $x\text{H}_2\text{SnO}_3$  can exist apart from other hydrates of the composition  $y\text{SnO}_2 \cdot z\text{H}_2\text{O}$ ; it is certain that the composition of the hydrates of  $\text{SnO}_2$  varies with very small variations of temperature, by whatever methods these hydrates are prepared (*v. p.* 726, HYDRATED STANNIC OXIDE).

That the hydrates of  $\text{SnO}_2$  obtained respectively by ppg. solution of stannates by dilute acids and by oxidising tin by  $\text{HNO}_3$  aq., differed in their reactions, was noticed by Berzelius in 1811 (*v. Lehrbuch* [5th ed.] 2, 596). Berzelius regarded these compounds as hydrates of two different modifications of stannic oxide; he called the oxide supposed to be a constituent of the hydrates obtained by ppg. solutions of stannates *stannic oxide*, and designated it as  $\alpha\text{SnO}_2$ ; the other

oxide he called *metastannic oxide*, and designated it as  $\text{bSnO}_2$ . Gmelin called the hydrate from stannates *ordinary stannic acid*, and the other hydrate *abnormal stannic acid*.

#### STANNIC ACID $\text{H}_2\text{SnO}_4$ .

**Preparation.**—By adding cold dilute  $\text{HClAq}$  to an aqueous solution of  $\text{K}_2\text{SnO}_3$  prepared by fusing  $\text{SnO}$  with  $\text{KOH}$ , or by heating tin with  $\text{KOH}$  and  $\text{KNO}_3$  (*v. POTASSIUM STANNATE*, p. 730), a gelatinous pp. is obtained which, when washed and dried *in vacuo*, has the composition  $\text{SnO}_2 \cdot \text{H}_2\text{O} = \text{H}_2\text{SnO}_4$  (Freymy, *A. Ch.* [3] 12, 463). The same hydrate is formed, according to F. (l.c.), by adding  $\text{CaCO}_3$  or  $\text{BaCO}_3$  to excess of  $\text{SnCl}_4\text{Aq}$ , washing, and drying *in vacuo*. (For details regarding the results obtained by different chemists who have examined the compositions of the stannic hydrates, *v. HYDRATED STANNIC OXIDE*, p. 726). Graham (*T.* 1861. 213) obtained colloidal stannic acid (no analyses are given) by dissolving  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$  ppd. from a stannic salt (? by alkali from  $\text{SnCl}_4\text{Aq}$ ) in  $\text{SnCl}_4\text{Aq}$ , and dialysing until all the Cl had passed into the dialysate. Colloidal forms of stannic acid are also obtained (1) by dialysing a solution of the ppd. acid in  $\text{HClAq}$  or in an alkali; (2) by the action of  $\text{CO}_2$ , or of air, on an alkaline solution of the ppd. acid (J. van Bemmelen, *R. T. C.* 7, 87; *abstract in C. J.* 54, 1160 [1888]; the results of experiments on the dehydration of the colloidal acid are given).

**Properties and Reactions.**—A gelatinous, amorphous solid, drying (in air or *in vacuo*) to hard, semi-transparent lumps, like gum arabic. Reddena litmus paper. Vignon (*C. R.* 108, 1049) found that the heat of neutralisation, by  $\text{KOH}\text{Aq}$ , of stannic acid formed by ppd.  $\text{SnCl}_4\text{Aq}$  by  $\text{KOH}\text{Aq}$ , decreased when the ppd. acid was kept in contact with water for some days, and decreased more rapidly when the acid was heated with water in a sealed tube for some hours. J. van Bemmelen (*J. pr.* [2] 23, 324) found that when stannic acid is shaken with solutions of  $\text{HCl}$ , or  $\text{H}_2\text{SO}_4$ , or with solutions of certain salts, such as  $\text{KCl}$  or  $\text{K}_2\text{SO}_4$ , a definite number of molecules of the acid or salt is taken up by the stannic acid so as to form a loose combination therewith; and that the number of molecules thus absorbed varies with the proportion between the quantities of stannic acid and the acid or salt in the solution used, and also with the concentration of the solution used. The loose compounds thus formed are called *absorption-compounds* by J. van B. Dissolves in the stronger acids ( $\text{HNO}_3$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{HCl}$ , &c.). According to Ditte (*C. R.* 104, 172), when a solution of stannic acid in warm  $\text{H}_2\text{SO}_4\text{Aq}$  (1 part acid to 8 parts water) is evaporated until not more than 5 to 4 vols. water are present to 1 vol.  $\text{H}_2\text{SO}_4$ , and allowed to cool, it yields white deliquescent crystals of  $\text{SnO}_2 \cdot 2\text{H}_2\text{SO}_4$ ; and a solution of stannic acid in warm  $\text{H}_2\text{SeO}_4\text{Aq}$  yields a similar crystalline compound  $\text{SnO}_2 \cdot 2\text{H}_2\text{SeO}_4$ . Dissolves in excess of caustic alkali solutions, forming stannates (*g. v. p.* 730)  $\text{M}_2\text{SnO}_3$ . According to J. van B. (l.c.) colloidal stannic acid does not form any compound when shaken with dilute cold  $\text{KOH}\text{Aq}$ , but only complex molecular aggregates, the composition of which varies considerably with temperature and concentration. Stannic acid, dried at the ordinary temperature by pressure, is

gradually changed to metastannic acid by heat; the change begins at c.  $55^\circ$  (J. van B., l.c.; *v. also infra*, *Change of stannic to metastannic acid, and vice versa*). For other reactions of stannic acid *v. infra*, *Distinctions between stannic and metastannic acids*.

#### METASTANNIC ACID $\text{H}_2\text{SnO}_3$ .

**Preparation.**—Tin, in thin pieces or granulated, is heated with  $\text{HNO}_3\text{Aq}$ , S.G. c. 1.35, until the metal is converted into a greyish-white powder, which is washed with dilute  $\text{HNO}_3\text{Aq}$ , and then with water, and dried. The solid is said to have the composition  $\text{H}_2\text{SnO}_3$  ( $= 5\text{SnO}_2 \cdot 5\text{H}_2\text{O}$ ) when dried *in vacuo* (Freymy, *A. Ch.* [3] 12, 463), when dried over  $\text{H}_2\text{SO}_4$  (Weber, *P.* 122, 358), or when dried at the ordinary temperature (Thomson, *Ann. Phil.* 1817. 149). For details of the results obtained by different chemists who have examined the compositions of the metastannic hydrates *v. HYDRATED STANNIC OXIDE* (p. 726); *v. also J. van Bemmelen, R. T. C.* 7, 87 (*abstract in C. J.* 54, 1160 [1888]). It should be noted that the empirical formula assigned to metastannic acid dried *in vacuo* (Freymy), or dried over  $\text{H}_2\text{SO}_4$  (Weber), is the same as that assigned to stannic acid dried *in vacuo* (Freymy); this formula is  $\text{SnO}_2 \cdot \text{H}_2\text{O}$ . The different reactions of the two compounds show that if both have the same empirical formula one must be an isomeride or a polymerside of the other. Metastannic acid is also obtained by decomposing an aqueous solution of the sodium salt (*v. p.* 730, *Metastannates*) by boiling. Graham (*T.* 1861. 213) obtained colloidal metastannic acid by adding a little  $\text{HClAq}$  to the acid obtained by the action of  $\text{HNO}_3\text{Aq}$  on tin, dissolving the solid so formed in water, and dialysing. Vignon (*C. R.* 108, 1049) found that the heat of neutralisation of metastannic acid by  $\text{KOH}\text{Aq}$  decreased when the acid was dried at  $110^\circ$ , and decreased very considerably when the acid was heated with water, for some hours, at  $250^\circ$  in a sealed tube.

**Properties and Reactions.**—A white powder. Insol. in nitric acid. Contact with conc.  $\text{HClAq}$  for a short time produces a compound (according to J. van Bemmelen, *R. T. C.* 7, 87; *abstract in C. J.* 54, 1160 [1888]), no definite compound is formed, but only complex molecular aggregates of metastannic acid and  $\text{HCl}$  which dissolves in water, but is insol. in  $\text{HClAq}$ . According to Barfoed (*J. pr.* 101, 298), the compound with  $\text{HCl}$  is quite insol. in  $\text{HClAq}$  S.G. 1.1, and may be purified by washing with acid of that concentration. The solution of this substance in water gives off  $\text{HCl}$  and  $\text{H}_2\text{O}$  with a very little  $\text{SnCl}_4$  when distilled; and metastannic acid separates out (Freymy, *A. Ch.* [3] 12, 463; 23, 893; H. Rose, *A.* 68, 272). Evaporation of the aqueous solution over  $\text{H}_2\text{SO}_4$  is said to give an oxychloride  $3\text{SnO}_2 \cdot \text{SnCl}_4 \cdot 5\text{H}_2\text{O}$  (Weber, *P.* 123, 358). Metastannic hydrate dissolves in conc.  $\text{HClAq}$  after prolonged boiling, forming  $\text{SnCl}_4$  solution (Löwenthal, *J. pr.* 77, 321). Barfoed (l.c.) says that conc.  $\text{HClAq}$  gradually converts recently ppd. and moist metastannic acid into stannic acid, and that the quantity of metastannic acid thus changed increases with the quantity of conc.  $\text{HClAq}$ , the time of contact, and the temperature. J. van Bemmelen (*J. pr.* [2] 23, 324) found that metastannic acid forms *absorption-compounds* with  $\text{HCl}$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{KCl}$ ,  $\text{K}_2\text{SO}_4$ , &c.

(cf. STANNIC ACID, *Properties*, p. 728). For other reactions of the solution in water of the product of the action of HClAq on metastannic acid *v. infra*, *Distinctions between stannic and metastannic acids*. According to Ditte (C. R. 104, 172), metastannic acid dissolves in warm  $\text{H}_2\text{SO}_4\text{Aq}$  (1 pt. acid to 8 pts. water), forming a solution which gives crystals of  $\text{SnO}_2 \cdot 2\text{H}_2\text{SO}_4$  when evaporated until not more than 3 to 4 vols. water are present for one vol.  $\text{H}_2\text{SO}_4$ ; the crystals are decomposed by water, with ppn. of  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$  (? metastannichydrate), when sufficient water is added to insure that not more than 43%  $\text{H}_2\text{SO}_4$  are present in 1,000 c.c. of the liquid. A similar compound was obtained with selenic acid, viz.  $\text{SnO}_2 \cdot 2\text{H}_2\text{SeO}_4$  (D., *l.c.*). Allen (C. J. 25, 274) found that metastannic acid dissolved in boiling conc.  $\text{H}_2\text{SO}_4$ , forming  $\text{Sn}(\text{SO}_4)_2$  solution; by pouring this solution into water some of the tin was ppd., after a time, as stannic acid, but on boiling the whole of the tin came down as metastannic acid. Metastannic acid is said to dissolve slowly in fairly dilute cold KOHAq or NaOHAq; addition of conc. KOHAq or NaOHAq is said to ppt. K or Na metastannate; when the solution in KOHAq or NaOHAq stands in the air metastannic acid gradually deposits. According to J. van Bemmelen (*l.c.*), colloidal metastannic acid does not form any definite compound with KOH when shaken with KOHAq of different concentrations. By fusing metastannic acid with  $\text{KHSO}_4$  or  $\text{NaHSO}_4$ , Allen (C. J. 25, 274) obtained a product which dissolved partially in water; the aqueous solution gave a pp. of metastannic acid on boiling.

*Distinctions between stannic and metastannic acids* (v. Frey, A. Ch. [3] 12, 462; 23, 393; H. Rose, P. 75, 1; 105, 561; Löwenthal, J. pr. 77, 321; Barfoed, J. pr. 101, 368; J. van Bemmelen, R. T. C. 7, 87; abstract in C. J. 54, 1160 [1888]).—Stannic acid is soluble in dilute  $\text{HNO}_3\text{Aq}$ ,  $\text{H}_2\text{SO}_4\text{Aq}$ , or HClAq; metastannic acid is insol. in these acids. Cold conc. HClAq dissolves stannic acid, and the solution gives the reactions of  $\text{SnCl}_4$ ; cold conc. HClAq forms a compound (? molecular aggregates) with metastannic acid, which is insol. HClAq of S.G. 1.1, or greater S.G., but dissolves in cold water.

The following reactions apply to solutions of stannic acid in HClAq on the one hand, and to solutions in water of the substance formed by the action of HClAq on metastannic acid on the other hand. Stannic acid solution, if conc., does not become turbid on boiling; long continued boiling, with additions of water, ppts. all the acid. Metastannic acid solution, even when conc., goes turbid on boiling; long-continued boiling, accompanied by dilution, ppts. all the acid. Stannic acid solution, when distilled, gives off  $\text{H}_2\text{O}$ , with a little HCl and  $\text{SnCl}_4$ ; and a little stannic acid separates. According to Barfoed (J. pr. 101, 368), when a solution of stannic acid in HClAq S.G. 1.1 is distilled, the whole of the tin passes over as  $\text{SnCl}_4$ . Metastannic acid solution, when distilled, gives off  $\text{H}_2\text{O}$ , with some HCl and a very little  $\text{SnCl}_4$ , and the meta-acid separates in the retort. Addition of tartaric acid to the stannic solution, followed by gradual addition of  $\text{NH}_3\text{Aq}$ , excess of  $\text{NH}_3\text{Aq}$  being avoided, produces no pp. Treatment of the metastannic solution with tartaric acid and  $\text{NH}_3\text{Aq}$  (not in

excess) ppts. the meta-acid.  $\text{SnCl}_4\text{Aq}$  gives no pp. with the stannic solution;  $\text{SnCl}_4\text{Aq}$  gives a yellowish pp. (?  $\text{SnO} \cdot 6\text{SnO}_2 \cdot 9\text{H}_2\text{O}$ ) with the metastannic solution. Addition of dilute  $\text{H}_2\text{SO}_4\text{Aq}$  to the stannic solution produces no pp., unless the stannic solution is very much diluted. Dilute  $\text{H}_2\text{SO}_4\text{Aq}$  produces a pp. even in very dilute metastannic solution; by washing this pp. with hot water, metastannic acid remains (cf. Ditte's experiments are described under both STANNIC ACID and METASTANNIC ACID, pp. 728, 729). The stannic solution is not ppd. by conc. HClAq. The metastannic solution, if nearly neutral, is ppd. by conc. HClAq. Addition of  $\text{K}_2\text{FeCy}_6\text{Aq}$  to the stannic solution, in the ratio  $\text{K}_2\text{FeCy}_6:\text{Sn}$  present, ppts. all the tin as  $\text{SnKFeCy}_6$ . To ppt. all the tin from the metastannic solution, the  $\text{K}_2\text{FeCy}_6\text{Aq}$  must be added in a. the ratio  $19\text{K}_2\text{FeCy}_6:\text{Sn}$  present; the pp. is not  $\text{SnKFeCy}_6$ , it is said by some observers to be metastannic acid; J. van B. (*l.c.*) calls it an *absorption compound* of metastannic acid and  $\text{K}_2\text{FeCy}_6$ . The stannic solution gives no pp. with excess of fairly conc. NaOHAq. The metastannic solution is completely ppd., as sodium metastannate, by excess of fairly conc. NaOHAq.

*Change of stannic to metastannic acid and vice versa*. A solution of stannic acid in HClAq gradually changes to metastannic acid; the change is the more rapid and complete the more dilute the solution (H. Rose, *l.c.*; Barfoed, *l.c.*); by boiling for some time with repeated additions of water the whole of the stannic acid may be converted into metastannic acid. A very conc. solution of stannic acid in HClAq remains unchanged (cf. reaction of meta-acid with conc. HClAq, *infra*). According to Löwenthal (*l.c.*), the change from stannic to metastannic acid is stopped by addition of tartaric acid, even when the solution of stannic acid in HClAq is dilute; the amount of change to the meta-acid may be determined (according to L., *l.c.*) by finding the quantity of  $\text{K}_2\text{FeCy}_6\text{Aq}$  required to completely ppt. the tin in solution. Barfoed (*l.c.*) says the best way to measure the amount of change is to add excess of fairly conc. NaOHAq, which ppts. all the meta-acid (as a sodium salt) but none of the stannic acid.

Stannic acid is converted into the meta-acid by heat (H. Rose, *l.c.*). J. van Bemmelen (*l.c.*) found that stannic acid dried by pressure at the ordinary temperature is completely soluble in conc. HClAq, but that by heating to c.  $55^\circ$ , or by heating with water to below  $100^\circ$ , some metastannic acid is formed which is insoluble in conc. HClAq.

A solution of stannic acid in excess of KOHAq gradually deposits metastannate of K on exposure to air, with formation of  $\text{K}_2\text{CO}_3\text{Aq}$ .

Metastannic acid is gradually changed to stannic acid, according to Barfoed (*l.c.*), by contact with conc. HClAq; the quantity of stannic acid produced increases with the quantity of HClAq used, the time of contact, and the temperature.

Stannic acid is said to be obtained from the meta-acid by fusing the latter with a large excess of KOH, dissolving in water, and ppg. by cold dilute HClAq (H. Rose, *l.c.*; Frey, *l.c.*).

OXYACIDS OF TIN OTHER THAN STANNIC AND METASTANNIC. (1)  $\text{H}_2\text{SnO}_3$ . Spring. [24] [5] 1.

180) obtained a colloidal solid, drying at  $100^{\circ}$  to a white mass with the composition  $H_2SnO_3$ , by adding excess of  $BaO \cdot xH_2O$  to a solution of  $SnCl_4$  in  $HClAq$ , and dialysing the turbid liquid until  $BaCl_2$  ceased to pass into the dialysate. S. regarded the new compound as an acid of the hypothetical perstannic oxide  $SnO_4$ , analogous to  $CeO_4$ ,  $TiO_4$ , and (?)  $ZnO_4$ . (2)  $Pt_2Sn_2O_7$  and  $H_2Sn_2O_7$ . The empirical formula of both these hydrates of stannic oxide is  $SnO_2 \cdot H_2O$ . According to Musculus (*C. R.* 65, 961), the hydrates differ somewhat in properties both from stannic and metastannic acids; they are said to be formed by keeping stannic acid under water, and to form K salts,  $KH_2Sn_2O_7$  and  $KH_4Sn_2O_7$ .

**STANNATES**,  $M_2SnO_4$  and  $M^{IV}SnO_4$ . The alkali stannates are obtained by dissolving stannic acid in  $MOHAq$  ( $M = NH_4$ , K, or Na), and evaporating over  $H_2SO_4$ ; the stannates of the alkaline earth metals may be obtained by the interactions of solutions of the alkali stannates with  $MO_2H_2$  or  $MCO_3$  ( $M = Ba, Ca, Sr$ ).

**Ammonium stannate**. A salt, said to have the composition  $(NH_4)_2SnO_4 \cdot SnO_2 \cdot fH_2O$ , is obtained, as a yellowish jelly, by evaporating a solution of stannic acid in  $NH_4Aq$  over  $H_2SO_4$  (Moberg, *J. pr.* 28, 230). When  $K_2SnO_4Aq$  is added to  $NH_4ClAq$ , stannic acid is ppd. according to Ditte (*C. R.* 96, 701).

**Barium stannate**. The normal salt  $BaSnO_4 \cdot 6H_2O$  is said to be obtained by adding  $BaCl_2Aq$  to  $K_2SnO_4Aq$ ; it is described as a heavy, white powder (Moberg, *l.c.*). By adding  $K_2SnO_4Aq$  to excess of  $BaCl_2Aq$ , Ditte (*l.c.*) obtained a basic salt  $Ba_2SnO_4 \cdot BaO \cdot 10H_2O$  as lustrous leaflets.

**Calcium stannate**. Ditte (*l.c.*) obtained the normal salt  $CaSnO_4 \cdot 5H_2O$ , in white crystals, by adding  $K_2SnO_4Aq$  to excess of  $CaCl_2Aq$ , washing, and drying at  $100^{\circ}$ . By heating for some hours a mixture of stannic acid and  $CaCl_2Aq$ , with a little  $CaO$ , D. obtained  $CaSnO_4$  in regular crystals.

**Potassium stannate**  $K_2SnO_4 \cdot xH_2O$ . Prepared by dissolving stannic acid in  $KOHAq$ , or by fusing  $SnO_2$  or metastannic acid with excess of  $KOH$  for some time and dissolving in water, and evaporating over  $H_2SO_4$ ; transparent, rhombic prisms; crystallising with  $4H_2O$  (Freymy, *A. Ch.* [3] 23, 393), with  $3H_2O$  (Moberg, *l.c.*). Marignac (*Ann. M.* [3] 15, 277) obtained the salt, in rhombohedral crystals, by gradually heating 8 pts. metastannic acid with 8 pts.  $KOH$  till the mixture boiled, allowing to cool, dissolving in water, filtering, and evaporating. Ordway (*Ann. S.* [2] 40, 173) prepared the pure salt by adding an equal volume of absolute alcohol to a solution of the commercial salt (*v. infra*), repeatedly treating the syrupy layer that separated with alcohol, drying the pasty mass so obtained by pressure, dissolving in water, evaporating *in vacuo*, and washing the crystals with alcohol. K stannate dissolves easily in water; O. (*l.c.*) gives S. at  $10^{\circ} - 106^{\circ}$ , and at  $20^{\circ} - 110^{\circ}$ ; solution reacts alkaline. Insoluble in alcohol. By adding a dilute acid solution sufficient to neutralise  $\frac{1}{2}$  of the alkali, a white flocculent pp. of K metastannate is said to be produced (O., *l.c.*); excess of cold dilute acid ppt. stannic acid.  $K_2SnO_4 \cdot xH_2O$  is dehydrated at a red heat.

**Commercial stannate of potash solution** is prepared (1) by fusing tinstone with  $K_2S$ ,  $KOH$  or

$KNO_3$ , and dissolving in water; (2) by boiling tinstone with  $KOHAq$ ; (3) by fusing tin with  $KNO_3$  and  $K_2CO_3$ , or boiling the metal with  $KOHAq$  containing  $KNO_3$  and  $KCl$  (*v. Haefely*, *D. P. J.* 144, 66; Vaughan, *B. S.* 896; and *DICTIONARY OF APPLIED CHEMISTRY*, vol. iii. pp. 843-4).

**Sodium stannate**  $Na_2SnO_4 \cdot xH_2O$ . Prepared similarly to the K salt. Crystallises in hexagonal plates with  $3H_2O$  (M., *l.c.*; O., *l.c.*). Marignac (*l.c.*) obtained rhombohedral crystals. Jonas (*C. C.* 1865, 607) obtained rhombic crystals of  $Na_2SnO_4 \cdot 3H_2O$  by recrystallising the commercial salt. Haefely (*D. P. J.* 144, 66) obtained crystals of  $Na_2SnO_4 \cdot 3H_2O$  by heating an aqueous solution of S.G. 1.3; on allowing to cool again the crystals dissolved, the S.G. became 1.35, and after a time crystals of  $Na_2SnO_4 \cdot 3H_2O$  were deposited. Scheurer-Kestner (*B.* [2] 8, 839) obtained crystals of the composition  $Na_2SnO_4 \cdot 10H_2O$  by evaporating a dilute solution of the ordinary salt, free from excess of  $NaOH$ , at a low temperature.  $Na_2SnO_4 \cdot 3H_2O$  is more soluble in cold than in hot water; O. (*l.c.*) gives S. at  $0^{\circ} = 67^{\circ}$ , and at  $20^{\circ} = 61^{\circ}$ . Insoluble in alcohol. According to H. (*l.c.*), an aqueous solution of the octohydrate gives a crystalline pp. of Na metastannate when heated, or when left at the ordinary temperature for some weeks. **Commercial stannate of soda solution** is prepared similarly to the solution of the potash salt (*v. supra*).

**Strontium stannate**. A basic salt  $2SrSnO_4 \cdot SrO \cdot 10H_2O$  was obtained by Ditte (*C. R.* 96, 701), in lustrous octahedra, by adding  $K_2SnO_4Aq$  to excess of  $SrCl_2Aq$ .

**METASTANNATES**. Only alkali metastannates have been prepared. The empirical formula of these salts is  $M_2O \cdot 5SnO_4 \cdot 4H_2O$ ; as they are decomposed by removing water, the formula is generally written as  $M_2H_4Sn_2O_7$  (*cf.* METASTANNIC ACID, p. 728). Metastannic acid dissolves slowly in  $KOHAq$  or  $NaOHAq$ ; on adding conc.  $MOHAq$  the salts are ppd. The salts are better obtained by adding conc.  $MOHAq$  to a solution in water of the substance obtained by the interaction of metastannic acid and conc.  $HClAq$  (Barfoed, *J. pr.* 101, 868). Dilute acid solutions ppt. metastannic acid from solutions of metastannates. Metastannates heated with excess of  $MOH$  give stannates. For more details regarding  $M_2H_4Sn_2O_7$  ( $M = K$  or  $Na$ ) *v.* Freymy (*A. Ch.* [3] 23, 393); Weber (*P.* 122, 358); Haefely (*D. P. J.* 144, 66).

**ARSENIO-STANNATES**. A compound  $Na_2O \cdot 2As_2O_3 \cdot 6SnO_4 \cdot 5H_2O$  was obtained by Haefely (*D. P. J.* 140, 290) by adding excess of  $HNO_3Aq$  to a boiling solution of  $Na_2SnO_4$  and  $Na_3AsO_4$ , and treating the gelatinous pp. with excess of  $NaOHAq$ .

**OXALO-STANNATES**. The compound  $2KHC_2O_4 \cdot SnO_4 \cdot 5H_2O$  was obtained, in lustrous leaflets, by Pechard (*C. R.* 116, 1513) by dissolving stannic acid in hot  $KHC_2O_4Aq$  and allowing to cool.

**PLATINO-STANNATES**. Compounds of  $SnO$  and  $SnO_2$  with  $PtO_2$  derived from the acids  $H_2Sn_2Pt_4O_{10}$  and  $H_2Sn_2Pt_2O_8$  (*v.* PLATINO-STANNATES, this vol. p. 285).

**PLATINO-SELENO-STANNATES** *v.* this vol. p. 285.

**SILICO-STANNATES.** Bourgeois (*Bl.* [2] 47, 197) obtained the salt  $\text{CaO} \cdot \text{SiO}_2 \cdot \text{SnO}$  in monoclinic, lustrous crystals, by fusing  $\text{SiO}_2$  and  $\text{SnO}_2$  with excess of  $\text{CaCl}_2$ , and extracting with water.

In connection with stannic and metastannic acids and their derivatives, v. *Chlor-stannic acid*, under STANNOUS CHLORIDE (p. 721); **TIN, OXIDES AND HYDRATED OXIDES OF** (p. 725); and **TIN, THIO-ACIDS AND SALTS OF** (p. 735).

**Tin, oxybromides of.** By adding pieces of tin to the mother-liquor from  $\text{BaSnBr}_6$  (v. *Stannibromides*, under STANNIC BROMIDE, p. 720). Rayman a. Preis (A. 223, 323) obtained colourless, prismatic crystals to which they gave the formula  $\text{Sn}_2\text{OBr}_4 \cdot 12\text{H}_2\text{O}$ ; and from the mother-liquor from this compound fine, colourless needles of  $\text{Sn}_2\text{OBr}_4 \cdot 10\text{H}_2\text{O}$  separated after a time.

**Tin, oxychlorides of.** According to Ditte (*A. Ch.* [5] 27, 145), when  $\text{SnO} \cdot 2\text{H}_2\text{O}$ , obtained by ppg. a stannous salt by  $\text{NH}_4\text{Aq}$ , is boiled with water containing a trace of  $\text{SnCl}_4$ , a gelatinous oxychloride is obtained having the composition,  $\text{Sn}_2\text{OCl}_2 \cdot 6\text{H}_2\text{O}$  ( $= \text{SnO} \cdot \text{SnCl}_2 \cdot 6\text{H}_2\text{O}$ ); and when this compound is boiled with a little more dilute  $\text{SnCl}_4\text{Aq}$  another oxychloride,  $\text{Sn}_2\text{O}_2\text{Cl}_2 \cdot 6\text{H}_2\text{O}$  ( $= 3\text{SnO} \cdot 2\text{SnCl}_2 \cdot 6\text{H}_2\text{O}$ ) is formed in small, white, pearly tablets.

The oxychloride  $\text{SnOCl}_2$  is obtained, according to Scheurer-Kestner (*A. Ch.* [3] 47, 1), by evaporating  $\text{SnCl}_4\text{Aq}$  at  $50^\circ$  to  $60^\circ$ ; also by heating 100 pts.  $\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$ , dissolved in 50 pts. water, with  $\text{HNO}_3\text{Aq}$  containing 16 pts.  $\text{N}_2\text{O}$ .

An oxychloride is also formed by treating metastannic acid with conc.  $\text{HClAq}$ , pouring off the excess of acid, dissolving in water, and evaporating over  $\text{H}_2\text{SO}_4$  and  $\text{CaO}$ ; to this oxychloride, which is an amorphous, white solid, Weber (P. 122, 358) gave the formula  $\text{Sn}_2\text{O}_2\text{Cl}_2 \cdot 5\text{H}_2\text{O}$  ( $= 3\text{SnO} \cdot 2\text{SnCl}_2 \cdot 5\text{H}_2\text{O}$ ). Tschermak (*W. A. B.* 44, 2) obtained a crystalline oxychloride  $\text{Sn}_2\text{O}_2\text{Cl}_4$  ( $= 4\text{SnO} \cdot 3\text{SnCl}_2 \cdot \text{SnCl}_4$ ) by dissolving moist metastannic acid in hot conc.  $\text{SnCl}_4\text{Aq}$  containing  $\text{HCl}$ .

Mallet (*C. J.* 35, 524) obtained a semi-transparent, jelly-like solid from  $\text{SnCl}_4\text{Aq}$  which had been kept in a loosely-stoppered bottle for a year or two; to this solid he gave the formula  $\text{SnO}_2 \cdot \text{HCl}$  ( $= \text{SnO} \cdot \text{OH} \cdot \text{Cl}$ ).

**Tin, oxyfluoride of.** When  $\text{SnF}_2$  is heated in air it is said to form the oxyfluoride  $\text{SnOF}_2$  ( $= \text{SnO} \cdot \text{SnF}_4$ ) (Frémy, *A. Ch.* [3] 47, 37; Marignac, *Ann. M.* [5] 15, 221).

**Tin, oxyiodides of.** According to Personne (*C. R.* 54, 216), various oxyiodides are formed by decomposing  $\text{SnI}_4$  by much water; P. analysed four compounds, to which he assigned the compositions  $\text{Sn}_2\text{OI}_2$  ( $= 2\text{SnO} \cdot \text{SnI}_2$ ),  $\text{Sn}_2\text{OI}_4$  ( $= \text{SnO} \cdot \text{SnI}_4$ ),  $\text{Sn}_2\text{OI}_6$  ( $= \text{SnO} \cdot 2\text{SnI}_4$ ), and  $\text{Sn}_2\text{OI}_8$  ( $= \text{SnO} \cdot 3\text{SnI}_4$ ).

**Tin, phosphides of.** By heating finely divided tin in vapour of P, Schrötter (*W. A. B.* 1849, 301) obtained a silver-white, brittle solid to which he gave the formula  $\text{SnP}$ ; S.G. 6.56; easily acted on by  $\text{HClAq}$ , but not by  $\text{HNO}_3\text{Aq}$ . Other crystalline solids have been obtained by heating tin and P together, but their compositions are not determined with certainty (v. Pelletier, *S.* 55, 106; Berthier, *A. Ch.* [2] 33, 180; H. Rose, P. 24, 326; Lüpke, C. C. 1890

[ii.] 643). Natanson a. Vortmann (*B. J.* 1459) obtained a phosphide of tin by heating glacial phosphoric acid with C and tin;  $\text{HClAq}$  gave off  $\text{PH}_3$  and left  $\text{SnP}$ .

**Tin, salts of.** Tin forms two classes of salts by replacing the H of acids; the stannous salts  $\text{SnX}_2$  and the stannic salts  $\text{SnX}_4$  ( $\text{X} = \text{ClO}_2$ ,  $\text{NO}_2$ ,  $\frac{1}{2}\text{CO}_2$ ,  $\frac{1}{2}\text{SO}_2$ ,  $\frac{1}{2}\text{P}_2\text{O}_5$ , &c.). The chief salts of oxyacids are the following: (1) *Stannous salts*: antimonite, arsenate, borate, carbonate, chlorate, chromate, iodate, nitrate, phosphates, phosphite, sulphates, and sulphite. (2) *Stannic salts*: antimonate, arsenate, bromate, chlorate, iodate, molybdate, nitrate, phosphates, phosphite, selenate, selenite, sulphates, and tungstates (v. NITRATES, SULPHATES, &c.).

**Tin, selenides of.** Tin and Se form two compounds,  $\text{SnSe}$  and  $\text{SnSe}_2$ . The former can be prepared by the direct union of the elements; the latter does not seem to be obtained by this method. Both selenides dissolve in alkali solutions, and in solutions of alkali sulphides.

**STANNOUS SELENIDE  $\text{SnSe}$ .** (*Tin monoselenide or protoselenide*.) Mol. w. unknown. Obtained by melting together Se and tin (Berzelius; Welsmann, A. 116, 122). With excess of Se the disulphide  $\text{SnS}_2$  was said to be formed (Little, A. 112, 213), but this was probably a mistake (Schneider, P. 127, 624). Also formed by adding powdered Se to molten  $\text{SnCl}_2$ , heating till  $\text{SnCl}_2$  is volatilised, and allowing to cool, when  $\text{SnSe}$  crystallises; excess of  $\text{SnCl}_2$  is removed by washing with dilute  $\text{HClAq}$  (Schneider, l.c.). Steel-grey, lustrous prisms; probably isomorphous with  $\text{SnS}$ ; S.G. 5.21 at  $152^\circ$  (S. L.). Also obtained, as a black powder, by passing  $\text{H}_2\text{Se}$  into  $\text{SnCl}_4\text{Aq}$ , washing, and drying at  $100^\circ$ .  $\text{SnSe}$  prepared by ppg. is soluble in alkali solution; the crystals prepared by heating Se with  $\text{SnCl}_2$  are insoluble, even in boiling alkali solutions. Both crystalline and amorphous  $\text{SnSe}$  are soluble in solutions of alkali sulphides or selenides.  $\text{SnSe}$  is insoluble in  $\text{HClAq}$ ; oxidised by  $\text{HNO}_3\text{Aq}$  to  $\text{SnO}_2 \cdot 2\text{H}_2\text{O}$ ,  $\text{H}_2\text{SeO}_3$ , and  $\text{H}_2\text{SeO}_4$ . Heated with I, forms  $\text{SnI}_2$  and  $\text{SnSe}_2$ ; or, with an excess of I,  $\text{SnI}_4$  and Se; reacts similarly with Br.  $\text{SnSe}$  is not reduced by heating in H. Heated in air it is gradually oxidised to  $\text{SnO}$ , and  $\text{SeO}_2$  (S. L.). According to Ditte (*C. R.* 96, 1790),  $\text{SnSe}$  can be sublimed in a stream of H at a red heat; D. says S.G. is  $6.179$  at  $0^\circ$ .

**STANNIC SELENIDE  $\text{SnSe}_2$ .** (*Tin diselenide*.) Mol. w. unknown. Not formed by heating together tin and Se, as excess of Se over that required to form  $\text{SnSe}$  sublimes; Little's statement that  $\text{SnSe}_2$  is formed by directly combining tin and Se by heat (A. 112, 213) is probably wrong (Schneider, P. 127, 624). Prepared by rubbing 5 pts. I and 4 to 10 pts. crystallised  $\text{SnI}_2$  (the  $\text{SnI}_2$  is used to enable the I to be thoroughly powdered), adding 4 pts. powdered tinSe, then sufficient  $\text{CS}_2$  to form a pasty mass (stirring constantly), and then adding more  $\text{CS}_2$  to dissolve  $\text{SnI}_2$ , and washing with  $\text{CS}_2$ , when  $\text{SnSe}_2$  remains as a dark, red-brown, indistinctly crystalline powder, which becomes darker when dried at  $100^\circ$  (Schneider, l.c.). S.G. 4.85. According to Welsmann (A. 116, 122),  $\text{SnSe}_2$  is obtained, as a dark reddish-brown powder, by passing  $\text{H}_2\text{Se}$  into  $\text{SnCl}_4\text{Aq}$ ; heated in H, this powder gives off Se and leaves  $\text{SnSe}$ .

**SnSe**, is not acted on by water, or by dilute acids; it is slowly attacked by conc. boiling HClAq; *aqua regia*, or conc. HNO<sub>3</sub>Aq, oxidises it to SnO<sub>2</sub>, H<sub>2</sub>SeO<sub>4</sub>, and H<sub>2</sub>SeO<sub>3</sub>; it dissolves in hot conc. H<sub>2</sub>SO<sub>4</sub>, and when the olive-green solution is poured into water Se separates and Sn(SO<sub>4</sub>)<sub>2</sub> remains dissolved. SnSe<sub>2</sub> is easily soluble in caustic alkali solutions, including NH<sub>4</sub>Aq, forming blood-red liquids. Heated with I, in the ratio SnSe<sub>2</sub>:4I, SnI<sub>4</sub> and Se are formed; Br reacts similarly to I (Schneider, *l.c.*).

**Tin, silicides of.** No definite compound has been isolated. Substances which seem to be of the nature of alloys are formed by heating together tin and Si; treatment with HClAq dissolves tin from these bodies, and separates Si along with SiO<sub>2</sub> (v. Winkler, *J. pr.* 91, 193).

**Tin, silicofluoride.** According to Berzelius (*Lehrbuch* [5th ed.] 3, 767), the salt SnSiF<sub>6</sub> separates (?) from solution of SnO<sub>2</sub>.xH<sub>2</sub>O in H<sub>2</sub>SiF<sub>6</sub>Aq in prismatic crystals, which are readily crystallised from water.

**Tin, sulphides of.** Two sulphides of tin are known, SnS and SnS<sub>2</sub>; the former is readily obtained by heating tin and S; the latter by heating tin with an excess of S and some substance (e.g. NH<sub>4</sub>Cl) which readily volatilises, and so removes heat, which would else drive off the S above that required to form SnS. Both sulphides are also formed by ppn. by H<sub>2</sub>S from corresponding salts in solution. Both sulphides dissolve in solutions of alkali polysulphides, forming *thioannates*, M<sub>2</sub>SnS<sub>3</sub>.

**STANNOUS SULPHIDE SnS. (Tin monosulphide or protosulphide).** Mol. w. unknown.

**Preparation.**—1. Finely divided tin is heated with a. equal parts of S; the product is powdered, and repeatedly heated with S in a closed vessel. Ditte (*C. R.* 96, 1790) recommends to sublime the SnS thus prepared, by heating to redness in a porcelain tube in a stream of H<sub>2</sub>.—2. H<sub>2</sub>S is passed into a solution of a stannous salt until the liquid smells strongly of H<sub>2</sub>S; the brownish black pp. of amorphous SnS is washed and dried, and is then added, little by little, to molten SnCl<sub>2</sub> as long as it is dissolved thereby; after cooling, SnCl<sub>2</sub> is dissolved out by dilute HClAq, and any dark-brown powder that is present is washed away from the heavier, greyish, lustrous, crystalline particles of SnS (Schneider, *P.* 95, 167).

**Properties.**—A dark, lead-grey, crystalline solid; S.G. 4.85° (Karsten, *S.* 65, 394), 5.27 (Boullay, *A. Ch.* [2] 43, 266). Ditte (*l.c.*) describes SnS, after sublimation in H<sub>2</sub>, as crystallising in thin, lustrous squares with an angle of c. 90°; with a grey-blue, metal-like lustre; soft and friable; S.G. 5.0802 at 0°. Crystalline SnS melts at a red heat; it expands considerably on cooling (Ditte, *l.c.*). Prepared by ppn. SnS is a brownish-black, amorphous solid.

**Reactions.**—1. SnS, prepared by heating together tin and S, may be sublimed in *hydrogen* at a red heat (Ditte, *C. R.* 96, 1790); but continued heating in H<sub>2</sub> is said to reduce it to tin, H<sub>2</sub>S being given off.—2. Heated in *air* SnS is gradually converted into SnO<sub>2</sub> and SO<sub>2</sub>.—3. Reacts with *chlorine*, even at the ordinary temperature, to form SnCl<sub>4</sub> and SnCl<sub>2</sub>.2SnCl<sub>2</sub> = (SnS<sub>2</sub>Cl<sub>2</sub>)<sub>2</sub> (H. Rose, *P.* 47, 517).—4. Fusion with *potassium cyanide* produces tin and KONS.—5. SnS dis-

solves gradually in boiling *hydrochloric acid*, forming SnCl<sub>4</sub> solution and giving off H<sub>2</sub>S (for details of interaction with HClAq of different concentration, and with HCl gas, v. Ditte, *C. R.* 97, 42).—6. Gradually oxidised to SnO<sub>2</sub> by heating with *nitric acid*.—7. Dissolves in solutions of *alkali polysulphides*, forming alkali thioannates M<sub>2</sub>SnS<sub>3</sub>.—8. SnS is generally said to be nearly insoluble in solutions of *alkali monosulphides* (M<sub>2</sub>S). According to Ditte (*C. R.* 94, 1419, 1470), SnS is not acted on by K<sub>2</sub>SAq at the ordinary temperature if the concentration of the solution does not exceed 20K<sub>2</sub>S:100H<sub>2</sub>O; but a more conc. solution of K<sub>2</sub>SAq, out of contact with air, gradually converts the SnS into a grey, spongy mass of tin; and still more conc. K<sub>2</sub>SAq dissolves this, forming K<sub>2</sub>SnS<sub>3</sub>Aq and giving off H<sub>2</sub>; if air is admitted the reactions are more complex.

**STANNIC SULPHIDE SnS<sub>2</sub>. (Tin disulphide.)** Mol. w. not known.

**Preparation.**—1. By saturating SnCl<sub>4</sub>Aq containing a little HClAq with H<sub>2</sub>S, warming, again saturating with H<sub>2</sub>S, warming gently for some hours, collecting the pp., washing with dilute H<sub>2</sub>SAq, drying, and heating to above 100° out of contact with air. Pure SnS<sub>2</sub> can scarcely be prepared in this way; there seems to be always some SnO<sub>2</sub>.xH<sub>2</sub>O present in the pp. (Kühn, *A.* 84, 110; Barfoed, *J. pr.* 101, 368).—2. By passing the mixed vapour of SnCl<sub>4</sub> and H<sub>2</sub>S through a red-hot porcelain tube, or by passing H<sub>2</sub>S into SnCl<sub>4</sub> and heating the white crystals of SnCl<sub>4</sub>.5H<sub>2</sub>S so obtained (Coldridge, *P. M.* [5] 29, 383).—3. A mixture of finely-divided tin and S, or of SnS and S, with some substance that gradually volatilises and so removes heat, is slowly heated to redness in a glass retort, or a loosely covered flask, imbedded in sand; the volatile substance gradually passes off, then the excess of S is volatilised and the SnS<sub>2</sub> remains, partly on the sides and partly on the bottom of the vessel. If tin is heated with S only, the heat produced in the reaction is so great that the SnS<sub>2</sub> formed is resolved into SnS and S. Various mixtures have been employed by different chemists; the following give good results: (1) equal parts sifted tin-filings, S, and NH<sub>4</sub>Cl (Pelletier); (2) 4 parts tin-filings, 3 parts S, 2 parts NH<sub>4</sub>Cl (Woulfe); (3) a pulverised amalgam of 12 parts tin and 6 parts Hg, with 7 parts S, and 6 parts NH<sub>4</sub>Cl (W.); (4) 6 parts SnS and 8 parts HgCl<sub>2</sub> (W.).

**References.**—Pelletier (*Crell's Chem. Ann.* 1797 [1] 46); Woulfe (*ibid.* 1, 149); Bullion (*ibid.* 1793 [1] 89); Proust (*Gehlen's Journ. f. Chem. und Phys.* 1, 250).

According to Gmelin (*Handbuch* [5th ed.] 3, 75) if NH<sub>4</sub>Cl is heated with tin and S there is formed a compound of NH<sub>4</sub>Cl and SnCl<sub>4</sub>, which then interacts with the S, forming SnS<sub>2</sub>, (2Sn + 8NH<sub>4</sub>Cl = 2(2NH<sub>4</sub>Cl.SnCl<sub>4</sub>) + 2H<sub>2</sub> + 4NH<sub>3</sub>; 2(2NH<sub>4</sub>Cl.SnCl<sub>4</sub>) + 2S = SnS<sub>2</sub> + 2NH<sub>4</sub>Cl.SnCl<sub>4</sub> + 2NH<sub>4</sub>Cl).

**Properties.**—Prepared by sublimation, SnS<sub>2</sub> is a soft golden-yellow, lustrous, crystalline solid; S.G. 4.6 (Karsten, *S.* 65, 394), 4.42 (Boullay, *A. Ch.* [2] 43, 266). Crystalline SnS<sub>2</sub> is known as *mosaic gold* (v. *DICTIONARY OF APPLIED CHEMISTRY*, vol. iii, p. 845).

**Reactions and Combinations.**—1. Heated in a closed vessel gives SnS and S, and a sublimate

of  $\text{SnS}_2$ .—3. Heated in air  $\text{SnO}_2$  and  $\text{SO}_2$  are formed.—4. Chlorine liquefies  $\text{SnS}_2$ , on cooling yellow crystals of  $\text{SnCl}_4 \cdot 2\text{SnCl}_2$  are formed (H. Rose, P. 42, 517).—5. The compound  $\text{SnS}_2 \cdot \text{I}_2$  ( $= \text{SnS}_2 \cdot \text{SI}_2$ ) is said to be formed by heating  $\text{SnS}_2$  with iodine in a stream of  $\text{CO}_2$  (Schneider, J. pr. 79, 419; v. also TIN, THIOIODIDE, *infra*). According to Schneider (*l.c.*) a boiling alcoholic solution of I does not act on  $\text{SnS}_2$ , prepared by sublimation, but with amorphous  $\text{SnS}_2$ , prepared by ppt. it gives  $\text{SnS}_2 \cdot \text{I}_2$ .—6. Amorphous, but not crystalline,  $\text{SnS}_2$  is slowly decomposed by boiling conc. hydrochloric acid,  $\text{H}_2\text{S}$  being given off and  $\text{SnCl}_4$  solution formed.—7. The amorphous sulphide is slowly oxidized by hot nitric acid; aqua regia oxidises both amorphous and crystalline  $\text{SnS}_2$  to  $\text{SnO}_2$  and  $\text{H}_2\text{SO}_4$ .—8. Fusion with lead monoxide produces a mixture of sulphides and oxides of tin and lead; with excess of  $\text{PbO}$ ,  $\text{SO}_2$  is given off and lead remains.—9.  $\text{SnS}_2$  was said by Dumas (S. 66, 409) to combine with stannic chloride, forming  $\text{SnS}_2 \cdot 2\text{SnCl}_4$ ; the compound being produced by the interaction of  $\text{SnCl}_4$  and  $\text{H}_2\text{S}$ . According to Coldridge (P. M. [5] 29, 383) this compound does not exist, the product of the reaction being  $\text{SnCl}_4 \cdot 5\text{H}_2\text{S}$ .—10.  $\text{SnS}_2$  dissolves in alkali sulphide solutions, forming thiostannates (q. v., *infra*),  $\text{M}_2\text{SnS}_3$ .—11. In alkali solutions  $\text{SnS}_2$  dissolves, probably forming stannates and thiostannates ( $? 3\text{SnS}_2 + 6\text{KOH} \text{Aq} = \text{K}_2\text{SnO}_3 \text{Aq} + 2\text{K}_2\text{SnS}_3 \text{Aq} + 3\text{H}_2\text{O}$ ).

TIN SESQUISULPHIDE. Berzelius (Lehrbuch [5th ed.] 2, 600) gave the formula  $\text{Sn}_2\text{S}_3$  to a greyish-yellow, lustrous solid obtained by heating a mixture of 3 parts  $\text{SnS}$  and 1 part S in a retort; the substance was almost certainly a mixture of  $\text{SnS}$  and  $\text{SnS}_2$ .

Tin, sulphochlorides of; v. TIN THIOCHLORIDES, *infra*.

Tin, sulpho-iodide of; v. TIN THIO-IOIDE, *infra*.

Tin, sulphocyanide of; v. vol. ii. p. 352.  
Tin, telluride of,  $\text{SnTe}$ . A grey, lustrous, metal-like, crystalline solid; S.G. 6.478 at  $0^\circ$ ; obtained by heating together tin and Te, and slowly subliming in a stream of H (Ditte, C. 12, 96, 1790).

Tin, thio-acids and salts of. It is doubtful whether a thio-acid of tin has been isolated with certainty; a few salts derived from the acid  $\text{H}_2\text{SnS}_3$  have been obtained.

THIOSTANNIC ACID. (Sulphostannic acid.) Kühn (A. 84, 110) obtained an olive-brown pp. by adding  $\text{HCl}$  Aq or  $\text{H}_2\text{C}_2\text{H}_3\text{O}_2$  Aq to a conc. solution of  $\text{Na}_2\text{SnS}_3 \cdot \text{Na}_2\text{S} \cdot 12\text{H}_2\text{O}$  (*v. infra*); after washing, and drying at  $100^\circ$ , the pp. was a leaden-grey, lustrous solid having the composition  $\text{H}_2\text{SnS}_3$ . Storch (M. 10, 255), repeating Kühn's experiments, always obtained brown pps., which did not contain more S than required by the ratio  $\text{Sn}:\text{S} = 1:2.19$ . S. concluded that the pps. were mixtures of  $\text{H}_2\text{SnS}_3$  and  $\text{SnS}_2$ . By adding dilute oxalic acid solution to solution of  $\text{Na}_2\text{SnS}_3$  (prepared by saturating  $\text{Na}_2\text{SnO}_3$  Aq with  $\text{H}_2\text{S}$ ) in quantity just sufficient to combine with the Na present, S. (*l.c.*) obtained a deep-yellow liquid which remained clear for hours; after removing the  $\text{H}_2\text{S}$  by a current of air S. found that the liquid contained tin and S in the ratio  $\text{Sn}:\text{S} 8$ ; he concluded that  $\text{H}_2\text{SnS}_3$  was pre-

sent in the liquid. The liquid was decolourised by  $\text{NH}_4\text{Aq}$ ,  $\text{KOH}$  Aq,  $\text{Na}_2\text{CO}_3$  Aq,  $(\text{NH}_4)_2\text{CO}_3$  Aq, and  $\text{NH}_4\text{Cl}$  Aq; strong acids gave brownish pps. containing rather more S than required by the formula  $\text{SnS}_3$ .

THIOSTANNATES (Kühn, *l.c.*; Höring, Hirsch's Zeit. für Pharm. 1851. No. 8). The alkali salts are obtained by dissolving  $\text{SnS}_2$  in alkali sulphide solutions,  $\text{M}_2\text{SAq}$ ; the alkaline earth salts are formed by double decomposition from the alkali salts.

Potassium thiostannate:  $\text{K}_2\text{SnS}_3 \cdot 10\text{H}_2\text{O}$ . Obtained by dissolving  $\text{SnS}_2$  in  $\text{K}_2\text{SAq}$ , and adding alcohol, when the salt separates as a dark brown heavy oil; all  $\text{H}_2\text{O}$  is given off at  $100^\circ$ .

Sodium thiostannates. The normal salt  $\text{Na}_2\text{SnS}_3 \cdot 2\text{H}_2\text{O}$  is obtained, in yellow, glassy, regular crystals, by adding tin, little by little, to molten  $\text{Na}_2\text{S}$ , treating the fused mass with water, and evaporating at a low temperature. A solution of  $\text{SnS}$  and S in  $\text{Na}_2\text{SAq}$  deposits colourless, monoclinic crystals of the basic salt, which, when dried over  $\text{H}_2\text{SO}_4$ , has the composition  $\text{Na}_2\text{SnS}_3 \cdot \text{Na}_2\text{S} \cdot 12\text{H}_2\text{O}$ . The stronger acids ( $\text{HCl}$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{CHCl}_3 \cdot \text{CO}_2\text{H}$ ) ppt.  $\text{SnS}_2$  at once from  $\text{Na}_2\text{SnS}_3$  Aq; but weak acids ( $\text{H}_3\text{PO}_4$ ,  $\text{H}_2\text{C}_2\text{O}_4$ ,  $\text{CH}_3\text{CO}_2\text{H}$ , &c.) form brown-yellow solutions from which red-brown pps. separate more or less slowly (Storch, M. 10, 255). Kühn (*l.c.*) gives the reactions of the two Na thiostannates with solutions of several metallic salts; many of the pps. were doubtless thiostannates of the metals employed.

PLATINO-THIOSTANNATES. Schneider (Z. [2] 5, 629; 6, 270, 613) obtained salts to which he gave the composition  $\text{M.Pt.SnS}_3$  ( $= \text{M.S} \cdot 3\text{PtS} \cdot \text{SnS}_3$ ), where M = K or Na, by fusing  $\text{SnS}_2$ , Pt,  $\text{M}_2\text{CO}_3$ , and S, and lixiviating with water.

Tin, thiochlorides of. A compound  $\text{SnS}_2\text{Cl}_2$  ( $= \text{SnCl}_2 \cdot 2\text{SnCl}_2$ ) is said to be formed, along with  $\text{SnCl}_4$ , by the interaction of Cl and  $\text{SnS}$  or  $\text{SnS}_2$  (H. Rose, P. 42, 517). Dumas (S. 66, 409) described a compound  $\text{Sn}_2\text{S}_3\text{Cl}_2$  ( $= \text{SnS}_2 \cdot \text{SnCl}_2$ ) as obtained by passing  $\text{H}_2\text{S}$  into  $\text{SnCl}_4$ ; but according to Coldridge (P. M. [5] 29, 383) this compound is not formed. C. (*l.c.*) says that the passage of  $\text{H}_2\text{S}$  into  $\text{SnCl}_4$  produces white crystals of  $\text{SnCl}_4 \cdot 5\text{H}_2\text{S}$ , which are decomposed by heat, giving off  $\text{HCl}$  and  $\text{H}_2\text{S}$ , and leaving  $\text{SnS}_2$ .

Tin, thio-iodide of. By melting together crystalline  $\text{SnS}_2$  and I, in the ratio  $\text{SnS}_2:4\text{I}$ , allowing the liquid to cool, and either heating in a stream of  $\text{CO}_2$ , or dissolving in  $\text{CS}_2$  and crystallising, Schneider (J. pr. 79, 419) obtained brown, lustrous crystals of  $\text{SnS}_2\text{I}_2$  ( $= \text{SnS}_2 \cdot \text{SI}_2$ ). This thio-iodide is dissolved unchanged by  $\text{CS}_2$ , or  $\text{CHCl}_3$ ; alcohol separates S; water, or a solution of a caustic alkali, produces  $\text{SnS}_2$ , S, and  $\text{HIAq}$  (or  $\text{MIAq}$ );  $\text{HCl}$  Aq or  $\text{HNO}_3$  Aq decomposes it, with separation of H. The compound  $\text{SnS}_2\text{I}_2$  is also produced by the interaction of a solution of I in  $\text{CS}_2$  and ppt., dried  $\text{SnS}_2$  (S., *l.c.*). M. M. P. M.

#### TIN ORGANIC COMPOUNDS.

Stannic methide  $\text{SnMe}_4$ . (78°). S.G. 1.313. V.D. 6.00 (calc. 6.15). Got by heating an alloy of tin and sodium (14 p.c.) with MeI (3 pt.) at  $100^\circ$ – $120^\circ$  (Ladenburg, A. Suppl. 8, 74; cf. Cahours, A. 111, 236; 111, 873). Oil, with ethereal odour. Reduces alcoholic  $\text{AgNO}_3$ .

**Stannic tri-methylo-iodide**  $\text{SnMe}_3\text{I}$ . (170°). S.G.  $\frac{2}{3}$  2.143. Formed by the action of I on  $\text{SnMe}_3$ . Oil. Yields crystalline  $\text{SnMe}_3\text{OH}$  and the salts  $(\text{SnMe}_3)_2\text{SO}_4$ ,  $\text{SnMe}_3\text{O.CO}_2\text{H}$ , and  $\text{SnMe}_3\text{OAc}$ . Forms the compounds  $\text{SnMe}_3\text{OEt}$  (Ladenburg, B. 3, 358) and  $\text{SnMe}_3\text{I}_2\text{NH}_3$  (Cahours, A. 122, 56).

**Stannic di-methylo-di-iodide**  $\text{SnMe}_2\text{I}_2$ . [30°]. (228°). S.G.  $\frac{2}{3}$  2.872. Formed by heating tinfoil with  $\text{MeI}$  at 150° (C.). Monoclinic crystals (from ether-alcohol). Converted by ammonia into amorphous  $\text{SnMe}_3\text{O}$ , which is insol. water, but dissolves in acids forming the following crystalline salts:  $\text{SnMe}_2\text{Cl}_2$  [90°] (159°), forming trimetric crystals;  $a:b:c = 834:1:941$ .— $\text{SnMe}_2\text{PtCl}_4$ , 7aq, forming trimetric crystals;  $a:b:c = 888:1:977$ .— $\text{SnMe}_2\text{Br}_2$ . (209°).— $\text{SnMe}_2\text{SO}_4$ , forming monoclinic crystals (Hjortdahl, C. 77, 88, 584).

**Stannic ethide**  $\text{SnEt}_4$ . Mol. w. 284. (181°). S.G.  $\frac{2}{3}$  1.187. Formed from  $\text{SnEt}_3\text{I}$  and  $\text{EtI}$  (Buckton, A. 109, 218; 112, 223; Frankland, A. 111, 44). Formed also, together with tin and  $\text{ZnEt}_2\text{Cl}$ , by adding fused  $\text{SnCl}_2$  to cooled  $\text{ZnEt}_2$ , and then distilling (Frankland & Lawrence, C. J. 35, 134). Prepared by heating powdered tin with  $\text{EtI}$  and the zinc-copper couple; and also by heating  $\text{ZnEtI}$  with powdered tin at 160° (Letts a. Collie, C. J. Proc. 2, 160). Oil. Has no action at 180° on Al, Na, or Mg. Slowly absorbs sulphur dioxide, forming crystalline  $\text{SO}_2(\text{OSnEt}_2)_2$ , insol. ether and an oil  $\text{SnEt}_3\text{SO}_2\text{Et}$ , sol. ether. Hot conc.  $\text{HClAq}$  forms ethane and  $\text{SnEt}_2\text{Cl}$ . Iodine forms  $\text{SnEt}_3\text{I}$  and  $\text{IEt}$ .

**Stannous ethide**  $\text{SnEt}_2$ . S.G.  $\frac{2}{3}$  1.538. Formed by adding zinc to a warm solution of  $\text{SnEt}_2\text{Cl}_2$  (Frankland). Oil. Decomposed at 150° into  $\text{SnEt}_2$  and tin. Br forms  $\text{SnEt}_2\text{Br}_2$ .

**Distannous hexa-ethide**  $\text{Sn}_2\text{Et}_6$ . (265°-270°). S.G.  $\frac{2}{3}$  1.412. V.D. 14.8 (calc. 14.7). Got by distilling  $\text{SnEt}_3\text{I}$  with sodium (Ladenburg, A. Suppl. 8, 66; B. 3, 647). Pungent oil. I forms  $\text{SnEt}_3\text{I}$ . Conc.  $\text{HClAq}$  forms  $\text{SnEt}_2\text{Cl}_2$ , ethane, and hydrogen.

**Stannic tri-ethylo-iodide**  $\text{SnEt}_3\text{I}$ . (231°). S.G.  $\frac{2}{3}$  1.833. Formed by the action of  $\text{EtI}$  on an alloy of tin and sodium (Ladenburg, A. Suppl. 8, 60; B. 3, 353, 647; cf. Löwig, A. 84, 308). Liquid. Combines with  $\text{NH}_3$  (2 mols.). On distilling with  $\text{KOHAc}$  it yields  $\text{SnEt}_2\text{OH}$  crystallising from ether in prisms [43°] (271°) converted by heat into oily  $(\text{SnEt}_2)_2\text{O}$ , which recombines with water forming the hydroxide.  $\text{NaOEt}$  converts the iodide into  $\text{SnEt}_2\text{OEt}$  (191°). S.G.  $\frac{2}{3}$  1.263, which is at once changed by water into the hydroxide. The hydroxide  $\text{SnEt}_2\text{OH}$  is sol. water, strongly alkaline, absorbs  $\text{CO}_2$  from the air, and is converted by acids into the salts:— $\text{SnEt}_2\text{Cl}_2$  [c. 0°]. (209°). S.G.  $\frac{2}{3}$  1.428.— $(\text{SnEt}_2)_2\text{PtCl}_6$ .— $\text{SnEt}_2\text{PtCl}_4$ .— $\text{SnEt}_2\text{Br}_2$ . (223°) (Cahours).— $\text{SnEt}_2\text{Cy}$ .— $\text{SnEt}_2\text{CyO}$ .— $(\text{SnEt}_2)_2\text{NO}_2$ .— $(\text{SnEt}_2)_2\text{SO}_4$ . Hexagonal prisms terminated by pyramids (Hjortdahl).— $(\text{SnEt}_2)_2\text{S}$ .— $\text{SnEt}_2\text{SH}$ .— $(\text{SnEt}_2)_2\text{H}_2\text{PO}_4$ .— $\text{SnEt}_2\text{OAc}$ .— $\text{SnEt}_2\text{OBz}$ .— $(\text{SnEt}_2)_2\text{CO}_3$ .— $(\text{SnEt}_2)_2\text{C}_2\text{O}_4$ , aq. — Formate  $(\text{SnEt}_2)_2\text{CHO}_2$ .—Butyrate  $(\text{SnEt}_2)_2\text{C}_4\text{H}_9\text{O}_2$ .—Tartrates  $(\text{SnEt}_2)_2\text{C}_4\text{H}_4\text{O}_6$ , aq.— $(\text{SnEt}_2)_2\text{HC}_2\text{H}_3\text{O}_4$ , aq.

**Stannic di-ethylo-di-iodide**  $\text{SnEt}_2\text{I}_2$ . [44.5°]. (246°). Formed from tin and  $\text{EtI}$  by exposure

to sunlight or by heating with  $\text{EtI}$  at 150° (Frankland, A. 85, 329; Löwig, A. 84, 308; Cahours a. Riche, A. 84, 333). Needles (from alcohol), al. sol. cold water. May be sublimed. Alcoholic  $\text{NH}_3$  forms  $\text{SnEt}_2\text{O}$ , which is an amorphous powder, insol. water, converted by acids into the following salts:  $\text{SnEt}_2\text{Cl}_2$ . (85°). (220°), forming trimetric crystals;  $a:b:c = 889:1:948$ .— $\text{SnEt}_2\text{Cl.OH}$ . plates.— $\text{SnEt}_2\text{Br}_2$ . (238°). V.D. 11.6 (calc. 11.7).— $\text{SnEt}_2(\text{NO}_3)_2$ .— $\text{SnEt}_2\text{ICy}$ .— $\text{SnEt}_2(\text{SCy})_2$ .— $\text{SnEt}_2\text{S}$ .— $\text{SnEt}_2\text{SO}_4$ .—Crystals.  $\text{SnEt}_2(\text{OAc})_2$ .— $\text{SnEt}_2\text{C}_2\text{O}_4$ .—Formate  $\text{SnEt}_2(\text{CHO}_2)_2$ .

**Stannic ethylo-trimethide**  $\text{SnEtMe}_3$ . (125°-128°). Formed from  $\text{SnMe}_3\text{I}$  and  $\text{ZnEt}_2$  (Cahours, A. 123, 59). Oil; converted by I into  $\text{EtI}$  and  $\text{SnMe}_3\text{I}$ .

**Stannic di-ethylo-di-methide**  $\text{SnEt}_2\text{Me}_2$ . (145°). S.G.  $\frac{2}{3}$  1.260. V.D. 6.84 (calc. 7.14). Formed from  $\text{SnEt}_3\text{I}$  and  $\text{ZnMe}_2$  (Frankland, A. 111, 50; Morgunoff, A. 144, 157). Oil.

**Stannic methylo-tri-ethide**  $\text{SnMeEt}_3$ . (163°). V.D. 6.72 (calc. 6.65). Formed from  $\text{SnEt}_3\text{I}$  and  $\text{ZnMe}_2$  in the cold (C.). Heavy oil.

**Stannic tetrapropylide**  $\text{SnPr}_4$ . (224°). S.G.  $\frac{2}{3}$  1.179. Formed from  $\text{SnPr}_3\text{I}$  and  $\text{ZnPr}_2$  (Cahours, C. R. 76, 133). Pungent oil.

**Stannic tripropylo-iodide**  $\text{SnPr}_3\text{I}$ . (261°). S.G.  $\frac{2}{3}$  1.692. Formed from  $\text{PrI}$  and an alloy of Na and tin (Cahours a. Demarçay, C. R. 88, 725, 1112). Oil, converted by moist  $\text{Ag}_2\text{O}$  into crystalline  $\text{SnEt}_2\text{OH}$ .

**Stannic di-propylo-di-iodide**  $\text{SnPr}_2\text{I}_2$ . (272°). Formed from tin and  $\text{PrI}$ . Oil. Converted by alkalis into amorphous  $\text{SnPr}_2\text{O}$ , insol. water, which yields  $\text{SnPr}_2\text{Cl}_2$  [81°].

**Stannic tri-isopropylo-iodide**  $\text{SnPr}_3\text{I}$ . (257°). Got in like manner.

**Stannic di-isopropylo-di-iodide**  $\text{SnPr}_2\text{I}_2$ . (267°). Yields  $\text{SnPr}_2\text{Cl}_2$  [57°].

**Stannic tri-isobutylo-iodide**  $\text{Sn}(\text{C}_4\text{H}_9)_3\text{I}$ . (285°). S.G.  $\frac{2}{3}$  1.540. Formed from  $\text{CH}_3\text{PrI}$  and a 9 p.c. alloy of Na in tin (Cahours a. Demarçay, C. R. 89, 68). Pungent oil, converted by  $\text{KOH}$  into  $\text{Sn}(\text{C}_4\text{H}_9)_2\text{OH}$  [313°].

**Stannic di-isobutylo-di-iodide**  $\text{Sn}(\text{C}_4\text{H}_9)_2\text{I}_2$ . (290°-295°). Formed by heating tinfoil with isobutyl iodide at 125°. Liquid, converted by alkalis into amorphous  $\text{Sn}(\text{C}_4\text{H}_9)_2\text{O}$ , and by  $\text{HCl}$  into  $\text{Sn}(\text{C}_4\text{H}_9)_2\text{Cl}_2$  [c. 6°] (261°).

**Stannic tetra-isoamylo-iodide**  $\text{Sn}(\text{C}_5\text{H}_{11})_4\text{I}$ . Formed from isoamyl iodide and an alloy of Na (1 pt.) and tin (6 pts.) (Grimm, A. 92, 388). Liquid.

**Stannic tri-isoamylo-iodide**  $\text{Sn}(\text{C}_5\text{H}_{11})_3\text{I}$ . (304°). Accompanies the preceding compound (C. a. D.). Converted by potash into oily  $\text{Sn}(\text{C}_5\text{H}_{11})_2\text{OH}$  (337°).

**Stannic tetraphenylide**  $\text{SnPh}_4$ . [226°]. (over 420°). Formed by heating bromo-benzene with a tin-sodium alloy and acetic ether (Polis, B. 22, 2915). Colourless prisms, insol. ligroin, v. sl. sol. alcohol, v. sol. boiling benzene.

**Stannic tri-phenylo-chloride**  $\text{SnPh}_3\text{Cl}$ . [105°]. Formed by the action of  $\text{NaNO}_2$  on a solution of  $\text{SnPh}_3\text{Cl}_2$  in  $\text{HOAc}$ , the yield being 85 p.c. of that represented by the equation  $8\text{SnPh}_3\text{Cl}_2 = 2\text{SnPh}_3\text{Cl} + \text{SnCl}_4$  (Ardheim, B. 12, 509). Converted by potash into  $\text{SnPh}_3\text{OH}$  14aq [118°].

**Stannic di-phenylo-dichloride**  $\text{SnPh}_2\text{Cl}_2$ . [42°]. (335°). Prepared by boiling  $\text{HgPh}_2$  with  $\text{SnCl}_4$  and ligroin (Aronheim, B. 10, 3229;

11, 2285;  $A = 194, 145$ . Triclinic prisms;  $a:b:c = 588:1:1.067$ ;  $\alpha = 62^\circ 47'$ ;  $\beta = 76^\circ 48'$ ;  $\gamma = 94^\circ 8'$ . Sol. alcohol and ligroin, miscible with ether. Converted by means of water into  $\text{SnPh}_2\text{Cl.OH}$ , an amorphous insoluble powder [187°]. Potash forms  $\text{SnPh}_2\text{O}$ . Ether, alcohol, and sodium-amalgam form  $\text{SnPh}_2(\text{OEt})_2$  [124°].

**Stannic di-phenyl-di-bromide**  $\text{SnPh}_2\text{Br}_2$  [c. 38°]. (230° at 42 mm.). Formed from  $\text{SnPh}_2$  and Br (Polis), and from the oxide and HBr (A.).

**Stannic di-phenyl-chloro-bromide**  $\text{SnPh}_2\text{BrCl}$  [39°]. Crystalline. Formed from  $\text{SnPh}_2\text{Cl}(\text{OH})$  and HBr.

**Stannic di-phenyl-chloro-iodide**  $\text{SnPh}_2\text{ClI}$  [69°]. Yellow monoclinic crystals (from ether), decomposed by water.

**TIN GROUP OF ELEMENTS.** Group IV. in the periodic classification of the elements contains the following members:—

<i>Even series</i>	2	4	6	8	10	12
	C	Ti	Zr	Ce	—	Th
<i>Odd series</i>	3	5	7	9	11	
	Si	Ge	Sn	—	Pb	

Subdividing this group in accordance with the chemical similarities of the elements we get the following families:—

**Carbon family:** C and Si.

**Titanium family:** Ti, Zr, Ce, —, Th.

**Tin family:** Ge, Sn, —, Pb.

The **carbon family** is considered in the article CARBON GROUP OF ELEMENTS (vol. i. p. 682); and that article also gives a sketch of the chemical relations of all the members of the group. The elements of the **titanium family** are considered under the heading TITANIUM GROUP OF ELEMENTS (this vol. p. 749). The **tin family** is considered in the present article.

Ge occurs in small quantities, as sulphide, in a very few rare minerals. Tin and lead are found native in not very large quantities. The chief ore of tin is *tinestone*, which contains  $\text{SnO}_2$ ;  $\text{SnS}_2$  is also found in *tin pyrites*; and various *micas* contain more or less  $\text{SnO}_2$ . *Galena*, containing  $\text{PbS}$ , is the chief ore of lead; sulphate, carbonate, phosphate, &c., are also found in considerable quantities. Ge is obtained by heating its ore with  $\text{Na}_2\text{CO}_3$  and S, dissolving in water, decomposing  $\text{Na}_2\text{S}$  by  $\text{H}_2\text{SO}_4$  aq. ppg. Ag ( $\text{Ag}_2\text{S}$  is a constituent of the ore) by  $\text{HCl}$  aq. then ppg.  $\text{GeS}_2$  by  $\text{H}_2\text{S}$ , oxidising the  $\text{GeS}_2$  to  $\text{GeO}_2$  by  $\text{HNO}_3$ , and reducing the  $\text{GeO}_2$  by heating in H or with C. Tin is obtained by calcining *tinestone*, washing, and reducing the  $\text{SnO}_2$  by heating with C. To obtain lead, *galena* is roasted in such a quantity of air that it is partially oxidised, both  $\text{PbO}$  and  $\text{PbSO}_4$  being formed; by then heating out of contact with much air the  $\text{PbS}$ ,  $\text{PbO}$ , and  $\text{PbSO}_4$  interact to form  $\text{SO}_2$  and lead. Tin and lead have been known from very early times. Ge was isolated in 1885.

The table on page 736 presents some of the principal physical and chemical properties of the tin elements.

**General formulae and characters of compounds.** Oxides:— $\text{MO}$ ,  $\text{MO}_2$ ; also  $\text{Pb}_2\text{O}$ , and  $\text{Pb}_3\text{O}_4$ ; various hydrates of most of these oxides are known. Sulphides:— $\text{MS}$ ,  $\text{MS}_2$  (?  $\text{PbS}_2$ ). Haloid compounds:— $\text{MX}$ , and  $\text{MX}_2$ . Acids:— $\text{H}_2\text{MX}$ , where  $\text{M} = \text{Ge}$  or  $\text{Sn}$ , and  $\text{X} = \text{either Br, Cl, F, or I}$ ; also  $\text{H}_2\text{PbI}_2$ ,  $\text{H}_2\text{SnO}_2$ ,

and  $\text{H}_2\text{H}_2\text{Sn}_2\text{O}_{11}$ ; ?  $\text{H}_2\text{SnS}_2$ . Salts:— $\text{MX}$ , and  $\text{MX}_2$ , where  $\text{M} = \text{Sn}$  or  $\text{Pb}$  and  $\text{X} = \text{NO}_3$ ,  $\frac{1}{2}\text{SO}_4$ ,  $\frac{1}{2}\text{PO}_4$ , &c. Salts containing  $\text{M}$  in the acidic radicle:— $\text{R}_2\text{MX}_2$ , where  $\text{M} = \text{Ge, Sn, (?Pb)}$ , and  $\text{X}$  is a halogen;  $\text{R}_2\text{MO}_2$ , where  $\text{M} = \text{Sn}$ , or  $\text{Pb}$ ; also  $\text{R}_2\text{PbO}_2$ ; also  $\text{R}_2\text{H}_2\text{Sn}_2\text{O}_{11}$ , &c. also  $\text{R}_2\text{SnS}_2$ .

The oxides  $\text{MO}$  are basic; they react with acids to form salts  $\text{MX}$ ,  $\text{X} = \text{NO}_3$ ,  $\frac{1}{2}\text{SO}_4$ ,  $\frac{1}{2}\text{PO}_4$ , &c. (no salts of  $\text{GeO}$  have yet been isolated).  $\text{PbO}$  also dissolves in molten  $\text{KOH}$ , forming  $\text{K}_2\text{PbO}_2$ . The oxides  $\text{MO}_2$ , where  $\text{M} = \text{Sn}$  or  $\text{Pb}$ , are both basic and acidic; they react with some acids to form salts  $\text{MX}_2$ ; several of these salts have been isolated when  $\text{M} = \text{Sn}$ , very few when  $\text{M} = \text{Pb}$ : they also react with molten  $\text{KOH}$  or  $\text{NaOH}$  ( $\text{SnO}_2 \cdot x\text{H}_2\text{O}$  also with  $\text{MOH}$  aq.) to form salts  $\text{K}_2(\text{or Na})_2\text{MO}_4$ ; when  $\text{M} = \text{Sn}$  two classes of salts are known, *stannates*  $\text{M}_2\text{SnO}_4$ , and *metastannates*, probably  $\text{M}_2\text{H}_2\text{Sn}_2\text{O}_{11}$ .  $\text{GeO}_2$  dissolves in acids, also in molten  $\text{KOH}$  or  $\text{K}_2\text{CO}_3$ , but the products of these reactions have not yet been examined.  $\text{Pb}_2\text{O}_3$  reacts with dilute strong acids to form  $\text{PbO}_2$  and  $\text{PbX}_2$ , which dissolves; with glacial acetic acid  $\text{Pb}_2\text{O}_3$  forms  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$  and  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_4$ .  $\text{Pb}_2\text{O}_3$  probably reacts with dilute strong acids to give  $\text{PbO}$  and a salt of  $\text{PbO}$ . The hydrates of  $\text{MO}$  and  $\text{MO}_2$  react similarly to the oxides. Some of the hydrates  $\text{SnO}_2 \cdot x\text{H}_2\text{O}$  are acidic; one class of these is probably polymeric with the other. There are indications of the existence of an oxide  $\text{MO}$ , in the case of tin; this oxide seems to be acidic.

The **sulphides** of Ge have not been much investigated;  $\text{GeS}_2$  dissolves in alkali sulphide solutions, and is probably acidic.  $\text{GeS}$  has been gasified and V.D. determined. The sulphides of tin are both basic and acidic; with hot conc.  $\text{HCl}$  aq. they give  $\text{SnCl}_2$  and  $\text{SnCl}_4$  respectively; both dissolve in alkali sulphide solutions to form *thiostannates*  $\text{M}_2\text{SnS}_2$ .  $\text{PbS}$  is basic; with acids it gives salts  $\text{PbX}_2$  and  $\text{H}_2\text{S}$ ; there are indications of the existence of a higher sulphide, perhaps  $\text{PbS}_2$ , which will probably form thioplumbates with the sulphides of strongly positive metals.

The **haloid compounds**  $\text{MX}_2$  (none isolated yet when  $\text{M} = \text{Ge}$ ) may be formed by the direct union of the elements, and by the other usual methods.  $\text{SnCl}_2$  and  $\text{PbCl}_2$  have been gasified, and the formulae are molecular; molecules of the composition  $\text{Sn}_2\text{Cl}_4$  probably exist, but are decomposed at c. the boiling-point of the compound. Several salts are known of the form  $\text{M}_2\text{SnX}_4$ , where  $\text{X} = \text{Br, Cl, F, or I}$ ; and an acid  $\text{H}_2\text{SnCl}_4 \cdot x\text{H}_2\text{O}$  and some salts  $\text{MSnI}_4$  are also said to exist.  $\text{H}_2\text{PbI}_4$  and salts  $\text{M}_2\text{PbI}_4$  have been isolated; and also several salts coming under the general formula  $x\text{PbX}_2 \cdot y\text{NH}_4\text{Cl}$ , where  $\text{X} = \text{Br or Cl}$ . The haloid compounds  $\text{MX}$  have been gasified, and V.D.s determined, when  $\text{M} = \text{Ge}$  and  $\text{X} = \text{Cl or I}$ , and when  $\text{M} = \text{Sn}$  and  $\text{X} = \text{Br or Cl}$ .  $\text{PbCl}_2$  has not been isolated with certainty, but salts of the form  $\text{M}_2\text{PbCl}_4$  are known, and also some salts  $x\text{PbCl}_2 \cdot y\text{NH}_4\text{Cl}$ . The acids  $\text{H}_2\text{GeF}_4$ ,  $\text{H}_2\text{SnBr}_4$ , and  $\text{H}_2\text{SnCl}_4$  have been obtained, and also salts derived from these acids; salts  $\text{M}_2\text{SnF}_6$  and  $\text{M}_2\text{PbCl}_4$  are also known.  $\text{GeHCl}_3$  has been isolated. Many **oxyhaloid compounds**  $x\text{MO} \cdot y\text{MX}_2$  and  $x\text{MO}_2 \cdot y\text{MX}_2$  are known.

The **oxyacids** of tin,  $\text{H}_2\text{SnO}_2$ , and (probably)  $\text{H}_2\text{H}_2\text{Sn}_2\text{O}_{11}$ , are to be classed with the weak

	GERMANIUM.	TIN.	LEAD.
<i>Atomic weights.</i>	72.3	118.8	206.4
	One or more compounds of each element have been gasified. Specific heats have also been determined directly. There is some evidence in favour of the conclusion that the molecules of tin and lead, in solution in Hg., are monatomic.		
<i>Melting-points. (approx.).</i>	900°	232°	330°

<i>Atom. wts.</i>	13.2	16.3	18.1
<i>Spec. gravs. (approx.).</i>			
<i>Occurrence and preparation.</i>	Double sulphide of Ge and Ag occurs as a rare mineral. $\text{GeO}_2$ also found in some specimens of <i>auxenite</i> , with oxides of Nb, Ta, and Y. Prepared by reducing $\text{GeO}_2$ by H or C.	Metal found in small quantities. $\text{SnO}_2$ occurs in tolerable quantities widely distributed. Prepared by reducing $\text{SnO}_2$ by C.	Small quantities of lead found. Chief ore contains PbS; widely distributed in considerable quantities. Prepared by interaction of PbS, PbO, and $\text{PbSO}_4$ ; also by reducing PbO by C.
<i>Physical properties.</i>	Greyish white, lustrous, very brittle. Crystallises in regular octahedra. Melts at c. 900°; slightly volatilised at 1,350° in N or H.	Silver-white, lustrous, malleable, but malleability varies with temperature; tenacity very small. Crystallises very easily in rhombic and quadric forms. Melts easily (at 232°), and boils between 1,450° and 1,600°.	White, with tinge of blue; lustrous; very malleable and ductile; tenacity very small; very soft. Crystallises easily in regular octahedra. Melts easily (at 330°), but at higher temperature than tin, and boils between 1,450° and 1,600°.
<i>Chemical properties.</i>	Unchanged in air at ordinary temperature; oxidised to $\text{GeO}_2$ when heated in fine division. Combines readily with Br, Cl, and I when heated, forming $\text{GeX}_4$ . Heated in HCl gas forms $\text{GeHCl}_3$ . Dissolves in $\text{H}_2\text{SO}_4$ aq. No salts have yet been isolated by replacing H of oxyacids by Ge. $\text{GeO}_2$ dissolves in fused KOH or $\text{K}_2\text{CO}_3$ . $\text{H}_2\text{GeF}_6$ aq and salts of this acid are known.	Unchanged in pure air at ordinary temperature. Heated in air gives $\text{SnO}$ and $\text{SnO}_2$ . Heated in Br, Cl, or I forms $\text{SnX}_2$ and $\text{SnX}_4$ . Heated with S forms $\text{SnS}$ and $\text{SnS}_2$ ; also forms $\text{SnSe}$ and $\text{SnSe}_2$ . Reacts with acids forming two series of salts, $\text{SnX}_2$ and $\text{SnX}_4$ , $\text{X} = \text{NO}_3, \frac{1}{2}\text{SO}_4, \frac{1}{2}\text{PO}_4$ , &c. Conc. $\text{HNO}_3$ produces $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ . $\text{SnO}$ is basic; $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ both basic and acidic, with strong acids forms salts $\text{SnX}_2$ , and with caustic alkalis forms stannates $\text{M}_2\text{SnO}_4$ . $\text{SnS}_2$ forms thio-stannates $\text{M}_2\text{SnS}_4$ , with alkali sulphides. Stannic fluorides $\text{M}_4\text{SnF}_6$ are known; the acids $\text{H}_2\text{SnCl}_4$ and $\text{H}_2\text{SnBr}_4$ have been isolated. Mol. w. perhaps same as at. w. in solution in Hg. Valency of atom varies from 2 in $\text{SnCl}_2$ gas to 4 in $\text{SnCl}_4$ gas.	Tarnishes in air, film of oxide ( $\text{Pb}_3\text{O}_2$ ) forming on surface. Melted in air forms $\text{PbO}$ and $\text{Pb}_2\text{O}_3$ . Combines with halogens to form $\text{PbX}_2$ ; $\text{PbCl}_2$ also probably isolated. Combines with S and Se, forming PbS and PbSe; $\text{PbS} \cdot x\text{S}$ also probably exists. Reacts with acids forming salts $\text{PbX}_2$ , $\text{X} = \text{NO}_3, \frac{1}{2}\text{SO}_4, \frac{1}{2}\text{PO}_4$ , &c. $\text{PbO}$ is basic; $\text{PbO}_2$ feebly basic and feebly acidic; $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$ has been isolated, and probably $\text{PbCl}_4$ ; with molten KOH, $\text{PbO}_2$ forms $\text{K}_2\text{PbO}_4$ . No thioplumbates isolated. No acid $\text{H}_2\text{PbF}_6$ , or salts thereof, isolated; but $3\text{KF} \cdot \text{HF} \cdot \text{PbF}_6$ probably exists. Mol. w. perhaps same as at. w. in solution in Hg. Atom is divalent in gaseous molecule $\text{PbCl}_2$ , and tetravalent in gaseous molecule $\text{PbMe}_4$ .

acids; the one is probably a polymeride of the other. The salts of these acids show very distinct differences: the acids themselves interact with strong acids to form salts containing tin in the positive radicles. Of acids containing tin and halogens the following have (probably) been isolated:  $\text{HSnCl}_3$ ,  $\text{H}_2\text{SnBr}_2$ , and  $\text{H}_2\text{SnCl}_4$ .  $\text{H}_2\text{GeF}_6$  is known, and  $\text{H}_2\text{PbF}_6$  is said to exist. It is doubtful whether *thiostannic acid*  $\text{H}_2\text{SnS}_3$  has been obtained pure, but salts of this acid have been isolated.

The salts of oxyacids containing these metals in the negative radicles are  $\text{M}_2\text{SnO}_3$  and  $\text{M}_2\text{H}_2\text{SnO}_3$ ,  $\text{M}_2\text{PbO}_3$  and  $\text{M}_2\text{H}_2\text{PbO}_3$ . These salts are generally easily decomposed. Oxyacids and salts of oxyacids of Ge have yet to be searched for.

Salts derived from oxyacids by replacing H by M are known when  $\text{M} = \text{Sn}$  or  $\text{Pb}$ ; no Ge salts of oxyacids have yet been isolated. The tin salts belong to two classes,  $\text{SnX}_2$  and  $\text{SnX}_4$ , where  $\text{X} = \text{NO}_3$ ,  $\frac{1}{2}\text{SO}_4$ ,  $\frac{1}{2}\text{PO}_4$ , &c.; both classes of salts readily undergo decomposition and show a general tendency to separate off  $\text{SnO}$  or  $\text{SnO}_2$ . Almost all the lead salts belong to the class  $\text{PbX}_2$ ; they are more definite and less ready to split off oxide or decompose to basic salts than the corresponding salts of tin.  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$  is the only lead salt of an oxyacid of the class  $\text{PbX}_2$  that has been certainly isolated; it is decomposed by the least trace of moisture, giving a pp. of  $\text{PbO}_2$ .

The elements of the tin family are distinctly metallic in their physical properties, and in most of their chemical properties also; they exhibit, however, non-metallic characters in their highest salt-forming oxides,  $\text{MO}_3$ , which are acidic towards strong bases, while they also react as basic oxides towards several acids. The tin elements are less chemically metallic, on the whole, than the members of the even-series, or titanium family, of Group IV.; the two distinctly non-metallic elements of the group are the first member of the even series—carbon, and the first member of the odd series—silicon.

In considering the chemical analogies of the tin elements, the position of the members of the family in their respective series should be looked to (v. table in vol. iii. p. 811). Ge comes in series 5; it is preceded by  $\text{Ga}$ , Zn, and Cu, and succeeded by As, Se, and Br: tin comes in series 7; it is preceded by In, Cd, and Ag, and succeeded by Sb, Te, and I: lead comes in series 11; it is preceded by Tl, Hg, and Au, and succeeded by Bi and two unknown elements. The highest salt-forming oxides of the elements preceding and succeeding the tin elements in the series are: series 5,  $\text{CuO}$ ,  $\text{ZnO}$ ,  $\text{Ga}_2\text{O}_3$ ;  $\text{GeO}_2$ ;  $\text{As}_2\text{O}_3$ ,  $\text{SeO}_2$ , —; series 6,  $\text{Ag}_2\text{O}$ ,  $\text{CdO}$ ,  $\text{In}_2\text{O}_3$ ;  $\text{SnO}_2$ ;  $\text{Sb}_2\text{O}_3$ ,  $\text{TeO}_2$ , ?  $\text{I}_2\text{O}_5$ —series 11,  $\text{Au}_2\text{O}$ ,  $\text{HgO}$ ,  $\text{Tl}_2\text{O}_3$ ;  $\text{PbO}_2$ ;  $\text{Bi}_2\text{O}_3$ , —. The preceding oxides  $\text{GeO}_2$  are, on the whole, more basic than the oxides preceding  $\text{SnO}_2$  or  $\text{PbO}_2$ ; and the oxides succeeding  $\text{GeO}_2$  are on the whole more acidic than the oxides succeeding  $\text{SnO}_2$  or  $\text{PbO}_2$ . Hence we should expect the three oxides,  $\text{GeO}_2$ ,  $\text{SnO}_2$ , and  $\text{PbO}_2$  to be about equally acidic and equally basic;  $\text{SnO}_2$ , perhaps, being the most acidic of the three. Looking at the position of the tin elements in the general periodic system, we may express the relationship of these

Vol. IV.

odd-series elements to the first member of the odd series of their group (Si) by the following statements: (1)  $\text{Pb}:\text{Si} = \text{Ti}:\text{Al} = \text{Hg}:\text{Mg} = \text{Au}:\text{Na} = \text{Bi}:\text{P}$ . — (2)  $\text{Sn}:\text{Si} = \text{In}:\text{Al} = \text{Cd}:\text{Mg} = \text{Ag}:\text{Na} = \text{Sb}:\text{P}$ . — (3)  $\text{Ge}:\text{Si} = \text{Ga}:\text{Al} = \text{Zn}:\text{Mg} = \text{Cu}:\text{Na} = \text{As}:\text{P}$ . On the whole, Bi is more unlike P than Ti is unlike Al, Hg is unlike Mg, or Au is unlike Na; Sn is more unlike P than In is unlike Al, Cd is unlike Mg, or Ag is unlike Na; and As is more unlike P than Ga is unlike Al, Zn is unlike Mg, or Cu is unlike Na. Hence the differences between Pb and Si, tin and Si, and Ge and Si, respectively, will be very decided. If the relations expressed in the preceding statements are worked out in detail, they show that the differences between Pb and Si will be more marked than those between tin and Si, and still more marked than those between Ge and Si; but at the same time there will not be any very great differences between these three pairs of differences. Lead, then, will on the whole be the most metallic, and Ge the least metallic, of the tin-elements. But the three elements will resemble each other closely in so far as their general positive or negative character is concerned. Then, considering the resemblances and differences between consecutive pairs of elements in (1) series 3 and 5 (i.e. Si and Ge series), and (2) series 5 and 7 (i.e. Ge and tin series), and (3) series 7 and 11 (i.e. tin and lead series), it is evident that Ge and Si will be more alike than Ge and tin, and that Ge and tin will more closely resemble one another than tin and lead. Hence, on the whole, we may expect that Ge will form several compounds wherein the element acts distinctly as a non-metal; it is possible that  $\text{GeH}_4$  may be isolated ( $\text{GeHCl}_3$  exists). Ge will form volatilisable organic compounds;  $\text{GeO}_2$  will probably be found to be di- or trimorphous.

C.* 1, 84); Fritz (*M.* 1892. 772) gives 13. S.V.S. 13.4.

Historical.—In 1791 Gregor found indications of a new element in a Cornish iron sand called *menaccanite*, from the village near which it was found (*Crell's Ann.* 1791 [1] 40, 103). The element was called *menachin* by Kirwan. In 1795 Klaproth found a compound of a new element in a mineral known as '*rother Schoerl zu Boinik in Ungarn*,' and called the element *titanium* (derived from *Titan*). In 1797 K. recognised that the chief constituent of the Hungarian mineral was the same as the characteristic constituent of *menaccanite* examined by

8 B

Gregor (K., *Beiträge zur Kenntniss der Mineralkörper*). The element was isolated for the first time by Berzelius in 1824 (P. 4, 3).

**Occurrence.**—Ti never occurs native. The chief ore of Ti is more or less pure  $\text{TiO}_2$ , which occurs in different crystalline forms as *rutile* and *anatase* (tetragonal) and *brookite* (rhombic). Various minerals contain  $\text{TiO}_2$ , combined with  $\text{SiO}_2$ , and alkaline earths, e.g. *titanite* or *sphene* and *ferrotitanite*; compounds of titanates and niobates are found in some rare minerals, e.g. *polycrase*, *euxenite*, and *pyrochlore*. Varying quantities of  $\text{TiO}_2$  occur in many *titaniferous iron ores*. The ores of Ti are found in small quantities. Some of them, especially the titaniferous iron ores, are widely distributed (for analyses of Ti ores v. H. Rose, P. 3, 163; 14, 501; 15, 270; Mosander, P. 19, 211; Hermann, J. 25, 368; Berzelius, J. pr. 43, 50; Kammelsberg, P. 1858, 507; Scheerer, P. 64, 489; Groth, *Tabellarische Uebersicht der Mineralien* [2nd ed.] 36; O. v. d. Pfordten, J. 22, 1485). Mazade (C. R. 34, 952) found traces of Ti compounds in the mineral spring of Negrac in France. For analyses and descriptions of *anatase*, *brookite*, and *rutile* v. Klein (J. M. 1875, 837); G. vom Rath (*ibid.* 1876, 61); Schrauf (*ibid.* 1877, 403); Koch (*ibid.* 1878, 652). Cornu (C. R. 86, 101, 983), obtained spectroscopic indications of the occurrence of Ti in the sun's atmosphere. The bright-reddish crystals that are often found in blast furnaces wherein titaniferous iron ore has been smelted were supposed for many years to be Ti; but Wöhler (A. 73, 34) showed that they contain C and N besides Ti (v. TITANIUM CARBONATIDE, p. 739).

**Formation.**—1. By heating  $\text{K}_2\text{TiF}_6$  with K or Na, out of contact with air (v. *Preparation*).—2. By heating  $\text{TiCl}_4$  with Na in a closed iron crucible heated in a wind furnace (Nilson a. Pettersson, W. 4, 554; cf. Kern, C. N. 33, 57). According to Robinson a. Hutchings (Am. 6, 74), Ti is formed by heating  $\text{TiCl}_4$  with Na to  $130^\circ$  in a sealed tube; but O. v. d. Pfordten (A. 237, 201) says that very little, if any, Ti is obtained, and that the main product is  $\text{TiCl}_3$ .—3. By fusing  $\text{K}_2\text{TiF}_6$  with an equal weight of iron filings, and dissolving away the iron by  $\text{HClAq}$  (Wehrlin a. Giraud, C. R. 85, 288).—4. By heating  $\text{TiCl}_4$  to  $180^\circ$  with Ag obtained by reducing a salt of Ag;  $\text{Ti}_2\text{Cl}_6$  is also formed (Friedel a. Guérin, A. Ch. [5] 7, 24).

**Preparation.**—Finely-powdered *rutile* is mixed with double its weight of  $\text{K}_2\text{CO}_3$ , and the mixture is fused in a Pt crucible placed inside an earthenware crucible. The fused mass is powdered and dissolved in the necessary quantity of  $\text{HFAq}$  in a Pt dish; water is added to dissolve  $\text{K}_2\text{TiF}_6$ , which begins to separate, the liquid is boiled and filtered, while boiling; the  $\text{K}_2\text{TiF}_6$ , which separates from the filtrate in lustrous crystalline crusts, is pressed between filter-paper, washed repeatedly with cold water, again pressed, and recrystallised several times from boiling water (Wöhler, A. 74, 212). The dry  $\text{K}_2\text{TiF}_6$  is placed in a porcelain boat in a porcelain (or hard glass) tube connected with a supply of pure dry H; another boat, containing Na, is also placed in the tube; H is passed through the apparatus, and the Na is gradually vaporised and driven over the  $\text{K}_2\text{TiF}_6$ , which is heated.

When the action is completed and the tube has cooled (the H stream being maintained), the solid is treated with water, which dissolves out KF, NaF, and Na (W. a. Deville, A. 103, 230). The Ti is finally washed with ether and dried over  $\text{H}_2\text{SO}_4$  (v. Kern, C. N. 33, 57). Merz (P. 73, 48) prepared Ti by heating a mixture of six pts.  $\text{K}_2\text{TiF}_6$  and three pts. NaCl with two pts. Na in a glass bulb placed in a sand-bath, while a stream of H was passed through the bulb, then adding zinc-powder and fusing, and dissolving out the zinc by cold dilute  $\text{HClAq}$ .

**Properties.**—A dark-grey or black lustrous powder; has not been obtained crystallised. Ti resembles iron reduced from  $\text{Fe}_2\text{O}_3$  by H at a low temperature.

According to Junot (J. 1853, 336), Ti was obtained by him as a silver-white lustrous deposit by electrolysing a solution prepared by dissolving titanate of K in boiling  $\text{H}_2\text{SO}_4\text{Aq}$ , evaporating to a syrup, and extracting with  $\text{Na}_2\text{SO}_4\text{Aq}$ . J.'s experiments do not seem to have been repeated. Lévy (C. R. 110, 1368) obtained hard, steel-white, cubical crystals, which he took to be nearly pure Ti, by passing  $\text{TiCl}_4$  vapour over Si, B, or several metals heated to bright redness. L. found only 80 p.c. Ti in the crystals. Ti burns brilliantly in a flame. When heated to redness in O, it is oxidised with production of an intensely brilliant white light. Ti also burns in Cl. It decomposes water at  $100^\circ$ . Warm  $\text{HClAq}$  dissolves Ti easily; it is also at once dissolved by  $\text{HFAq}$ . Heated by electric sparks, Ti gives an emission-spectrum very rich in lines (v. Thalen, A. Ch. [4] 18, 239; Troost a. Hautefeuille, C. R. 73, 620; Cornu, C. R. 86, 101, 983; Liveing a. Dewar, Pr. 32, 402).

The atomic weight of Ti has been determined (1) by analyses of  $\text{TiCl}_4$  (H. Rose, P. 15, 145 [1829]; Pierre, A. Ch. [3] 20, 257 [1847]; Thorpe, C. J. 47, 108 [1885]); (2) by determining the weight of  $\text{TiO}$ , got from a determinate weight of  $\text{TiCl}_4$  (H. Rose, l.c.; Thorpe, l.c.); (3) by analyses of  $\text{TiBr}_3$  (Thorpe, l.c.); (4) by determining the weight of  $\text{TiO}$ , got from a determinate weight of  $\text{TiBr}_3$  (Thorpe, l.c.); (5) by measuring S.H. of Ti (Nilson a. Pettersson, Z. P. C. 1, 34); (6) by determining V.D. of  $\text{TiCl}_4$  and  $\text{TiH}_4$  (v. these compounds). Rose's determinations gave values for the at. w. of Ti varying from 47.92 to 48.32; Picrre's values varied from 50.2 to 50.29. The very accurate series of determinations made by Thorpe has settled the at. w. to be almost exactly 48 (48.01 if O=16; 47.9 if O=15.96).

The atom of Ti is tetravalent in the gaseous molecules  $\text{TiCl}_4$  and  $\text{TiH}_4$ . Ti is metallic in many of its chemical properties; it decomposes water, giving off H; the oxides  $\text{Ti}_2\text{O}_3$  and  $\text{TiO}$ , form corresponding salts; the chloride and iodide (and ? also bromide) can be gasified without decomposition; the sulphide  $\text{TiS}_2$  does not show any acidic characters so far as it has been examined. The chlorides give pps. of corresponding hydrated oxides by reacting with alkalis, &c. On the other hand, Ti exhibits distinctly non-metallic or chlorous properties; hydrates of  $\text{TiO}$ , act as feeble acids, producing salts wherein Ti forms part of the negative radicle. The acids  $\text{H}_2\text{TiF}_6$  and  $\text{H}_2\text{TiO}_6$  are known, and also salts derived therefrom.  $\text{TiCl}_4$  is very easily decomposed by

water, giving  $\text{HClAq}$  and  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ , &c. As might be expected from the two-sided character of the reactions of Ti, most of the salts obtained by replacing the H of oxyacids by Ti are basic salts. The oxide  $\text{TiO}_2$  has been isolated; it is probably a superoxide. Ti is closely related to Zr, Ce, and Th; these elements, with Ti, form the even-series family of Group IV. (v. **TITANIUM GROUP OF ELEMENTS**, p. 749). Ti is also closely related to Ge, Sn, and Pb, which form the odd-series elements of Group IV. (v. **TIN GROUP OF ELEMENTS**, p. 735). Ti also shows distinct relationships to C and Si, which are the first and second members of Group IV. (v. **CARBON GROUP OF ELEMENTS**, vol. i. p. 682). The similarity between Ti and Si is shown very distinctly in the titanic and silicic acids, the relations between which may be expressed by such a general equation as  $n\text{MH}_2\text{O}_4 - m\text{H}_2\text{O} = \text{M}_n\text{H}_{4n-2m}\text{O}_{4n-m}$  ( $\text{M} = \text{Ti}$  or  $\text{Si}$ ). Ti is the only element of Group IV, which is known to form compounds of the type  $\text{M}_2\text{TiO}_4\text{F}_4 = \text{Ti}(\text{OM})_2\text{F}_4 = \text{TiX}_4$ .

**Reactions and Combinations.**—1. Heated in air or in oxygen, burns brilliantly to  $\text{TiO}_2$ .—2. Burns when heated in chlorine, forming  $\text{Ti}_2\text{Cl}_4$ .—3.  $\text{TiI}_3$  is formed by passing vapour of iodine over hot Ti.—4. Combines with nitrogen when heated therewith (v. **NITRIDES**, p. 743).—5. Ti is violently oxidised to  $\text{TiO}_2$  by heating with cupric oxide or red lead.—6. Interacts with water at  $100^\circ$ , forming  $\text{TiO}_2$  and H.—7. Dissolves in warm hydrochloric acid, forming  $\text{Ti}_2\text{Cl}_4$  (Glutzelt, *B.* 9, 1831; Rammelsberg, *B.* 1871, 490).—8. Ti dissolves easily in hydrofluoric acid (? forming  $\text{Ti}_2\text{F}_6$ ); also in warm dilute nitric or sulphuric acid, according to Glutzelt (*l.c.*), the solution in  $\text{H}_2\text{SO}_4\text{Aq}$  deposits crystals of  $\text{Ti}_2(\text{SO}_4)_3$  on cooling. Conc. hot  $\text{H}_2\text{SO}_4$  reacts with Ti, giving off  $\text{SO}_2$  (? forming  $\text{Ti}(\text{SO}_4)_2$ ); conc. hot  $\text{HNO}_3$  oxidises Ti to metatitanic acid (q. v., p. 747) according to Weber (P. 120, 247).

**Detection and Estimation.**—Compounds of Ti are not reduced to metal by heating on charcoal in the blowpipe flame. Ti compounds, if not containing elements which give a colour to microcosmic salt, form a colourless glass when melted in the microcosmic salt bead in the outer blowpipe flame; in the inner flame they give a glass which is colourless when hot, but becomes violet on cooling; the delicacy of the reaction is much increased by adding a little zinc to the bead (Riley, *C. J.* 12, 13). Solutions of  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  in  $\text{HClAq}$  or  $\text{H}_2\text{SO}_4\text{Aq}$  give white pps. of  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  on boiling; addition of a piece of tin to a solution of  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  in  $\text{HClAq}$  causes evolution of H and produces a violet-blue solution which becomes rose-coloured on dilution with water (von Kobell, *P.* 62, 599). A solution of  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  in  $\text{HClAq}$  gives a violet-red liquid ( $\text{Ti}_2\text{Cl}_4$  solution) by digestion for some time with Cu (Fuchs, *A.* 56, 319). Ti is estimated as  $\text{TiO}_2$ , ppd. from solutions by a slight excess of  $\text{NH}_4\text{Aq}$ . Insoluble compounds of Ti are generally fused with  $\text{KHSO}_4$ , the fused mass is dissolved in water, and  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  is ppd. by long continued boiling.

**Titanium alloys of.** The alloys of Ti have not been much examined. Wöhler & Michel (*A.* 113, 248; 115, 102) obtained an alloy with aluminium approaching in composition to  $\text{TiAl}$ , by heating a mixture of  $\text{TiO}_2$ , KCl, NaCl, and

*cryolite*, and treating with  $\text{HClAq}$ . By heating a mixture of Ti and Al with KCl or NaCl in an earthenware crucible in a stream of H, Lévy (*C. R.* 106, 66) obtained brittle steel-grey crystals which he took to be an isomorphous mixture of  $\text{TiAl}$  and  $\text{TiAl}_3$ . Ti alloys with iron; it is often present in pig-iron, but rarely in bar-iron or steel (v. *Riley*, *C. J.* 16, 387).

**Titanium bromides of.** Only one bromide has been isolated,  $\text{TiBr}_4$ .

**Titanic bromide  $\text{TiBr}_4$ .** (*Titanium tetrabromide*.) Mol. w. has not been determined, but the formula is almost certainly molecular from analogy of  $\text{TiCl}_4$  and  $\text{TiI}_4$ .

Prepared by passing Br vapour over a mixture of  $\text{TiO}_2$  and charcoal heated to full redness, collecting the liquid that distils over and solidifies in the receiver, and redistilling it from Hg (to remove free Br) (Duppa, *Pr.* 8, 42). Also prepared by passing HBr gas over  $\text{TiCl}_3$  kept a few degrees below its boiling-point in a distilling flask connected with an upright condenser; the whole of the Cl of the  $\text{TiCl}_3$  is expelled (Thorpe, *C. J.* 47, 126). Thorpe used 350 g.  $\text{TiCl}_3$ , and continued the passage of HBr for three days. The HBr is conveniently obtained by the interaction of Br and amorphous P in a little water; it is freed from Br by passing through a U tube containing broken glass and amorphous  $\text{I}_2$ , and is dried by passing through another U tube containing  $\text{CaCl}_2$ .

$\text{TiBr}_4$  forms dark-yellow or orange crystals, S.G. 2.6, melting at  $c. 40^\circ$ , and boiling at  $c. 229^\circ$  (D., *l.c.*; T., *l.c.*). It is very hygroscopic, easily decomposed by water, forming a perfectly clear solution containing HBr and  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ .

**Titanium bromochlorides of.** By adding Br to  $\text{TiCl}_2$  (q. v., p. 741) Friedel & Guérin (*A. Ch.* [5] 8, 21) obtained a colourless liquid, fuming in the air, boiling at  $176^\circ$ , which they said was probably  $\text{TiBr}_2\text{Cl}_2$ ; and by the reaction of Br with  $\text{Ti}_2\text{Cl}_6$  they obtained a liquid boiling at  $154^\circ$ , probably  $\text{TiBrCl}_3$ .

**Titanium carbonitride of  $\text{Ti}_2\text{CN}$ .** (*Titanium nitrocyanoide*, or *cyanonitride*  $\text{Ti}_2(\text{CN})_2\text{N}_2$ .) This compound is often found in blast furnaces where titaniferous ironstone has been smelted. It was supposed by Wollaston to be Ti (*l.c.* A. 75, 220), and was for many years generally mistaken for the metal. In 1850 Wöhler (*A.* 73, 34) proved it to contain C and N besides Ti.

The compound is found in blast furnaces as heinous, opaque, copper-coloured, prismatic crystals. By treating these crystals with conc.  $\text{HClAq}$ , then with conc.  $\text{H}_2\text{SO}_4$ , washing, treating with  $\text{HFAq}$ , and again washing, the compound is freed from admixed Fe, &c.; small leaflets of graphite generally remain mixed with the carbonitride.  $\text{Ti}_2\text{CN}$  can be prepared by heating a mixture of dry  $\text{K}_2\text{FeCy}_4$  and  $\text{TiO}_2$  in a closed crucible for an hour or two at  $c.$  the melting-point of Ni ( $1400^\circ$  to  $1450^\circ$ ), dissolving out Fe, &c., by conc.  $\text{HClAq}$ , washing, and drying. By examining the brown powder thus obtained with a magnifying power of 300 diameters copper-coloured crystals of  $\text{Ti}_2\text{CN}$  can be detected (Wöhler, *A.* 73, 34). It is also obtained by heating a mixture 1 part C and 5½ parts  $\text{TiO}_2$  in a closed carbon crucible for some hours at  $1400^\circ$  to  $1450^\circ$ ; also by passing N over a mixture of C and  $\text{TiO}_2$  in the ratio 1:5½ heated in a carbon

boat placed in a carbon tube to the melting-point of Pt (c. 1800°) (W. a. Deville, *A.* 103, 231).

When  $Ti_2CN_4$  is fused with KQH it gives off  $NH_3$ ; heated to redness in a stream of water vapour  $TiO_2$  is formed, and H,  $NH_3$ , and HCN are given off (W., *l.c.*); heated in Cl it gives  $TiCl_4$  and  $TiCl_3 \cdot 2HCN$  (W., *l.c.*; also p. 219); the compound is burnt by heating with  $PbO$ ,  $CuO$ , or  $HgO$ , giving off  $CO_2$  and leaving  $TiO_2$  and  $Pb$ ,  $Cu$ , or  $Hg$  (much heat is produced in the reaction) (W., *l.c.*).

The simplest formula that expresses the composition of Ti carbonitride is  $Ti_2CN_4$  (W., *l.c.*; cf. Reinhardt, *Zeit. für anorgan. Chemie*, 1, 121). This formula is generally doubled and written  $Ti(CN)_2 \cdot 3Ti_2N_4$ , and the substance is regarded as a compound of cyanide and nitride of Ti; Joly (*C. R.* 83, 1195) regards it as a compound of carbide and nitride of Ti, and writes the formula  $TiC_4TiN$  (or  $2TiC_8TiN$ ).

**Titanium, chlorides of.** Ti and Cl combine to form  $TiCl_4$ ; by the regulated action of H on  $TiCl_3$  one-fourth of the Cl can be removed and  $TiCl_2$  produced; and by the further action of H on  $TiCl_2$  one-third of the Cl can be removed and  $TiCl$  produced. The V.D. of the tetrachloride has been determined, and the formula  $TiCl_4$  is molecular; from the analogy of  $C_2Cl_6$  and  $Si_2Cl_6$  it is probable that the molecular formula of the trichloride is  $Ti_2Cl_6$ ; from the analogy of  $PbCl_2$  and  $SnCl_2$  the formula  $TiCl_2$  may be supposed to be molecular, but if the analogy of  $C_2Cl_4$  is to be followed, the molecular formula must be  $Ti_2Cl_4$ .

**TETRACHLORIDE  $TiCl_4$ .** (*Titanium tetrachloride*.) Mol. w. 189.38. Melts at  $-25^\circ$  (Haase, *B.* 26, 1052). Boils at  $136.41^\circ$  at 760 mm. (Thorpe, *C. J.* 37, 329). S.G.  $d_4^{20}$  1.76041; S.G. at b.p. 1.52223 (Thorpe, *l.c.*). V.D. 98.8 at  $143^\circ$  (Dumas, *A. Ch.* [2] 33, 388). S.V. 121.47 (Thorpe, *l.c.*).

**Preparation.**—1.  $TiO_2$  is intimately mixed with c. half its weight of lampblack previously heated to redness in a stream of Cl, and the mixture is heated to full redness in a tube of hard glass connected with a receiver, while a stream of dry Cl is passed over it. The  $TiCl_4$  which collects in the receiver is freed from Cl by shaking with Cu, Hg, or Na amalgam (Merz, *B.* [2] 7, 401), or by boiling for some time (Thorpe, *C. J.* 47, 119), and is then distilled. Thorpe (*l.c.*) conducted the final distillation in dry N.—2. Vapour of  $CCl_4$ , or a mixture of equal volumes of Cl and  $CO_2$ , is passed over  $TiO_2$  in small lumps, heated to bright redness in a tube of hard glass connected with a receiver. The  $TiCl_4$  is purified as described above (Watts a. Bell, *C. J.* 33, 443).

**Properties.**—A colourless liquid, solidifying at  $-25^\circ$  (Haase, *B.* 26, 1052). Does not conduct electricity (O. v. d. Pfordten, *A.* 237, 201). Fumes in the air, rapidly absorbing moisture and solidifying to the hydrate  $TiCl_4 \cdot 5H_2O$  (Demoly, *A.* 72, 213). (For an apparatus for collecting  $TiCl_4$  for analysis, v. Thorpe, *l.c.*)  $TiCl_4$  is violently decomposed by water, forming  $HCl$  aq. and  $TiO_2 \cdot xH_2O$  some of which ppts. (v. *Reactions*, No. 8).

**Reactions.**—1. Hydrogen reduces  $TiCl_4$  at a high temperature, to  $TiCl_3$  and then to  $TiCl_2$  (v. *trichloride and dichloride*).—2. Mixed with oxygen and passed through a red-hot porcelain

tube,  $Ti_2O_3Cl_2$  is formed (v. *Oxychlorides*, p. 748).

3. Heated to  $130^\circ$  in a sealed tube with sodium, the chief product is  $TiCl_2$ , according to O. v. d. Pfordten (*A.* 237, 201); Robinson a. Hutchings (*Am.* 6, 74) say that Ti is produced in this reaction. Nilson a. Pettersson (*W.* 4, 554) obtained Ti by reducing  $TiCl_4$  by Na at a very high temperature.—4. Sodium-amalgam produces  $Ti_2Cl_6$  and  $TiCl_2$  (O. v. d. P., *l.c.*).—5. Reduced silver gives  $Ti_2Cl_6$  and Ti when heated with  $TiCl_4$  to  $180^\circ$  (Friedel a. Guérin, *A. Ch.* [5] 7, 24).—6. By passing vapour of  $TiCl_4$  over silicon, boron, or several metals, heated to bright redness, Lévy (*C. R.* 110, 1368) obtained hard, steel-white, cubical crystals which he supposed to be nearly pure Ti.—7. Pure, dry, hydrogen sulphide reacts at the ordinary temperature, forming  $Ti_2Cl_6$ ; at a higher temperature a pp. is produced which is probably a thiochloride of Ti (O. v. d. P., *A.* 234, 257).—8. Cold water reacts violently with  $TiCl_4$ , with production of much heat and formation of a turbid liquid containing  $HCl$  and holding in suspension  $2TiO_2 \cdot H_2O$  (v. *Metatitanic acid* under **TITANIUM OXYACIDS, AND SALTS AND DERIVATIVES THEREOF**, p. 747); after 30 or 40 hours the liquid becomes clear, but ppn. occurs again on heating to c.  $85^\circ$  when about 7 pts. water are present to 1 pt.  $TiCl_4$  used (v. Thorpe, *C. J.* 47, 120; and cf. **TITANIUM OXYACIDS**, p. 746). According to Merz (*B.* [2] 7, 401), an oxychloride, approximately  $TiCl_3 \cdot 3TiO_2 \cdot 16H_2O$ , is obtained by evaporating  $TiCl_4$  aq. or  $TiCl_4$  that has deliquesced in air, over  $H_2SO_4$  and  $CaO$  (v. *Oxychlorides*, p. 748).  $TiO_2$ , in the form of brookite, is obtained by passing vapour of  $TiCl_4$  and water, mixed with  $CO_2$ , through a red-hot porcelain tube (Daubrée, *C. R.* 29, 227; 39, 153).—9. With hydrochloric acid the compounds  $TiCl_3 \cdot OH$  and  $TiCl_2 \cdot (OH)_2$  are formed (v. **TITANIUM HYDROXYL CHLORIDES**, p. 743).—10. Chlorosulphonic acid ( $SO_3 \cdot HCl$ ) reacts with  $TiCl_4$  at the ordinary temperature to form a yellow, amorphous, deliquescent powder, having the composition  $TiCl_3 \cdot SO_3 \cdot Cl$  (Clausnizer, *B.* 11, 2011).—11. By passing vapour of  $TiCl_4$ , mixed with H, through a white-hot tube containing titanium dioxide the oxychloride  $Ti_2O_3Cl_2$  is obtained (v. *Oxychlorides*, p. 748).

**Combinations.**—1. With water to form a pentahydrate and a dihydrate. Demoly (*A.* 72, 213) obtained  $TiCl_4 \cdot 5H_2O$ , as deliquescent crystals, by allowing  $TiCl_4$  to absorb moisture from the air, then adding a little more water, and evaporating under reduced pressure. By drying the pentahydrate over  $H_2SO_4$  in *vacuo*, D. obtained  $TiCl_4 \cdot 2H_2O$ .—2. With ammonia, to form  $TiCl_4 \cdot 4NH_3$ , according to H. Rose (*P.* 16, 57),  $TiCl_4 \cdot 6NH_3$ , according to Persoz (*A. Ch.* [2] 46, 315); easily decomposed in air; heated in a tube gives off  $NH_3$ , then  $NH_4Cl$  and a yellowish sublimate of  $TiCl_3 \cdot 3NH_4Cl$ , and leaves Ti; heated in  $NH_3$  gives  $Ti_2N_4$  (v. **TITANIUM NITRIDES**, p. 743). 3. With hydrogen phosphide, to form a brown powder, which when heated gives a sublimate of  $3TiCl_4 \cdot 2PH_3 \cdot Cl$  according to H. Rose (*P.* 42, 527). 4. With hydrogen cyanide to form  $TiCl_4 \cdot 2HCN$  (Wöhler, *A.* 73, 226); by vaporizing this compound through a red-hot tube  $Ti_2N_4$  and C are formed (W., *l.c.*).—5. With cyanogen chloride, to form yellow crystals of  $TiCl_4 \cdot ONCl_2$ ; sublimable at  $100^\circ$  (W., *A.* 73, 219).—6. With phosphorus

**pentachloride to form  $TiCl_5.PCl_5$** ; obtained by heating  $TiCl_4$  and  $PCl_5$  to  $150^\circ$  in a sealed tube (Bertrand, *Bl.* [2] 33, 565); also by heating  $TiO_2$  and  $PCl_5$  in the ratio  $TiO_2:3PCl_5$ , or by saturating a mixture of  $TiCl_4$  and  $PCl_5$  with  $Cl$  (Tüttscheff, *A.* 141, 111), and removing excess of  $TiCl_4$  by heating in a stream of  $Cl$  (Weber, *P.* 132, 452). A citron-yellow, loose, semi-crystalline solid; sublimes without melting; deliquescent in air.—7. With **phosphorus trichloride** to form yellow crystals of  $TiCl_4.PCl_3$ , melting at  $85.5^\circ$  (Bertrand, *l.c.*).—8. With **sulphur tetrachloride**, to form  $2TiCl_4.SCl_4$ ; obtained by saturating a mixture of  $TiCl_4$  and  $S_2Cl_2$  with  $Cl$ , and warming in a stream of  $Cl$  (Weber, *P.* 132, 454).—9. By mixing  $TiCl_4$  and **sulphurous chloride** *l.* Rose obtained large yellow crystals, probably a compound of the two chlorides (*P.* 42, 527).—10. With **ammonium chloride**, to form  $TiCl_4.3NH_4Cl$  (*v. supra*, *Combinations*, No. 2).—11. With **phosphoryl chloride** to form  $TiCl_4.POCl_3$ ; obtained by gradually adding  $POCl_3$  to  $TiCl_4$ , and gently warming (Weber, *P.* 132, 453); colourless, deliquescent crystals, melting at  $110^\circ$ , and boiling at  $140^\circ$  (Wehrlin a. Giraud, *C. R.* 85, 288).—12. With **selenion oxychloride** to form a yellow powder, decomposed by heat, having the composition  $TiCl_4.2SeOCl_2$ ; obtained by adding  $SeOCl_2$  to  $TiCl_4$ , and drying the solid that separates on cooling on a tile over  $H_2SO_4$  (Weber, *B. L.* 1865, 154).—13. With **nitrosyl chloride**; obtained by saturating  $TiCl_4$  with  $NO_2$ , and subliming (Hampe, *A.* 126, 47), also by passing the vapours from *aqua regia* into  $TiCl_4$  (Weber, *P.* 118, 476). Hampe (*l.c.*) gives the composition  $3TiCl_4.NOCl$ , Weber (*l.c.*) the composition  $TiCl_4.2NOCl$ . A deep citron-yellow, crystalline mass; decomposes in air; sublimable out of air; with water gives off  $NO$ .—14. With **sulphur trioxide** to form  $TiCl_4.SO_3$  (or  $TiCl_4.OSO_3Cl$ ), formed by the interaction of  $TiCl_4$  and  $SO_3.OHCl$  at the ordinary temperature; a yellow, amorphous, deliquescent powder (Clausnizer, *B.* 11, 2011).—15. Demarcay (*Bl.* [2] 20, 127) obtained a great many compounds of  $TiCl_4$  with *esters, mercaptans, and ethyl sulphide* (*cf.* Bedson, *C. J.* 29, 309).

**TITANIUM TRICHLORIDE  $TiCl_3$ .** (*Titanium sesquichloride. Titanous chloride.*) Mol. w. not determined; but from analogy of  $C_2Cl_6$  and  $Si_2Cl_6$  the formula  $Ti_2Cl_6$  is probably molecular.

**Formation.**—1. By reducing  $TiCl_4$  by  $H$  (*v. Preparation*).—2. By reducing  $TiCl_4$  by sodium-amalgam (O. v. d. Pfordten, *A.* 237, 201); or by pure, dry  $H_2S$  (O. v. d. P., *A.* 234, 257).—3. By heating  $TiCl_4$  with reduced  $Ag$  to  $180^\circ$ ;  $Ti$  is also formed, and probably  $TiCl_2$  also (Friedel a. Guérin, *A. Ch.* [5] 8, 24).—4. A solution of  $TiCl_4$  is obtained by digesting a solution of  $TiO_2.xH_2O$  in  $HClAq$  with  $Cu$  at  $40^\circ-50^\circ$  (Fuchs, *A.* 56, 319); or with  $Ag$  ppd. by zinc from  $AgCl$  (von Kobell, *P.* 62, 599).  $Ti_2Cl_6$  is also probably present in the greenish liquid obtained by adding  $Na$  amalgam to  $K_2TiF_6$  in  $HClAq$  (O. v. d. P., *A.* 237, 201).

**Preparation.**— $TiCl_4$  is placed in a retort connected with a tube of porcelain or hard glass (if a glass tube is used it should be wrapped in copper-foil) which is placed horizontally in a furnace; the other end of the tube projects considerably out of the furnace and is connected with a receiver to collect undecomposed  $TiCl_4$ .

The delivery tube from an apparatus evolving pure and dry  $H$  passes into the retort beneath the surface of the  $TiCl_4$ .  $H$  is passed through the apparatus until it is entirely filled with the gas; the tube is then heated to redness, and the retort is gently warmed.  $Ti_2Cl_6$  is formed and condenses as dark-violet scales on the part of the tube that projects out of the furnace. When all the  $TiCl_4$  has been driven out of the retort, the  $Ti_2Cl_6$  in the cooler part of the tube is gently warmed, while the passage of  $H$  is continued, to remove any adhering  $TiCl_4$ ; the  $Ti_2Cl_6$  is allowed to cool in the stream of  $H$  (Ebelmien, *A. Ch.* [3] 20, 385).

**Properties.**—A dark-violet, very lustrous solid, deliquescent in air, and dissolving in water to form a violet liquid, which gradually decolourises with ppn. of  $TiO_2.xH_2O$ .  $Ti_2Cl_6$  is easily soluble in alcohol, forming a violet or green liquid; it is insoluble in ether, and sparingly soluble in  $HClAq$  (O. v. d. P., *A.* 237, 201).

**Reactions.**—1. Heated in *hydrogen* to c.  $440^\circ$ ,  $TiCl_4$  distils over and  $TiCl_2$  remains (Friedel a. Guérin, *A. Ch.* [5] 8, 24). 2. Heated in *air*,  $TiCl_4$  vaporises and  $TiO_2$  remains.—3. Dissolves in *water*, forming a violet, or green-violet, liquid which slowly becomes colourless, with ppn. of  $TiO_2.xH_2O$ .—4. *Alkalis, or alkali carbonates*, in solution ppt.  $Ti_2O_3.xH_2O$  from  $Ti_2Cl_6Aq$ ; *ammonium sulphide* forms the same ppt.; *hydrogen sulphide* gives no ppt. (Ebelmien, *l.c.*).—5.  $Ti_2Cl_6Aq$  reduces *solutions of gold, silver, or platinum salts* with ppn. of the metals; *ferric and cupric salts* are reduced to ferrous and cuprous salts; *sulphurous acid solution* is reduced by heating with  $Ti_2Cl_6Aq$  with ppn. of  $S$  (*l.c.*).—6.  $Ti_2Cl_6$  reacts with *bromine* to form a liquid boiling at  $151^\circ$ , probably  $TiBrCl$  (*P. a. G.*, *l.c.*).

**Combinations.**—With *water* to form  $Ti_2Cl_6.8H_2O$ ; obtained by Glatzel (*B.* 9, 1829) by evaporating a solution of  $Ti$  in  $HClAq$  to the crystallising point, filtering off ppd.  $TiO_2.xH_2O$  from time to time. The hydrate is a green solid; it dissolves in water, forming an opalescent violet solution containing a little suspended  $TiO_2.xH_2O$ ; the solution becomes colourless on standing, and then gives the reactions of titanous acid.

**TITANIUM DICHLORIDE  $TiCl_2$ .** (Sometimes called *titanous chloride*.) Mol. w. is not known. From the analogy of  $SnCl_2$  and  $PbCl_2$ , the formula  $TiCl$  would be molecular; but from the analogy of  $C_2Cl_6$  the molecular formula would be  $Ti_2Cl_4$ .

**Formation.**—1. By reducing  $TiCl_4$  by  $H$  (*v. Preparation*).—2.  $TiCl_2$  is probably formed, along with  $TiCl_3$ , by heating  $TiCl_4$  with reduced  $Ag$  (Friedel a. Guérin, *A. Ch.* [5] 8, 24).—3. Along with  $Ti_2Cl_6$ , by the action of  $Na$  amalgam on  $TiCl_4$ ; also by heating  $TiCl_4$  with  $Na$  to  $130^\circ$  in a sealed tube (O. v. d. Pfordten, *A.* 237, 201).

**Preparation.**— $TiCl_4$  reacts with  $H$  at a red heat to give  $TiCl_2$  and  $TiCl_3$ . Friedel a. Guérin (*l.c.*) proceed as follows. The tube containing  $TiCl_4$ , prepared from  $TiCl_4$  (*v. supra*), while still filled with  $H$ , is connected with an apparatus evolving pure, dry  $CO_2$ , and the whole of the  $H$  in the apparatus is driven out by  $CO_2$ . The  $Ti_2Cl_6$  is then shaken into a small tubulated retort, placed on a sand-tray, and previously filled with  $CO_2$ ; the  $CO_2$  is displaced by pure, dry  $H$ ; the retort is then heated to dull red.

ness, while a stream of H is passed through it, until  $TiCl_4$  ceases to distil off; the retort is allowed to cool in the stream of H, and  $CO_2$  is then passed in until all the H is removed (if this is omitted the  $TiCl_4$  takes fire in the air), and the black  $TiCl_4$  in the retort is quickly shaken into small dry tubes filled with  $CO_2$ , which are at once sealed off.

**Properties.**—A black, light powder; very rapidly absorbs water, forming a kind of mud; insoluble in  $CS_2$ ,  $CHCl_3$ , or  $Et_2O$ . Volatilised without melting by heating to full redness in II. Shaken with  $Et_2O$  and  $KCNsAq$ , the  $Et_2O$  becomes dark brown; this is a delicate test for  $TiCl_4$  (O. v. d. Pfordten, A. 237, 201).

**Reactions.**—1. Takes fire when touched with a drop of water (? with formation of  $Ti_2O_3Cl_2$ ; v. F. a. G., l.c.); thrown into water, it hisses like red-hot iron, decomposing the water with evolution of H and formation of a yellowish liquid.—2. Decomposes absolute alcohol, giving off H and forming a yellowish liquid.—3. Heated in air,  $TiCl_4$  burns like tinder, giving off  $TiCl_3$  and leaving  $TiO_2$ —4. With bromine it forms a liquid boiling at  $176^\circ$ , probably  $TiCl_3Br_2$  (F. a. G., l.c.).

**Titanium, chlorobromides of, v. TITANIUM BROMOCHLORIDES, p. 739.**

**Titanium, cyanonitride of, v. TITANIUM CARBONITRIDE, p. 739.**

**Titanium, ferrocyanides of, v. vol. ii. p. 337.**

**Titanium, fluorides of.** The only compound that has been isolated with certainty is  $TiF_4$ . There are indications of the existence of  $Ti_2F_6$ , and compounds of this fluoride with alkali fluorides are known.

**TITANIO FLUORIDE  $TiF_4$ .** (*Titanium tetrafluoride*.) Formula probably molecular, from analogy of  $TiCl_4$  and  $TiF_3$ . By heating a mixture of  $TiO_2$  and  $CaF_2$  with  $H_2SO_4$ , Unverdorben (P. 7, 320) obtained a colourless distillate, which he supposed to contain a compound of Ti and F. Berzelius (P. 4, 1) obtained crystals (?  $TiF_4$ ) by dissolving  $TiO_2 \cdot xH_2O$  in  $HFAq$ . The crystals were decomposed by water, giving an acid solution (?  $H_2TiF_6Aq$ ), and an insoluble, 'so to say basic,' compound.  $TiO_2$  is obtained by passing vapour of  $TiF_4$ , mixed with  $H_2O$ , through a tube heated to c.  $800^\circ$  or  $1000^\circ$  (Hautefeuille, A. Ch. [4] 4, 131; cf. TITANIUM DIOXIDE, p. 741). Heated to redness in H, perhaps gives  $Ti_2F_6$  (H., l.c.).

**Combinations.**—1.  $TiF_4$  probably combines with hydrogen fluoride to form  $H_2TiF_6$ . By dissolving  $TiO_2 \cdot xH_2O$  in  $HFAq$ , evaporating, adding water to the crystals (?  $TiF_4$ ) thus formed, and filtering from an insoluble solid (? oxyfluoride). Berzelius (P. 4, 1) obtained an acid solution from which, by neutralisation with  $KOH$  and evaporation, he obtained the salt  $K_2TiF_6$ . The acid solution probably contained  $H_2TiF_6$ . This compound (if it exists) is best called *titaniofluorhydric acid*. It is analogous to  $H_2SiF_6$ ,  $H_2SnF_6$ , and other acids of the type  $H_2MX_6$ , where M = an element of Group IV. (except Cr), and X = a halogen.—2. With various metallic fluorides to form  $TiF_3 \cdot 2MF = M_2TiF_6$ . These salts were obtained from the K salt, which was got by neutralising the acid solution prepared as described under 1. Salts of  $NH_4$ , Ca, Cu, Fe, Pb, Mg, and Ni are described (B., l.c.; Weber,

P. 120, 291). These salts are best called *titaniofluorides*; they are similar to stanniofluorides.—3.  $TiF_4$  also combines with ammonium fluoride to form  $TiF_3 \cdot 3NH_4F$  (besides  $TiF_3 \cdot 2NH_4F$ ) (Baker, C. J. 85, 763).

By adding  $NH_4Aq$ , drop by drop, to warm  $(NH_4)_2TiF_6Aq$ , Piccini (G. 17, 479) obtained a compound of the form  $TiO_2 \cdot F_2 \cdot xNH_4F$ ; from this he prepared  $TiO_2 \cdot F_2 \cdot BzF_3$ , and by carefully decomposing this salt by  $H_2SO_4$  he obtained a solution of the acid  $TiO_2 \cdot F_2 \cdot 2HF$ . P. regards this acid as a F derivative of the hypothetical *perititanic acid*  $H_2TiO_4$  (the acid of  $TiO_2$ ); he calls the acid *fluoroxypertitanic acid*, and the salts *fluoroxypertitanates*. Following the plan adopted in this Dictionary, the acid will be called *titaniooxyfluorhydric acid*  $H_2TiO_2F_2$ , and the salts,  $M_2TiO_2F_2$ , will be called *titaniooxyfluorides*.  $H_2TiO_2F_2Aq$  is a yellow liquid, not pptd. by Ba salts, giving a pp. of  $TiO_2$  with alkali carbonates.

**TITANIUM TRIFLUORIDE  $TiF_3$ .** This compound is said to be formed by strongly heating  $K_2TiF_6$  in a stream of H with a little  $HCl$ , according to Hautefeuille (C. R. 59, 189; cf. 57, 151). According to H., the compound is a purple-red solid, soluble in water. By treating  $TiCl_4Aq$  with  $KHF_4$  or  $NH_4F$ , Piccini (G. 16, 104) obtained violet pps. of  $Ti_2F_6 \cdot 2MF$ , where M =  $NH_4$  or K; he also obtained  $Ti_2F_6 \cdot 3NH_4F$ . The K salt is slightly soluble in water; soluble in dilute acids, forming green liquids, from which alkalis throw down azure-blue pps. that gradually oxidise to  $TiO_2 \cdot xH_2O$  on exposure to air. The salt  $TiF_3 \cdot 3NH_4F$ , when exposed to air, gradually oxidises to  $TiO_2 \cdot F_2 \cdot 3NH_4F$ .

**Titanium, haloid compounds of.** Ti combines with the halogens directly to form compounds  $TiX_4$ ; these tetrahalides are generally prepared by passing the halogen as gas over a red-hot mixture of  $TiO_2$  and C.  $TiF_4$  is best prepared by heating  $TiCl_4$  in HI gas, and  $TiBr_4$  is very conveniently prepared by heating  $TiCl_4$  in  $HBr$  gas;  $TiF_4$  is prepared by dissolving  $TiO_2 \cdot xH_2O$  in  $HFAq$  and evaporating. The two tetrahalides  $TiCl_4$  and  $TiI_4$  have been gasified. These formulæ are molecular, hence the formulæ  $TiF_4$  and  $TiBr_4$  probably also represent the compositions of the gaseous molecules of these compounds. By the action of H, or certain other reducing agents, on  $TiCl_4$ , two chlorides are obtained,  $Ti_2Cl_3$  and  $TiCl_3$ . The V.D. of neither has been determined, but from the analogy of  $C_2Cl_4$  and  $Si_2Cl_4$ , the value of x in  $Ti_2Cl_3$  is probably 2; from the analogy of  $C_2Cl_4$ , the molecular formula of the lowest chloride is probably  $Ti_2Cl_3$ , but from the analogy of  $SnCl_2$  and  $PbCl_2$ , the formula  $TiCl_2$  would be given to it.  $TiF_3$  or  $TiF$  probably exists. No bromide or iodide of either type  $Ti_2X_3$  or  $TiX_3$  has been isolated. Two bromochlorides of the types  $Ti_2X_3$  and  $Ti_2X_2$  probably exist.  $TiCl_4$  and  $TiBr_4$  dissolve in cold water; the solutions contain  $HXAq$  and  $TiO_2 \cdot xH_2O$ ; dilution, and more quickly heating, ppts. insoluble  $TiO_2 \cdot xH_2O$  from the solution of  $TiCl_4$ .  $TiF_4$  is decomposed by water, giving  $H_2TiF_6Aq$  (and ? an oxyfluoride).  $TiI_4$  is also decomposed by water; on heating insoluble  $TiO_2 \cdot xH_2O$  separates.  $TiCl_4$  combines with many non-metallic chlorides and oxychlorides.  $TiF_4$  combines with metallic fluorides,

forming salts  $M.TiF_3$ , and also some more complex salts  $xTiF_3.yMF_3$ . A few oxyhaloid compounds have been isolated, but a great number can doubtless be formed. The acid  $H_2TiO_3.F$ , and salts of this acid have been isolated.  $TiCl_3$  dissolves in water, and after a time  $TiO_2.xH_2O$  separates; the solution is an energetic reducing agent; alkalis ppt.  $Ti_2O_3.xH_2O$ .  $TiCl_3$  reacts violently with water, giving off H, and probably forming an oxychloride.

**Titanium, hydroxyl chlorides of.** By the reaction of the proper quantity of 36 p.c.  $HClAq$  with  $TiCl_3$ , the compound  $Ti(OH)Cl_2$  was obtained by Koenig a. O. v. d. Pfordten (*B.* 21, 1708); using the calculated quantity of 36 p.c.  $HClAq$ , the compound  $Ti(OH)_2Cl_2$  was produced; and the prolonged action of ordinary air on either of the preceding compounds resulted in the formation of  $Ti(OH)_2Cl$ . These compounds are regarded by K. a. O. v. d. P. as derived from  $Ti(OH)_3$ , by replacement of OH by Cl; the compounds may be called *orthotitanic chlorhydrins*. The compounds are yellow or white deliquescent solids; they dissolve in water;  $Ti(OH)_2Cl_2$  very rapidly with a hissing noise,  $Ti(OH)_2Cl$  less violently, and  $Ti(OH)Cl_2$  with some difficulty. The aqueous solutions give pps. of  $TiO_2.xH_2O$  on boiling. When the compounds are heated they give (1)  $TiCl_3$  and  $TiO_2.xH_2O$ , (2)  $TiO_2.xH_2O$  and  $HCl$ , and (3)  $TiO_2.xH_2O$ ,  $HCl$ , and  $H_2O$ . By reducing  $Ti(OH)Cl_2$  by Na amalgam, in  $H_2$ ,  $Ti_2O_3$  is produced (K. a. O. v. d. P., *B.* 22, 2070; cf. *B.* 22, 1485).

**Titanium, hydroxyl fluoride of.** This name may be given to the compound  $Ti(OH)_2F$ ; it is described as *titanoxylfluorhydric acid*, under TITANIC FLUORIDE (p. 742).

**Titanium, iodides of.** Only one compound has been isolated,  $TiI_4$ .

**TITANIC IODIDE  $TiI_4$ .** (*Titanium tetra-iodide*.) Mol. w. 554.02. V.D. at  $410^\circ = 261.2$  (Hautefeuille, *Bl.* [2] 7, 201).

**Formation.**—1. Vapour of I is passed over Ti heated to redness (Weber, *P.* 120, 287).—2. A mixture of  $TiCl_3$  vapour, I vapour, and H is passed through a tube heated to dull redness;  $TiI_4$ , mixed with free I, condenses on the colder part of the tube (Hautefeuille, *Bl.* [2] 7, 201).—3. By decomposing  $TiCl_3$  by HI.

**Preparation.**—Dry HI gas is passed into  $TiCl_3$ , which is gradually heated to its b.p. and kept at that temperature until the reaction is completed; the  $TiI_4$  is freed from traces of I, which give it a violet tinge, by a few distillations in H (*H.*, *Lc.*).

**Properties and Reactions.**—A reddish-brown, lustrous, brittle solid; when melted and cooled, crystallises in octahedra, changing after some days to tufts of silky, prismatic crystals. Melts at  $150^\circ$ , and boils a little above  $360^\circ$ ; can be distilled without decomposition; melted  $TiI_4$  remains liquid till cooled below  $100^\circ$ . Fumes strongly in the air. Dissolves easily in water; solution turns brown on exposure to air and ppts.  $TiO_2.xH_2O$ . When vapour of  $TiI_4$  is heated in air it burns to  $TiO_2$  and  $I_2$  (*H.*, *Lc.*).

**Titanium, nitrides of.** Four compounds of Ti and N have been described; but according to later experiments only two seem to exist.

**TITANIUM TETRANITRIDE  $Ti_4N_4$ .** Mol. w. unknown. This compound is obtained by heating

$TiCl_3.4NH_3$  (*v.* TITANIC CHLORIDE, *Combinations*, No. 2, p. 740), loosely packed in a tube of hard glass, in a stream of dry  $NH_3$ , until the glass begins to melt, and allowing to cool in  $NH_3$  (Wöhler, *A.* 73, 43; Friedel a. Guérin, *A. Ch.* [5] 8, 24). Indigo-blue powder, or golden-yellow (? rhombohedral) crystals; strongly heated in H gives  $Ti_3N_4$  (*F.* a. G., *Lc.*).

**DITITANIUM DINITRIDE  $Ti_2N_2$ .** Mol. w. unknown. Prepared by placing two porcelain boats, one containing Na and the other  $K.TiF_6$ , in a hard-glass tube previously filled with N, passing a stream of dry N through the tube, heating the  $K.TiF_6$  to full redness while the Na is volatilised over it, and allowing to cool in N after all the Na has been volatilised; boiling with  $HClAq$ , washing, and drying (Wöhler a. Deville, *A.* 102, 231). Also obtained by heating  $K.TiF_6$  with K,  $KCl$ ,  $NaCl$ , and Al in N; also by passing  $TiCl_3$  vapour and H over heated Al in N; also by passing vapour of  $TiCl_3$  over heated  $NH_4Cl$  (*W.* a. D., *Lc.*). *F.* a. G. (*Lc.*) obtained the same compound by strongly heating  $TiO_2$  in a stream of dry  $NH_3$  for some hours; *W.* (*A.* 73, 43) said that  $Ti_2N_2$  was formed by this reaction. *F.* a. G. also obtained  $Ti_2N_2$  by strongly heating  $Ti_3N_4$  in H; *W.* said that  $Ti_2N_2$  was formed by this reaction. An amorphous, brown-yellow, very hard powder; S.G. 5.28 at  $18^\circ$  (*F.* a. G., *Lc.*).

The nitrides of Ti are not decomposed by heating, out of air, to c.  $950^\circ$ – $1,000^\circ$ ; fused with KOH, or strongly heated in steam (*F.* a. G., *Lc.*). They give off  $NH_3$ ; heated in  $Cl_2$ ,  $TiCl_3$  is produced (*F.* a. G., *Lc.*); heated with  $CuO$ ,  $PbO$ , or  $HgO$ , the nitrides burn, and Cu, Pb, or Hg is produced (*W.*, *A.* 123, 31).

**TITANIUM DINITRIDE  $Ti_2N_2$ .** This compound is formed, according to Wöhler (*A.* 73, 43), by heating  $TiO_2$  in  $NH_3$  for some time. Friedel a. Guérin (*A. Ch.* [5] 8, 21) say that the substance obtained by *W.* contained  $Ti_2O_3$ , and that if the heating is continued until a definite nitride is formed the compound so produced is  $Ti_2N_2$ .

**PENTATITANIUM HEXANITRIDE  $Ti_5N_6$ .** Formed, according to *W.* (*Lc.*), by heating  $Ti_3N_4$  to full redness in H; or, mixed with C, by heating  $TiO_2$  in CN or HCN gas. *F.* a. G. (*Lc.*) say that the product of either reaction is  $Ti_5N_6$ , in the latter reaction mixed with C.

**Titanium, nitrocyanoide of, *v.* TITANIUM CARBONITRIDE** (p. 739).

**Titanium, oxides and hydrated oxides of** (*cf.* TITANIUM OXYACIDS AND SALTS AND DERIVATIVES THEREOF, p. 746). Ti burns when heated in  $O_2$ , forming  $TiO_2$ ; by the reaction of reducing agents on  $TiCl_3Aq$ , and addition of alkalis,  $Ti_2O_3$  is obtained; when the reduction is carried further it is probable that  $TiO.xH_2O$  is formed. By the reaction of  $H_2O$  in presence of alkali on salts of  $TiO_2$ , a pp. of  $TiO_2$  is obtained. Oxides intermediate between  $TiO_2$  and  $Ti_2O_3$  probably exist.  $TiO_2$  is a basic oxide, forming salts  $TiX_2$ , where  $X = NO_3, ASO_3$ , &c.; many of the salts are basic. A few salts corresponding with  $Ti_2O_3$  have been isolated; no salt corresponding with  $TiO$  and derived from an oxyacid has yet been obtained. Some of the hydrates of  $TiO_2$  react as feeble acids.

**TITANIUM DIOXIDE  $TiO_2$ .** (*Titanic oxide, Titanic anhydride*.) Mol. w. unknown.

**Occurrence.**—As *rutile*, *anatase*, and *brookite*; *rutile* occurs in dimetric prisms, isomorphous with *tinstone*; *anatase* in dimetric octahedra; and *brookite* in trimetric octahedra.

**Formation.**—1. By burning Ti in air or O.—2. By ppg.  $\text{TiCl}_4$  by alkali, and washing, drying, and strongly heating the ppd.  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ .—3. By ppg.  $\text{K}_2\text{TiF}_6$  by  $\text{NH}_4\text{Aq}$ , and strongly heating the pp. after washing and drying.—4. Vapour of  $\text{TiCl}_4$ , or  $\text{TiF}_4$ , mixed with steam is passed through a red-hot tube.—5.  $\text{TiS}_2$  is heated in dry  $\text{CO}_2$  ( $\text{TiS}_2 + 2\text{CO}_2 = \text{TiO}_2 + 2\text{CO} + 2\text{S}$ ; O. v. d. Pfordten, *B.* 22, 2070).

**Preparation.**—A. Amorphous titanic oxide.—1. Pure  $\text{TiCl}_4$  is added, little by little, to water; sufficient  $\text{NH}_4\text{Aq}$  to neutralise the  $\text{HCl}$  produced is added, the solution is evaporated to dryness, and the residue is heated to somewhat above  $700^\circ$  until it ceases to lose weight.  $\text{TiCl}_4$  may be obtained from *rutile* by mixing the finely-powdered mineral with c. half its weight of dry charcoal-powder, making into little pellets with starch-paste, drying the pellets, heating them to full redness in a covered crucible, then heating in a tube of hard glass (to get quite dry), and then passing dry  $\text{Cl}$  over the pellets while they are heated to bright redness, and a dry receiver is connected with the end of the hard glass tube. The  $\text{TiCl}_4$  may be purified (from  $\text{SiCl}_4$ ,  $\text{FeCl}_3$ , &c.) by repeatedly distilling, best in a stream of  $\text{N}$  (v. Merz, *J. pr.* 99, 161).—2.  $\text{K}_2\text{TiF}_6$  is dissolved in water,  $\text{NH}_4\text{Aq}$  is added, the pp. of  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  is thoroughly washed, dried, and heated to somewhat above  $700^\circ$ . (For a method of getting  $\text{K}_2\text{TiF}_6$  from *rutile* v. *Preparation of titanium*, p. 738.) For other methods of preparing  $\text{TiO}_2$  from Ti ores v. Lévy (*A. Ch.* [6] 25, 511), Austen a. Wilber (*Am.* 4, 211), Hempel (*Zeit. f. anorg. Chemie*, 3, 193), Jones (*Fr.* 9, 41, 330). B. Crystalline titanic oxide.—3. By long-continued heating to whiteness  $\text{TiO}_2$  is said to become crystalline (v. Rammelsberg, *B.* 5, 1006).—4. Amorphous  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  is heated to incipient redness in  $\text{HCl}$  gas, at a pressure of three atmospheres; the crystals have the form of *anatase* (Hautefeuille a. Perrey, *C. R.* 110, 1038).—5. Crystalline  $\text{TiO}_2$  is also formed, according to Hautefeuille (*A. Ch.* [4] 4, 127), by passing the mixed vapours of  $\text{TiF}_4$ ,  $\text{HF}$ , and  $\text{HCl}$ —obtained by decomposing molten  $\text{K}_2\text{TiF}_6$  by  $\text{HCl}$  gas—through a Pt tube into which a stream of moist  $\text{H}$  is also passed; at c.  $860^\circ$  (boiling-point of  $\text{Cd}$ ) crystals of *anatase* are produced, and at temperatures between  $860^\circ$  and  $1,000^\circ$  *brookite* is formed.—6. Heating amorphous  $\text{TiO}_2$  in an atmosphere of  $\text{HF}$  causes crystallisation; at an incipient red heat *anatase* forms, at a higher temperature *brookite*, and at a very high temperature *rutile* ( $\text{H.}$ , *l.c.*).—7. Crystals of *rutile* are formed by heating amorphous  $\text{TiO}_2$  with microcosmic salt (Ebelmen, *A. Ch.* [3] 33, 34), or with borax (G. Rose, *B.* 1867, 129; Knop, *A.* 157, 365), in a porcelain oven. For other methods of producing crystals of  $\text{TiO}_2$  v. Deville (*C. R.* 53, 161, 163), Senarmont (*A. Ch.* [3] 30, 129), Michel (*C. R.* 115, 1020), Wöhler (*A.* 73, 35), Daubrée (*C. R.* 29, 227; 39, 153), H. Rose (*A.* 56, 127; 68, 163).

**Properties.**— $\text{TiO}_2$  obtained by strongly heating  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  forms reddish-brown lumps, more nearly resembling *rutile* in colour and lustre the

higher the temperature to which it is heated. The dehydration by heat of  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  is accompanied by the appearance of shades of colour from white, though grey and greenish, to black, according to Wagner (*B.* 21, 960); these colours are similar to those shown by *anatase*, *brookite*, and *rutile*. Nilson a. Pettersson (*Z. P. C.* 1, 33 note) prepared  $\text{TiO}_2$  as a white powder with faintest yellow tinge, by decomposing  $\text{TiCl}_4$  by  $\text{NH}_4\text{Aq}$ , evaporating, and heating to whiteness. When melted by the O-H flame the colour is blue to black. S.G.  $\text{TiO}_2$  increases as the oxide is heated; heated to c.  $700^\circ$  S.G. is c. 3.95 (Karsten, *S.* 65, 394), after being very strongly heated S.G. rises to 4.25 (Ebelmen, *J.* 4, 15; 12, 14). S.G. of *anatase* is 3.75 to 3.9 (Breithaupt, *J.* 2, 730; Damour, *J.* 10, 666); S.G. of *brookite* is 4 to 4.2 (Rammelsberg, *J.* 2, 730; Beck, *J.* 3, 701); S.G. of *rutile* is c. 4.3 (Schreier, *P.* 65, 296; Müller, *J.* 5, 847). After fusion in the O-H flame and cooling S.G. is 4.1, according to Hautefeuille (*A. Ch.* [4] 40, 140). S.H.  $0^\circ$  to  $100^\circ = 1.785$ ,  $0^\circ$ – $211^\circ = 1.791$ ,  $0^\circ$ – $301^\circ = 1.843$ ,  $0^\circ$ – $440^\circ = 1.919$  (Nilson a. Pettersson, *Z. P. C.* 1, 27;  $\text{TiO}_2$  prepared by decomposing  $\text{TiCl}_4$  by  $\text{NH}_4\text{Aq}$ , evaporating to dryness, and heating to white heat).  $\text{TiO}_2$  crystallises in dimetric prisms (*rutile*), dimetric octahedra (*anatase*), and trimetric octahedra (*brookite*); it is isotrimorphous with  $\text{SnO}_2$  (Wunder, *J. pr.* [2] 2, 206).  $\text{TiO}_2$  is somewhat hygroscopic, even after prolonged and intense heating (Thorpe, *C. J.* 47, 125). It is insoluble in water, and in all acids except conc.  $\text{H}_2\text{SO}_4$ ; when powdered  $\text{TiO}_2$  is heated with conc.  $\text{H}_2\text{SO}_4$  until the excess of acid is removed, the solid thus produced dissolves in water.  $\text{TiO}_2$  melts in the O-H flame. According to Moissan (*C. R.* 115, 1034), when heated in an electric furnace to c.  $2500^\circ$   $\text{TiO}_2$  forms black crystals of  $\text{TiO}$ .

**Reactions.**—1. According to Ebelmen (*A. Ch.* [3] 20, 394),  $\text{TiO}_2$  is reduced to  $\text{TiO}$ , by heating to redness in *hydrogen*; but O. v. d. Pfordten (*A.* 237, 201) says the product has the composition  $\text{Ti}_2\text{O}_3$ .—2. A mixture of  $\text{TiO}_2$  and magnesium powder heated to redness in  $\text{H}$  gives  $\text{MgTiO}_3$ , and a brown powder which is probably  $\text{TiO}$  (Winkler, *B.* 23, 2657).—3. A mixture of  $\text{TiO}_2$  and carbon strongly heated in *chlorine* gives  $\text{TiCl}_4$ .—4. By long-continued heating in dry ammonia  $\text{Ti}_3\text{N}_4$  is formed (Friedel a. Guérin, *A. Ch.* [5] 8, 24).—5. The compound  $\text{TiCl}_4 \cdot \text{PCl}_5$  is obtained by heating an intimate mixture of  $\text{TiO}_2$  and phosphorus pentachloride, in the ratio  $\text{TiO}_2 : 3\text{PCl}_5$ , in a retort until the  $\text{POCl}_3$  formed is driven off (Weber, *P.* 132, 452).—6. Heated to redness in carbon tetrachloride vapour,  $\text{TiCl}_4$  is formed (Watts a. Bell, *C. J.* 33, 443). Demarcay (*C. R.* 104, 111) says that the first product is  $\text{TiOCl}_2$ .—7.  $\text{TiCl}_4$  is formed by heating  $\text{TiO}_2$  to redness in a mixture of equal volumes of *chlorine* and carbon monoxide (W. a. B., *l.c.*).—8.  $\text{Ti}_3\text{N}_4$  mixed with  $\text{C}$  is formed by heating  $\text{TiO}_2$  in cyanogen or in *hydrogen cyanide* (Friedel a. Guérin, *A. Ch.* [5] 8, 24).—9. Heating in a mixture of *hydrogen sulphide* and carbon disulphide forms  $\text{Ti}_2\text{S}_3$ , or  $\text{TiS}_2$ , according to the temperature (Thorpe, *C. J.* 47, 491).—10. When  $\text{TiO}_2$  is fused with sodium or potassium carbonate the weight of  $\text{CO}_2$  expelled corresponds with the formation of  $\text{M}_2\text{TiO}_3$ ; on treating the fused mass

with water  $\text{MOH.Aq}$  is formed, and an acid Na or K titanate which is insoluble in water (v. Hermann, *J. pr.* 38, 92).—11. Fusion with *potassium hydrogen sulphate* forms a substance soluble in water; by evaporating the fused mass with conc.  $\text{H}_2\text{SO}_4$ , and then treating with water, the double salt  $(\text{Ti}(\text{SO}_4)_2)_x \cdot \text{K}_2\text{SO}_4 \cdot 3\text{H}_2\text{O}$  is obtained (Warren, *P.* 102, 449; Glatzel, *B. 9*, 1833; Hermann, *l.c.*).—12. Heating powdered  $\text{TiO}_2$  with conc. *sulphuric acid* produces a substance that dissolves wholly in water (? forming  $\text{Ti}(\text{SO}_4)_2 \cdot x\text{H}_2\text{O}$  or  $\text{TiO} \cdot \text{SO}_3$ ; v. Merz, *J. pr.* 99, 157). For reactions of  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  v. *infra*, *hydrated titanic oxide*; and v. also *titanic acid* under TITANIUM OXYACIDS AND SALTS AND DERIVATIVES THEREOF, p. 746).

**HYDRATED TITANIC OXIDE.** Hydrates of  $\text{TiO}_2$  are obtained by gradually adding  $\text{TiCl}_3$  or  $\text{TiBr}_3$  to cold  $\text{NH}_4\text{Aq}$ ; by fusing  $\text{TiO}_2$  with  $\text{KHSO}_4$ , dissolving in water, diluting, and boiling for some time; by adding water to  $\text{TiCl}_3$  and boiling; by fusing  $\text{TiO}_2$  with  $\text{K}_2\text{CO}_3$ , washing the fused mass with small quantities of water till all KOH is removed, adding a little conc.  $\text{HCl.Aq}$ , filtering cold, and allowing the liquid to stand, when it gradually deposits gelatinous  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  (O. v. d. Pfordten, *B.* 17, 727); by decomposing  $\text{Ti}(\text{OEt})_4$  by  $\text{H}_2\text{O}$  (Demarcay, *C. R.* 80, 51); and by other reactions. The isolation of a great many definite hydrates of  $\text{TiO}_2$  has been announced from time to time. By decomposing  $\text{TiCl}_3 \cdot \text{PCl}_5$  (v. TITANIC CHLORIDE, *Combinations*, No. 6, p. 740) by the action of moist air, and drying over  $\text{H}_2\text{SO}_4$ , Tittschschaff (*A.* 141, 111) said that the *dihydrate*  $\text{TiO}_2 \cdot 2\text{H}_2\text{O}$  was formed, and by drying this at  $110^\circ$ – $120^\circ$  he said that the *monohydrate*  $\text{TiO}_2 \cdot \text{H}_2\text{O}$  was obtained. According to Carnelley a. Walker (*C. J.* 53, 66, 81), dehydration of  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  (obtained by adding  $\text{TiCl}_3$  to cold  $\text{NH}_4\text{Aq}$ ), air-dried for 14 days, proceeds continuously from  $15^\circ$  to  $710^\circ$  whereas the whole of the water is removed. A very large number of hydrates probably exists, and these pass one into the other as temperature rises without any of them remaining unchanged through more than a few degrees.

Two classes of hydrates of  $\text{TiO}_2$  exist; one obtained by ppg.  $\text{TiCl}_3$  by  $\text{NH}_4\text{Aq}$ , or warming  $\text{TiO}_2$  with conc.  $\text{H}_2\text{SO}_4$ , dissolving in water, diluting, and ppg. by alkali; the other obtained by dissolving hydrates of the former class in dilute acid, and boiling. Hydrates of the former class dissolve easily in dilute acids, while those of the latter class are insoluble in dilute acids (for more details v. TITANIUM OXYACIDS, p. 746).

Hydrated  $\text{TiO}_2$ , obtained by ppg. by alkali in the cold, dissolves in dilute acids, forming salts  $\text{TiX}_3$ , where  $\text{X} = \text{NO}_3$ ,  $\frac{1}{2}\text{SO}_4$ , &c.; not many salts of this form have been isolated, and most of those that are known are basic salts.  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  dissolves in molten  $\text{H}_3\text{PO}_4$ ; on cooling crystals of  $\text{TiO} \cdot \text{P}_2\text{O}_5$  (=  $\text{TiP}_2\text{O}_7$ ) are obtained (Haute-feuille a. Margottet, *C. R.* 102, 1017). By heat- $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  with a little cold conc.  $\text{HCl.Aq}$ , pouring off the solution after a few days, and evaporating it in *vacuo*, Koenig a. O. v. d. Pfordten obtained crystals approximating to  $\text{Ti}(\text{OH})_2\text{Cl}_2$ , but differing from  $\text{Ti}(\text{OH})_2\text{Cl}_2$  prepared by the interaction of  $\text{TiCl}_3$  and  $\text{HCl.Aq}$  (*B.* 22, 1485; cf. TITANIUM HYDROXYL CHLORIDES, p. 743).

**TITANIUM SESQUIOXIDE  $\text{Ti}_2\text{O}_3$ .** (*Titanous*

*oxide*.) Mol. w. unknown. By digesting a solution of  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  in  $\text{HCl.Aq}$  with Cu at  $40^\circ$  to  $50^\circ$ , Fuchs (*A.* 56, 319) obtained a violet solution which gave a brownish black pp. with  $\text{NH}_4\text{Aq}$ ; the pp. quickly reacted with water, giving off H and forming  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ . Von Kobell (*P.* 62, 599) obtained similar reactions by using reduced Ag in place of Cu. Ebelmen (*J. pr.* 42, 73) obtained a nearly black pp. by adding alkali to  $\text{TiCl}_3\text{Aq}$ . According to Ebelmen (*J. pr.* 42, 76)  $\text{TiO}$ , can be prepared by heating  $\text{TiO}$ , to redness in perfectly dry H.  $\text{TiO}_2$ , thus prepared is described as a black solid; unacted on by  $\text{HNO}_3$  or  $\text{HCl.Aq}$ ; oxidised to  $\text{TiO}_2$  only by heating to a very high temperature; soluble in  $\text{H}_2\text{SO}_4\text{Aq}$ , forming a violet solution. According to O. v. d. Pfordten (*A.* 237, 201), the product of reducing  $\text{TiO}_2$  in H is not  $\text{TiO}$ , but has the composition  $\text{Ti}_2\text{O}_3$ . Friedel a. Guérin (*A. Ch.* [5] 8, 38) obtained  $\text{Ti}_2\text{O}_3$ , but not free from other compounds, by passing  $\text{TiCl}_3$  vapour mixed with H over  $\text{TiO}_2$  at a red heat. They describe  $\text{Ti}_2\text{O}_3$  as a copper-rod, metal-like, microscopically crystalline powder; not acted on by boiling  $\text{HNO}_3\text{Aq}$ , but oxidised to  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  by boiling  $\text{H}_2\text{SO}_4\text{Aq}$ ; soluble in  $\text{HFAq}$  or warm *aqua regia*; giving off NH<sub>3</sub> and H with hot alkali solutions; oxidised to  $\text{TiO}_2$  by heating to redness in air. Koenig a. O. v. d. Pfordten (*B.* 22, 2070) failed to obtain  $\text{TiO}$ , by the method of P. a. G.

When Ti is dissolved in hot  $\text{HCl.Aq}$ , in an atmosphere of H, the solution contains  $\text{Ti}_2\text{Cl}_6$  (Grunnfeldt, *J. pr.* 99, 176); a solution of  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  in  $\text{HCl.Aq}$  reduced by zinc also contains  $\text{Ti}_2\text{Cl}_6$  (K. a. O. v. d. P., *l.c.*); in these solutions alkalis give black pps., probably  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ ; the pps. soon change in contact with  $\text{H}_2\text{O}$  to  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ , H being given off. According to O. v. d. P. (*A.* 237, 201), a solution of  $\text{K}_2\text{TiF}_6$  in a little  $\text{HCl.Aq}$  gives a pp. of  $\text{Ti}_2\text{O}_3 \cdot x\text{H}_2\text{O}$  on treatment with Na-amalgam.

Sabatier a. Senderens (*C. R.* 114, 1429; 115, 236) say that  $\text{Ti}_2\text{O}_3$  is oxidised to  $\text{TiO}_2$  by heating to c.  $500^\circ$  in  $\text{NO}$ , or to c.  $300^\circ$  in  $\text{NO}_2$ .

**TITANIUM MONOXIDE  $\text{TiO}$ .** This oxide has not been isolated with certainty. According to Moissan (*C. R.* 115, 1031) black prisms, which he took to be  $\text{TiO}$ , are formed by heating  $\text{TiO}_2$  to c.  $2500^\circ$  in an electric furnace, and at a higher temperature the (?)  $\text{TiO}$  melts and then volatilises. By heating a mixture of  $\text{TiO}_2$  and  $\text{Mg}$  powder to redness, in H, Winkler (*B.* 23, 2657) obtained a brown powder which probably contained some  $\text{TiO}$ , mixed with  $\text{MgTiO}_3$ . According to Berthier (*A. Ch.* [2] 54, 374)  $\text{TiO}$ , lost 6 p.c. O when heated strongly in a carbon crucible, 13 to 16 p.c. O when heated with 12 p.c. C, and 20 p.c. O when heated with 24 p.c. C ( $\text{TiO}$  loses 20 p.c. O in becoming  $\text{TiO}_2$ ); the product may have contained  $\text{TiO}$ , or it may have been a mixture of  $\text{TiO}$ ,  $\text{Ti}_2\text{O}_3$ , and  $\text{Ti}$ .

**HYDRATED TITANIUM MONOXIDE**  
 $\text{TiO} \cdot \text{H}_2\text{O} = \text{TiO} \cdot \text{H}_2\text{O}$ . O. v. d. Pfordten (*A.* 237, 201) obtained a black pp., said by him to be  $\text{TiO} \cdot \text{H}_2\text{O}$ , by the continued action of Na-amalgam on a solution of  $\text{K}_2\text{TiF}_6$  in a fair amount of  $\text{HCl.Aq}$  (if there is little  $\text{HCl.Aq}$ ,  $\text{TiO}_2$  is ppg.); the solution became green, then colourless, and then the black pp. was formed. The black pp. formed by  $\text{NH}_4\text{Aq}$ , alkali carbonates, or  $(\text{NH}_4)_2\text{S}_2\text{O}_8$  in solutions of  $\text{TiCl}_3$  (*q. v.*, p. 741) is  $\text{TiO} \cdot \text{H}_2\text{O}$ , according

to O. v. d. P. (l.c.). With  $\text{Na}_2\text{HPO}_4\text{Aq.}$  and  $\text{Na}_2\text{C}_2\text{O}_4\text{Aq.}$ ,  $\text{TiCl}_3$  is said to give bluish-black and greenish-black pps., which may be salts of  $\text{TiO}$  (O. v. d. P., l.c.).

**TITANIUM PEROXIDE.**  $\text{TiO}_2$ . (*Titanium trioxide* or *superoxide*.) In 1882 (*Atti dei Lincei*, 1882.

1) Piccini dropped  $\text{H}_2\text{O}_2\text{Aq.}$  into solution of  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ ; from the quantity of  $\text{H}_2\text{O}_2$  that reacted he concluded that an oxide  $\text{TiO}_2$  was produced. In the same year (B. 15, 2599) Weller obtained a yellow pp., which reacted with  $\text{HClAq.}$  giving off  $\text{Cl}_2$  by the interaction of  $\text{H}_2\text{O}_2\text{Aq.}$  and freshly ppd.  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  or a solution of  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ . In 1888, Classen (B. 21, 370) added  $\text{TiCl}_3$ , drop by drop, to dilute alcohol, then added to this solution a very large excess of  $\text{H}_2\text{O}_2\text{Aq.}$  and then  $\text{KOH Aq.}$ ,  $\text{NH}_4\text{Aq.}$  or  $(\text{NH}_4)_2\text{CO}_3\text{Aq.}$ ; in each case he obtained a yellow liquid from which a yellow pp. separated after some time; after syphoning off the liquid, washing the pp. by decantation, and drying it on a tile, he obtained a yellow solid approximating to the composition  $\text{TiO}_2 \cdot 3\text{H}_2\text{O}$ . In 1889, Lévy (C. R. 108, 294) approximately determined the composition of the pp. obtained by adding  $\text{H}_2\text{O}_2\text{Aq.}$  to  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  in  $\text{H}_2\text{SO}_4\text{Aq.}$  by dropping in  $\text{H}_2\text{O}_2\text{Aq.}$  of known concentration, and determining the quantity of  $\text{H}_2\text{O}_2$  used in the reaction; L. concluded that the results could be accounted for by supposing the yellow pp. to be  $\text{TiO}_2 \cdot \text{H}_2\text{O}$ , or  $\text{Ti}_2\text{O}_3 \cdot \text{H}_2\text{O}$ , but that probably the pp. was  $\text{TiO}_2$ . In 1893 Bailey a. Dawson (*Studies from the Phys. and Chem. Laboratories of the Owens College*, vol. i. p. 216) obtained yellow to orange solids, agreeing fairly in composition with the formula  $\text{TiO}_2$ . B. a. D. added (1)  $\text{H}_2\text{O}_2\text{Aq.}$  (2) freshly ppd.  $\text{BaO}_2$  to  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  in dilute  $\text{H}_2\text{SO}_4\text{Aq.}$  diluted the deep-red liquids thus obtained with twice their volumes of alcohol, added conc. alcoholic solution of  $\text{KOH}$ , washed the pps. with alcohol (to remove  $\text{H}_2\text{O}$  and  $\text{H}_2\text{O}_2$ ), and then with ether, and, in some cases, dried in the air. According to B. a. D.,  $\text{TiO}_2$  dissolves in water, forming a deep-red liquid; this solution decolourises  $\text{KMnO}_4\text{Aq.}$ ;  $\text{TiO}_2$  dissolves in  $\text{HClAq.}$  giving off  $\text{Cl}_2$ . By allowing ppd.  $\text{TiO}_2$  to stand for some time, B. a. D. say that a modification is formed insoluble in water.

**OXIDES OF TITANIUM INTERMEDIATE BETWEEN  $\text{TiO}_2$  AND  $\text{Ti}_2\text{O}_3$ .**

I. By heating  $\text{TiO}_2$  with  $\text{HCl}$  gas in a reducing atmosphere, Deville (C. R. 53, 163) obtained a blue, crystalline solid, to which he gave the formula  $\text{Ti}_2\text{O}_3$ . A similar solid (same composition) was obtained by Friedel a. Guérin (A. Ch. [5] 8, 44) by passing  $\text{H}$  and  $\text{HCl}$  over  $\text{TiO}_2$  strongly heated in a porcelain tube. This blue solid is said to decompose water, in presence of strong bases, giving off  $\text{H}$  and forming  $\text{TiO}_2$ .

II. By very strongly heating  $\text{TiO}_2$  in  $\text{H}$ , O. v. d. Pfordten (A. 237, 228) obtained a dark indigo-blue solid, to which he gave the formula,  $\text{Ti}_2\text{O}_3$ ; according to Ebelen (J. pr. 42, 76),  $\text{Ti}_2\text{O}_3$  is formed by this reaction. Heated in air the compound burns to  $\text{TiO}_2$ .

III. By adding alcoholic solution of  $\text{KOH}$  to a solution of  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  in dilute  $\text{H}_2\text{SO}_4\text{Aq.}$  after treating the solution with  $\text{BaO}_2$ , Piccini (*Atti dei Lincei*, 1882. 1) obtained yellow pps. with compositions varying from  $\text{Ti}_2\text{O}_3$  to  $\text{Ti}_2\text{O}_5$ .

**Titanium oxyacids and salts and derivatives thereof.** The hydrates of  $\text{TiO}_2$  react as feeble acids, besides reacting with the stronger acids as feeble bases. The salts wherein  $\text{Ti}$  forms part of the acidic radicals are generally obtained by fusing  $\text{TiO}_2$  with salts of the metals which are to be converted into titanates. Only a very few titanates are soluble in water; several dissolve in  $\text{HClAq.}$  but on diluting and boiling most, if not all, of the  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  is ppd.

**TITANIC ACIDS.** Hydrates of  $\text{TiO}_2$  are obtained by various reactions (v. HYDRATED TITANIC OXIDE, p. 745). By drying under different conditions solids are obtained approximately corresponding with the formula  $x\text{TiO}_2 \cdot y\text{H}_2\text{O}$ , where  $x = 1, 2, 3$ , and  $y = 1, 2, 3, 4$ , or 5. (For a list of the hydrates obtained by different experimenters v. Tütttscheff, A. 141, 111.) There seems to be a series of hydrates of  $\text{TiO}_2$ , all of which may be classed together under the name *titanic acids*, none of them being stable through more than a few degrees of temperature (v. Carnelley a. Walker, C. J. 53, 66, 81); the relations of composition of these acids may be expressed by such a general equation as  $n\text{TiH}_2\text{O}_4 - m\text{H}_2\text{O} = \text{Ti}_n\text{H}_{4n-2m}\text{O}_{4n-2m}$ .

The titanic acids belong to two classes: those which are formed by decomposing  $\text{TiCl}_3$  or  $\text{TiBr}_3$  by dilute cold alkali solutions, or by warming  $\text{TiO}_2$  with conc.  $\text{H}_2\text{SO}_4$  dissolving the product in water, and ppge by dilute cold alkali solutions; and those which are formed by decomposing  $\text{TiCl}_3$  or  $\text{TiBr}_3$  by water and boiling, or by dissolving titanic acids of the former class in dilute acid and boiling, or by fusing  $\text{TiO}_2$  with  $\text{KHSO}_4$  dissolving in much water and boiling. The acids of the former class are generally called *titanic acids* or *ortho-titanic acids*, and those of the latter class *meta-titanic acids*. *Orthotitanic acids* dissolve easily in dilute acids; *metatitanic acids* are insol. dilute acids; by prolonged heating with conc.  $\text{H}_2\text{SO}_4$  compounds are produced which dissolve on adding water. *Metatitanic acids* are also formed by heating *ortho-acids* to c.  $100^\circ$ . Experiments made by Merz (J. pr. 99, 166) show that the *meta-acids* lose water, on heating, more easily than the *ortho-acids*.

**ORTHOTITANIC ACIDS.** According to Wagner (B. 21, 960), a clear solution of an orthotitanic acid is obtained by adding water, a drop at a time, to  $\text{TiCl}_3$  with constant shaking;  $\text{HCl}$  and  $\text{TiCl}_3$  are given off (by the heat of the reaction), a solid is produced, then a greenish-yellow liquid, and finally a clear solution. By adding 1 pt.  $\text{TiCl}_3$  to c. 6 to 7 pts. water, Thorpe (C. J. 47, 120) obtained an opalescent liquid which became clear after standing for 40 hours, and then contained orthotitanic acid; when this solution was heated ppn. of metatitanic acids began at c.  $87^\circ$ , and at c.  $90^\circ$  most of the  $\text{Ti}$  was ppd. A solution of  $\text{TiBr}_3$  in water forms a perfectly clear liquid containing ortho-acid (T. l.c. p. 126). The white flocculent solid obtained by adding  $\text{TiCl}_3$  to dilute  $\text{HClAq.}$  ppge by  $\text{NH}_4\text{Aq.}$  when cold, washing with cold water, and drying in the air is  $\text{TiO}_2 \cdot 2\text{H}_2\text{O}$  ( $= \text{TiO}_2\text{H}_2$ ), according to Merz (J. pr. 99, 166); this composition is also assigned to the solid formed by keeping  $\text{TiCl}_3 \cdot \text{PCl}_5$  under a bell-jar, with water and  $\text{CaO}$ , for some days, and then drying over  $\text{H}_2\text{SO}_4$  (Tütttscheff, A. 141, 111). When  $\text{TiO}_2\text{H}_2$  is dried in *vacuo* (Tütttscheff, l.c.), or over  $\text{H}_2\text{SO}_4$ ,

(Merz, *l.c.*), the product is said to be  $\text{TiO}_2 \cdot \text{H}_2\text{O}$  ( $= \text{H}_2\text{TiO}_4 = \text{TiO}_2 \cdot \text{O}_2\text{H}_2$ ). The composition  $2\text{TiO}_2 \cdot \text{H}_2\text{O}$  ( $= \text{H}_2\text{Ti}_2\text{O}_5 = \text{Ti}_2\text{O}_5 \cdot \text{O}_2\text{H}_2$ ) is given to the product dried at  $100^\circ$  (Merz, *l.c.*; Demoly, *C. R.* 1849, 325), dried at  $140^\circ$  (Tütttscheff, *l.c.*), or dried *in vacuo* over  $\text{H}_2\text{SO}_4$  (H. Rose, *A.* 52, 268); after drying at  $100^\circ$  or upwards, meta-acids are probably produced.

Orthotitanic acids are insoluble in water or alcohol; but dissolve easily in dilute acids; said also to dissolve in alkali carbonate solutions. The solutions in acids probably contain salts of the type  $\text{TiX}_x$ ,  $\text{X} = \text{Cl}, \text{NO}_3, \text{SO}_4$ , &c.; but compounds of the form  $\text{Ti}(\text{OH})_x\text{X}_y$ , where  $\text{X}$  is a monovalent acid radicle, and  $x$  is not greater than 3, may be formed, similar to the compounds  $\text{Ti}(\text{OH})_2\text{Cl}$ ,  $\text{Ti}(\text{OH})_2\text{Cl}_2$ , and  $\text{Ti}(\text{OH})\text{Cl}_3$ , obtained by O. v. d. Pfordten by the interaction of  $\text{HClAq}$  and  $\text{TiCl}_4$  (*B.* 21, 1708; v. TITANIUM HYDROXYL CHLORIDES, p. 753). By adding a little conc. cold  $\text{HClAq}$  to orthotitanic acid, allowing to stand for some days, pouring off the clear liquid from undissolved acid, and evaporating *in vacuo*, Koenig a. O. v. d. P. (*B.* 22, 1485) obtained a white solid containing  $\text{Ti}$  and  $\text{Cl}$  in the ratio 1:1.47; they regarded this as consisting chiefly either of  $\text{TiCl}(\text{OH})_2$  but different in some properties from  $\text{TiCl}(\text{OH})_2$  obtained from  $\text{TiCl}_4$ —or chiefly of  $\text{TiCl}(\text{OH})_2 \cdot \text{HCl}$ . White pps. are obtained by adding  $\text{H}_3\text{PO}_4\text{Aq}$ ,  $\text{H}_3\text{AsO}_4\text{Aq}$ , or  $\text{H}_2\text{C}_2\text{O}_4\text{Aq}$  to solutions of orthotitanic acids in dilute  $\text{HClAq}$ ,  $\text{HNO}_3\text{Aq}$ , or  $\text{H}_2\text{SO}_4\text{Aq}$ , after making nearly neutral by  $\text{NH}_4\text{Aq}$ . When acid solutions of orthotitanic acids are diluted considerably and boiled for some time the whole of the  $\text{Ti}$  is pptd. as meta-acids. Ortho-acids are also partly changed to meta-acids by keeping under water for a long time (Wagner, *B.* 21, 960), or by washing with hot water. When an orthotitanic acid is heated strongly  $\text{TiO}_2$  is produced, with vivid incandescence; the change from a meta-acid to  $\text{TiO}_2$  is not accompanied by incandescence. According to Wagner (*l.c.*), the dehydration of moist ortho-acids by gently warming is accompanied by changes of colour from white to grey, green, and black.

**METATITANIC ACIDS.** Formed, as white powders, by dissolving ortho-acids in dilute acid and boiling for some time; also by fusing  $\text{TiO}_2$  with  $\text{KHSO}_4$  and boiling with much water; also by adding water to  $\text{TiCl}_4$  or  $\text{TiBr}_4$  and boiling; also by oxidising  $\text{Ti}$  by  $\text{HNO}_3$ , S.G. 1.25 (Weber, *P.* 120, 287). According to Weber (*l.c.*), freshly prepared dilute  $\text{TiCl}_4\text{Aq}$  is not rendered turbid by  $\text{HClAq}$ ,  $\text{HNO}_3\text{Aq}$ , or  $\text{H}_2\text{SO}_4\text{Aq}$ , but these acids at once ppt. metatitanic acids when added to dilute  $\text{TiCl}_4\text{Aq}$  that has been boiled even for a few seconds. The pp. obtained by boiling a diluted solution of an orthotitanic acid in dilute  $\text{H}_2\text{SO}_4$  is said to have the composition  $\text{TiO}_2 \cdot 2\text{H}_2\text{O}$  ( $= \text{TiO}_2\text{H}_2$ ) when dried over  $\text{H}_2\text{SO}_4$ , the composition  $3\text{TiO}_2 \cdot 4\text{H}_2\text{O}$  ( $= \text{Ti}_3\text{O}_8 \cdot \text{H}_2\text{O} = \text{Ti}_3\text{O}_9 \cdot \text{O}_2\text{H}_2$ ) when dried at  $120^\circ$ , and the composition  $8\text{TiO}_2 \cdot 2\text{H}_2\text{O}$  ( $= \text{Ti}_8\text{O}_{20} \cdot \text{H}_2\text{O} = \text{Ti}_8\text{O}_{21} \cdot \text{O}_2\text{H}_2$ ) when dried at  $140^\circ$  (Tütttscheff, *A.* 141, 111); Merz (*J. pr.* 99, 166) gives the composition  $\text{TiO}_2 \cdot \text{H}_2\text{O}$  ( $= \text{TiO}_2\text{H}_2 = \text{TiO}_2 \cdot \text{O}_2\text{H}_2$ ) to the air-dried sp., and the composition  $2\text{TiO}_2 \cdot \text{H}_2\text{O}$  ( $= \text{Ti}_2\text{O}_5 \cdot \text{H}_2\text{O} = \text{Ti}_2\text{O}_6 \cdot \text{O}_2\text{H}_2$ ) to the pp. dried over  $\text{H}_2\text{SO}_4$ , or at  $60^\circ$ .

Metatitanic acids are white powders, insoluble

in water or dilute acids; after heating with conc.  $\text{H}_2\text{SO}_4$ , the products dissolve in water; when strongly heated  $\text{TiO}_2$  is formed without incandescence.

**COLLOIDAL TITANIC ACIDS.** Graham (*T.* 1861, 212) obtained a gelatinous, probably orthotitanic, acid, insoluble in water, by dialysing a solution of  $\text{TiO}_2 \cdot \text{H}_2\text{O}$  in  $\text{HClAq}$ ; by dissolving this gelatinous acid in such a quantity of cold dilute  $\text{HClAq}$  that not more than 1 p.c. titanic acid was present in the solution, and dialysing for several days, G<sup>2</sup> (*C. J.* 17, 325) obtained a dilute aqueous solution of colloidal titanic acid. Colloidal, insoluble, titanic acids have also been prepared by Knop (*A.* 123, 351), Rose (*G. A.* 73, 76 [1823]), and O. v. d. Pfordten (*B.* 17, 727).

**TITANATES.** These salts have not been thoroughly investigated. Those which have been best examined are either derivatives of  $\text{H}_2\text{TiO}_4$  or  $\text{H}_2\text{TiO}_3$ , or are basic salts of the type  $x\text{MO} \cdot x\text{TiO}_2$ , where  $x > 1$ . Some acid salts  $\text{MO} \cdot x\text{TiO}_2$ , where  $x > 1$ , are also known. The older investigations were made chiefly by H. Rose (*P.* 61, 507) and by Hautefeuille (*A. Ch.* [2] 4, 129).

**Barium titanates.** An acid salt  $2\text{BaO} \cdot 3\text{TiO}_2$  ( $= 2\text{BaTiO}_3 \cdot \text{TiO}_2$  or  $\text{Ba}_2\text{TiO}_7 \cdot 2\text{TiO}_2$ ) was obtained by Bourgcois (*C. R.* 101, 111) in lustrous microscopic crystals, by heating to full redness a mixture of equivalent parts of  $\text{TiO}_2$  and  $\text{BaCO}_3$ , with excess of  $\text{BaCl}_2$ , and washing with very dilute  $\text{HClAq}$ .

**Calcium titanates.** The normal salt  $\text{CaTiO}_3$  occurs native as *perovskite*. The same salt was formed by heating to bright redness a mixture of equivalent parts of  $\text{TiO}_2$  and  $\text{CaCO}_3$ , with excess of  $\text{CaCl}_2$ , and washing with very dilute  $\text{HClAq}$  (Bourgcois, *l.c.*).

**Iron titanates.** The mineral *titaniferous iron* or *ilmenite* is more or less pure  $x\text{FeO} \cdot y\text{TiO}_2$ . By fusing a mixture of 2 pts.  $\text{TiO}_2$  and 5 pts.  $\text{Fe}_2\text{O}_3$  with a large excess of  $\text{NaCl}$ , washing with water, and then with very dilute acid, Hautefeuille (*C. R.* 59, 733) obtained dark purple-violet, lustrous crystals of *ferrous titanate*  $\text{Fe}_2\text{TiO}_5$  ( $= 2\text{FeO} \cdot \text{TiO}_2$ ); but according to Koenig a. O. v. d. Pfordten (*B.* 22, 1485) the salt produced is *ferric titanate*  $\text{Fe}_3(\text{TiO}_4)_2$  ( $= 2\text{Fe}_2\text{O}_3 \cdot 3\text{TiO}_2$ ). K. a. O. v. d. P. say that the salt dissolves in water after warming with conc.  $\text{H}_2\text{SO}_4$ , forming a green solution containing  $\text{Fe}_2(\text{SO}_4)_3$  and titanic acid.

**Magnesium titanates.** The normal salt  $\text{MgTiO}_3$  ( $= \text{MgO} \cdot \text{TiO}_2$ ) was obtained (by Hautefeuille, *l.c.*) by heating to whiteness, for a short time in a closed crucible, a mixture of 1 pt.  $\text{TiO}_2$  and 10 pts.  $\text{MgCl}_2$  with a little  $\text{NH}_4\text{Cl}$ , washing with extremely dilute acetic acid, and then with water; lustrous, six-sided (probably trimetric) crystals, S.G. 3.91. The same salt is formed, according to Winkler (*B.* 23, 2657), by heating a mixture of  $\text{TiO}_2$  and  $\text{Mg}$  powder. By heating a mixture of 2 pts.  $\text{TiO}_2$ , 1 pt.  $\text{MgO}$ , and 40 pts.  $\text{MgCl}_2$ , and washing with very dilute acetic acid, the salt  $\text{Mg}_2\text{TiO}_5$  ( $= 2\text{MgO} \cdot \text{TiO}_2$ ) is said to be formed in hard, lustrous, regular octahedra, S.G. 3.42 (H.).

**Potassium titanates.** When  $\text{TiO}_2$  is fused with excess of  $\text{K}_2\text{CO}_3$ , the quantity of  $\text{CO}_2$  given off corresponds with the formation of the

**normal salt**  $K_2TiO_4$ ; after fusion two layers are obtained, the lower of which is said to consist of  $K_2TiO_4$ , while the upper contains the undecomposed  $K_2CO_3$ .  $K_2TiO_4$  is described as a yellowish, fibrous, easily fused solid (H. Rose, *P.* 61, 507). Water resolves it (according to Rose) into an insoluble *acid salt*, and a soluble *basic salt*; but according to Hermann (*J. pr.* 38, 92) no trace of titanic acid goes into solution in water, but all remains in the insoluble acid salt.

**Sodium titanates.** The *normal salt*  $Na_2TiO_4$  was obtained by H. Rose (*l.c.*) similarly to the K salt; water resolves it into an insoluble *acid salt* and  $NaOHAq$ . By heating  $Na_2WO_4$ , and in some cases also  $WO_3$ , with mixtures of  $TiO_2$  and  $Na_2CO_3$  previously fused, Cormimbœuf (*C. R.* 115, 823) obtained three *acid salts*:

(1)  $2Na_2O \cdot 3TiO_2 (= 2Na_2TiO_3 \cdot TiO_2)$ , or  $Na_2TiO_3 \cdot 2TiO_2$ ; (2)  $Na_2O \cdot 2TiO_2 (Na_2TiO_3 \cdot TiO_2)$ , or  $Na_2TiO_3$ ; (3)  $Na_2O \cdot 3TiO_2 (= Na_2TiO_3 \cdot 2TiO_2)$ , or  $Na_2TiO_3$ .

**Strontium titanates.** An *acid salt*  $2SrO \cdot 3TiO_2 (= 2SrTiO_3 \cdot TiO_2)$  or  $Sr_2TiO_3 \cdot 2TiO_2$  was obtained, in pale-greenish-yellow cubes, S.G. 5.1, by Bourgeois (*C. R.* 103, 141), by heating equivalent parts of  $TiO_2$  and  $SrCO_3$ , with excess of  $SrCl_2$ , and washing with very dilute  $HClAq$ .

**Zinc titanates.** The *normal salt*  $ZnTiO_3$  was obtained by Lévy (*C. R.* 107, 421), by heating to redness a mixture of 2 pts.  $TiO_2$ , 8 pts.  $ZnSO_4$ , and 3 pts.  $K_2SO_4$ , and washing with dilute  $HClAq$ ; pale-violet, silky needles, S.G. 3.17, scarcely acted on by boiling conc. acids or conc.  $KOHAq$ . By varying the proportion of  $TiO_2$ ,  $ZnSO_4$ , and  $K_2SO_4$  used, L. (*l.c.*) obtained the *normal salt*  $ZnTiO_3$ , which may also be regarded as a *basic salt*  $ZnTiO_3 \cdot ZnO$ ; the *basic salt*  $3ZnO \cdot 2TiO_2 (= 2ZnTiO_3 \cdot ZnO)$ ; and the *acid salt*  $4ZnO \cdot 5TiO_2 (= 4ZnTiO_3 \cdot TiO_2)$ .

**FLUOTITANATES**; v. *Titaniumfluorides*, under **TITANIC FLUORIDE**, *Combinations*, No. 2 (p. 742).

**FLUOROXYTITANATES**; v. *Titanoxylfluorides*, under **TITANIC FLUORIDE** (p. 742).

**MOLYBDOTITANATES.** A few compounds of the form  $TiO_2 \cdot 12MoO_3 \cdot 2M_2O \cdot xaq$ , where  $M = NH_4$  and K, are described by Péchard (*C. R.* 117, 788). By shaking with ether a solution of the  $NH_4$  salt, acidified by  $HClAq$ , and allowing the ethereal liquid to evaporate, P. (*l.c.*) obtained *molybdotitanic acid*  $TiO_2 \cdot 12MoO_3 \cdot 22aq$ , in golden yellow octahedra, melting at c.  $60^\circ$ , very soluble in water.

**OXALOTITANATES.** By dissolving  $TiO_2 \cdot xH_2O$  in hot  $KHC_2O_4Aq$  and cooling, Péchard (*C. R.* 116, 1513) obtained triclinic crystals of  $2KHC_2O_4 \cdot TiO_2 \cdot 11H_2O$ . By treating a solution of this salt with  $BaCl_2Aq$ , crystals of  $Ba(HC_2O_4)_2 \cdot TiO_2 \cdot H_2O$  were obtained; and by decomposing this by an equivalent quantity of dilute  $H_2SO_4Aq$ , filtering, and evaporating *in vacuo*, long needles of *oxalotitanic acid*  $2H_2C_2O_4 \cdot TiO_2 \cdot 2H_2O$  were obtained.

**SILICOTITANATES**; v. this heading, p. 464.

**Titanium, oxychlorides of.** Several oxychlorides are known. (1)  $TiOCl_2$ . According to Demarcay (*C. R.* 104, 111), this is the first product of heating  $TiO_2$  and  $CCl_4$  in a sealed tube; it is described as a yellow crystalline solid. Heated with  $CCl_4$  it gives  $TiCl_4$  and  $COCl_2$ .

(2)  $TiOCl$ . Obtained by passing a mixture of  $TiCl_4$  vapour and dry H over  $TiO_2$  in a tube heated white hot;  $Ti_2O_3$  and  $Ti_2Cl_6$  are also produced in the reaction (Friedel a. Guérin, *Bl.* [2] 22, 481). Brown, orthorhombic leaflets; heated in air burns to  $TiO_2$  and  $TiCl_4$ . (3)  $Ti_2O_2Cl_2$ . Formed by passing  $TiCl_4$  vapour through a red-hot tube containing fragments of porcelain (Troost a. Hautefeuille, *C. R.* 73, 563). (4) By allowing  $TiCl_4$  to deliquesce in air, and then evaporating over  $H_2SO_4$  and  $CaO$ , Merz (*Bl.* [2] 7, 401) obtained a solid approximating in composition to  $Ti_2O_2Cl_2 \cdot 16H_2O$ . In connection with oxychlorides cf. **TITANIUM HYDROXYL CHLORIDES** (p. 743).

**Titanium, oxyfluoride of.** By decomposing by water the crystals formed by dissolving  $TiO_2 \cdot xH_2O$  in  $HFAq$  and evaporating, Berzelius (*P.* 4, 1) obtained a white solid, of which he said it was an insoluble, 'so to say, *basic*,' compound.

The *titanoxylfluorides*  $TiO_2F_2 \cdot 2MF$  may be regarded as compounds of the oxyfluoride  $TiO_2F_2$  (v. **TITANIC FLUORIDE**, p. 742).

**Titanium, oxythiochloride of.** The compound  $TiCl_2 \cdot OSO_2Cl$  formed by the reaction of  $TiCl_4$  with  $SO_2 \cdot OHCl$  may be regarded as  $TiO_2 \cdot SCl_2$  (v. **TITANIC CHLORIDE**, *Reactions*, No. 10, p. 740).

**Titanium, salts of.** Not many salts have been prepared by replacing H of oxyacids by Ti; most of those that have been isolated are basic salts derived from the oxide  $TiO_2$ . One salt,  $Ti_2(SO_4)_3$ , corresponding with the oxide  $Ti_2O_3$ , has been isolated. For the individual salts v. **NITRATES**, vol. iii. p. 517; **PHOSPHATES**, this vol. p. 112,  $Ti_2P_2O_7$ , prepared by dissolving  $TiO_2 \cdot xH_2O$  in molten  $H_3PO_4$  (Hautefeuille a. Margottet, *C. R.* 102, 1017) should be added; and **SULPHATES**, this vol. p. 580.

**Titanium, sulphides of.** Three compounds of Ti and S have been isolated:  $TiS_2$ ,  $Ti_2S_3$ , and  $TiS$ , corresponding with the three oxides  $TiO_2$ ,  $Ti_2O_3$ , and  $TiO$ .

**TITANIUMDISULPHIDE  $TiS_2$ .** (*Titanic sulphide*.) Mol. w. unknown. H. Rose (*P.* 8, 177) said that this compound was obtained by passing vapour of  $CS_2$  over very strongly heated  $TiO_2$ ; but O. v. d. Pfordten (*B.* 17, 727) and Thorpe (*C. J.* 47, 421) have found that it is not possible by this method to obtain  $TiS_2$  free from Ti oxides.  $TiS_2$  is prepared by passing perfectly dry  $H_2S$  into  $TiCl_4$ , kept somewhat below its b.p., and sending the mixed vapours through a glass tube heated to incipient redness;  $TiS_2$  deposits in the tube, and  $HCl$  is given off (Ebelmen, *A. Ch.* [3] 20, 285; confirmed by O. v. d. Pfordten, *B.* 17, 727). According to O. v. d. P. (*A.* 234, 257), the  $H_2S$  should be passed through  $CrCl_3Aq$ , to remove traces of O, and dried by means of  $P_2O_5$ ; and the tube should be filled with  $H_2S$  before the mixed vapours are passed into it.

$TiS_2$  forms large, brass-yellow, lustrous, metal-like scales.

$TiS_2$  is decomposed to  $Ti_2S_3$  and S by heating in *hydrogen* or *nitrogen*; it is not changed by heating in *hydrogen* in presence of excess of *hydrogen sulphide*; heated to redness in *carbon dioxide* it is completely oxidised to  $TiO_2$  (O. v. d. P., *A.* 234, 257). Ebelmen (*l.c.*) gives the following reactions: with dry *chlorine* gives  $TiCl_4$  and  $S_2Cl_2$ ; heated in air,  $TiS_2$  is burnt to

$\text{TiO}_2$  and  $\text{SO}_2$ ; exposure to moist air decomposes  $\text{TiS}_2$  gradually, with evolution of  $\text{H}_2\text{S}$ ; heated to redness with steam gives  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ ,  $\text{H}_2\text{S}$ , and  $\text{H}$ ; nitric acid produces  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ ,  $\text{S}$ , and  $\text{NO}$ ; aqua regia oxidises it to  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$  and  $\text{H}_2\text{SO}_4\text{Aq}$ ; not acted on by hydrochloric acid ( $\text{H}$ . Rose said that  $\text{TiS}_2$  dissolved slowly in  $\text{HClAq}$ , giving off  $\text{H}_2\text{S}$ ); insoluble in potassium sulphide solution; digestion with potash solution produces  $\text{K}$  titanate and  $\text{KHSO}_4\text{Aq}$  (Rose).

**TITANIUM SESQUISULPHIDE  $\text{TiS}_{1.5}$ .** Mol. w. unknown. Thorpe (*C. J.* 47, 491) obtained this compound by passing the vapours of moist  $\text{H}_2\text{S}$  and  $\text{CS}_2$  over powdered  $\text{TiO}_2$ , heated to very bright redness in a porcelain tube; dry  $\text{H}_2\text{S}$  and  $\text{CS}_2$  had no action on  $\text{TiO}_2$ .  $\text{T}$ . describes  $\text{TiS}_{1.5}$  as a greenish-black powder; he did not obtain it quite free from  $\text{TiS}_2$ , as by heating at a lower temperature than full redness in  $\text{H}_2\text{S}$  and  $\text{CS}_2$ , it is slowly changed to  $\text{TiS}_2$ . O. v. d. Pfordten (*A.* 234, 257) obtained  $\text{TiS}_{1.5}$  by heating  $\text{TiS}_2$  to full redness in dry  $\text{H}$  or  $\text{N}$  ( $\text{S}$  being set free); he describes it as a grey, metal-like solid; insoluble in  $\text{NaOHAq}$ ; soluble in  $\text{HNO}_3\text{Aq}$  or conc.  $\text{H}_2\text{SO}_4$ , forming green solutions.

**TITANIUM MONOSULPHIDE  $\text{TiS}$ .** Mol. w. unknown. Formed by very strongly heating  $\text{TiS}_2$  in perfectly dry  $\text{H}$  quite free from  $\text{O}$  ( $\text{T}$ . *l.c.*; O. v. d. P., *l.c.*). A black powder ( $\text{T}$ . *l.c.*); forms dark-red crystals (O. v. d. P., *l.c.*). Slowly acted on by  $\text{HNO}_3\text{Aq}$  or aqua regia; insoluble in  $\text{NaOHAq}$ .

**Titanium, sulphochloride of, v. TITANIUM THIOCHLORIDE, *infra*.**

**Titanium, thiochloride of.** The pp. formed by passing pure dry  $\text{H}_2\text{S}$  into hot  $\text{TiCl}_4$  is probably a thiochloride, according to O. v. d. Pfordten (*A.* 234, 257). M. M. P. M.

**TITANIUM GROUP OF ELEMENTS.** The four elements, titanium, zirconium, cerium, and thorium form, with carbon, the even-series family of Group IV. in the periodic classification of the elements. There is yet an element to be discovered between  $\text{Ce}$  and  $\text{Th}$ ; this unknown element will come in series 10 of Group IV. The titanium family of elements is closely allied to the tin family— $\text{Ge}$ ,  $\text{Sn}$ ,  $\text{Pb}$ —which, with  $\text{Si}$ , form the odd-series members of Group IV. Carbon is the first even-series member, and silicon the first odd-series member, of the group; these two elements are more like one another than they are like the rest of the group.

For the properties and relations of  $\text{C}$  and  $\text{Si}$  v. CARBON GROUP OF ELEMENTS, vol. i. p. 682; and for the tin family v. TIN GROUP OF ELEMENTS, this vol. p. 735.

The presence of an element, before unknown, in a Cornish mineral was recognised by Gregor in 1791, and by Klaproth a few years later; the element—called titanium by Klaproth—was isolated by Berzelius in 1824. Klaproth, in 1789, recognised the presence of a new earth in zirconite from Ceylon; the metal-zirconium was isolated by Berzelius in 1824. In 1803 the presence of a new earth in a Swedish mineral was announced by Klaproth, who gave the name of cerium to the metal of the earth; he had discovered; Mosander isolated the element in 1826. Berzelius discovered a new earth, in a Norwegian mineral, in 1828, and isolated the metal of the

earth, which he called thorium, in the same year.

None of the four elements  $\text{Ti}$ ,  $\text{Zr}$ ,  $\text{Ce}$ , or  $\text{Th}$  occurs native; the compounds of these elements are comparatively rare, especially those of  $\text{Ce}$  and  $\text{Th}$ .

The most frequently found compounds are the oxides  $\text{MO}_2$ , generally in combination with  $\text{SiO}_2$  and with alkaline earths. The metals are obtained by reducing their double fluorides by  $\text{Al}$ ,  $\text{K}$ , or  $\text{Na}$ ; also in some cases by reducing the chlorides by  $\text{H}$  or  $\text{Na}$ ;  $\text{Ce}$  has also been isolated by electrolysis molten  $\text{CeCl}_2$ . The table on the following page presents some of the physical and chemical properties of the elements.

**General formulae and characters of compounds.**—Oxides.— $\text{MO}_2$ , probably for all ( $\text{ThO}_2$ );  $\text{MO}_3$  for all;  $\text{M}_2\text{O}_3$ , when  $\text{M}=\text{Ti}$  or  $\text{Ce}$ ; perhaps  $\text{TiO}$ . Hydrates of  $\text{MO}_2$  exist.

Sulphides.— $\text{MS}_2$ , when  $\text{M}=\text{Ti}$  or  $\text{Th}$ ,  $\text{? ThS}$ ;  $\text{M}_2\text{S}_3$ , when  $\text{M}=\text{Ti}$  or  $\text{Ce}$ ;  $\text{TiS}$ .

Haloid compounds.— $\text{MX}_n$ , when  $\text{X}=\text{Br}$ ,  $\text{Cl}$ ,  $\text{F}$  or  $\text{I}$  (only  $\text{CeF}_3$  prepared);  $\text{MX}_n$ , when  $\text{M}=\text{Ti}$ , and  $\text{X}=\text{Cl}$ , also when  $\text{M}=\text{Ce}$  and  $\text{X}=\text{Br}$ ,  $\text{Cl}$ ,  $\text{F}$  or  $\text{I}$ ;  $\text{TiCl}_2$ . Salts.— $\text{MR}_n$ ,  $\text{R}=\text{NO}_3$ ,  $\frac{1}{2}\text{SO}_4$ ,  $\frac{1}{2}\text{PO}_4$ , &c.; most are basic when  $\text{M}=\text{Ti}$  or  $\text{Zr}$ , but when  $\text{M}=\text{Ce}$  many are normal, and when  $\text{M}=\text{Th}$  most are normal; several salts  $\text{Ce}_2\text{R}_n$  are known, and a few  $\text{Ti}_2\text{R}_n$ ; the  $\text{Ce}_2\text{R}_n$  salts are more stable than the  $\text{CeR}_n$  salts. Salts containing  $\text{M}$  in the acidic radicle.— $\text{M}_2\text{TiO}_4$ , and others of general form  $x\text{MO}_2 \cdot y\text{TiO}_2$ ;  $\text{M}_2\text{ZrO}_4$ ,  $\text{M}_2\text{ZrO}_4$ , and others of general form  $x\text{MO}_2 \cdot y\text{ZrO}_2$ . No cerates or thorates isolated. Salts  $\text{XAlF}_6$  known when  $\text{M}=\text{Ti}$ ,  $\text{Zr}$ , or  $\text{Th}$ ;  $\text{3CeF}_3 \cdot \text{3AlF}_3$  known. Acids.  $\text{H}_2\text{TiO}_4$ ,  $\text{H}_2\text{TiO}_3$ ,  $\text{H}_2\text{TiF}_6$ ; various hydrates:  $\text{ZrO}_2 \cdot y\text{H}_2\text{O}$  act as feeble acids;  $\text{H}_2\text{ThO}_4$  and  $\text{H}_2\text{ThO}_3$  are perhaps feeble acids, but it is said that  $\text{ThO}_2$  does not decompose alkali carbonates when fused therewith.

The oxides  $\text{MO}_2$  are basic, and also feebly acidic when  $\text{M}$  is  $\text{Ti}$  or  $\text{Zr}$ ; they interact with some acids to form corresponding salts, and, when  $\text{M}=\text{Ti}$  or  $\text{Zr}$ , with alkalis to form salts wherein  $\text{M}$  forms part of the acidic radicle; no salts of oxyacids with  $\text{Ce}$  or  $\text{Th}$  in the negative radicles have yet been isolated. Several hydrates of  $\text{MO}_2$  exist, they easily pass one into the other with small changes of temperature; some of these hydrates react as feeble acids towards strong bases, forming salts of the types  $\text{X}_2\text{MO}_2$ ,  $\text{X}_2\text{MO}_3$ , and, generally,  $x\text{X}_2\text{O}_2 \cdot y\text{MO}_2$ ; these salts are not referable to such definite forms as the stannates or silicates are, but they resemble these classes of salts fairly closely.

The salts which are derived from the oxides  $\text{MO}_2$ , by the interactions of these oxides with acids, are of the form  $\text{MX}_n$ , where  $\text{X}=\text{NO}_3$ ,  $\frac{1}{2}\text{SO}_4$ ,  $\frac{1}{2}\text{PO}_4$ , &c.; when  $\text{M}=\text{Ti}$  most of the salts that are known are basic; when  $\text{M}=\text{Zr}$ , many are basic, but a fair number of normal salts is also known; when  $\text{M}=\text{Ce}$  or  $\text{Th}$ , most of the salts that have been isolated are normal. Little is known of the oxides  $\text{MO}_3$ ; as they are obtained by adding  $\text{H}_2\text{O}_2\text{Aq}$  and an alkali to solutions of salts  $\text{MX}_n$ , they are probably superoxides; the formula  $\text{Th}_2\text{O}_4$ , that is assigned to the oxide of  $\text{Th}$  formed in this way cannot be accepted as final. The oxides  $\text{Ti}_2\text{O}_3$  and  $\text{Ce}_2\text{O}_3$  are basic; the most definite and stable salts of

	TITANIUM.	ZIRCONIUM.	CEURIUM.	THORIUM.
<i>Atomic weights.</i>	48	90	139.9	232
	Molecular weights unknown. Mol. weights of one or more compounds of each element, except Ce, have been determined by Avogadro's law; spec. heats determined directly.			
<i>Melting-points.</i>	Has not been fused	c. 1200°	c. 800°	Has not been fused
<i>Spec. gravities (approx.)</i>	3.6	4.2	6.7	11.0
<i>Spec. heats.</i>	.13	.066	.0448	.0276
<i>Atomic weight.</i>				
<i>Spec. gravities (approx.)</i>	13.4	21.4	21.1	21.1
<i>Physical properties.</i>	Obtained only as a powder; black, lustrous, apparently amorphous. The powder has not been fused.	A black amorphous powder; resembling lampblack, but much heavier. Also obtained as a very lustrous, hard, brittle solid, resembling Sb. Said to melt above m.p. of Si.	Steel-grey, very lustrous metal; malleable, and ductile. Melts much more easily than any other member of the family.	Dark-grey, lustrous powder; also obtained in microscopic octahedral crystals. Has not been fused.
<i>Occurrence and Preparation.</i>	The four metals occur chiefly as silicates, Ti and Zr in moderate quantities and the others only in a few rare minerals. The metals are prepared by reducing the chlorides, or alkali salts of the form $K_2$ (or $Na_2$ ) $MF_6$ , by heating with K or Na; Ce also prepared by electrolysing molten $CeCl_3$ .			
<i>Chemical properties.</i>	Burns brilliantly when heated in air, or in O, forming $TiO_2$ . Decomposes $H_2O$ at 100°, giving off H. Combines readily with Cl, less readily with Br, and with I only when vapour of I is passed over heated Ti. Dissolves in warm dilute $HClAq$ , $H_2SO_4Aq$ , $HNO_3Aq$ , or $HFAq$ . Forms two classes of salts $TiX_3$ and $TiX_4$ , $X = NO_2$ , $\frac{1}{2}SO_4$ , &c.; very few $TiX_3$ salts isolated, and not many $TiX_4$ ; all salts easily decomposed. Salts derived from the acidic hydrates $\alpha TiO_2 \cdot yH_2O$ also known. The acids $H_2TiF_6$ and $H_2TiO_4F_6$ , and salts derived therefrom, are known. $TiO_2$ , probably a superoxide, exists. Combines fairly readily with N, and with N and O. Atom of Ti is tetravalent in gaseous molecules $TiCl_4$ and $TiH_4$ .	Amorphous Zr burns brilliantly when heated in air, or O, forming $ZrO_2$ ; the metal is superficially oxidised at a white heat; it burns in O-H flame. Combines with Cl, probably also with Br and I; compounds $ZrX_3$ are formed by heating $ZrO_2$ and C in X. Combines directly with S. Dissolves slowly in hot $H_2SO_4$ , $HClAq$ , $HNO_3Aq$ ; rapidly in $HFAq$ . Decomposes molten KOH; crystalline Zr is said not to be oxidised by molten $KNO_3$ or $KClO_4$ . Forms salts $ZrX_3$ , $X = NO_2$ , $\frac{1}{2}SO_4$ , &c.; most salts isolated are basic, $\alpha ZrO_2 \cdot yH_2O$ . Salts derived from acid $H_2ZrF_6$ are known. Also forms zirconates $yMO \cdot zZrO_2$ , where Zr enters into negative radicle of salts. Oxide higher than $ZrO_2$ , probably $ZrO_3$ (? superoxide) exists. Atom of Zr is tetravalent in gaseous molecule $ZrCl_4$ .	Burns when heated in air, or O, to $CeO_2$ . Decomposes cold water, giving off H. Combines directly with Cl, Br, I vapour, S vapour, and P vapour. Dissolves easily in $HClAq$ , $HNO_3Aq$ , $H_2SO_4Aq$ , or $HFAq$ . Forms two classes of salts, $Ce_2X_6$ and $CeX_3$ , $X = NO_2$ , $\frac{1}{2}SO_4$ , &c.; salts $Ce_2X_6$ are more stable than $CeX_3$ , the latter are easily reduced to $Ce_2X_6$ . No cerates, where Ce forms part of negative radicle, have been isolated. Salts of form $M_2CeF_6$ not isolated. $CeO_3$ , probably a superoxide, seems to exist.	Burns, when heated in air or O below redness, to $ThO_2$ . Combines with Cl, Br, or I when heated; also with S vapour when heated therein. Easily dissolved by $HClAq$ or $HFAq$ ; slowly by hot $H_2SO_4Aq$ ; $HNO_3Aq$ has only a slight action. Forms salts $ThX_3$ , $X = NO_2$ , $\frac{1}{2}SO_4$ , &c.; fair number of basic salts known. Hydrates of $ThO_2$ , $ThO_2 \cdot 2H_2O$ and $4ThO_2 \cdot H_2O$ , are probably weak acids, but thorates have not been isolated. Oxide higher than $ThO_2$ , probably $ThO_3$ , isolated (? superoxide). $ThH_4$ perhaps exists. Atom of Th is tetravalent in gaseous molecule $ThCl_4$ .

Ce are derived from this oxide. Several of the haloid compounds MX, have been gasified without decomposition, viz.  $\text{TiCl}_4$ ,  $\text{TiI}_4$ ,  $\text{ZrCl}_4$ , and  $\text{ThCl}_4$ . The haloid compounds MX, form many double compounds with other halides; some of these are certainly best regarded as salts of hypothetical acids containing M and X in their acidic radicles; the salts of this class  $\text{R}_m\text{MF}_n$  are characteristic of the elements of Group IV.; all the elements of the group, except C and Ce, give these salts  $\text{R}_m\text{MF}_n$ . Ce is said to form  $\text{K}_2\text{CeF}_{11}$  ( $= 2\text{CeF}_4 \cdot 3\text{KF}$ ), but further examination will most probably lead to the isolation of salts  $\text{R}_m\text{CeF}_n$ . Ti and Ce form chlorides  $\text{MX}_3$ , or more probably  $\text{M}_2\text{X}_6$  from the analogy of  $\text{C}_2\text{Cl}_6$  and  $\text{Si}_2\text{Cl}_6$ ; Ce also forms  $\text{Ce}_2\text{Br}_6$ ,  $\text{Ce}_2\text{I}_6$ , and  $\text{Ce}_2\text{F}_6$ , indeed the only haloid compound of Ce belonging to the form MX, that has yet been isolated is  $\text{CeF}_3$ . The sulphides have not been thoroughly examined; Ti is the only member of Group IV. which is known to form three sulphides corresponding with the oxides,  $\text{TiS}$ ,  $\text{Ti}_2\text{S}_3$ , and  $\text{TiS}_2$ ; one sulphide of Zr is known, probably  $\text{ZrS}_2$ ;  $\text{ThS}_2$  is the only sulphide of Th that has been isolated; and the only known sulphide of Ce is  $\text{Ce}_2\text{S}_3$ . So far as investigation has gone, the sulphides of Ti, Zr, Ce, and Th are basic.

A comparison of the titanium family with the tin family, which comprises the odd-series members of Group IV. (C and Si being omitted), shows that Ti, Zr, Ce, and Th are more metallic, on the whole, than Ge, Sn, and Pb. Th is certainly the most markedly positive element of Group IV., and Ti is at least not more negative than Ge; Zr is more metallic than Ge, and Ce more metallic than tin. The following formulae show that, so far as composition goes, there is about an equal similarity between C and Si and the Ti elements, as between C and Si and the tin elements:

Oxides				Sulphides				Chlorides, &c.			
CO	? $\text{C}_2\text{O}_3$	$\text{CO}_2$	$\text{SiO}_2$	CS	? $\text{C}_2\text{S}_3$	$\text{CS}_2$	$\text{SiS}_2$	? $\text{SiCl}_2$	$\text{C}_2\text{Cl}_4$	$\text{CCl}_4$	$\text{SiCl}_4$
? $\text{SiO}$				? $\text{SiS}$							
? $\text{TiO}$	$\text{Ti}_2\text{O}_3$	$\text{TiO}_2$	$\text{TiO}_2$	$\text{TiS}$	$\text{Ti}_2\text{S}_3$	$\text{TiS}_2$	$\text{ZrS}_2$ (?)	$\text{TiCl}_2$	$\text{Ti}_2\text{Cl}_4$	$\text{TiCl}_4$	$\text{ZrCl}_4$
	$\text{Ce}_2\text{O}_3$	$\text{CeO}_2$	$\text{CeO}_2$		$\text{Ce}_2\text{S}_3$				$\text{Ce}_2\text{Cl}_4$	$\text{CeF}_3$	$\text{ThCl}_4$
		$\text{ThO}_2$	? $\text{ThO}_3$			$\text{ThS}_2$					
GeO		$\text{GeO}_2$		GeS		$\text{GeS}_2$		? $\text{GeCl}_2$		$\text{GeCl}_4$	
SnO	? $\text{Sn}_2\text{O}_3$	$\text{SnO}_2$		SnS	? $\text{Sn}_2\text{S}_3$	$\text{SnS}_2$		$\text{SnCl}_2$		$\text{SnCl}_4$	
PbO	$\text{Pb}_2\text{O}_3$	$\text{PbO}_2$		PbS		? $\text{PbS}_2$		$\text{PbCl}_2$		$\text{PbCl}_4$ (?)	

A comparison of the odd-series families of the different groups with the even-series families (omitting series 2 and 3) shows that, speaking broadly, the members of the even-series families are more metallic in their chemical properties than the members of the odd-series families; and that the general difference between even and odd families becomes more marked in the higher than in the lower groups (v. Table in vol. iii. p. 811). For instance, the even family of Group VI.—Cr, Mo, W, and U—is decidedly more metallic than the odd family of the same group—S, Se, and Te; but although the even family of Group II.—Ca, Sr and Ba—is more metallic than the odd family of the same group—Mg, Zn, Cd and Hg—there is not nearly so great a difference between these two families as

there is between the two families of Group VI. Considering that the titanium and the tin elements belong to even and odd series, respectively, of Group IV., which group comes midway in the general periodic scheme of classification, we should expect the titanium (even-series) family to be rather more metallic than the tin (odd-series) family, but at the same time we should expect these two families to be very like one another; this is exactly what a study of the two families shows to be the case.

In connection with this article v. Tin group of elements, this vol. p. 735, and Carbon group of elements, vol. i. p. 682).

Tolane chlorides v. Chloro-phenyl-ethane and Chloro-phenyl-ethylene.

TOLENE v. Tolu balsam.  
p-TOLENYL-AMIDINE  $\text{C}_6\text{H}_4\text{N}_2$  i.e.  $\text{C}_6\text{H}_4\text{Me.C}(\text{NH})(\text{NH}_2)$ . [102?]. Formed by the action of alcoholic  $\text{NH}_3$  on the hydrochloride of

p-tolenyl-imido-ethyl-ether (Hook, B. 21, 2653). Pearly plates, sol. alcohol and ether.

Reactions.—1.  $\text{CO.C}_6\text{H}_4$  in toluene and NaOH give  $\text{C}_6\text{H}_4\text{C}(\text{NH})(\text{NH}_2)\text{CO}$  and  $\text{C}_6\text{H}_4\text{C}(\text{N}(\text{C}_6\text{H}_5)_2)\text{N}$  [over 300°] (Pinner, B. 25, 1425).—2. Oxalacetic ether and NaOH form  $\text{C}_6\text{H}_4\text{C}(\text{NH})(\text{NH}_2)\text{CO.CH}_2\text{CO.CO.Et}$  [190°] and  $\text{C}_6\text{H}_4\text{C}(\text{N}(\text{C}_6\text{H}_5)_2)\text{CH}$  [252°] (Pinner, B. 25, 1422).

Salts.— $\text{B}^+\text{HCl}$  aq. [218?].— $\text{B}^+\text{H}_2\text{PO}_4$  [225?].— $\text{B}^+\text{HNO}_3$  [133?]. Needles, v. sol. water (Kirschnick, A. 265, 187).— $\text{B}^+\text{HNO}_3$  2aq. [96?].— $\text{B}^+\text{H}_2\text{SO}_4$  2aq. [240?], v. sol. water.  
o-TOLENYL-AMIDOXIM  $\text{C}_6\text{H}_3\text{N}_2\text{O}$  i.e.  $\text{C}_6\text{H}_3\text{C}(\text{NOH}).\text{NH}_2$ . [149°5']. Formed by heat-

ing *o*-toluic nitrile with hydroxylamine hydrochloride, alcohol, and  $\text{Na}_2\text{CO}_3$  (Schubart, *B.* 22, 2438). Needles (from hot water), v. sol. alcohol and ether.

*Ethyl ether*  $\text{C}_6\text{H}_4\text{C}(\text{NOEt})\text{NH}_2$ . [140°]. Prisms, v. sol. alcohol.

*Benzoyl derivative*  $\text{C}_6\text{H}_4\text{C}(\text{NOBz})\text{NH}_2$ . [145°]. Needles, sol. alcohol. Conc.  $\text{H}_2\text{SO}_4$  forms  $\text{C}_6\text{H}_4\text{C}(\text{N}=\text{O})\text{CPh}$  [80°].

*o*-Toluyll derivative  $\text{C}_6\text{H}_3\text{C}(\text{NO.CO.C}_6\text{H}_5)\text{NH}_2$ . [138°]. Converted at 180° into  $\text{C}_6\text{H}_3\text{C}(\text{N}=\text{O})\text{C.C}_6\text{H}_5$  [59°] (Stieglitz, *B.* 22, 3156). Sodium diazobenzene sulphinate forms  $\text{C}_6\text{H}_3\text{C}(\text{N}=\text{O})\text{C}(\text{NH}_2)\text{C}_6\text{H}_5$  [110°].

*p*-Toluyll-amidoxim  $\text{C}_6\text{H}_4\text{N}_2\text{O}$  i.e.  $\text{C}_6\text{H}_4\text{Me.C}(\text{NOH})\text{NH}_2$ . *Toluamidoxim*. [146°]. Formed by combination of toluic nitrile with hydroxylamine (Schubart, *B.* 19, 1487). White plates, sol. alcohol, ether and hot water. Yields  $\text{NaA}$ , a hygroscopic mass, and  $\text{HA}\cdot\text{HCl}$  [187°], crystallising in prisms.

*Reactions*.—1. *Benzene sulphonic chloride* forms  $\text{C}_6\text{H}_4\text{C}(\text{N}=\text{O})\text{SO}_2\text{C}_6\text{H}_5$  [89°] (Pinner, *B.* 24, 4173).—2. *Aceto-acetic ether* gives rise to  $\text{C}_6\text{H}_4\text{C}(\text{N}=\text{O})\text{C.CH}_2\text{Ac}$  [97°] (Schubart, *B.* 22, 2438).—3. *Acetic aldehyde* forms the compound  $\text{C}_6\text{H}_4\text{C}(\text{N}=\text{O})\text{CHMe}$  [127.5°].—4. Hot  $\text{HOAc}$  forms  $\text{C}_6\text{H}_4\text{C}(\text{N}=\text{O})\text{C.C}_6\text{H}_5$  [135°].—5.  $\text{COCl}_2$  produces  $\text{C}_6\text{H}_4\text{C}(\text{N}=\text{O})\text{CO}$  [220°].—6.  $\text{ClCO}_2\text{Et}$  yields  $\text{C}_6\text{H}_4\text{C}(\text{NH})\text{NO.CO}_2\text{Et}$  [130°].—7. *Phenyl cyanate* gives  $\text{C}_6\text{H}_4\text{C}(\text{NOH})\text{NH.CO.NHPh}$  [155°].—8. *Phenyl thio-carbimide* reacts forming  $\text{C}_6\text{H}_4\text{C}(\text{NOH})\text{NH.CS.NHPh}$ .—9. *Potassium cyanate* acting on the hydrochloride gives rise to  $\text{C}_6\text{H}_4\text{C}(\text{NOH})\text{NH.CO.NH}_2$  [170°].—10.  $\text{Ac}_2\text{O}$  and  $\text{NaOAc}$  acting on the hydrochloride form  $\text{NH}(\text{C}(\text{NH})\text{C}_6\text{H}_5)_2$  [153°] (Glock, *B.* 21, 2657).—11. *Succinic anhydride* forms the compound  $\text{C}_6\text{H}_4\text{C}(\text{N}=\text{O})\text{C.CH}_2\text{CH}_2\text{CO}_2\text{H}$  [138.5°].—12.

Boiling  $\text{Ac}_2\text{O}$  forms  $\text{C}_6\text{H}_4\text{C}(\text{N}=\text{O})\text{CMe}$  [80°]. 13.  $\text{CS}_2$  and alcohol form, on long boiling,  $\text{C}_6\text{H}_4\text{C}(\text{NSH})\text{NH.CS.SiH}_3\text{N.C}(\text{NSH})\text{C}_6\text{H}_5$  (Crayen, *B.* 24, 390).—14.  $\text{CS}_2$  and alcoholic potash yield  $\text{C}_6\text{H}_4\text{C}(\text{N}=\text{S})\text{CS}$  [165°].

*Methyl ether*  $\text{C}_6\text{H}_4\text{C}(\text{NOMe})\text{NH}_2$ . [85°]. *Ethyl ether*  $\text{EtA}$ . [64°]. Needles. Converted by  $\text{HBr}$  and  $\text{NaNO}_2$  into  $\text{C}_6\text{H}_4\text{CBr:NOEt}$ , an oil, decomposed at 155° (Schubart, *B.* 22, 2434), while hydrogen chloride and  $\text{NaNO}_2$  form  $\text{C}_6\text{H}_4\text{CCL:NOEt}$  (200°).

*Benzoyl derivative*  $\text{C}_6\text{H}_4\text{C}(\text{NOBz})\text{NH}_2$ . [178°]. Converted by heat into  $\text{C}_6\text{H}_4\text{C}(\text{N}=\text{O})\text{CPh}$ .

*References*.—*Nitro- and Oxy-TOLUAMIDOXIM*.

*p*-TOLENYL-IMIDO-ETHYL ETHER  $\text{C}_6\text{H}_4\text{C}(\text{NH})\text{OEt}$ . The hydrochloride  $\text{B}\cdot\text{HCl}$  [161°] formed by the action of dry  $\text{HCl}$  on *p*-toluic nitrile dissolved in ether-alcohol forms

prisms, yielding  $\text{B}\cdot\text{H.PtCl}_2\cdot 2\text{aq.}$  converted at 200° into *p*-toluic amide, by  $\text{NH}_3$  into *p*-tolenyl-amidine, by aniline into di-phenyl-tolenyl-amidine [168°], and by  $\text{Ac}_2\text{O}$  into the compound  $\text{C}_6\text{H}_4\text{Me.C}(\text{NH})\text{OAc}$  [147°] (Glock, *B.* 21, 2650). The free base is liquid and changes on keeping into a polymeride [260°].

#### TOLENYL-PHENYLENE-DIAMINE

$\text{C}_6\text{H}_4\text{C}(\text{NH})\text{C.C}_6\text{H}_5$ . [268°]. Formed by reduction of tolyl-*o*-nitro-aniline and also from *p*-toluyl chloride and *o*-phenylene-diamine in benzene (Hübner & Hanemann, *A.* 210, 323). Prisms, sl. sol. water, sol. alcohol.

#### TOLENYL-PHTHALAMIDONE $\text{C}_{11}\text{H}_9\text{N}_2\text{O}$ i.e.

$\text{C}_6\text{H}_4\text{Me.C}(\text{N}=\text{C})\text{CO}$   $\text{C}_6\text{H}_5$ . [188°]. Got from

tolenyl-benzoyl-amidino *o*-carboxylic acid (Bistrzycki, *B.* 25, 1984).

#### TOLENYL-XYLYLENE-DIAMINE $\text{C}_{12}\text{H}_{10}\text{N}_2$

i.e. [1:4]  $\text{C}_6\text{H}_4\text{Me.C}(\text{NH})\text{C}_6\text{H}_4\text{Me}_2$   $\left[ \begin{smallmatrix} 5 \\ 6:1:3 \end{smallmatrix} \right]$

[217°]. Formed by reducing the *p*-toluyl derivative of nitro-xylydine (Brückner, *A.* 205, 125; Hübner, *A.* 210, 333). Long crystals (from dilute alcohol).— $\text{B}\cdot\text{HCl}$ .— $\text{B}\cdot\text{HNO}_3$ .— $\text{B}\cdot\text{H}_2\text{SO}_4$ .

#### TOLIDINE v. DI-AMIDO-DITOLYL.

#### TOLIL v. DI-TOLYL-DITOLONE.

#### TOLIL-BENZOLIN v. BENZOIN, Reaction 9.

#### TOLINDOLE v. METHYL-INDOLE.

#### TOLISATIN v. METHYL-ISATIN.

#### TOLU-ACET-ALDEHYDINE $\text{C}_{11}\text{H}_{11}\text{N}_2$ i.e.

$\text{C}_6\text{H}_4(\text{N:CHMe})_2$  or  $\text{C}_6\text{H}_4\text{C}(\text{NEt})\text{CMe}$  (?) [91° uncor.]. Formed together with a small quantity of ethenyl-tolylene-diamine, by mixing tolylene *o*-diamine (1 mol.) with aldehyde (2 mols.) in cold  $\text{HOAc}$  (Hinsberg, *B.* 20, 1588).

#### TOLU-AMIDOXIM v. TOLENYL-AMIDOXIM.

**TOLU-BALSAM**. Obtained from incisions in the stem of *Myrozyllum toluiferum* growing in Columbia, South America. It contains a terpene, toluene  $\text{C}_{10}\text{H}_{18}$  (154°–170°), benzoic and cinnamic acids, benzyl cinnamate and two resins:  $\text{C}_{15}\text{H}_{18}\text{O}_4$  [60°] v. sol. alcohol and ether and  $\text{C}_{15}\text{H}_{20}\text{O}_5$  [above 100°], insol. alcohol and ether (Deville, *A.* 44, 304; Scharling, *A.* 97, 71; K. Kopp, *A.* 64, 372; Busso, *B.* 9, 830; Bailon, *Ph.* [3] 4, 385).

#### TOLUBENZYLAMINE v. METHYL-BENZYL-AMINE.

**TOLUENE**  $\text{C}_6\text{H}_6$  i.e.  $\text{C}_6\text{H}_5\text{CH}_3$ . *Methylbenzene*. *Retinaphtha*. *Phenyl-methane*. Mol. w. 92. V.D. 3.20 (calc. 3.23). (109°) (R. Schiff, *A.* 220, 91); (111°) (Wilbrand & Beilstein, *A.* 128, 259; Tollens & Fittig, *A.* 131, 304). S.G.  $\frac{4}{4}$  8656 (Brühl);  $\frac{25}{25}$  8566 (Gladstone, *C.* J. 59, 290);  $\frac{15}{15}$  8708 (S.). Q.E. (13°–109°) 001242. S.V. 118 (S.).  $\mu_D = 1.4893$  (G.).  $\mu_D = 1.507$  (B.).  $R_\infty = 50.06$ . H.F.p. = 8520. H.F.v. = 5260 (Thomsen, *Th.*). H.C. 933,762 (Stohmann, *J. pr.* [2] 35, 41). *Critical temperature* 321° (Pawlewski, *B.* 46, 2634). Occurs in cold tar (Mansfield). Obtained by dry distillation from balsam of tolu (Deville, *A. Ch.* [3] 3, 168; Muspratt & Hofmann, *A.* 54, 9), from dragon's blood (Glénard & Boudault, *C. R.* 19, 505), from the resin of *Pinus maritima* (Pelletier & Walter,

*A. Ch.* [2] 67, 278), and from wood (Vöckel, *A.* 86, 384).

**Formation.**—1. By distilling vulpic acid with KOH (Möller & Strecker, *A.* 113, 69).—2. By the action of sodium on a mixture of bromobenzene and Mel (Fittig & Tollens, *A.* 131, 303).—3. By passing petroleum vapour over red-hot charcoal (Letny, *B.* 11, 1210).—4. By heating petroleum with  $\text{AlCl}_3$  in presence of PbO and air (Friedel & Crafts, *Z.* 1878, 1166).—5. By passing  $\text{MeCl}$  or  $\text{CH}_3\text{Cl}$  into benzene containing  $\text{AlCl}_3$  (Friedel & Crafts, *A. Ch.* [6] 1, 460; 11, 264).—6. Together with  $\text{CH}_4$  by heating benzene with Mel and I (Rayman & Preis, *A.* 223, 317).—7. By distilling cresol with  $\text{P}_2\text{S}_5$  (Geuther, *A.* 221, 58).—8. By distilling toluic acid with baryta (Noad, *A.* 63, 305).

**Properties.**—Oil, smelling like benzene.

**Reactions.**—1. When passed through a red-hot tube it yields benzene, styrene, naphthalene, diphenyl, anthracene, phenanthrene, and other products (Ferko, *B.* 20, 661; cf. Berthelot, *Bl.* 7, 218; Graebe, *B.* 7, 48).—2. Distillation over red-hot PbO gives benzene, di-phenyl-ethylene, diphenyl, phenanthrene, and anthracene (Lorenz, *B.* 7, 1097; Vincent, *C. R.* 100, 908).—3. By electrolysis of toluene to which alcohol and  $\text{H}_2\text{SO}_4$  have been added benzoic aldehyde and phenose are formed (Rénard, *C. R.* 92, 966).—4.—When electric sparks are passed through toluene, acetylene and hydrogen are given off (Destrem, *Bl.* [2] 42, 267).—5.  $\text{AlCl}_3$  at  $200^\circ$  in sealed tubes forms benzene, and *m*- and *p*-xylene (Friedel & Crafts, *C. R.* 100, 692; Anschütz, *A.* 235, 178).—6. Oxygen passed through toluene containing  $\text{AlCl}_3$  forms cresol (Friedel & Crafts, *C. R.* 86, 884).—7. A mixture of toluene and ethylene passed through a red-hot tube yields benzene, styrene, and anthracene (Ferko).—8.  $\text{CH}_3\text{Cl}$  and  $\text{AlCl}_3$  yield di-tolyl-methane ( $280^\circ$ – $290^\circ$ ), di-methyl-anthracene ( $232^\circ$ ), and *m*-, and *p*-xylenes (Friedel & Crafts, *Bl.* [2] 41, 322).—9. Bromine acts upon toluene in the dark as readily as in diffused daylight, with production of *o*- and *p*-bromo-toluene. The addition of iodine greatly hastens the reaction, but the same products are formed. In direct sunlight the substitution takes place entirely in the side-chain, with production of benzyl bromide. But if iodine (even 2 p.c.) is present the effect of the sunshine is entirely counteracted, and the substitution takes place wholly in the nucleus (Schramm, *B.* 18, 606; cf. Zakrzewski, *M.* 8, 304).—10. Chlorine, in presence of I, acting even on boiling toluene, forms chloro-toluene and benzyl chloride (Beilstein & Geitner, *A.* 231, 170; cf. Aronheim, *B.* 8, 1401).—11.  $\text{CrO}_3\text{Cl}$  added slowly to a solution of toluene in  $\text{CS}_2$  gives  $\text{C}_6\text{H}_4\text{CrO}_3\text{Cl}_2$ , which slowly absorbs moisture, being converted into benzoic aldehyde (Etard, *A. Ch.* [9] 22, 223).—12.  $\text{H}_2\text{SO}_4$  yields the *o*- and *p*-sulphonic acids, converted by potash-fusion into *o*- and *p*-cresol (Wurtz, *A. Ch.* [4] 25, 108).—13.  $\text{Bz}_2\text{O}_2$  forms  $\text{C}_6\text{H}_4$  (c.  $260^\circ$ ) isomeric with the di-phenyl-ethylenes, and yielding benzoic acid on oxidation (Lippmann, *M.* 7, 621).—14.  $\text{HNO}_3$  forms *o*- and *p*-nitro-toluene.—15. *Paraldehyde* and conc.  $\text{H}_2\text{SO}_4$  form ditolylethane and  $\text{C}_8\text{H}_{12}$  ( $350^\circ$ – $360^\circ$ ) (*O.* Fischer, *B.* 7, 1194).

**Compounds** ( $\text{C}_6\text{H}_4$ ) $\cdot\text{AlCl}_3$ . S.G. 2.108 (Gus. Vol. IV.

tavson, *B.* 11, 2151). Oil.—( $\text{C}_6\text{H}_5$ ) $\cdot\text{AlBr}_3$ . S.G. 2.137.

**Dihydride**  $\text{C}_6\text{H}_8$ . ( $105^\circ$ – $108^\circ$ ). Formed by heating toluene with  $\text{PH}_3$  at  $350^\circ$  (Baeyer, *A.* 155, 271; *Z.* [2] 4, 445).

**Tetrahydride**  $\text{C}_6\text{H}_{10}$ . ( $104^\circ$ ). S.G. 0.797. Occurs in the product of distillation of colophony (Rénard, *A. Ch.* [6] 1, 231). Oil, sol. alcohol and ether. Rapidly absorbs oxygen. In contact with water it forms crystalline  $\text{C}_6\text{H}_8\text{O}_2$ .  $\text{H}_2\text{SO}_4$  forms two polymerides ( $230^\circ$ – $235^\circ$ ), one only being oxidisable by air.

**Hexahydride**  $\text{C}_6\text{H}_{12}$ . ( $97^\circ$ ). S.G. 0.7741. C.E. ( $0^\circ$ – $20^\circ$ ) 0.0110. S.V. 142 (Lössen, *A.* 225, 109). H.C. 1,092,800 (Longuine, *C. R.* 93, 275). Formed by heating toluene with conc.  $\text{HHAq}$  at  $280^\circ$  (Wreden, *A.* 187, 161; cf. Berthelot, *Bl.* [2] 7, 124; 26, 146). Occurs in oil of resin. Completely oxidised by a hot mixture of  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$ .

**References.**—TRI-AMIDO-, BROMO-, BROMO-IBO-, BROMO-IBO-NITRO-, BROMO-NITRO-, CHLORO-, CHLORO-IBO-, CHLORO-NITRO-, IBO-, IBO-NITRO-, NITROSO-, NITRO-, and OXY- TOLUENE.

**TOLUENE ARSONIC ACID** v. ARSENIC.

**TOLUENE-AZIMIDO-TOLUENE** v. AZIMIDO-COMPOUNDS.

**TOLUENE-AZO-** compounds v. AZO-COMPOUNDS AND DIAZO-COMPOUNDS.

**TOLUENE-AZOXY-** compounds v. AZOXY-COMPOUNDS.

**TOLUENE CARBOXYLIC ACID** v. TOLUIC ACID.

**Toluene dicarboxylic acid**  $\text{C}_6\text{H}_4\text{O}_4$ . *i.e.*  $\text{C}_6\text{H}_4\text{Me}(\text{CO}_2\text{H})_2$  [4:2:1]. **Methyl-phthalic acid.** Mol. w. 180. [ $152^\circ$ ]. Formed from (a)-amido-*p*-toluic nitrile by Sandmeyer's reaction, the resulting nitrile being saponified (Niemcewicz, *M.* 12, 623). V. sol. water and alcohol. With *o*-amido-phenol it forms  $\text{C}_6\text{H}_4\text{Me}(\text{CO})_2\text{N}(\text{C}_6\text{H}_4\text{OH})$  [ $205^\circ$ ], whence boiling aqueous sodium carbonate gives rise to  $\text{C}_6\text{H}_4\text{Me}(\text{CO}_2\text{H})_2\text{CO.NH.C}_6\text{H}_4\text{OH}$  [ $200^\circ$ ].

**Amide**  $\text{C}_6\text{H}_4\text{Me}(\text{CONH}_2)_2$ . [ $188^\circ$ ]. Formed from the imide and  $\text{NH}_3\text{Aq}$ .

**Anhydride.** [ $32^\circ$ ]. Needles.

**Imide**  $\text{C}_6\text{H}_4\text{Me}_2\text{C}_2\text{O}_2\text{NH}$ . [ $196^\circ$ ]. Got by fusing the anhydride with urea. Needles.

**Nitrile**  $\text{C}_6\text{H}_4\text{Me}(\text{CN})_2$ . [ $120^\circ$ ] (N); [ $117^\circ$ ] (Glock, *B.* 21, 2663). Needles. Converted by alcohol and HCl into  $\text{C}_6\text{H}_4\text{Cy}(\text{C}(\text{NH}_2)\text{Cl})_2\text{OEt}$  [ $190^\circ$ ].

**Toluene dicarboxylic acid**

$\text{C}_6\text{H}_4\text{Me}(\text{CO}_2\text{H})_2$  [4:3:1]. (B). **Xylydic acid. Methyl-isophthalic acid.** [ $320^\circ$ – $330^\circ$ ]. Formed by oxidation of *m*-xylene carboxylic acid (Jacobsen, *B.* 14, 2112) and of  $\text{C}_6\text{H}_4\text{Me}(\text{CH}_2\text{OH})_2$  (Hjelt & Guld, *B.* 19, 868). Formed also by fusing potassium toluene *m*-disulphonate or the salt  $\text{C}_6\text{H}_4\text{Me}(\text{SO}_3\text{NH}_2)_2\text{CO}_2\text{K}$  with sodium formate (Håkansson, *B.* 5, 1048; Remsen & Iles, *Am.* 1, 119). The same acid (?) is got by oxidation of  $\text{C}_6\text{H}_4\text{Me}_2\text{CO}_2\text{H}$  [1:4:2] by  $\text{HNO}_3$  (S.G. 1.12) at  $150^\circ$  (Claus & Wollner, *B.* 18, 1858). Small crystals, sl. sol. hot water. May be sublimed. —Ag.A'': crystals, v. sol. hot water.

**Toluene dicarboxylic acid,**

$\text{C}_6\text{H}_4\text{Me}(\text{CO}_2\text{H})_2$  [2:4:1]. **Methyl-terephthalic acid.** *i.e.* Xylydic acid. [c.  $282^\circ$ ]. Formed by boiling pseudocumene with dilute  $\text{HNO}_3$  (Fittig & Laubinger, *A.* 151, 276). Got also by fusing

S.C.

$C_6H_5Me(SO_3NH_2)CO_2K$  with sodium formate (Remsen a. Iles, *Am.* 1, 114). Needles (by sublimation). Sl. sol. Aq. Oxidised by  $KMnO_4$  to trimellitic and isophthalic acids (Krinon, *B.* 10, 1494).— $ZnA''$ , S. 36 at  $0^\circ$ ;  $735$  at  $100^\circ$ ,  $5$  at  $180^\circ$  (Jacobsen, *B.* 10, 859).

**Toluene dicarboxylic acid**  $C_6H_4Me(CO_2H)_2$ , [310°-315°]. Formed by fusing potassium toluene ( $\gamma$ )-disulphonate with sodium formate (Senhofer, *A.* 164, 134). Minute needles, v. sl. sol. cold water, v. sol. alcohol and ether. May be sublimed. — $BaA''$  2aq.— $AgA''$ : amorphous pp.

**Toluene  $\omega$ -dicarboxylic acid**  
 $CO_2H.CH_2.C_6H_4.CO_2H$ . [2:1]. *Homophthalic acid*  
*v. o-Carboxy-phenyl-acetic acid.*

*Nitrile v. o-Cyano-benzyl cyanide.*

**Toluene  $\omega$ -dicarboxylic acid**  
 $CO_2H.CH_2.C_6H_4.CO_2H$  [3:1]. Formed by oxidation of *m*-di-ethyl-benzene (Allen a. Underwood, *Bl.* [2] 40, 100). Needles (from alcohol). Sublimes without melting at  $200^\circ$ . 210.— $Ag_2A''$ .

**Toluene  $\omega$ -p-dicarboxylic acid**  
 $CO_2H.CH_2.C_6H_4.CO_2H$ . [285°-288°]. S. 1 at  $50^\circ$ . S. (alcohol) 14.3 at  $30^\circ$ . Formed by the action of dilute (25 p.c.)  $HCl$  on the amide (Mellinghoff, *B.* 22, 3215). V. sl. sol. ether and benzene.— $Ag_2A''$ : crystalline pp. The same (?) acid formed by oxidation of  $C_6H_4PrPr$  [1:4] yields  $BaA''$  1.5aq. (Paterno a. Spica, *B.* 10, 1746).

**Amide**  $CO(NH_2).CH_2.C_6H_4.CO.NH_2$ . [235°]. Formed from  $CH_3Cy.C_6H_4.Cy$  and  $H_2SO_4$ . Small hard nodules.

**Amic acid**  $CO(NH_2).CH_2.C_6H_4.CO.H$ . [261°]. Formed from  $CH_3Cy.C_6H_4.CO.H$  and  $H_2SO_4$ . Sl. sol. ether, hot water and alcohol.— $AgA'$ : crystalline.

**Iso-amic acid**  $CO_2H.CH_2.C_6H_4.CO.NH_2$ . [229°]. Formed from *p*-cyano-phenyl-acetic acid. Crystalline, v. sol. alcohol and hot water.— $AgA'$ : Crystalline.

**Nitrile**  $CH_3Cy.C_6H_4.Cy$ . *p-Cyano-benzyl cyanide*. [100°]. (above  $360^\circ$ ). Formed from  $CH_3Cl.C_6H_4.Cy$  and  $KCy$  (Mellinghoff, *B.* 22, 3203). Needles, v. sl. sol. hot water, sol. alcohol and ether.

**Semi-nitrile**  $CH_3Cy.C_6H_4.CO.H$ . [201°]. Formed from  $\omega$ -chloro-*p*-toluic acid by treatment with  $KOH$  aq. and alcoholic  $KCy$  (Mellinghoff, *B.* 22, 3213). Crystalline, v. sol. alcohol and ether.— $AgA'$ .

**Semi-nitrile**  $CO_2H.CH_2.C_6H_4.Cy$ . [152°]. Formed from the nitrile and  $HCl$  at  $105^\circ$ . Prisms, v. sol. alcohol.— $AgA'$ . Crystalline.

**Nitrile-amide**  $CH_3Cy.C_6H_4.CO.NH_2$ . [182°]. Formed from  $\omega$ -chloro-*p*-toluic amide and  $KCy$ . Plates.

**Amide-nitrile**  $CO(NH_2).CH_2.C_6H_4.Cy$ . [196-5°]. Formed from the nitrile and  $HCl$  at  $70^\circ$ . Crystalline, v. sol. alcohol.

**Toluene tri-carboxylic acid**  
 $C_6H_2(CO_2H)_3$ .  $CH_3.CO_2H$ . Formed in small quantity by oxidation of *s*-tri-ethyl-benzene (Friedel a. Balsohn, *Bl.* [2] 34, 635). Needles. Sublimes before melting.— $Ag_2A''$ . Tables (from hot water).

**TOLUENE  $\omega$ -PHOSPHINIC ACID**  
 $C_6H_5Me.P(OH)_2$ . Obtained by decomposing its chloride with water (Michaelis a. Panecck, *A.* 212, 223). Oil. Monobasic acid.— $CaA'$  aq.

**Chloride**  $C_6H_5Me.PCl_2$ . (244°). Formed

by the action of  $PCl_5$  on mercury ditolyl [107°] and by warming toluene with  $AlCl_3$  and  $PCl_5$ . Liquid.

**Toluene  $p$ -phosphinic acid**  $C_6H_5Me.P(OH)_2$ . [105°]. Formed in like manner. Plates, v. sl. sol. water. Oxidised by  $HNO_3$  to the phosphonic acid. Decomposed on heating into tolyl-phosphine and toluene phosphonic acid.— $KA'$ . — $NH_4A'$ . — $BaA'$  aq. — $FbA'$ . — $CuA'$  4aq.

**Ether**  $C_6H_5Me.P(OEt)_2$ . [280°]. Formed from the chloride and dry  $NaOEt$ .

**Chloride**  $C_6H_5Me.PCl_2$ . [25°]. (245°). Formed, together with the *o*-isomeride, from toluene,  $PCl_3$ , and  $AlCl_3$  (Michaelis a. Panecck, *A.* 212, 203). Formed also from  $Hg(C_6H_5)_2$  [235°] and  $PCl_3$ . Needles, v. sol. ether and benzene.

*References.*—NITRO- and OXY-TOLUENE PHOSPHINIC ACID.

**TOLUENE PHOSPHINIC ANHYDRIDE v. PHOSPHINO-TOLUENE.**

**TOLUENE  $\omega$ -PHOSPHONIC ACID**  
 $C_6H_5Me.PO(OH)_2$ . [141°]. Formed by the action of water on its chloride (Michaelis a. Panecck, *A.* 212, 231). Crystals, v. sol. water.— $Ag_2A''$ .

**Chloride**  $C_6H_5Me.PCl_2$ . This is formed from  $C_6H_5Me.PCl_2$  and chlorine. Yellow solid.

**Toluene  $p$ -phosphonic acid**  $C_6H_5Me.PO(OH)_2$ . [189°]. Formed from  $C_6H_5Me.PCl_2$  and cold water. Woolly needles. Oxidised by alkaline  $KMnO_4$  to  $CO_2H.C_6H_4.PO(OH)_2$ . Bromine forms bromo-toluene.— $KHA''$ : needles.— $BaHA''$ :— $AgHA''$ . — $Ag_2A''$ .

**Chloride**  $C_6H_5Me.PCl_2$ . [42°]. Formed from  $C_6H_5Me.PCl_2$  and chlorine. Yellow mass, converted by dry  $SO_2$  into liquid  $C_6H_5Me.POCl_2$  (285°).

**Toluene  $\omega$ -phosphonic acid**  
 $C_6H_5Me.PO(OH)_2$ . [166°]. Formed, together with  $(C_6H_5)_2PO(OH)$  [191°], from benzoic aldehyde and  $PH_3I$  (Lithman, *B.* 22, 2145). Stellate groups of prisms (from  $HIOAc$ ).

*Reference.*—OXY-TOLUENE PHOSPHONIC ACID.

**TOLUENE  $\omega$ -SELINIC ACID**  $C_6H_5SeO_2$ . *i.e.*  $C_6H_5.CH_2SeO.OH$ . [85°]. Formed by oxidising benzyl diselenide with  $HNO_3$  (Jackson, *A.* 179, 8). Needles, sl. sol. cold water, v. sol. alcohol, nearly insol. ether.— $AgA'$ : slender crystals (from hot water).

**TOLUENE SULPHAMINE v. AMIDO-TOLUENE SULPHINIC ACID.**

**TOLUENE  $\omega$ -SULPHINIC ACID**  $C_6H_5SO_2$ . *i.e.*  $C_6H_5Me.SO.OH$ . [80°]. Formed by boiling  $C_6H_5.N_2H_5.SO_2.C_6H_5$  with barytes water (Limpricht, *B.* 20, 1241). Long needles, v. sol. ether.— $BaA'$  3aq. Nodules, v. sol. water.

**Toluene  $p$ -sulphinic acid**  $C_6H_5Me.SO_2H$ . [85°]. Formed in like manner (Limpricht), and also from toluene *p*-sulphonic chloride and sodium-amalgam, zinc-dust, or  $Na_2SO_3$  (Otto, *A.* 142, 92; 145, 19; *B.* 9, 1586; Blomstrand, *B.* 3, 965). Plates, v. sol. ether. Fuming  $HNO_3$  forms crystals [190°]. The Na salt heated with  $CH_3CHCl_2$  and alcohol at  $150^\circ$  gives a small quantity of  $CH_3CHCl_2.SO_2.C_6H_5$ ; [48°] (Otto, *J. pr.* [2] 40, 519). The Na salt with  $ClCO_2Et$  gives the ether (Otto, *B.* 26, 808).— $BaA'$ : lates.— $CaA'$  4aq.— $ZnA'$  2aq.— $AgA'$ .

**Methyl ether.** Formed from the Na salt and  $ClCO_2Et$  in  $MeOH$ . Oil (Otto, *J. pr.* [2] 47, 166).

**Ethyl ether EtA'.** Oil. Oxidised by  $\text{KMnO}_4$  in  $\text{HOAc}$  to toluene *p*-sulphonic ether (Otto a. Rossing, *B.* 19, 1226).

**Toluene *exo*-sulphonic acid  $\text{C}_6\text{H}_4\text{CH}_2\text{SO}_3\text{H}$ .** Prepared by reducing  $\text{C}_6\text{H}_4\text{CH}_2\text{SO}_2\text{Cl}$  with sodium-amalgam (Otto a. Lüders, *B.* 13, 1288). Very unstable.— $\text{NaA}'$ : leaflets, sol. hot alcohol.

*Reference*.—AMIDO-TOLUENE SULPHINIC ACID.

**TOLUENE *o*-SULPHONIC ACID  $\text{C}_6\text{H}_4\text{SO}_3\text{H}$  i.e.  $\text{C}_6\text{H}_4\text{MeSO}_3\text{H}$  [1:2].**

*Formation*.—1. In small quantity together with the *p*-isomeride, by dissolving toluene in hot fuming  $\text{H}_2\text{SO}_4$  (Engelhardt a. Latschinoff, *Z.* [2] 5, 617; Anna Wolkoff, *Z.* [2] 6, 321).—2. Together with the *m*- and *p*-isomerides by the action of  $\text{ClSO}_3\text{H}$  on toluene (Claesson a. Wallin, *B.* 12, 1848; Noyes, *Am.* 8, 176).—3. From *o*-toluidine by diazotisation followed by treatment with  $\text{H}_2\text{SO}_4$  (Müller a. Wiesinger, *B.* 19, 1348).—4. By reducing *p*-bromo-toluene sulphonic acid with sodium-amalgam (Terry, *J.* 169, 27).—5. From (4,1,2)-nitro-toluene sulphonic acid by elimination of  $\text{NO}_2$  (Jenssen, *A.* 172, 235).

*Preparation*.—By adding toluene (60 g.) to  $\text{ClSO}_3\text{H}$  (150 g.) in the cold, and pouring the product into water (Noyes).

*Properties*.—Thin leaflets (containing 2aq.), v. sol. water. Deliquescent.

*Salts* (C. a. W.; Hubner a. Post, *A.* 169, 1).— $\text{KA}'$ aq.— $\text{NaA}'$ aq.: scales, sol. water.— $\text{NH}_4\text{A}'$ : thin leaflets.— $\text{CaA}'_2$ : leaflets, sl. sol. water.— $\text{BaA}'_2$ aq. S. 4 at  $12^\circ$ .— $\text{BaA}'_2$ aq.— $\text{PbA}'_2$ aq.— $\text{PbA}'_2$ aq.— $\text{MgA}'_2$ aq.— $\text{ZnA}'_2$ aq.— $\text{CuA}'_2$ aq.— $\text{CdA}'_2$ aq.— $\text{MnA}'_2$ aq.— $\text{AgA}'$ : sl. sol. water.

*Chloride  $\text{C}_6\text{H}_4\text{SO}_2\text{Cl}$ .* Oil.

*Amide  $\text{C}_6\text{H}_4\text{SO}_2\text{NH}_2$ .* [154°]. S. 1 at  $9^\circ$ ; S. (alcohol) 3.5 at  $5^\circ$ . Octahedra, sl. sol. water. Yields a benzoyl derivative [112°], which forms  $\text{C}_6\text{H}_4\text{SO}_2\text{NKBz}$  1.5aq. and  $(\text{C}_6\text{H}_4\text{SO}_2\text{NKBz})_2$  3aq. (Wolkoff, *Z.* [2] 6, 57). Oxidised by  $\text{KMnO}_4$  in acid solution to *o*-sulpho-benzoic acid and in neutral solution to  $\text{C}_6\text{H}_4\text{SO}_2\text{NH}_2$  (Fahlberg a. List, *B.* 21, 242).

*Anilide  $\text{C}_6\text{H}_4\text{SO}_2\text{NHPh}$ .* [136°].

*Toluide  $\text{C}_6\text{H}_4\text{SO}_2\text{NHC}_6\text{H}_5$ .* [131°].

**Toluene *m*-sulphonic acid  $\text{C}_6\text{H}_4\text{MeSO}_3\text{H}$  [1:3].** *Formation*.—1. By the action of  $\text{H}_2\text{SO}_4$  on *m*-diazotoluene salts (Müller a. Wiesinger, *B.* 12, 1349).—2. A product of the action of  $\text{ClSO}_3\text{H}$  on toluene (Claesson a. Wallin, *B.* 12, 1848).—3. From *o*-bromo-toluene *m*-sulphonic acid and sodium-amalgam (Müller, *A.* 169, 47).—4. By the diazo-reaction from *p*-toluidine sulphonic acid and from *o*-toluidine sulphonic acid (Pechmann, *A.* 173, 202; Pagel, *A.* 176, 297; Nevie a. Winther, *C. J.* 37, 628; Klason, *B.* 19, 2887).

*Properties*.—Thin deliquescent scales (containing aq.), v. sol. water.

*Salts*.— $\text{KA}'$ aq.— $\text{NaA}'$ aq.— $\text{NH}_4\text{A}'$ : scales, v. sol. water.— $\text{CaA}'_2$ aq.: needles, v. sol. water.— $\text{BaA}'_2$ aq.— $\text{BaA}'_2$ aq. S. 22.75 at  $12^\circ$  (C. a. W.).—15.5 at  $15^\circ$  (Vallin, *B.* 19, 2932).— $\text{PbA}'_2$ aq.— $\text{PbA}'_2$ aq.— $\text{PbA}'_2$ aq.— $\text{MgA}'_2$ aq.— $\text{ZnA}'_2$ aq.— $\text{CuA}'_2$ aq.— $\text{CdA}'_2$ aq.— $\text{MnA}'_2$ aq.— $\text{AgA}'$ : v. sol. water.

*Chloride  $\text{C}_6\text{H}_4\text{SO}_2\text{Cl}$ .* Oil.

*Amide  $\text{C}_6\text{H}_4\text{SO}_2\text{NH}_2$ .* [108°]. S. 4 at  $9^\circ$  (C. a. W.); 265 at  $14^\circ$  (V.). S. (alcohol) 18 at

$5^\circ$  (C. a. W.); 17.4 at  $14^\circ$  (V.). Monoclinic tables and octahedra (from alcohol). Melts at  $91^\circ$  according to Noyes. Oxidised by alkaline  $\text{K}_2\text{FeCy}_2$  to  $\text{C}_6\text{H}_4\text{SO}_2\text{NH}_2$  (Noyes a. Walker, *Am.* 8, 187).

*Anilide  $\text{C}_6\text{H}_4\text{SO}_2\text{NHPh}$ .* [72°].

*m-Toluide  $\text{C}_6\text{H}_4\text{SO}_2\text{NHC}_6\text{H}_5$ .* [103°].

**Toluene *p*-sulphonic acid  $\text{C}_6\text{H}_4\text{MeSO}_3\text{H}$  [1:4].** The chief product of sulphonation of boiling toluene (Deville, *A. Ch.* [3] 3, 172; Pittig a. Tollens, *A.* 131, 310; Märcker, *A.* 136, 85; Engelhardt a. Latschinoff, *Z.* [2] 5, 617; Jaworsky, *Z.* 1865, 221; Otto a. Gruber, *A.* 142, 92; 145, 10; Christoff, *B.* 7, 1167; Fahlberg, *B.* 12, 1048).—2. From toluene and  $\text{ClSO}_3\text{H}$  (Claesson a. Wallin, *B.* 12, 1848).—3. By the action of  $\text{H}_2\text{SO}_4$  on *p*-diazotoluene salts (M. a. W.).

*Properties*.—Thick leaflets or flat prisms (containing aq.). Deliquescent. Melts at  $92^\circ$  (Norton a. Otten, *Am.* 10, 140). Fusion with sodium formate yields *p*-toluic acid (Remsen, *B.* 8, 1112). Potash-fusion gives *p*-cresol. Hydrolysis by steam begins at  $150^\circ$  (Armstrong a. Miller, *C. J.* 45, 148).

*Salts*.  $\text{KA}'$ aq. Trimetric crystals;  $a:b:c = 86.4:1.3:237$ .— $\text{NaA}'$  3aq.— $\text{NaA}'$  2aq.— $\text{NH}_4\text{A}'$ .— $\text{CaA}'_2$  4aq.— $\text{BaA}'_2$ .— $\text{BaA}'_2$ aq. S. 21 at  $12^\circ$ .— $\text{BaA}'_2$  3aq. (Kelbe, *B.* 16, 621).— $\text{PbA}'_2$ .— $\text{MgA}'_2$  6aq.— $\text{ZnA}'_2$  6aq.— $\text{CdA}'_2$  6aq.— $\text{MnA}'_2$  6aq.— $\text{CuA}'_2$  6aq.— $\text{AgA}'$ : long plates, v. sol. water.

*Methylamine salt* [125°].

$\text{NMe}_2\text{HA}'$ . [78°].  $\text{NMe}_2\text{HA}'$ . [92°]. Aniline salt [223°].—*o*-Toluidine salt [180°] (N. a. O.).

*Chloride  $\text{C}_6\text{H}_4\text{SO}_2\text{Cl}$ .* [69°]. Triclinic crystals;  $a:b:c = 768:11:114$ ;  $\alpha = 97^\circ 24'$ ;  $\beta = 117^\circ 6'$ ;  $\gamma = 81^\circ 28'$ . Acetoxim and  $\text{NaOH}$  form  $\text{C}_6\text{H}_4\text{SO}_2\text{ONCMe}$  [89°] (Wege, *B.* 24, 3538). In ethereal solution it is reduced by sodium-amalgam to toluene sulphonic acid and the compound  $\text{C}_6\text{H}_4\text{SO}_2$  [76°]. In presence of isoamyl ether ( $\text{C}_5\text{H}_{11}\text{O}$ ) the compound  $\text{C}_6\text{H}_4\text{S}_2\text{O}_4$  [36°] is formed (Otto, *A.* 143, 216).

*Bromide  $\text{C}_6\text{H}_4\text{SO}_2\text{Br}$ .* [96°].

*Iodide  $\text{C}_6\text{H}_4\text{SO}_2\text{I}$ .* [85°]. Formed by adding an alcoholic solution of I to aqueous  $\text{C}_6\text{H}_4\text{SO}_2\text{Na}$  (Otto a. Tröger, *B.* 24, 479). Yellow crystalline powder, v. sol. ether, turning brown in air. Heated with water at  $100^\circ$  it forms  $\text{C}_6\text{H}_4\text{S}_2\text{O}_4\text{C}_6\text{H}_5$ . Reduced silver acts in like manner.  $\text{ZnEt}_2$  forms zinc toluene sulphinate.

*Methyl ether MeA'*. [c.  $30^\circ$ ].

*Ethyl ether EtA'*. [32°]. S.G. 1.174.

Thick prisms (Kraft a. Roos, *B.* 25, 2259).

*Phenyl ether  $\text{C}_6\text{H}_4\text{SO}_2\text{OPh}$ .* [95°]. Formed by the action of  $\text{NaOPh}$  on the chloride dissolved in benzene (Otto, *B.* 19, 1832). Trimetric crystals;  $a:b:c = 289:476$ . Not affected by alcoholic  $\text{NH}_3$ , even at  $200^\circ$ .

*Amide  $\text{C}_6\text{H}_4\text{SO}_2\text{NH}_2$ .* [136°]. S. 2 at  $9^\circ$ . S. (alcohol) 7.4 at  $5^\circ$ . Leaflets. Yields  $\text{C}_6\text{H}_4\text{SO}_2\text{NHK}$  aq.  $\text{BzCl}$  forms  $\text{C}_6\text{H}_4\text{SO}_2\text{NHBz}$  [147°–150°], which gives  $\text{KA}'$ ,  $\text{CaA}'_2$ aq.,  $\text{BaA}'_2$ ,  $\text{AgA}'$ , and  $\text{AgA}'\text{NH}_2$ , and is converted by  $\text{PCl}_5$  into  $\text{C}_6\text{H}_4\text{SO}_2\text{NCClC}_6\text{H}_5$  [100°], whence ammonium carbonate solution forms  $\text{C}_6\text{H}_4\text{N}_2\text{SO}_2$  [114°] (Wolkoff, *B.* 5, 140). Succinyl chloride forms crystalline  $\text{C}_6\text{H}_4\text{SO}_2\text{NCC}_6\text{H}_4\text{CO}_2$ , converted by  $\text{NH}_3$ aq into  $\text{C}_6\text{H}_4\text{SO}_2\text{N}_2\text{H}_2(\text{C}_6\text{H}_4\text{O})$  [180°] and

( $C_6H_5SO_3$ ),  $NH_4(C_6H_5O_3)$ , which crystallises from alcohol (Wolcott, Z. 1870, 580).

**Methylamide**  $C_6H_5SO_3NHMe$ . [75°]. Rectangular plates, sl. sol. hot water. Yields  $C_6H_5SO_3NBzMe$  [58°].

**Ethylamide**  $C_6H_5SO_3NHEt$ . [58°].

**Anilide**  $C_6H_5SO_3NHPh$ . [103°].  $BzCl$  forms  $C_6H_5SO_3NBzPh$  [149° cor.] (Riemann a. Palmer, Am. 8, 242).

**Methylanilide**  $C_6H_5SO_3NMePh$  [95°]. Monoclinic crystals (Otto, J. pr. [2] 47, 371).

**Ethyl-anilide** [88°]. Prisms, insol. water.

**p-Toluide**  $C_6H_4SO_3NHC_6H_5$ . [118°].

**Toluene exo-sulphonic acid**  $C_6H_4CH_3SO_3H$ . Formed by boiling benzyl chloride with aqueous  $K_2SO_3$  (Böhler, A. 154, 50; 221, 215; Mohr, A. 221, 216; Otto a. Lüders, B. 13, 1286). Formed also by oxidising benzyl disulphide with  $HNO_3$  (Barbaglia, B. 5, 270, 688), and also, together with acetic acid, by heating benzyl methyl ketone with  $H_2SO_4$  (Krekeler, B. 19, 2625). Very hygroscopic crystals. The K salt heated with  $KCl$  yields  $C_6H_4CH_3CN$ .

**Salts**.— $NH_4A'$ .— $KA'$  aq. Trimetric prisms. — $BaA'$  2aq. Plates, sl. sol. water. — $CaA'$  2aq. — $PbA'$  (OH): crystals. — $PbA_2$ .— $AgA'$ : crystalline.

**Chloride**  $C_6H_4CH_3SO_3Cl$ . [93°]. Decomposed by heat into  $SO_2$  and benzyl chloride.

**Amide**  $C_6H_4CH_3SO_3NH_2$ . [102°] (O. a. L.) [105°] (Pechmann, B. 6, 534). Needles, sol. water and alcohol.

**Toluene (a)-disulphonic acid**  $C_6H_4Me(SO_3H)_2$  [1:2:4]. Formed by sulphonation of toluene and of toluene o- or p-sulphonic acid (Hakansson, B. 5, 1084; Senhofer, A. 161, 129; Gnehm a. Forrer, Z. 10, 542; Claesson a. Berg, B. 13, 1170; Klason, B. 20, 354). Formed also by heating toluene p-sulphonic chloride with  $H_2SO_4$  (Fahlberg, B. 12, 1052; Am. 1, 170; 2, 182). Thick liquid. — $(NH_4)A''$  aq. — $KA''$  aq. — $BaA''$  aq. S. 75 at 17°. Insol. alcohol. — $AgA''$  2aq.

**Chloride**  $C_6H_4(SO_3Cl)_2$ . [52°].

**Amide**  $C_6H_4(SO_3NH_2)_2$ . [186°].

**Toluene (β)-disulphonic acid**  $C_6H_4Me(SO_3H)_2$  [1:2:5]. Formed by heating toluene o-sulphonic acid with fuming  $H_2SO_4$  at 160° (H.), or toluene m-sulphonic acid with  $H_2SO_4$  at 180° (Klason, B. 19, 2889; 20, 352). — $KA''$  aq. — $BaA''$  aq. S. 3.9 at 15° (K.).

**Chloride**  $C_6H_4Me(SO_3Cl)_2$ . [96°].

**Amide**  $C_6H_4Me(SO_3NH_2)_2$ . [224°].

**Toluene disulphonic acid**  $C_6H_5Me(SO_3H)_2$  [1:2:3]. Formed by the action of sodium-amalgam on p-iodo-toluene disulphonic acid (Limpricht a. E. Richter, B. 18, 2179; A. 230, 826), and by heating toluene m-sulphonic acid with fuming  $H_2SO_4$  at 180° (Klason). Slender needles, v. sol. water and alcohol. — $KA''$  aq. — $BaA''$  3aq. Prisms, v. sol. water.

**Chloride**  $C_6H_5Me(SO_3Cl)_2$ . [55°].

**Amide**  $C_6H_5Me(SO_3NH_2)_2$ . [214°].

**Toluene o-disulphonic acid**  $C_6H_4Me(SO_3H)_2$  [1:2:6]. Formed by reduction of p-bromo-toluene disulphonic acid with sodium-amalgam (Kornatzki, A. 221, 199). — $KA''$ . — $BaA''$  4aq. V. e. sol. water.

**Chloride** [86.5°]. Prisms (from ligroin).

**Amide** [above, 260°]. Needles, v. sol. Aq.

**Toluene disulphonic acid**  $C_6H_5Me(SO_3H)_2$  [1:3:4]. Formed from p-toluidine sulphonic acid by conversion into  $C_6H_5Me(SH).SO_3H$  and

oxidation of the product (Klason, B. 20, 356). — $KA''$  aq. — $BaA''$  2aq. S 15. Prisms.

**Chloride**. [111°]. V. sol.  $CHCl_3$ .

**Amide**. [235°-239°]. V. sol. water.

**Toluene-s-disulphonic acid**

$C_6H_4Me(SO_3H)_2$  [1:3:5]. Formed from o-iodo- (or bromo-) toluene disulphonic acid or o-diazo-toluene disulphonic acid by long boiling with conc.  $HI$  (Limpricht a. Hasse, B. 18, 2177; A. 230, 295). — $KA''$  2aq. — $(NH_4)A''$ .

**Chloride** [132°]. Long prisms.

**Amide** [over 240°]. Small plates.

**Toluene trisulphonic acid**  $C_6H_3Me(SO_3H)_3$ . Formed by heating sodium toluene (a)-disulphonate with  $ClSO_3H$  at 240° (Claesson, B. 14, 307). Slender needles (containing 6aq), v. sol. water. Salts. — $KA'''$  3aq. — $PbA'''$  2aq. — $BaA'''$  14aq. Crystals, v. sol. water.

**Chloride**  $C_6H_3Me(SO_3Cl)_3$ . [153°].

**Amide**  $C_6H_3Me(SO_3NH_2)_3$ . [above 300°].

Minute crystals, nearly insol. water.

**References**.—AMIDO-, BROMO-, BROMO-AMIDO-, BROMO-NITRO-, CHLORO-, IODO-, IODO-AMIDO-, NITRO-AMIDO-, NITRO- and OXY-TOLUENE SULPHONIC ACID.

**TOLUENE p-THIOSULPHONIC ACID**

$C_6H_4MeSO_3SH$ . Formed by heating a solution of a salt of toluene p-sulphonic acid with sulphur (Otto, B. 15, 129; 20, 2087) or by adding a mixture of  $Na_2S$  and  $C_6H_5SO_3Na$  to an alcoholic solution of iodine (Otto a. Tröger, B. 24, 1132). A solution of Na salt gives a white pp. of cuprous salt on adding  $CuSO_4$ .

**Reactions**.—1. Iodine added to an alcoholic solution of the K salt forms the three compounds ( $C_6H_5SO_3$ )<sub>2</sub>S [134°], ( $C_6H_4SO_3$ )<sub>2</sub>S [109°], and ( $C_6H_3SO_3$ )<sub>2</sub>S [182°]. The compound ( $C_6H_4SO_3$ )<sub>2</sub>S is also formed by the action of I on a mixture of  $C_6H_5SO_3Na$  and  $C_6H_4SO_3Na$ , and crystallises from benzene in monoclinic forms  $a:b:c = 2.829:1.3221; \beta = 60^\circ 7'$ . The compound ( $C_6H_4SO_3$ )<sub>2</sub>S is split up by boiling  $H_2O$  into ( $C_6H_5SO_3$ )<sub>2</sub>S and ( $C_6H_4SO_3)<sub>2</sub>S (Otto a. Tröger, B. 24, 1126). —2.  $Cl.CO.Et$  acting on the Na salt forms the ethyl and tolyl ethers and the compound ( $C_6H_5SO_3$ )<sub>2</sub>S [182°] (Otto a. Rössing, B. 24, 1148).$

**Salts**.— $NaA'$  2aq. Trimetric tables. — $KA'$  2aq. — $AgA'$  aq: small tables, sl. sol. water.

**Ethyl ether**  $C_6H_4SO_3SEt$ . **Tolyl ethyl disulphoxide**. Got from  $NaA'$  and  $EtI$ . Oil.

**Ethylene ether**  $C_6H_4SO_3$ . [77°]. Needles. Decomposed by zinc-dust into the zinc salts of toluene sulphonic acid and ethylene mercaptan (Otto a. Heydecke, B. 25, 1478).

**Tolyl ether**  $C_6H_4SO_3SC_6H_5$ . **Tolyl disulphoxide**. [78°]. Formed by oxidation of p-tolyl mercaptan (Märcker, A. 136, 83). Formed also from toluene p-sulphonic acid and water at 100° (Otto a. Tröger, B. 24, 480). Monoclinic prisms (from alcohol). Decomposed on saponification by alkalis into toluene p-sulphonic acid and di-tolyl disulphide [41°] (Otto a. Rössing, B. 19, 1240). Reduced by zinc and dilute  $H_2SO_4$  to tolyl mercaptan. Bromine forms ( $C_6H_4S_2O_3$ )<sub>2</sub>Br<sub>2</sub> (Otto a. Grüber, A. 149, 105). Alcoholic  $H_2S$  forms, on warming, toluene p-sulphonic acid, di-tolyl disulphide, and tolyl tetrasulphide.

**Reference**.—AMIDO-TOLUENE THIOSULPHONIC ACID.

**TOLUENYL- o. TOLUENYL-**

**o-TOLUIC ACID**  $C_6H_4Me.CO_2H$  [1:2]. Mol. w. 136. [104°]. H.C.v. 928,800. H.C.p. 929,400. H.F. 98,600 (Stohmann, *J. pr.* [2] 40, 133).

**Formation.**—1. By oxidation of *o*-xylene with dilute  $HNO_3$  (Bieber a. Fittig, *Z.* [2] 6, 496; *A.* 156, 242).—2. From toluene *o*-sulphonic acid *via*  $C_6H_4.ON$  (Ramsay a. Fittig, *Z.* [2] 7, 584; *A.* 168, 246).—3. By the action of sodium-amalgam on a mixture of  $ClCO_2Et$  and *o*-iodo-toluene and saponification of the resulting  $C_6H_4.CO_2Et$  (Kekulé, *B.* 7, 1007).—4. By boiling phthalide (3 mols.) with  $HIAq$  (127°) and yellow P (2 at.), the yield being 97 p.c. (Hessert, *B.* 11, 238; Racine, *A.* 239, 72).—5. From *o*-toluidine *via* the nitrile (Cahn, *A.* 240, 280).

**Properties.**—Plates (containing 2ag), volatile with steam, sl. sol. cold water. Oxidised by alkaline  $KMnO_4$  to phthalic acid (Weith, *B.* 7, 1057). Bromine-vapour above 100° forms phthalide; in the cold Br forms bromo-toluic acid  $C_6H_3MeBr.CO_2H$  [167°].

**Salts.**— $NaA'$  2ag. [228°]. Efflorescent plates.— $CaA'$  2ag. — $BaA'$  2ag. **Ethyl ether  $EtA'$ .** (220°).

**Amido-ethyl ether**  $C_6H_4.CO.O.CH_2CH_2NH_2$ . Formed from *o*-tolyl-oxazoline and  $HClAq$ . Oil. Yields  $B'HB'r$  [156°],  $B'C_6H_4N_3O$  [188°].

**Amido-propyl ether**  $C_6H_4.CO.O.CH_2Me.CH_2NH_2$ . Formed by evaporating tolyl-methyl-oxazoline with  $HClAq$ . Yields  $B'HB'r$  [140°],  $B'C_6H_4N_3O$  [192°], and a platinum-chloride [214°].

**Benzyl ether  $C_6H_4A'$ .** (315°). S.G. 1.12. Oil (Hodgkinson, *C. J. Proc.* No. 103, p. 167).

**Chloride**  $C_6H_4.OCl$ . (211° at 733 mm.).

**Anhydride**  $(C_6H_4.CO)_2O$ . [c. 38°]. (above 325°). Formed from the Na salt (6 mols.) and  $POCl_3$  (1 mol.). Insol. water, sol. ether and benzene.

**Amide**  $C_6H_4.CONH_2$ . [140°] (Hutchinson, *B.* 24, 174; *C. J.* 57, 957; cf. Weith, *B.* 6, 420). On reduction in acid solution it yields *o*-tolyl alcohol and a small quantity of the dihydride  $C_6H_4.CO.NH_2$  [156°], which on boiling with water yields an acid [68°]. The dihydride is also formed by reducing the amide in alkaline solution.

**Anilide**  $C_6H_4.CO.NHPh$ . [125°]. Formed from anti-phenyl-*o*-tolyl ketoxim and  $PCl_5$ , followed by water (Smith, *B.* 24, 4047).

**Xylide**  $C_6H_4.CO.NH.C_6H_4Me$  [1:2:4]. [165°]. Formed by heating *o*-tolyl xylid ketone with hydroxylamine at 120° (Smith).

**Bromo-ethylamide**  $C_6H_4.CO.NH.CH_2CH_2Br$ . [71°] (Salomon, *B.* 26, 1322).

**Chloro-ethylamide**  $C_6H_4.CO.NH.CH_2CH_2Cl$ . [73°]. White needles.

**Bromo-propyl-amide**  $C_6H_4.CO.NH.CH_2CH_2CH_2Br$ . [86°]. Needles (from benzene-ligroin) (Salomon, *B.* 26, 1323).

**Chloro-propyl-amide**  $C_6H_4.CO.NH.CH_2CH_2CH_2Cl$ . [84°]. Formed by evaporating *o*-tolyl-methyl-oxazoline with excess of  $HClAq$ . Needles (from ligroin).

**o-Nitro-benzyl-amide**  $C_6H_4.CO.NH.CH_2C_6H_4.NO_2$ . [135°]. Needles (from alcohol). May be reduced to the *o*-amido-

benzyl-amide [116°], which yields  $B'HB'r$  [314°] (Wolff, *B.* 25, 3034).

**Imide**  $(C_6H_4.CO)_2NH$ . [148°].

**Nitrile**  $C_6H_4.CN$ . (204° cor.). V.D. 4.03 (obs.).  $II_F$  = 84,800 (Berthelot a. Petit, *A. Ch.* [6] 17, 123). Formed by heating  $KCy$  with potassium toluene *o*-sulphonate or with tri-*o*-tolyl phosphite (Heim, *B.* 16, 1776), by heating *o*-tolyl thiocarbimide with finely-divided copper (Weith, *B.* 6, 419), by boiling *o*-tolyl carbamine (Weith, *B.* 7, 722), by heating *o*-iodo-toluene with  $AgCy$  at 350° (Merz a. Weith, *B.* 10, 751), by boiling the formyl derivative of *o*-toluidine with zinc-dust (the yield being 18 p.c.) (Gasirowski a. Merz, *B.* 17, 74; 18, 1004), and by Sandmeyer's reaction from *o*-toluidine (Cahn, *B.* 19, 756). Liquid.  $H_2SO_4$  at 60° to 70° forms  $C_6H_4.C(NH).NH.CO.C_6H_4$  [103°], which is converted, by warming its acid solution, into the imide  $(C_6H_4.CO)_2NH$  (Kraft a. Kerstens, *B.* 25, 455). Conc.  $HIAq$  forms  $C_6H_4.Cl_2.NH_2$  [98°] (Biltz, *B.* 25, 2540).

**Hex-Phydrate**  $\nu$ . METHYL-HEXAMETHYLENE CARBOXYLIC ACID.

**m-Toluic acid**  $C_6H_4Me.CO_2H$  [1:3]. [110°] (Jacobsen, *B.* 14, 2317; Bornemann, *B.* 20, 1382). (263°). H.C.v. 928,500. H.C.p. 929,100. H.F. 98,900 (Stohmann, *J. pr.* [2] 40, 134). S. 0.9 at 15°; 1.66 at 100°.

**Formation.** 1. By oxidising bromo-xylene and reducing the resulting bromo-toluic acid with sodium-amalgam (Ahrens, *Z.* [2] 5, 106; Richter, *B.* 5, 424; Böttger a. Ramsay, *A.* 168, 255). 2. By distilling nitric acid with lime (Fittig, *B.* 5, 268). 3. By oxidation of *m*-xylene with dilute  $HNO_3$  (Tavildaroff, *B.* 4, 410; Bruckner, *B.* 9, 406; Reuter, *B.* 17, 2028).—4. By saponifying the nitrile.

**Preparation.**—1. By boiling *o*-chloro-xylene with  $HNO_3$  (1 vol. of S.G. 1.1) and water (3 vols.) (Senff, *A.* 220, 217).—2. By sulphonating crude xylene, then preparing  $C_6H_4Me.SO_2NH_2$ , oxidising by  $KMnO_4$ , heating the resulting  $C_6H_4Me(SO_2NH_2).CO_2H$  with  $HCl$  at 230°, and distilling with steam (Jacobsen, *B.* 14, 2317).

**Properties.**—Long needles, volatile with steam, v. sol. alcohol and ether. Oxidised by chromic acid mixture to isophthalic acid.

**Salts.**— $CaA'$  3ag. S. 3.17 at 15°; 8.2 at 100°.— $BaA'$  2ag; trimetric plates or tables.— $AgA'$ .

**Ethyl ether  $EtA'$ .** (226°).

**Chloride** (188° at 724 mm.) (Ador a. Billiet, *B.* 12, 2300).

**Nitrile**  $C_6H_4.CN$ . (209°). Formed by heating *m*-tolyl thiocarbimide with  $Ca$  (Weith a. Landolt, *B.* 8, 720), and in other ways (Buchka a. Schachtelbeck, *B.* 22, 841).

**p-Toluic acid**  $C_6H_4Me.CO_2H$  [1:4]. [179°]. (275° cor.) (Fischl, *B.* 12, 615). H.C.v. 926,800. H.C.p. 927,400. H.F. 100,600 (Stohmann, *J. pr.* [2] 40, 134).

**Formation.**—1. By the action of dilute  $NHO_3$  on cymene (Nowak, *P. M.* [2] 32, 19; *A.* 63, 289) on *p*-xylene (Beilstein, *A.* 137, 302; Bruckner, *A.* 205, 113), and on terpenes (Hirzel, *Z.* 1866, 205).—2. By saponification of the nitrile.—3. By heating *p*-bromo-toluene with  $ClCO_2Et$  and sodium-amalgam and saponifying the product (Wurtz, *C. R.* 63, 1298).—4. From *p*-bromo-toluene,  $CO_2$ , and sodium (Kekulé, *A.*

187, 184).—5. By the action of  $\text{POCl}_3$  (40 g.) on a mixture of toluene (40 g.),  $\text{HOAc}$  (80 g.) and  $\text{ZnCl}_2$  (80 g.) at  $110^\circ$  (Frey, *J. pr.* [2] 43, 116).—6. By reducing bromo-*p*-toluic acid with sodium-amalgam (Reinsen a. Morse, *Am.* 1, 138).—7. From the chloride which is formed by the action of  $\text{COCl}_2$  on toluene in presence of  $\text{AlCl}_3$  (Ador a. Crafts, *B.* 10, 2176).—8. From the amide which is formed by the action of  $\text{AlCl}_3$  on a mixture of toluene,  $\text{CS}_2$ , and  $\text{NH}_4\text{COCl}$  (Gattermann a. Schmidt, *B.* 20, 859).—9. By fusing  $\text{C}_6\text{H}_5\text{CO}_2\text{C}_6\text{H}_5$  with potash (Friedel a. Crafts, *Bl.* [2] 35, 508), and also by passing gaseous cyanic acid and  $\text{HCl}$  into toluene at  $100^\circ$  containing  $\text{AlCl}_3$  (Gattermann a. Rossolimo, *B.* 23, 1195).

**Properties.**—Needles, v. sol. hot water, v. o. sol. alcohol and ether. Volatile with steam. Oxidised by  $\text{CrO}_3$  or  $\text{KMnO}_4$  to terephthalic acid. Yields a di-nitro-derivative [158°].

**Salts.**— $\text{KA}'$ .— $\text{BaA}'_2$ , 2aq.; needles (Buchka a. Irish, *B.* 20, 1764).— $\text{CaA}'_2$ , 3aq.;  $\text{MgA}'_2$ , 3aq.;  $\text{CuA}'_2$ .— $\text{AgA}'$ .

**Methyl ether**  $\text{MeA}'$ . [32°]. (217°).

**Ethyl ether**  $\text{EtA}'$ . (228°). Oil.

**Amido-ethyl ether**  $\text{C}_6\text{H}_5\text{CO.O.C}_2\text{H}_5\text{NH}_2$ . Yields  $\text{B'HB'r}$  [167°] and  $\text{B'C}_6\text{H}_4\text{N}_3\text{O}$  [180°].

***p*-Amido-propyl ether**  $\text{C}_6\text{H}_5\text{CO.O.C}_3\text{H}_7\text{NH}_2$ . The hydroxamide  $\text{B'HB'r}$  is formed by evaporating a solution of the bromo-propyl-amide. It yields  $\text{B'C}_6\text{H}_4\text{N}_3\text{O}$  [180°] and  $\text{B}_2\text{H}_2\text{N}_2\text{OCl}_2$ .

**Phenyl ether**  $\text{PhA}'$ . [72°].

**Chloride** (225° at 720 mm.).

**Amide**  $\text{C}_6\text{H}_5\text{CO.NH}_2$ . [159°]. Formed by heating the  $\text{NH}_4$  salt in sealed tubes at  $230^\circ$  (Hallemann, *R. T. C.* 6, 79).

**Methylamide**  $\text{C}_6\text{H}_5\text{CO.NHMe}$ . [143°]. Formed by the action of  $\text{NHMeCOCl}$  on toluene in presence of  $\text{AlCl}_3$  (Gattermann a. Schmidt, *B.* 20, 120; *A.* 241, 51). Tables.

**Ethylamide**  $\text{C}_6\text{H}_5\text{CO.NHEt}$ . [96°].

**Bromo-ethyl-amide**  $\text{C}_6\text{H}_5\text{CO.NHCH}_2\text{CH}_2\text{Br}$ . [129°] (Salomon, *B.* 26, 1325). Formed from *p*-toluic chloride and bromo-ethylamine. Plates. Converted by boiling water into the amido-ethyl ether.

**Chloro-ethyl-amide**  $\text{C}_6\text{H}_5\text{CO.NHCH}_2\text{CH}_2\text{Cl}$ . [122°]. Needles (from ligroin).

**Bromo-propyl-amide**  $\text{C}_6\text{H}_5\text{CO.NHCH}_2\text{CH}_2\text{CH}_2\text{Br}$ . Melts at  $74^\circ$ , becomes solid, and melts again at  $158^\circ$  (*B.* 26, 1326).

**Chloro-propyl-amide**  $\text{C}_6\text{H}_5\text{CO.NHCH}_2\text{CH}_2\text{CH}_2\text{Cl}$ . [78°].

**Anilide**  $\text{C}_6\text{H}_5\text{CO.NHPh}$ . [145°]. Formed from toluene, phenylcyanate, and  $\text{AlCl}_3$  (Leuckart, *J. pr.* [2] 41, 306).

***o*-Nitro-anilide**. [110°]. Yellow prisms.

***p*-Toluide**  $\text{C}_6\text{H}_4\text{CO.NHC}_6\text{H}_5$ . [160°]. Formed by the action of sodium-amalgam and  $\text{HOAc}$  at  $60^\circ$  on an alcoholic solution of di-*p*-tolyl ketoxim (Goldschmidt a. Stücker, *B.* 23, 2747; 24, 2799). Needles.

**Nitro-toluide**  $\text{C}_6\text{H}_4\text{CO.NHC}_6\text{H}_4\text{Me(NO}_2)$  [4:1:3]. [166°].

**Diphenylamide**  $\text{C}_6\text{H}_5\text{CO.NPh}_2$ . [155°]. Prisms (from alcohol) (Lellmann a. Bonhöffer, *B.* 20, 2118).

**Xylide**  $\text{C}_6\text{H}_4\text{CO.NHC}_6\text{H}_4\text{Me}_2$ . [139°]. Yields  $\text{C}_6\text{H}_4\text{CO.NHC}_6\text{H}_4\text{Me}_2(\text{NO}_2)$  [187°].

**Phenyl-methyl-amide**  $\text{C}_6\text{H}_5\text{CO.NPhMe}$ . [70°] (Lellmann a. Benz, *B.* 24, 2114).

***o*-Nitro-benzyl-amide**  $\text{C}_6\text{H}_4\text{CO.NHCH}_2\text{C}_6\text{H}_4\text{NO}_2$ . [142°] (Wolff, *B.* 25, 3036).

**Nitrile**  $\text{C}_6\text{H}_5\text{Me.CN}$ . [28-5°]. (218°). Formed by distilling potassium toluene *p*-sulfonate with  $\text{KC}_6\text{H}_4(\text{SO}_3\text{Na})_2$  (Merz, *Z.* [2] 4, 33), by heating  $\text{C}_6\text{H}_5\text{N.CS}$  with  $\text{Cu}$  (Weith, *B.* 6, 421), by heating tri-*p*-tolyl phosphate with  $\text{KC}_6\text{H}_4$  (Heim, *B.* 16, 177-9), and by passing  $\text{C}_6\text{H}_5\text{NH.CHO}$  over heated zinc-dust (G. a. M.). Obtained also from *p*-toluidine by Sandmeyer's reaction (Glock, *B.* 21, 2650). Sodium added to its boiling alcoholic solution forms a small quantity of  $\omega$ -amido-*p*-xylene, the greater part being saponified (Bamberger a. Lottler, *B.* 20, 1710).  $\text{H}_2\text{SO}_4$  gives  $\text{C}_6\text{H}_4\text{C}(\text{NH})\text{NH.CO.C}_6\text{H}_4$  [145°]. Easily converted into the imide ( $\text{C}_6\text{H}_4\text{CO.NH}$ ) [155°] (Krafft a. Karstens, *B.* 25, 154). Conc.  $\text{HIAq}$  forms  $\text{C}_6\text{H}_4\text{Cl}_2\text{NH}_2$  [115°-120°], decomposed by fusion (Biltz, *B.* 25, 2539).

**Tetrahydride**  $\text{C}_6\text{H}_5\text{O}_2$ . (252°). Formed by reduction of  $\text{CH}_2\text{C}(\text{CH}_2\text{CH})\text{C.CO}_2\text{H}$  with sodium-amalgam (Finhorn a. Willstätter, *B.* 26, 2009). Needles, melting below  $0^\circ$ . Yields  $\text{CaA}'_2$ , 4aq.;  $\text{CuA}'_2$ , 2aq.;  $\text{MeA}'$ . (210°-220°), and an amide [158°]. Boiling  $\text{NaOHIAq}$  converts the acid into a solid isomeride [47°] (254°-260°) which yields  $\text{CaA}'_2$ , 4aq. and an amide [135°]. **Hexahydride** (Serebojakkoff, *B.* 25, 3355).

**References.**—AMIDO-, BROMO-, BROMO-NITRO-, CHLORO-, NITRO-, NITRO-AMIDO-, OXY-, OXY-AMIDO-, and SULFHO-TOLUIC ACID.

**$\alpha$ -Tolucic acid is PHENYL-ACETIC ACID.**

**$\alpha$ -TOLUIC ALDEHYDE**  $\text{C}_6\text{H}_4\text{Me.CHO}$  [1:2]. ***o*-Toluylic aldehyde**. (200°). Prepared by boiling  $\omega$ -chloro-*o*-xylene with lead nitrate solution (Lauth a. Grimaux, *Bl.* [2] 7, 233; Rayman, *Bl.* [2] 27, 498). Prepared also from *o*-xylene by the successive action of  $\text{CrO}_2\text{Cl}_2$  and water (Bornemann, *B.* 17, 1167), and by oxidising  $\text{C}_6\text{H}_4\text{Me.CH}_2\text{OH}$  with chromic acid mixture (Krober, *B.* 23, 1029). Oil, smelling like bitter almonds. Yields a crystalline compound with  $\text{NaHSO}_4$ . Reduced by sodium-amalgam to *o*-tolyl-carbinol.

**Oxim**  $\text{C}_6\text{H}_4\text{Me.CH.NOH}$ . [49°]. Is an *antioxim*. White crystals (from ether), v. sol. alcohol. Yields a crystalline hydrochloride.  $\text{Ac}_2\text{O}$  yields an acetyl derivative [56°].  $\text{AcCl}$  acts in like manner. The acetyl derivative is decomposed by alkalis with regeneration of the oxim, no nitrile being formed (Dollfus, *B.* 25, 1921). The oxim is converted in ethereal solution by  $\text{PCl}_5$  into the nitrile (204°).

***m*-Tolucic aldehyde**  $\text{C}_6\text{H}_4\text{Me.CHO}$  [1:3]. (199°). S.G. 1.037. Formed by boiling  $\omega$ -chloro-*m*-xylene or  $\omega$ -bromo-*m*-xylene with lead nitrate solution (Gundelach, *Bl.* [2] 26, 44; Müller, *B.* 20, 1213), and also by the action of water on  $\text{C}_6\text{H}_4\text{CrO}_2\text{Cl}_2$  obtained from *m*-xylene (Étard, *B.* 14, 848; Bornemann, *B.* 17, 1464). Oil, smelling like almonds. Combines with  $\text{NaHSO}_4$ . Aniline forms  $\text{C}_6\text{H}_4\text{CH.NPh}$ . (314°).

**Phenyl-hydrazide**  $\text{C}_6\text{H}_4\text{Me.CH.N.NHPh}$ . [91°]. (*B.*); [88°] (Rudolph, *A.* 248, 100). Prisms (from ligroin), v. sol. ether.

**p-Toluic aldehyde**  $C_6H_4Me.CHO$  [1:4]. (205°). Formed by distilling calcium p-toluate with calcium formate (Cannizzaro, A. 124, 254). Formed also by the action of water on the product of combination of p-xylene with  $CrO_2Cl_2$  (Bornemann). Oil, with peppery smell. Oxidised by air to toluic acid. Alcoholic potash forms potassium toluate and tolyl-carbinol.

Reference.—NITRO- AND OXY-TOIUID ALDEHYDE.

**TOIUID CHLORIDE** v. Chloride of Toiuid ACID.

**TOIUIDS.** Compounds derived from toluidine by displacement of H in  $NH_2$  by an acid radical.

**O-TOIUIDINE**  $C_6H_4Me.NH_2$  [1:2]. Mol. w. 107. (198°). S.G. 2° 9986 (Brühl, A. 200, 189). H.C.p. 964,700. H.C.v. 963,750. H.F. 3,800 (Petit, C. R. 107, 266).  $\mu_d$  1.5895.  $n_D$  57.56. S.V. 126.6. Formed from o-cresol,  $ZnBr_2$ ,  $NH_3$ , and  $NH_4Cl$  at 335° (Merz a. Müller, B. 20, 547). Prepared by reduction of o-nitro-toluene. May be separated from p-toluidine by means of the acid oxalates (Bindschedler, B. 6, 448; Ihle, J. pr. [2] 14, 449; Miniati, Booth a. Cohen, S. G. I. 67 418), by freezing (Rosenstiel, *ibid.* [2] 17, 7), by means of the nitrates (Schad, B. 6, 1361), hydrochlorides, sulphates, or phosphates (Lewy, Fr. 23, 269; B. 19, 1717, 2728; cf. Wulfing, B. 19, 2132). o-Toluidine can be prepared from  $C_6MeHBr(NH_2)(NO_2)H$  *via*  $C_6MeHBrI(NO_2)H$ ,  $C_6MeHBrI(NH_2)H$ ,  $C_6MeHBrBrH$ , followed by  $C_6Me(NO_2)BrH$  and  $C_6Me(NH_2)BrH$ . It can also be got from  $C_6Me(NH_2)BrH$  *via*  $C_6MeHBrBrH$ , followed by  $C_6MeHBrBr(NO_2)$  and  $C_6MeHBrBr(NH_2)$  thus proving that the toluidine  $C_6H_4Me(NH_2)$  [1:2] is identical with  $C_6H_4Me(NH_2)$  [1:6] (Wroblewsky, A. 192, 213).

**Properties.**—Oil. A solution in  $H_2SO_4$ ,  $H_2O$  is coloured orange by  $HNO_3$  and blue by  $CrO_3$ , the solution in the latter case becoming reddish-violet on dilution. Forms a crystalline compound with liquid  $CO_2$  at 8° (Hille, C. R. 105, 614). With  $PbO$ , and aqueous acetic acid gives a green colour, while  $PbO$  and alcoholic acetic acid gives a reddish-violet colour (Lauth, C. Z. 111, 975). Unlike p-toluidine, it forms a crystalline compound with alloxan (Pellizzari, C. C. 1887, 1288, 1396). If an ethereal solution of o-toluidine is shaken with very dilute bleaching-powder solution the aqueous layer becomes yellow or brown, and the ethereal layer, if decanted and shaken with dilute  $H_2SO_4$ , colours this reddish-violet. A solution of p-tolylene diamine hydrochloride mixed with a little o-toluidine gives a green colour on addition of  $FeCl_3$  or  $K_2Cr_2O_7$  (Nietzki, B. 10, 1157).

**Reactions.**—1.  $POCl_3$  forms  $PO(NHC_6H_4Me)_3$  [225°] (Michaelis a. Rudert, B. 26, 565), v. sol. water, whence Br forms  $PO(NHC_6H_4Me)_3$  [253°]. Another product of the action of  $POCl_3$  on o-toluidine is  $POCl(NHC_6H_4Me)_3$ , whence water forms  $HO.PO(NHC_6H_4Me)_3$  [95°].  $PCl_5$  forms  $PS(NHC_6H_4Me)_3$  [135°].—2.  $SiCl_4$  forms  $SiCl_2(NHC_6H_4Me)_3$ , a white granular powder (Harden, C. J. 51, 40).—3. On heating with malic acid it yields the mono-toluide [178°], di-toluide [181°], and a tolyl-imide [116°] of malic acid (Bischoff, B. 23, 2043).—4. Chloro-citryl chloride forms  $C_6H_4N < CO.CH < CO.CCH_2.CO.NHC_6H_4$  [214°] (Skinner

a. Ruhemann, C. J. 55, 239).—5.  $SO_3$ , alcohol, and nitrous acid give rise to the 'sulphazide'  $C_6H_4N_2SO_3$  [142°] (Linprich, B. 20, 1241).—6. On nitration of o-toluidine or its acetyl derivative  $NO_2$  enters the p- and o-positions, but in presence of  $H_2SO_4$  (10 pts.) the compound  $C_6H_4Me(NO_2)(NH_2)$  [1:4:6] [107°] is formed (Nöling a. Collin, B. 17, 265), together with the (1,2,6)-isomeride (Green a. Lawson, C. J. 59, 1018).—7. Benzoic aldehyde forms  $C_6H_4CH_2NC_6H_5$ , an oil (316°) (Etard, *ibid.* [2] 39, 530; Pictet, B. 19, 1063). 8. Hydrobenzamide or warming forms the same body (310°) (Lachovitch, M. 9, 695).—9. Toluidine heated with toluidine hydrochloride and benzoic aldehyde in sealed tubes at 120° forms  $C_6H_4CH(C_6H_4Me.NH_2)_2$ , a crystalline powder turning blue in the air (Ullmann, J. pr. [2] 36, 251).—10. The methyl derivative of p-ary-benzoic aldehyde at 120° produces the compound  $C_6H_4(OMe).CH(NC_6H_5)_2$  [132°] (Steinhart, A. 241, 310). 11. Bromo-propionic acid reacts, forming  $C_6H_4N_2O_3$  [185°] (Mahery a. Krause, B. 22, 3308).—12.  $\alpha$ -Bromo-acrylic acid produces pale-yellow needles [115°] (M. a. K.).—13. The hydrochloride heated with  $MeOH$  at 250°–300° gives rise to dimethyl-toluidine, xylydine  $C_6H_4Me_2(NH_2)$  [4:3:1] and mesidine (Lampach, B. 21, 640).—14. Cyanogen passed into an alcoholic solution forms crystalline  $C_6H_4N_4$ , which yields  $B'H_2Cl_2$  and  $B'HNO_3$  (Bladin, *ibid.* [2] 41, 128).—15. On heating with S it yields  $C_6H_4N_2S$  [120°] crystallising from alcohol in yellow plates and yielding a dibromide  $C_6H_4Br_2N_2S$  [190°] (Gattermann, B. 22, 425).—16.  $ClSO_3H$  in  $CHCl_3$  forms  $C_6H_4NH_2SO_3H$ , which yields  $BaA_2$  2aq. Both the acid and the salts reproduce o-toluidine when treated with hot water (Traube, B. 23, 1656).

**Salts** (Beilstein a. Kuhlberg, A. 156, 66; Rosenstiel).  $B'TCl_2$  aq. S. 374 at 15.5°. S. (alcohol) 100. —  $B'H_2PtCl_6$ . Decomposed by boiling water (difference from p-toluidine) (De Coninck, *ibid.* [2] 45, 131). —  $B'H_2ZnCl_4$ . White tables (Bibaut, *Monit. scient.* [3] 4, 925). —  $B'ZnCl_2$  2aq (Lachovitch, M. 9, 513). —  $B'H_2HgCl_4$  [115°]. Prepared by shaking an alcoholic solution of the base with  $HgCl_2$  (Klein, B. 11, 743). Crystalline powder, sol. alcohol and ether. —  $B'MnCl_2$ .  $B'H_2CuCl_4$ . Yellow crystalline pp. got by adding  $CuCl_2$  to a solution of the hydrochloride (Poncy, C. R. 101, 365). —  $B'HBr$ . Trimetric prisms. —  $B'H_2Br_2$  [101°]. Leaflets (Klein, B. 13, 835). —  $B'ZnBr_2$  (Towds, J. 1882, 503). —  $B'HI$ . Trimetric prisms (Stadel, B. 16, 28). —  $B'HgI_2$ . White needles. —  $B'ZnI_2$ . —  $B'CaI_2$ . —  $B'HgCy_2$ . —  $B'H_2FeCy_2$ . crystals. —  $B'H_2Cu(SO_4)_2$ . Formed by adding aqueous cupric sulphate and  $NaHSO_4$  to a solution of the base in acetic acid (Deimes, C. R. 112, 870). —  $B'Hg_2(SO_4)_2$  aq.  $B'H_2SO_4$ . Crystals (Wellington a. Tollens, B. 18, 343). —  $B'H_2SO_4$ . S. 7.8 at 22°. S. (89 p.c. alcohol) 1.6 at 21.5°. —  $B'HNO_3$ . S. 10 at 19°. S. (89 p.c. alcohol) 23.5 at 16.5°. —  $B'H_2PO_4$ . Crystals, v. sol. water (Lewy, B. 19, 1717). The salts  $B'H_2PO_4$  and  $B'H_2P_2O_7$  could not be prepared. Aniline sets free o-toluidine from  $B'H_2PO_4$ . p-Toluidine also sets free o-toluidine from its phosphate. —  $B'HSyCr(SCy)_2NH_2$ . Red plates, v. sol. hot water (Christensen, J. pr. [2] 45, 362). — Oxalate: small plates. S. 2.38 at 21°. S. (84 p.c.

alcohol) 2.68 at 21°. S. (ether) .65 at 21°.—Chloroacetate  $\text{C}_6\text{H}_4\text{CH}_2\text{ClO}_2$ . [95°] (Bischoff, R. 21, 1257).—(8 ?)-naphtholate [81°] (Dyson, C. J. 43, 470).

**Formyl derivative**  $\text{C}_6\text{H}_4\text{NH}_2\text{CHO}$ . [58°] (288°). Plates (Ladenburg, B. 10, 1129; Tobias, B. 15, 2446). The crystalline polymefide [211°] is v. sol. hot HOAc, nearly insol. ether and cold alcohol.

**Thioformyl derivative**  $\text{C}_6\text{H}_4\text{NH}_2\text{CSH}$ : [96°]; yellow needles; bitter taste; sol. alcohol and ether, insol. water. Formed by heating the formyl derivative with  $\text{P}_2\text{S}_5$ . It dissolves unaltered in cold aqueous NaOH, and is reprecipitated by an acid. By distillation in vacuo it

forms di-tolyl-formamidine  $\text{C}_6\text{H}_4\text{NH} \cdot \text{CH} = \text{CH} \cdot \text{NHC}_6\text{H}_4$  with

evolution of  $\text{H}_2\text{S}$  and  $\text{CS}_2$ . By heating for 7 hours at 190° under pressure a crystalline compound  $\text{C}_{12}\text{H}_{16}\text{N}_2\text{S}$  [160°] is formed with evolution of  $\text{H}_2\text{S}$  (Senier, B. 18, 2292; C. J. 47, 762).

**Acetyl derivative**  $\text{C}_6\text{H}_4\text{NHAc}$ . [109°] (Bedson a. King, C. J. 37, 753). (296°). S. 85 at 19°. Formed from the base and HOAc (Beilstein a. Kuhlberg, A. 156, 77; Alt, A. 252, 318), or by shaking it with water and  $\text{Ac}_2\text{O}$  (Hinsberg, B. 23, 2962). Converted by  $\text{PCl}_5$  into the compound  $\text{C}_6\text{H}_4\text{N}:\text{CClMe}$ , which when carefully heated gives a base  $\text{C}_6\text{H}_4\text{N}:\text{CMe.CH}_2\text{CCl}:\text{NC}_6\text{H}_4$  [53°], and when treated with excess of *o*-toluidine gives di-tolyl-acetamidine [69°]. Br in HOAc forms  $\text{C}_6\text{H}_4\text{MeBr}(\text{NHAc})$  [1:6:2] [157°].

**Chloro-acetyl derivative**  $\text{C}_6\text{H}_4\text{NH.CO.CH}_2\text{Cl}$ . [112°]. Formed by the action of chloro-acetyl chloride on *o*-toluidine dissolved in benzene (Widman, J. pr. [2] 38, 299). Needles (from dilute alcohol). Converted by alcoholic potash into a pyrazine derivative [160°].

**Di-chloro-acetyl derivative**  $\text{C}_6\text{H}_4\text{NH.CO.CHCl}_2$ . Needles, volatile with steam (Rügheimer a. Hoffmann, B. 18, 2987).

**Tri-chloro-acetyl derivative**  $\text{C}_6\text{H}_4\text{NH.CO.CCl}_3$ . [67°]. Formed from hexachloro-acetone and *o*-toluidine (Cloez, A. Ch. [6] 9, 216). Needles, sl. sol. cold alcohol.

**Bromo-acetyl derivative**  $\text{C}_6\text{H}_4\text{NH.CO.CH}_2\text{Br}$ . [113°]. Formed from *o*-toluidine and bromo-acetyl bromide (Widman, J. pr. [2] 38, 298). Needles. Converted by alcoholic potash into  $\text{C}_{10}\text{H}_8\text{N}_2\text{O}_2$  [160°].

**Thio-acetyl derivative**  $\text{C}_6\text{H}_4\text{NH.CO.SCH}_3$ . [68°] (Wallach, B. 13, 520; 16, 147). Converted by NaOEt and EtBr into oily  $\text{C}_6\text{H}_4\text{N}:\text{CMe.SEt}$  (262°).

**Propionyl derivative**  $\text{C}_6\text{H}_4\text{NH.COEt}$ . [87°]. (299° at 730 mm.) Formed from *o*-toluidine and propionic acid (Pictet a. Duparc, B. 20, 3421). Needles, sl. sol. hot water. Oxidised by  $\text{KMnO}_4$  to propionyl-*o*-amido-benzoic acid [117°].

**$\alpha$ -Bromo-propionyl derivative**  $\text{C}_6\text{H}_4\text{NH.CO.CHBr.CH}_3$ . [131°]. Needles, insol. ligroin (Tigerstedt, B. 25, 2920).

**Benzoyl derivative**  $\text{C}_6\text{H}_4\text{NH.Bz}$ . [131°] (Gudeman, B. 21, 2553; [143°] (Brückner, A. 205, 130). Long broad needles. Yields benzoyl-*o*-amido-toluic acid on oxidation by  $\text{KMnO}_4$ .  $\text{PCl}_5$  forms  $\text{C}_6\text{H}_4\text{N}:\text{CClC}_6\text{H}_5$  (Just, B. 19, 982).

**Oxalyl derivative**  $\text{C}_6\text{H}_4\text{N(CO}_2\text{C}_6\text{H}_5)_2$ .

[181°]. Plates (from alcohol) (Bladin, Bl. [2] 41, 130).

**Phthalyl derivative**  $\text{C}_6\text{H}_4\text{N}:\text{C}_6\text{H}_4\text{C}_2\text{O}$ . [182°]. (near 360°). Needles, sol. hot HOAc (Fröhlich, B. 17, 2679).

**Phenacetyl derivative**  $\text{C}_6\text{H}_4\text{NH.CH}_2\text{CO.C}_6\text{H}_5$ . [89°]. Formed from the base in alcohol and *m*-bromo-acetophenone (Bischler, B. 25, 2865). Needles. Yields  $\text{B}^m\text{HCl}$  and an acetyl derivative [92°].

***m*-Toluidine**  $\text{C}_6\text{H}_4\text{Me.NH}_2$  [1:3]. (197°) (Beilstein a. Kuhlberg, A. 156, 83); (201°) (Buchka a. Schachtebeck, B. 22, 840); (205°) (Lorenz, A. 172, 180; Morz a. Müller, B. 20, 548). S. G. 25 .998. S.N. 128.1. H.C.v. 961,600. H.C.p. 965,600. H.F. 2,900 (Petit, A. Ch. [6] 17, 155). Formed by reduction of *m*-nitro-toluene. Obtained also from *p*-toluidine by successive acetylation, nitration, saponification, diazotisation, boiling with alcohol, and reduction (Lorenz, B. 7, 448). Formed also by heating *m*-cresol with  $\text{ZnBr}_2$ , ammonia, and  $\text{NH}_4\text{Br}$  at 300° (M. a. M.). Prepared from benzoic aldehyde by nitration, conversion into *m*-nitro-benzylidene chloride and reduction of this body by zinc and  $\text{HClAq}$  in the cold (Vienne a. Steiner, Bl. [2] 35, 428; Widman, B. 13, 676; Bl. [2] 36, 216; Ehrlich, B. 15, 2011; Harz, B. 18, 3398). *m*-Toluidine can be shown to exist in commercial toluidine by means of the nitroso-derivative of di-methyl-*m*-toluidine, since *o*- and *p*-di-methyl-toluidines do not give nitroso-derivatives (Wurster a. Riedel, B. 12, 1796).

**Properties.**—Oil. Its solution in  $\text{H}_2\text{SO}_4\text{H}_2\text{O}$  is coloured yellowish-brown by  $\text{CrO}_3$  and blood-red by  $\text{HNO}_3$ . Its ethereal solution, shaken with water and a little bleaching-powder, is coloured reddish, the aqueous layer being brownish yellow.  $\text{HNO}_3$ , added to its solution in a mixture of  $\text{H}_2\text{SO}_4$  and HOAc below 0° forms nitro-toluidine [134°] and some of its isomerides. Cyanogen passed into its alcoholic solution gives the compound  $(\text{C}_6\text{H}_4\text{NH}_2)_2\text{C}_2\text{N}_2$  [200°] which forms  $\text{B}^m\text{HCl}$ ,  $\text{B}^m\text{HNO}_3$ , and  $\text{B}^m\text{H}_2\text{SO}_4$  (Clève a. Bladin, Bl. [2] 41, 129). Yields (4,2,1)-xylydine when its hydrochloride is heated with MeOH at 200°–300° (Limpach, B. 21, 616).

**Salts.**— $\text{B}^m\text{HCl}$ . S. 96.3 at 12°. S. (94 p.p. alcohol) 61.9 at 9°.— $\text{B}^m\text{H}_2\text{PtCl}_6$ .— $\text{B}^m\text{HNO}_3$ . S. 20.1 at 23.5°. S. (94 p.p. alcohol) 46 at 15°.— $\text{B}^m\text{HBI}_3$  (Kraut, A. 210, 323).— $\text{B}^m\text{H}_2\text{SO}_4$ . S. 6.25 at 14°. S. (94 p.p. alcohol) 41 at 15°.— $\text{B}^m\text{H}_2\text{FeCy}_3$  (Eisenberg, A. 205, 270).— $\text{B}^m\text{H}_2\text{C}_6\text{O}_4$ . Silky needles. S. 2.65 at 13°. S. (94 p.p. alcohol) 1.77 at 15°. S. (ether) .13 at 15°.— $\text{B}^m_2\text{H}_2\text{C}_6\text{O}_4$ . White plates, S. 1.45 at 15°. S. (94 p.p. alcohol) .96; S. (ether) .128 at 15.5°.— $\text{B}^m_2\text{H}_2\text{C}_6\text{O}_4$ , aq. Very unstable.

**Formyl derivative**  $\text{C}_6\text{H}_4\text{NH}_2\text{CHO}$ . (278° at 724 mm.) (Niementowski, B. 20, 2892). Converted by long boiling into  $\text{C}_6\text{H}_4\text{N}:\text{CH.NHC}_6\text{H}_5$  [123°].

**Acetyl derivative**  $\text{C}_6\text{H}_4\text{NHAc}$ . [65°]. (303°). S. 44 at 13°.

**Di-chloro-acetyl derivative**  $\text{C}_6\text{H}_4\text{NH.CO.CHCl}_2$ . [106°]. Silky plates (Rügheimer a. Hoffmann, B. 18, 2988).

**Benzoyl derivative**  $\text{C}_6\text{H}_4\text{NH.Bz}$ . [125°] (Just, B. 19, 983).

**Phthalyl derivative**  $\text{C}_6\text{H}_4\text{N}:\text{C}_6\text{H}_4\text{C}_2\text{O}$ .

[168°]. Needles, v. sol. HOAc (Fröhlich, B. 17, 2679).

*p*-Toluidine  $C_7H_7Me(NH_2)$  [1.4]. [45°] (Städeler); [42.8°] (Mills). (198°) (M. a. H.); (206°) (Städeler, J. pr. 96, 85). S.G. 1.046. S. 35 at 11.5°. H.C.p. 958,800. H.C.v. 957,860. H.F. 9,700 (Petit, C. R. 107, 266). S.V. 128,700. Formed by reduction of *p*-nitrotoluene (Muspratt a. Hofmann, A. 54, 1; 66, 144; Noad, A. 63, 305; Hugo Müller, Z. 186, 161; Sell, C. J. 16, 186; v. also *o*-TOLUIDINE). Formed also by heating *p*-cresol with ammoniacal  $ZnCl_2$  (Buch, B. 17, 2637; Merz a. Müller, B. 20, 545) and by treating methyl-aniline hydrochloride at 350° (Hofmann, B. 5, 720). On sulphonating a mixture of *o*- and *p*-toluidine the *o*-toluidine is first attacked and the *p*-toluidine can then be distilled off.

*Properties*.—Plates (from ligroin or dilute alcohol). Its solution in  $H_2SO_4/H_2O$  is turned yellow by  $CrO_3$  and blue by  $HNO_3$  in the latter case changing to red and finally brown (Rosenstiel, Bl. 10, 200). Bleaching-powder does not colour its solution in water or ether.  $PbO_2$  and HOAc diluted with water or alcohol give a bright red colour (Lauth, C. R. 111, 975). When boiled with water, crystals of an efflorescent hydrate separate on cooling (Lewy, B. 19, 2728).

*Reactions*.—1. Oxidised by  $KMnO_4$ , alkaline  $K_2FeC_2O_8$ , or chromic acid to  $C_7H_7N_2$  or  $C_7H_7Me(NC,H_2)_2(NH_2)$  [1:2:5:4], which may be readily reduced to  $C_7H_7Me(NHCH_2)_2(NH_2)$  crystallising from alcohol in colourless plates [166°], readily re-oxidised to  $C_7H_7N_2$  (Barsilowsky, A. 207, 102, 118; J. R. 1887, 132; Perkin, C. J. 35, 728; 37, 546; Klinger a. Pitschke, B. 17, 2439; Green, C. J. 63, 1395). The compound  $C_7H_7N_2$  crystallises from xylene in dark-red plates [227°], dissolving in acids, forming maroon-red liquids, quickly decomposing with separation of *p*-toluidine. Conc.  $H_2SO_4$  dissolves  $C_7H_7N_2$ , forming a greenish-blue liquid which on warming becomes wine-red with production of *p*-toluidine. — 2. Oxidised by  $CrO_3$  and HOAc to toluene-azo-toluene  $C_7H_7N_2 \cdot C_7H_7$ . — 3. Nitrous acid forms  $C_7H_7N_2 \cdot NHO_2H$ . When  $NaNO_2$  is added to a solution of the hydrochlorides of *o*- and *p*-toluidine, the *o*-toluidine is first attacked, yielding  $C_7H_7N_2 \cdot C_7H_7NH_2$  and can thus be removed when mixed with *p*-toluidine (Walling, D. P. J. 263, 260). — 4. Substituents usually enter positions 3 and 5 [Me : 1] but when *p*-toluidine or its acetyl derivative is dissolved in  $H_2SO_4$  (20 pts.) and nitrated the compound  $C_7H_7Me(NO_2)(NH_2)$  [1:2:4] is formed instead of the (1,3,4)-isomeride (Nölting a. Collin, B. 17, 263). — 5. Bromine in conc.  $HClAq$  at 0° forms  $C_7H_7BrMe(NH_2)$  [5:3:1:4]; but  $C_7H_7BrMe(NH_2)$  [2:1:4] is formed in presence of conc.  $H_2SO_4$  (Hafner, B. 22, 2538, 2902). — 6.  $ICl$  forms  $C_7H_7I_2Me(NH_2)$  [5:3:1:4] (Michael a. Norton, B. 11, 107). — 7. Chlorine passed into *p*-toluidine dissolved in  $H_2SO_4$  at 0° forms  $C_7H_7MeCl(NH_2)$  [1:3:4] and larger quantities of its (1,2,4)-isomeride. In  $HClAq$  (40 p.c.) the chief product is  $C_7H_7MeCl(NH_2)$  [1:3:5:4] (Hafner). — 8. Cyanogen passed into an alcoholic solution forms  $C_7H_7N_2$  or  $(C_7H_7N)_2C_2N_2$  crystallising in pearly scales [222°–230°] and yielding the crystalline salts  $B \cdot 2HCl$ ,  $B' \cdot 2HNO_3$ ,  $B'' \cdot H_2SO_4$ , 6aq, and  $B''' \cdot H_2C_2O_4$

(Hofmann, C. J. 1, 170; A. 66, 144; Clève a. Bladin, Bl. [2] 41, 125). The mother-liquor contains  $C_7H_7N_2$  [182°] which yields the salts  $B'HCl$  3aq (a. red powder) and  $B''H_2PtCl_6$ . The compound  $C_7H_7N_2$  is also formed when *p*-toluidine is heated with oxalimido-ether at 100° (Vorländer, B. 24, 805). — 9. Cyanuric chloride forms  $C_7H_7N_2(NHCH_2)_2$  [288°] (Klason, J. pr. [2] 23, 291). — 10. Chloro-acetic acid ( $\frac{1}{2}$  mol.) forms  $C_7H_7NH_2CH_2CO_2H$ , while chloro-acetamide forms  $C_7H_7NH_2CH_2CO_2NH_2$  (P. F. Meyer, B. 8, 1458). An alcoholic solution of chloro-acetic acid and  $HCl$  yields  $C_7H_7N_2SO_4$  [176°–182°] (Nencki, J. pr. [2] 16, 1). — 11. Dichloro-acetic acid forms tolylamido-methyl-oxindole. — 12. Chloral reacts, with formation of  $CCl_3CH(NHCH_2)_2$  [115°] (Wallach, A. 173, 278). When chloral is warmed with an alcoholic solution of *p*-toluidine there is also formed  $CCl_3CH(OEt)NHCH_2$  [77°]. — 13. Aldehyde forms crystalline  $CH_3CH(NHCH_2)_2$  [c. 60°]. — 14. Furfuraldehyde added to a hot alcoholic solution of *p*-toluidine and its hydrochloride forms brown amorphous  $C_7H_7N_2O_2$ , which yields  $B'HCl$  and  $B'INO_3$  both crystallising in purple needles (Stenhouse, A. 156, 203). — 15. Nascent formic aldehyde produces a base  $C_7H_7N_2$  [134°] which is converted by nitrous acid with evolution of  $CO_2$  into  $C_7H_7N_2O_2$  [260°–264°] (Tollens, J. pr. [2] 26, 225). — 16. Benzoic aldehyde at 100° reacts, forming  $C_7H_7CH(NHCH_2)_2$  [100°] (326° i.v. at 723 mm.), which changes at 160° into an isomeride [120°–125°] and is converted by  $Br$  in  $CS_2$  into  $C_7H_7BrN$  [160°–165°] (Schiff, Z. 1865, 400; Mazzara, J. 1880, 556; Pictet, B. 19, 1063). In the action of *p*-toluidine and its hydrochloride on benzoic aldehyde at 120° there is produced  $C_7H_7N_2$  [178°] and  $C_7H_7CH(C_7H_7Me.NH_2)$  [186°] (c. 430°), which yield a di-acetyl derivative [218°] and a di-benzoyl derivative [196°] (Ullmann, J. pr. [2] 36, 267). — 17. *p*-Methoxybenzoic aldehyde forms  $C_7H_7(OMe)CH(NC,H_2)$  [92°] (Steinhart, A. 241, 332). — 18. *p*-Methoxybenzophenone chloride yields the compound  $C_7H_7(OMe)CPh:NC,H_2$  [96°] Hantzsch a. Kraft, B. 24, 3520). — 19. An ethereal solution of  $C_7H_7CCl:NNO,Ph$ , obtained from benzene sulphonic anilide and  $PbCl_2$ , forms the compound  $C_7H_7C(NHCH_2)_2:N.NO,Ph$ , which separates in monoclinic crystals;  $a:b:c = 660:1:533$ ;  $\beta = 69^\circ$ . — 16, insol. water (Wallach a. Gossmann, A. 214, 216). — 20. Alcohol,  $SO_2$  and nitrous acid form the sulphazide  $C_7H_7N_2SO_4$  [140°] (Limpricht, B. 20, 1241). — 21. Heated with persulphocyanic acid it gives *p*-tolyl-thiobiuret (B. 17, 584). — 22. On heating with sulphur it yields dehydrothiotoluidine and primuline; v. Primuline. — 23. Diazobenzene chloride yields  $C_7H_7N_2 \cdot NHC_6H_5$  [85°] which is identical with the product of the action of *p*-diazotoluene chloride on aniline (Nölting a. Binder, B. 20, 3005). — 24. Bromo-propionic acid forms di-tolyl-acetamide  $C_7H_7N_2$  [120°] (Mabery a. Krause, B. 22, 3307), which is also formed by the action of HOAc and  $PbCl_2$  on *p*-toluidine (Mofmann, Pr. 15, 57). — 25. Itaconic acid in boiling aqueous solution forms  $C_7H_7N < CH_2 \cdot CH \cdot CO_2H$  [185°] (Scharfenberg, A. 254, 150). — 26. Acetyl-citric anhydride dissolved in chloroform forms

$C_6H_4O(CO_2H)(CO.NH.C_6H_5)_2$  [189°] Klingemann, *B.* 22, 987).—27. *Malic acid* at 160° yields  $C_6H_4O(CO.NH.C_6H_5)_2$  [208°] (Bischoff, *B.* 23, 2045).—28. The hydrochloride heated with MeOH yields  $C_6H_4Me_2(NH_2)_2$  [1:3:4] (Limpach, *B.* 21, 640).—29. *Ethylene oxide* forms oxethyl-*p*-toluidine (Demole, *B.* 7, 635).—30.  $SOCl_2$  forms thionyl-toluidine (*q. v.*).—31.  $POCl_3$  forms  $PO(NH.C_6H_5)_2$  [192°] which yields  $PO(NH.C_6H_5.Br)_2$  [180°] and  $PO(NH.C_6H_5.NO_2)_2$  [247°] (Rudert, *B.* 26, 569). Another product of the action of  $POCl_3$  is  $POCl(NH.C_6H_5)_2$ , whence water forms  $HO.PO(NH.C_6H_5)_2$  [121°].—32.  $PSCl_3$  forms  $PS(NH.C_6H_5)_2$  [N5°].

**Salts.**— $B^+HCl$ . *S.* 22.9 at 11°; *S.* (89 p.c. alcohol) 25 at 17°.  $B^+H_2AuCl_2$ .— $B^+H_2PtCl_4$ . Not decomposed by boiling water (De Coninck, *Bl.* [2] 45, 131).— $B^+PtCl_2$  (Gordon, *B.* 3, 177; Coochin, *Bl.* [2] 31, 499).— $B^+H_2PtCl_4$  (Scholz, *M.* 1, 905).— $B^+PtCl_2Et_2O_2$  (Sailhard, *Bl.* [2] 18, 111).— $B^+PtCl_2Me_2PO_2$ .— $B^+PtCl_2Et_2PO_2$  (Cochin, *J.* 1878, 315).— $B^+ZnCl_2aq$  (Iachovitch, *M.* 9, 513).— $B^+H_2ZnCl_4$  (Gräffinghoff, *Z.* 1865, 599).— $B^+HgCl_2$  [125°]. Thick needles, sol. alcohol and ether (Klein, *B.* 11, 743).— $B^+NiCl_2.2MeOH$ . Green pp. (Lippmann a. Vortmann, *B.* 12, 81).— $B^+CoCl_2$ . Blue needles.— $B^+H_2SnCl_4$ . Monoclinic crystals (Hjortdahl, *J.* 1882, 535).— $B^+H_2CuCl_4$  (Pomey, *C. R.* 104, 900).— $B^+MnCl_4$  (Jedds, *J.* 1882, 503).— $B^+UO_2Cl_2$ .— $B^+HBr$ . Plates (Stüdel, *B.* 16, 28).— $B^+HgBr_2$  [121°]. Plates (Klein, *B.* 13, 835).— $B^+ZnBr_2$ .— $B^+CdBr_2$ .— $B^+HCl$ .— $B^+HgCl_2$  [81°].— $B^+H_2BiCl_4$  (Kraut, *A.* 210, 321).— $B^+(H_2SCl_2)_2HCl$  (Jørgensen, *J. pr.* [2] 14, 386).— $B^+ZnI_2$ .— $B^+CdI_2$ .— $B^+HNO_3$ . *S.* 17.7 at 23.5°; *S.* (89 p.c. alcohol) 42 at 20°.  $B^+AgNO_3$  [101°] (Mixer, *Ann.* 1, 239).— $B^+Cd(NO_3)_2$ .— $B^+Hg(NO_3)_2$ .— $B^+H_2SO_4$ . *S.* 5.06 at 22°; *S.* (84 p.c. alcohol) 1.3 at 23°.— $B^+H_2SO_4$ . Crystals, converted into  $B^+H_2SO_4$  by water (Tollens, *B.* 18, 3312).— $B^+Ag_2SO_4.2aq$  (Mixer).— $B^+H_2PO_4$ . Thick needles, v. sl. sol. cold water (Lewy, *B.* 19, 1717).— $B^+(NH_4Ph)H_2CoCy_2.1.5aq$  (Weselsky, *J.* 1869, 314).— $B^+H_2CoCy_2.2aq$ .  $B^+HgCy_2$ .— $B^+HCr(SCy)_2.2NH_3$ . Plates (Christensen, *J. pr.* [2] 45, 362).— $B^+CuH_2(SO_4)_2$ . Yellowish-white hexagonal plates.— $B^+HgH_2(SO_4)_2$  (Denigès, *C. R.* 112, 870).—Oxalate  $B^+H_2C_2O_4.1.5aq$  (Bornemann, *B.* 22, 2710). *S.* 8.7 at 14°; *S.* (84 p.c. alcohol) 48 at 22°. Insol. ether.—Chloroacetates  $B^+C_6H_4ClO_2$  [102°] (Baralis, *J.* 1884, 698).— $B^+C_6H_4ClO_2$ . [141°]. (B.) [136°] (Dulberg, *B.* 18, 194).— $B^+C_6H_4ClO_2$ . [137°].—Tri-chloro-lactate  $B^+C_6H_4ClO_3$  [135°].—Muonate  $B^+C_6H_4O_3$ . Yellowish crystals, sol. hot water.—Picrate  $B^+C_6H_4N_3O_7$ . [169°] (Smolka, *M.* 6, 923). *S.* 5.4 at 18.5°; *S.* (95 p.c. alcohol) 4.29 at 18°.—Phenate [31.1°].  $Gq$  by heating *p*-toluidine with phenol (Dyson, *C. J.* 43, 468). Needles (from lignin).—Compound with picramide  $B^+C_6H_4(NO_2)_2NH_2$ . Black needles with green reflex (Mertens, *B.* 11, 813).

**Formyl derivative**  $C_6H_4.NH.CHO$ . [45°] (Hübner a. Rudolph, *A.* 209, 371); [52°] (Tobias, *B.* 15, 2446); [53°] (Bamberger a. Wulz, *B.* 24, 2080). Formed by boiling *p*-toluidine with formic acid or, together with the oxalyl derivative  $C_6H_4(NHCO_2H)_2$  [263°], by heating *p*-toluidine oxalate. Prisms. Converted by heating with  $P_2S_5$  into  $C_6H_4.NH.CHS$  [174°]

(Senier, *B.* 18, 2294; *C. J.* 47, 766). Yields  $C_6H_4.NNA.CHO$  aq.

**Acetyl derivative**  $C_6H_4.NHAc$ . [147°] (Hübner a. Wallach, *A.* 154, 302; Kelbe, *C. J.* 44, 915). (807°) (Beilstein a. Kuhlberg, *A.* 156, 74). *S.* 0.89 at 22°. Dimorphous, crystallising in monoclinic forms; *a:b:c* = 1.216:1:788;  $\beta$  = 106° 7', and also in trimetric crystals; *a:b:c* = 651:1:329 (Pancbianco, *G.* 9, 362). Oxidised by  $KMnO_4$  to acetyl-*p*-amido-benzoic acid (Hofmann, *B.* 9, 1299). Oxidised in like manner in the animal body (Jaffe a. Hilbert, *H.* 12, 295).  $PCl_5$  forms a liquid product which solidifies when strongly cooled, the crystals doubtless being  $C_6H_4.NH.CCl_2.CH_3$ . This readily splits up into  $HCl$  and  $C_6H_4.N:CCL_2CH_3$ . This is a colourless solid which is converted by  $Aq$  into acetyl-*p*-toluidine; by toluidine into di-tolyl-acetamide. The chloro-imide  $C_6H_4.N:CCL_2CH_3$  at 100° forms a base  $C_6H_4.N.Cl$  [72°], which may be crystallised from alcohol. It is probably  $C_6H_4.N:CMe.CH_2.CCl_2NC_6H_5$ . It is decomposed by moist air or water with production of  $MeC(NC_6H_5)NC_6H_5$ ,  $HOAc$  and  $MeCONHC_6H_5$ , and by heat with production of an amorphous base  $C_6H_4.N_2$  (Wallach a. Fasshender, *A.* 214, 202). Nitrous acid converts acetyl-*p*-toluidine into  $C_6H_4.NAc.NO$  [80°] (O. Fischer, *B.* 10, 959).

**Chloro-acetyl derivative**  $C_6H_4.NH.CO.CH_2Cl$ . [162°]. Needles (Tommasi, *Bl.* [2] 19, 400; Meyer, *B.* 8, 1154).

**Di-chloro-acetyl derivative**  $C_6H_4.NH.CO.CHCl_2$ . [153°] (Rügheimer a. Hoffmann, *B.* 18, 2980).

**Tri-chloro-acetyl derivative**  $C_6H_4.NH.CO.CCl_3$ . [80°] (C.); [102°] (J.). *S.* (alcohol) 12.5 at 14°. Formed from *p*-toluidine and  $(CCl_3)_2CO$  (Cloeze, *A. Ch.* [6] 9, 145), and also from *p*-toluidine and  $CCl_3COCl$  (Judson, *B.* 3, 784).

**Bromo-acetyl derivative**  $C_6H_4.NH.CO.CH_2Br$ . [164°]. Needles (Abenius, *J. pr.* [2] 40, 433) converted by alcoholic potash into an azine and  $C_6H_4.NH.CO.CH_2OEt$  [32°] which is v. e. sol. alcohol.

**Thio-acetyl derivative**  $C_6H_4.NH.CS.CH_3$ . [131°]. Formed from the acetyl derivative and  $P_2S_5$  (Jacobsen a. Ney, *B.* 22, 206). Got also by heating tolyl-acetamide with  $CS_2$  at 100°, or di-tolyl-acetamide with  $H_2S$  (Bernthsen a. Trompeter, *B.* 11, 1759; Wallach a. Pannes, *B.* 13, 529). Converted by  $NaOEt$  and  $EtBr$  into oily  $C_6H_4.N:CMe.SEt$  (272°) (Wallach a. Wüsten, *B.* 16, 147).

***a*-Bromo-propionyl derivative**  $C_6H_4.NH.CO.CHBr.CH_3$ . [125°] (Tigerstedt, *B.* 25, 2921). Plates, v. sol.  $CHCl_3$ .

**Benzoyl derivative**  $C_6H_4.NH.Bz$ . [158°]. (232°). Formed from *p*-toluidine and  $BzCl$  (Jaillard, *Z.* 1865, 440; Kelbe, *B.* 8, 875; Hübner, *A.* 208, 310; Wallach, *A.* 214, 217; Gudehn, *B.* 21, 2553; Müller, *B.* 22, 2404). Needles, v. sol. alcohol. Converted by  $PCl_5$  into  $C_6H_4.N:CCL_2CH_3$  [52°] (Just, *B.* 19, 980) crystallising from lignin in prisms.

***p*-Nitro-benzoyl derivative**  $C_6H_4(NO_2).CO.NH.C_6H_5$ . [197°]. Formed from *p*-toluidine and *p*-nitro-benzoyl chloride. Yellow needles (Gätermann, *B.* 25, 1082). Converted by  $PCl_5$  into  $C_6H_4(NO_2).CCL_2NHC_6H_5$  [119°] crystallising in golden prisms.

**Phenacyl derivative**

$C_6H_5NH.CH_2.CO.C_6H_5$ . [127°]. Formed from *o*-bromo-acetophenone and *p*-toluidine in alcohol (Bischler, *B.* 25, 2866). Yellow prisms, yielding  $HCl$  and an acetyl derivative [89°] crystallising in white needles (from alcohol).

**Phthalyl derivative**  $C_6H_5N:C_6O_2:C_6H_5$ . [205°] (Fröhlich, *B.* 17, 2679).

**References.**—Bromo-, Dibromo-iodo-, Bromo-nitro-, Chloro-, Tri-chloro-nitro-, Iodo-, Nitro-, and Nitroso-toluidines.

**TOLUIDINE SULPHONIC ACID** *v.* AMIDO-TOLUENE SULPHONIC ACID and also Nitro- and Iodo-toluidine sulphonic acid.

**TOLUIDINE THIOSULPHONIC ACID** *v.* AMIDO-TOLUENE THIOSULPHONIC ACID.

**TOLUIDO.** *v.* TOLYL-AMIDO.

**TOLUIDYL-MELAMINE** *v.* CYANIC ACIDS.

**TOLUISATIN** *v.* DI-TOLYL-OXINDOLE.

**TOLU-( $\alpha\beta$ )-NAPHTHAZINE**  $C_{11}H_7N_2$  *i.e.*

$C_6H_4 \begin{array}{c} \text{CH:CH.C.N} \\ \text{C.N} \end{array} > C_6H_5Me$  [180°].

Formed by oxidation of a mixture of tolylene-*o*-diamine (1 mol.) and ( $\beta$ )-naphthol (1 mol.) with  $K_2FeCy_6$ . Formed also, together with the isomeride [169°], by the action of ( $\beta$ )-naphthoquinone on tolylene-*o*-diamine (Witt, *B.* 20, 577). Dissolves in conc.  $H_2SO_4$  with violet-red colour. Forms with its isomeride a molecular compound [142°].

**Tolu-( $\alpha\beta$ )-naphthazine**  $C_{11}H_7N_2$  *i.e.*

$C_6H_4 \begin{array}{c} \text{CH:CH.C.N} \\ \text{C.N} \end{array} > C_6H_5Me$  [169°].

Formed as above, and also, together with amido-benzene *p*-sulphonic acid, by boiling sulphobenzene-azo-( $\beta$ )-naphthyl-*p*-tolyl-amine with dilute  $H_2SO_4$ , and by boiling 'wood black'  $C_6H_4(SO_3H).N_2.C_6H_4(SO_3H).N_2.H_2C_6H_4.NH.C_6H_5$  with dilute  $H_2SO_4$  (Witt, *B.* 20, 577). Yellow crystals, *v. sl.* sol. alcohol. Conc.  $H_2SO_4$  forms a brownish-red solution.

**TOLUNITRANILIC ACID** *v.* NITRO-DI-OXY-TOLUQUINONE.

**TOLUOIN** *v.* DI-METHYL-BENZOIN.

**TOLUOL** *v.* TOLUENE.

**TOLUPHOSPHINIC ACID** *v.* PHOSPHOTOLUIC ACID.

**TOLUQUINOL** *v.* HYDROTOLUQUINONE.

**TOLUQUINOLINE** *v.* METHYL-QUINOLINE.

**TOLUQUINONE**  $C_6H_4O_2$  *i.e.*

$C_6H_4MeO_2$  [24:1]. [69°].

**Formation.**—1. By oxidation of tolylene-*p*-diamine or of *o*-toluidine (Nietzki, *B.* 10, 832, 1934; *A.* 215, 158; Ladenburg, *B.* 10, 1128).—2. By boiling crude cresol with  $MnO_2$  and dilute  $H_2SO_4$  (Carstanjen, *J. pr.* [2] 23, 425). Separated from accompanying xyloquinone by reduction with  $SO_2$ , crystallising the hydrotoluquinone from benzene, and re-oxidising by fuming  $HNO_3$ .—3. By oxidation of *m*-xylidine (Nölting a. Baumann, *B.* 18, 1151).

**Preparation.**—20 g. of *o*-toluidine are dissolved in 600 c.c. of water containing 160 g. of  $H_2SO_4$ ; 20 g. of finely powdered potassium bichromate are added by degrees, with continual agitation, keeping the temperature at 10°–15°. After standing over night, 33 g. more  $K_2Cr_2O_7$  are added; the quinone is then extracted with ether, dried over  $CaCl_2$ , and the ether removed by dis-

tillation. The yield is about 86 p.c. of the theoretical quantity (Schnitzer, *B.* 20, 2283).

**Properties.**—Golden-yellow plates smelling like quinone. Very volatile. *M. sol.* hot water, *v. sol.* alcohol and ether. Its aqueous solution is turned brown by alkalis.  $SO_2$  reduces it to hydrotoluquinone. Dilute (50 p.c.)  $H_2SO_4$  changes it to isotoquinone ( $C_6H_4O_2$ ), a powder not melted at 300° (Spica, *G.* 12, 225). An aqueous solution of toluquinone mixed with one of hydrotoluquinone deposits steel-blue needles of the quinhydrone [52°], *v. s.* sol. water. *o*-Nitro-aniline forms [2:1:4:6]  $C_6H_4MeO_2.NH.C_6H_4NO_2$ , crystallising from alcohol in red crystals decomposing at 200° (Leicester, *B.* 23, 2796). Nitro-*p*-toluidine  $C_6H_4Me(NO_2).NH_2$  [1:3:4] forms a homologous body.

**Chlorimide**  $C_6H_4Me \begin{array}{c} \text{O} \\ \text{NCl} \end{array} [1:2]$ . [88°]

(Hirsch, *B.* 18, 1514). Formed by the action of a solution of bleaching-powder on the hydrochloride of amido-*o*-cresol. Yellow prisms (from alcohol) volatile with steam. Decomposes violently at 100°–115°. By digestion with  $NaHSO_3$  for several hours it is converted into amido-cresol sulphonic acid.

**Chlorimide**  $C_6H_4Me \begin{array}{c} \text{O} \\ \text{NCl} \end{array} [1:2]$ . [75°].

Made in like manner from amido-*m*-cresol (Staedel, *J.* 259, 218). Yellow prisms (from alcohol), volatile with steam.

**Oxim**  $C_6H_4MeO(NOH)$  [2:1:4]. **Nitroso-*o*-cresol**. [135°]. Formed by the action of nitrous acid on *o*-cresol (Nölting a. Kohn, *B.* 17, 370). Formed also by the action of hydroxylamine hydrochloride on toluquinone (Goldschmidt a. Schmidt, *B.* 17, 2063). Needles (from water), decomposed by fusion. *V. sol.* alcohol and ether. Yields nitro-cresol [95°] on oxidation.  $NaA^33aq.$   $\cdot KA^3$ : brown needles, *v. sol.* water.

**Oxim**  $C_6H_4MeO(NOH)$  [2:1:4]. **Nitroso-*m*-cresol**. Formed by boiling nitroso-di-methyl-*m*-toluidine with dilute (10 p.c.)  $NaOH$  (Wurster a. Riedel, *B.* 12, 1799). Formed also by the action of  $NO.SO_3H$  on *m*-cresol and water at 0° (Bertoni, *G.* 12, 303). Small needles (from water). Decomposes at 145°–150°. *Sl. sol.* hot water. Gives Liebermann's reaction. Forms an acetyl derivative  $C_6H_4MeO(NOAc)$  [92°] crystallising in large prisms.

**Di-oxim**  $C_6H_4Me(NOH)_2$  [2:1:4]. Formed by the action of hydroxylamine on either monooxim (Nietzki a. Guitermann, *B.* 21, 430) or by boiling nitroso-*o*- or *m*-toluidine with hydroxylamine hydrochloride (Mehne, *B.* 21, 729). Yellow needles, exploding at 220°–234°, *v. sl.* sol. benzene, *sol.* hot water, alcohol, and ether. Reduced by  $Sn$  and  $HCl$  to tolylene-*p*-diamine. Alkaline  $K_2FeCy_6$  forms di-nitroso-toluene.  $Ac_2O$  forms  $C_6H_4Me(NOAc)_2$  [120°], crystallising from alcohol in colourless needles.

**Ditolylimide**  $C_6H_4Me(NC_6H_5)_2$ . [146°]. Formed by oxidation of tolylene-di-tolyl-diamine in alkaline solution (Green, *C.* 7, 63, 1409). Red prisms, *v. sol.* alcohol, *v. s.* sol. benzene.

**References.**—Di-bromo-, Chloro-, Iodo-, and Oxy-toluquinone.

**TOLUQUINOXALINE** *v.* METHYL-QUINOXALINE.

***o*-TOLURIC ACID**  $C_6H_4HNO_2$  *i.e.*

$C_6H_4CO.NH.CH_2.CO_2H$ . **Toluyol** - glycochil

[162-5°]. Formed from toluyl chloride, amido-acetic acid, and NaOH (Gleditsch a. Möller, A. 250, 376). Found in the urine of dogs that have taken *o*-toluic acid. Thick plates, sol. water.

*m*-Toluric acid. [139°]. Formed as above, and also when *m*-xylene or *m*-toluic acid is administered to a dog (G. a. M.; cf. Schultzen a. Naunyn, Z. 1868, 29). M., sol. water.—ZnA', 4aq.—CuA', 6aq.

*p*-Toluric acid. [161°]. Formed from *p*-toluyl chloride and glycocholl (G. a. M.) and also by passage of *p*-xylene or *p*-toluic acid through the animal body (Kraut, A. 98, 360). Plates (from water), sl. sol. cold water, v. sol. alcohol.—CaA', 3aq.—BaA', 5aq.—AgA'.

**TOLUYL.** The radicle  $\text{CH}_2\text{C}_6\text{H}_4\text{CO}$ . The same name has been given to the radicle  $\text{CH}_2\text{C}_6\text{H}_4\text{CH}_2$ , which is isomeric with xylyl, and has also been called tolyl, but may be more conveniently named methyl-benzyl. Toly is  $\text{CH}_2\text{C}_6\text{H}_4$ .

#### *o*-TOLUYL-ACETIC ACID

*Ethyl ether*  $\text{C}_6\text{H}_4\text{Me.CO.CH}_2\text{CO}_2\text{Et}$ . Oil, got by boiling the nitrile with alcohol and HCl. Gives a violet colour with  $\text{FeCl}_3$ .

*Nitrile*  $\text{C}_6\text{H}_4\text{CO.CH}_2\text{CN}$ . [74-4°]. Formed by boiling *o*-toluyl-cyano-acetic ether with water (Haller, C. R. 108, 1117). Prisms, sol. alcohol and alkalis. Diazobenzene chloride and NaOH form  $\text{C}_6\text{H}_4\text{CO.CH(Cy).N}_2\text{C}_6\text{H}_5$  [125°]. Cold alcoholic HCl forms the hydrochloride of  $\text{C}_6\text{H}_4\text{CO.CH}_2\text{C(NH).OEt}$  [116°].

**TOLUYL-ACRYLIC ACID**  $\text{C}_6\text{H}_4\text{O}_2$ , i.e.  $\text{C}_6\text{H}_4(\text{CH}_2\text{CO.CH=CH.CO}_2\text{H})$ . [138°]. Formed by the action of  $\text{AlCl}_3$  on a mixture of maleic anhydride and toluene (Pechmann, B. 15, 888).

**TOLUYL ALCOHOL** v. **TOLYL-CARBINOL**.

**TOLUYLAMIDE** v. **AMIDE OF TOLURIC ACID**.

***p*-TOLUYL-*o*-BENZOIC ACID**  $\text{C}_6\text{H}_3\text{O}_2$ , i.e.  $[\text{14}] \text{C}_6\text{H}_3\text{Me.CO}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$  [1:2]. *Phenyl tolyl ketone carboxylic acid*. Mol. w. 240. [146°].

Formed by the action of phthalic anhydride on toluene in presence of  $\text{AlCl}_3$  (Friedel a. Crafts, A. Ch. [6] 14, 447; C. R. 92, 833). Prisms (containing aq) from alcohol-toluene, v. sl. sol. hot water. Its dilute aqueous solution tastes sweet. Potash-fusion yields benzoic and *p*-toluic acids. Warm conc.  $\text{H}_2\text{SO}_4$  forms (*β*)-methyl-anthraquinone. — BaA', 4aq. — CdA', 2aq. — CuA', 4aq.

*Methyl ether* MeA'. [53°].

*Ethyl ether* EtA'. [69°].

**Toluyl-benzoic acid**  $\text{C}_6\text{H}_4\text{CO}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ . [222°]. Formed by oxidation of di-tolyl-methane and of *u*-di-tolyl-ethane (Weiler, Z. 7, 1184; Ador a. Crafts, C. R. 85, 1163; O. Fischer, B. 7, 1195; Anschütz, A. 235, 316). Slender needles (from MeOH), sl. sol. hot water.—KA': tufts of long needles.—AgA'.

**Reference.**—DI-CHLORO-TOLUYL-BENZOIC ACID.

**TOLUYLENE** v. **TOLYLENE**.

***p*-TOLUYL-PROPIONIC ACID**  $\text{C}_6\text{H}_4\text{O}_2$ , i.e.  $\text{C}_6\text{H}_4\text{CO}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$ . [127°] (C); [126°] (B). Formed by the action of succinyl chloride or succinic anhydride on toluene and  $\text{AlCl}_3$  (Claus, B. 20, 1878; Burcker, Bl. [2] 49, 448). Plates or needles (from water), v. sol. ether.—BaA', 4aq; sol. hot water.—AgA': small needles, insol. Aq.

***o*-TOLUYL-TOLUIC ACID.** *Lactone*

$\text{C}_6\text{H}_4\text{CH}_2\text{CO}_2\text{C}_6\text{H}_4\text{CH}_2\text{CO}_2\text{H}$ . [93°]. Got from nitro-tolyl-

methylene-phthalide, HIAq, and P (Heilmann, B. 23, 8166). Thin prisms. Converted by alcoholic  $\text{NH}_3$  into  $\text{C}_6\text{H}_4\text{CH}_2\text{CO}_2\text{NH}_2$  [196°].

***oo*-DITOLYL**  $\text{C}_6\text{H}_4$ , i.e.

$[\text{1:2}] \text{C}_6\text{H}_4\text{Me.C}_6\text{H}_4\text{Me}$  [1:2]. Mol. w. 182. (272°). S.G.  $\frac{10}{4}$  9945. Formed from *o*-bromo-toluene and Na (Fittig, A. 139, 178). Liquid.

*mm*-ditolyl  $[\text{1:3}] \text{C}_6\text{H}_4\text{Me.C}_6\text{H}_4\text{Me}$  [1:3]. (280°) (Schultz, B. 17, 468); (288°) (Perrier, C. R. 114, 481); (289°) (Stolle, B. 21, 1096). S.G.  $\frac{10}{4}$  9993. Formed by diazotising di-amido-*o*-ditolyl and boiling the product with alcohol. Formed also by the action of Na on *m*-bromo-toluene (P.), and by reduction of di-*oxy-m*-ditolyl and di-chloro-*m*-ditolyl. Oil; yields diphenyl di-*m*-carboxylic acid and isophthalic acid on oxidation.

*pp*-ditolyl  $[\text{1:4}] \text{C}_6\text{H}_4\text{Me.C}_6\text{H}_4\text{Me}$  [1:4]. [121°]. S.V. 198-0. Formed by adding Na to a solution of *p*-bromo-toluene in toluene (Zincke, B. 4, 396; Longuinine, B. 4, 514). Monoclinic prisms (from ether). Yields on oxidation *p*-tolyl-benzoic acid [244°] and diphenyl di-*p*-carboxylic acid (Carnelley, C. J. 32, 653).  $\text{SbCl}_5$  at 360° forms  $\text{C}_6\text{H}_4$  and per-chloro-diphenyl.

*om*-Ditolyl  $[\text{1:2}] \text{C}_6\text{H}_4\text{Me.C}_6\text{H}_4\text{Me}$  [1:3]. (270°). Formed from  $[\text{2:4:1}] \text{C}_6\text{H}_4\text{Me}(\text{NH}_2)\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)$  [1:3:4] by elimination of amidogen by the diazo-reaction (Schultz, B. 17, 471). Yields isophthalic acid on oxidation by  $\text{CrO}_3$ .

*op*-Ditolyl  $[\text{1:2}] \text{C}_6\text{H}_4\text{Me.C}_6\text{H}_4\text{Me}$  [1:4]. (272°–280°). Formed from crude bromo-toluene and Na. It is also one of the products of the passage of a mixture of benzene and toluene through a red-hot tube (Carnelley, C. J. 37, 707; 47, 587). Oxidised by  $\text{CrO}_3$  and  $\text{HOAc}$  to *o*-tolyl-*p*-benzoic acid [180°] and terephthalic acid.

Ditolyls have also been obtained by Barbier (C. R. 78, 1769) and Varet a. Vienne, Bl. [2] 47, 919).

**References.**—DI-AMIDO-, DI-BROMO-, DI-iodo-, NITRO-AMIDO-, OXY-AMIDO-, and OXY-DITOLYL.

***p*-TOLYL-ACETAMIDINE**  $\text{C}_6\text{H}_4\text{N}_2$ , i.e.  $\text{CH}_2\text{C}_6\text{H}_4\text{NHC(=O)NHMe}$  [1:4]. [96°]. Formed from *p*-toluidine hydrochloride and acetonitrile (Bernthsen a. Trompeter, B. 11, 1757). Prisms. Alkaline in reaction.—B'' $\text{H}_2\text{PtCl}_6$ .—B'' $\text{H}_2\text{C}_2\text{O}_4$ . Prisms, v. sol. water and alcohol.

**Di-*o*-tolyl-acetamidine**

$[\text{1:2}] \text{C}_6\text{H}_4\text{Me.NH.CMe.NC}_6\text{H}_4\text{Me}$  [1:2]. [136°] (W.); [140°] (L.). Formed by the action of  $\text{PCl}_5$  on *o*-toluidine and  $\text{HOAc}$  (Ladenburg, B. 10, 1262), and also by the action of *o*-toluidine on  $\text{CMe(SET)NC}_6\text{H}_4$  or on  $\text{CMeCl.NC}_6\text{H}_4$  (Wallach a. Wüsten, B. 16, 148; A. 214, 208). Needles.

**Di-*p*-tolyl-acetamidine**

$[\text{1:4}] \text{C}_6\text{H}_4\text{Me.NH.CMe.NC}_6\text{H}_4\text{Me}$  [1:4]. *Acetyl-tolyl-insid-tolyl-amide*. [120°]. Formed from *p*-toluidine and  $\text{CMeCl.NC}_6\text{H}_4$ , which is the product of the action of  $\text{PCl}_5$  on acetyl-*p*-toluidine (Wallach a. Fassbender, A. 214, 203; B. 9, 1214; 16, 148). Formed also from *p*-toluidine and bromopropionic acid (Mabery a. Krause, B. 22, 8307). Prisms (from benzene). Formed also from *p*-toluidine,  $\text{HOAc}$ , and  $\text{PCl}_5$ .—B'' $\text{H}_2\text{PtCl}_6$ .—B'' $\text{HCl}$ . [200°].

***op*-Di-tolyl-acetamidine**

$\text{C}_6\text{H}_4\text{Me.NH.CMe.NC}_6\text{H}_4\text{Me}$ . [149°]. Formed from *o*-toluidine and the product of the action of  $\text{PCl}_5$  on acetyl-*p*-toluidine, and also from

*p*-toluidine and the product of the action of  $\text{PCl}_5$  on acetyl-*o*-toluidine (Wallach a. Pannes, *A.* 214, 209). Formed also from *p*-toluidine and  $[\text{1:2}] \text{C}_6\text{H}_4\text{MeN:CMc:SEt}$ , and from *o*-toluidine and  $[\text{1:4}] \text{C}_6\text{H}_4\text{MeN:CMc:SEt}$ ; the compounds obtained,  $[\text{148}^\circ]$  and  $[\text{140}^\circ]$  respectively, being perhaps isomeric and not identical (Wallach, *B.* 16, 148).

***o*-TOLYL-ACETIC ACID**  $\text{C}_8\text{H}_9\text{O}_2$  i.e.  $[\text{1:2}] \text{C}_6\text{H}_4\text{Me.CH}_2\text{CO}_2\text{H}$ .  $[\text{89}^\circ]$ . Formed by saponification of its nitrile (Radziszewski a. Wispeck, *B.* 15, 1747; 18, 1281). Needles, sl. sol. cold water. Yields phthalic acid on oxidation.— $\text{CaA}'_2$ , 4aq.— $\text{AgA}'$ . Plates, sol. hot water. *Amide*  $[\text{161}^\circ]$ . Plates, sl. sol. ether.

*Nitrile*  $\text{C}_8\text{H}_7\text{N}$ . (244°). S.G.  $\frac{2}{25}$  1.0156. Formed from  $\omega$ -bromo-*o*-xylene and  $\text{KCy}$ . Oil.

*m*-Tolyl-acetic acid  $[\text{1:3}] \text{C}_6\text{H}_4\text{Me.CH}_2\text{CO}_2\text{H}$ .  $[\text{61}^\circ]$ . Formed by saponifying its nitrile, which is obtained from  $\omega$ -bromo-*m*-xylene (R. a. W.). Needles, sol. hot water.— $\text{CaA}'_2$ , 3aq.— $\text{AgA}'$ .

*Amide*  $[\text{141}^\circ]$ . Sl. sol. cold water.

*Nitrile* (241°). S.G.  $\frac{2}{25}$  1.0022. Oil.

*Methyl ether*  $\text{MeA}'$ . (228°). S.G.  $\frac{2}{25}$  1.041. Liquid (Senkowski, *M.* 9, 854).

*Ethyl ether*  $\text{EtA}'$ . (238°). S.G.  $\frac{2}{25}$  1.018.

*p*-Tolyl-acetic acid  $[\text{1:4}] \text{C}_6\text{H}_4\text{Me.CH}_2\text{CO}_2\text{H}$ .  $[\text{94}^\circ]$ . Formed in like manner from  $\omega$ -bromo-*p*-xylene (R. a. W.; Strassmann, *B.* 22, 1230). Got also by reducing *p*-tolyl-glyoxylic acid with  $\text{HI}$  (Claus a. Krosenberg, *B.* 20, 2051). Needles, sl. sol. cold water. Phthalic anhydride and

$\text{NaOAc}$  yield  $\text{C}_6\text{H}_4\text{C}(\text{CO})_2\text{CH}(\text{CH}_2\text{C}_6\text{H}_4\text{Me})\text{O}$   $[\text{151}^\circ]$ ,

whence  $\text{HNO}_2$  at  $0^\circ$  forms the compound

$\text{C}_6\text{H}_4\text{C}(\text{CO})_2\text{CH}(\text{NO}_2)\text{CH}(\text{NO}_2)\text{C}_6\text{H}_4\text{O}$   $[\text{140}^\circ]$ , which

is converted by treatment with boiling alcohol into

$\text{C}_6\text{H}_4\text{C}(\text{CO})_2\text{CH}(\text{CNO}_2)\text{C}_6\text{H}_4\text{O}$   $[\text{207}^\circ]$ , and is reduced

by  $\text{HI}$  and  $\text{P}$  to  $\text{C}_6\text{H}_4\text{C}(\text{CO})_2\text{CH}(\text{C}_6\text{H}_4\text{O})_2$   $[\text{116}^\circ]$  (Ruhmann, *B.* 24, 3965).— $\text{NaA}'$ : needles, sol. water.—

$\text{CaA}'_2$ , 3aq.— $\text{AgA}'$ : needles, sol. hot water.

*Ethyl ether*  $\text{EtA}'$ . (240°).

*Amide*  $\text{C}_8\text{H}_9\text{NO}$ .  $[\text{185}^\circ]$ . Plates. Formed from the acid, and also by the action of yellow ammonium sulphide on *p*-tolyl methyl ketone (Willgerodt, *B.* 21, 534).

*Nitrile*  $\text{C}_8\text{H}_7\text{CN}$ .  $[\text{18}^\circ]$ . (213°). S.G.  $\frac{2}{25}$  0.9922.

*Reference.*—Nitro- and Oxy-TOLYL-ACETIC ACID.

***m*-TOLYL-ACETYLENE**  $[\text{1:3}] \text{C}_6\text{H}_4\text{Me.C}\equiv\text{CH}$ .

*Methyl-styrene*. (161°). Formed by distilling barium *m*-tolyl-propiolate with lime (Müller, *B.* 20, 1216). Formed also by saturating a solution of *m*-tolyl-acrylic acid with  $\text{HBr}$  at  $0^\circ$  and

treating the product with  $\text{NaOH}$  aq. Oil, becoming solid on standing. Gives an explosive red pp. with ammoniacal  $\text{Cu}_2\text{Cl}_2$ . Br forms

$\text{C}_6\text{H}_4\text{CHBr.CHBr.C}\equiv\text{CH}$   $[\text{46}^\circ]$ .

*Di*-tolyl-acetylene  $\text{C}_6\text{H}_4\text{C}\equiv\text{C.C}_6\text{H}_4$ .  $[\text{136}^\circ]$ .

Formed by heating  $\text{C}_6\text{H}_4\text{CHBr.CI}\text{Br}.\text{C}_6\text{H}_4$  with alcoholic potash at  $140^\circ$  (Goldschmidt a. Hepp, *B.* 6, 1505). Needles (from alcohol).

**DI-TOLYL-ACIPIPERAZINE** v. OXY-DI-TOLYL-PYRAZINE.

**DI-tolyl-di-aci-piperazine** v. DI-OXY-DI-TOLYL-PYRAZINE.

***m*-TOLYL-ACRYLIC ACID**  $\text{C}_8\text{H}_9\text{O}_2$  i.e.

$[\text{1:3}] \text{C}_6\text{H}_4\text{Me.CH}(\text{CH}_3)\text{CO}_2\text{H}$ . *Methyl-cinnamic acid*.  $[\text{111}^\circ]$ . Formed by heating *m*-toluic aldehyde with  $\text{Ac}_2\text{O}$  and  $\text{NaOAc}$  (Bornemann, *B.* 17, 1474; 20, 1382; Von Miller, *B.* 20, 1213; 23, 1899). Silky needles, v. sol. alcohol, sl. sol. ligroin.  $\text{FeCl}_3$  gives a bright-yellow pp. in neutral solutions. Reduced by sodium-amalgam to *m*-tolyl-propionic acid  $[\text{43}^\circ]$ .  $\text{KMnO}_4$  oxidises it to *m*-toluic acid. Br forms  $\text{C}_6\text{H}_4\text{Me.CHBr.CHBr.CO}_2\text{H}$   $[\text{167}^\circ]$ .— $\text{BaA}'_2$ — $\text{AgA}'$ . Crystalline powder.

*p*-Tolyl-acrylic acid

$[\text{1:4}] \text{C}_6\text{H}_4\text{Me.CH}(\text{CH}_3)\text{CO}_2\text{H}$ .  $[\text{197}^\circ]$ . Formed from *p*-toluic aldehyde,  $\text{NaOAc}$ , and  $\text{Ac}_2\text{O}$  (Von Miller, *B.* 23, 1897; cf. Köber, *B.* 23, 1033). Needles (from benzene), sl. sol. hot water. Reduced by  $\text{HI}$  and  $\text{P}$  to *p*-tolyl-propionic acid. Br forms  $\text{C}_6\text{H}_4\text{Me.CHBr.CHBr.CO}_2\text{H}$ .

**TOLYL ALCOHOL** v. TOLYL-CARBINOL.

***p*-TOLYL-ALLYL-HYDRAZINE**  $\text{C}_{10}\text{H}_{11}\text{N}_2$  i.e.

$\text{C}_6\text{H}_4\text{N}(\text{C}_6\text{H}_4)\text{NH}_2$ . (160°–170° at 90 mm.). Got from tolyl-hydrazine and allyl bromide (Michaelis, *B.* 26, 2177). Oil. Yields  $\text{B}^+\text{HCl}$ .  $[\text{129}^\circ]$ . Benzoyl aldehyde forms the compound  $\text{C}_6\text{H}_4\text{N}(\text{C}_6\text{H}_4)\text{N.CI}\text{Ph}$   $[\text{61}^\circ]$ , while cinnamic aldehyde forms the corresponding hydrazide  $[\text{118}^\circ]$ . Ferric chloride gives the tetrazone  $(\text{O}_2\text{H}(\text{C}_6\text{H}_4)\text{N})_2\text{N}_2$   $[\text{104}^\circ]$ .

***o*-TOLYL-ALLYL-THIO-SEMI-CARBAZIDE**

$\text{C}_8\text{H}_9\text{NH.NH.CS.NHC}_6\text{H}_4$ .  $[\text{105}^\circ]$ . Formed by warming *o*-tolyl-hydrazine with allyl thiocarbimide (Avenarius, *B.* 24, 268). Needles, insol. water, v. sol. alcohol and  $\text{CS}_2$ .

*p*-Tolyl-allyl-thio-semi-carbazide  $[\text{128}^\circ]$ . Formed in like manner (A.). Needles.

***o*-TOLYL-ALLYL-THIO-UREA**  $\text{C}_8\text{H}_9\text{N}_2\text{S}$  i.e.

$\text{C}_6\text{H}_4\text{NH.CS.NHC}_6\text{H}_4$ . *Tolyl-thioisaminine*.  $[\text{98}^\circ]$ . Formed from *o*-toluidine and oil of mustard (Jailard, *Z.* 1865, 441; Maly, *Z.* [2] 5, 258; Weith, *B.* 8, 1528; Prager, *B.* 22, 2398). Pearly crystals, m. sol. ether, v. sol.  $\text{HOAc}$ . According to Dixon (*C. J.* 55, 622), it melts at  $76^\circ$ . Converted by heating with  $\text{HCl}$  aq into tolyl-propylene- $\psi$ -thio-urea  $[\text{126}^\circ]$ . Cyanogen passed into its alcoholic solution forms  $\text{C}_8\text{H}_9\text{N}_2\text{S}$ , which on warming with dilute  $\text{H}_2\text{SO}_4$  and alcohol gives a pp. of oxalyl-tolyl-allyl-thio-urea  $\text{CS} \langle \text{NC}_6\text{H}_4 \rangle \text{C}_2\text{O}_2$   $[\text{157}^\circ]$ .

*Reference.*—OXY-TOLYL-ALLYL-THIO-UREA.

***o*-TOLYL-AMIDO-ACETIC ACID**  $\text{C}_8\text{H}_9\text{NO}$  i.e.

$\text{C}_6\text{H}_4\text{Me.NH.CHO}$ . *Tolyl-glycolol*.  $[\text{150}^\circ]$ . Prepared by the action of chloro-acetic acid and aqueous  $\text{NaOAc}$  on *o*-toluidine (Staats, *B.* 13, 137; Cosack, *B.* 13, 1091; Ehrlich, *B.* 16, 201; Bischoff a. Nagel, *B.* 22, 1787).— $\text{CaA}'_2$ , 2aq. Small needles.— $\text{CaA}'_2$ , 3aq: needles, m. sol. water (Mantlimer, *M.* 11, 377).

*Ethyl ether*  $\text{EtA}'$ . (281°). S.G.  $\frac{2}{25}$  1.058. Oil (Bischoff, *B.* 25, 2270).

*Acetyl derivative*  $\text{C}_8\text{H}_7\text{N}.\text{NaOAc}.\text{CH}_2\text{CO}_2\text{H}$   $[\text{212}^\circ]$ . Tables (from dilute alcohol).

*Chloro-acetyl derivative*

$\text{C}_6\text{H}_4\text{N}(\text{CO}.\text{CH}_2\text{Cl}).\text{CH}_2\text{CO}_2\text{H}$ .  $[\text{117}^\circ]$ . Formed from the acid and chloro-acetyl chloride, in ether (Widman, *J. pr.* [2] 38, 304). Rectangular plates, v. sol. hot alcohol, sl. sol. water.

*Bromo-acetyl derivative*

$\text{C}_6\text{H}_4\text{N}(\text{CO}.\text{CH}_2\text{Br}).\text{CH}_2\text{CO}_2\text{H}$ .  $[\text{124}^\circ]$ . Rectangular plates.

*Glycolyl derivative*

$C_6H_5N(CO.CH_2.OH).CH_2.CO_2H$ . [144°]. Formed by boiling the chloro-acetyl derivative with conc.  $Na_2CO_3$  (Abenius, *J. pr.* [2] 40, 503). V. e. sol. water. Yields  $KA'$ ,  $BaA'$ ,  $AgA'$ , and is converted by heating at 160° into  $C_6H_5N<\frac{CO.CH_2}{CH_2.CO}>O$  [109°], whence alcoholic  $NH_3$  produces  $C_6H_5N(CO.CH_2.OH).CH_2.CO.NH_2$  [152°], crystallising in plates (from alcohol).

*o*-Toluide  $C_6H_4NH_2.CH_2.CO.NH.C_6H_5$ . [92°]. Formed by boiling chloro-acetic ether with *o*-toluidine (Ehrlich, *B.* 16, 205). Needles, insol. water and  $HClAq$ .

*m*-Tolyl-amido-acetic acid

[1:3]  $C_6H_4Me.NH.CH_2.CO_2H$ . Formed from chloro-acetic acid and *m*-toluidine in ether (Ehrlich, *B.* 15, 2011). Solid mass.— $CuA_2$  2aq.

*Ethyl ether EtA'*. [68]. Formed from chloro-acetic ether and *m*-toluidine. Six-sided plates, v. sol. alcohol and ether, sl. sol.  $Aq$ .

*p*-Tolyl-amido-acetic acid

[1:4]  $C_6H_4Me.NH.CH_2.CO_2H$ . [119°]. Formed, together with a compound [168°], from *p*-toluidine chloro-acetic acid and  $NaOAc$  (dissolved in a little water) at 100° (P. J. Meyer, *B.* 8, 1158; 14, 1323; Staats, *B.* 13, 137; Schwebel, *B.* 10, 2047; Bischoff, *B.* 23, 1997; 25, 2281). Got also by saponifying its ether. Needles (from water). When fused with potash it yields a product which, when dissolved in water, is oxidised by air to an indigo-derivative (Heumann, *B.* 24, 1346). When fused with *p*-chloro-acet-toluide it yields methyl-indigo (Eckeroth, *B.* 24, 693). The compound [168°], formerly supposed to be *p*-tolyl-amido-acetic acid, ought, according to Bischoff a. Hausdörfer (*B.* 25, 2281) to be represented as  $CO_2H.CH_2.N(C_6H_5).CH_2.CO.ONH.C_6H_5$ .

*Ethyl ether EtA'*. [49°]. Formed from chloro-acetic ether and *p*-toluidine. Monoclinic plates, v. sl. sol. hot water.

• *Amide*  $C_6H_4N_2O$ . [163°]. Formed by heating *p*-toluidine with chloro-acetamide. Plates, v. sl. sol. cold water.

*Anilide*  $C_6H_5NH.CH_2.CO.NHPh$ . [83°]. Formed by heating chloro-acetic acid with aniline. Needles (from hot water).

*p*-Toluide  $C_6H_4NH_2.CH_2.CO.NC_6H_5$ . [136°]. Formed in like manner, and also by heating toluidine with the compound of glyoxal with  $NaHSO_3$  (Hinsberg, *B.* 21, 112). Plates, v. sl. sol. hot water. Yields a chloro-acetyl derivative [158°].

*Nitrile*  $C_6H_4NH.CH_2.CN$ . [126°]. A product of the action of heat on the amide.

*Acetyl derivative*  $C_6H_4.NAc.CH_2.CO_2H$ . [175°]. Formed from chloro-acetic ether and  $C_6H_5.NaCNa$ , the product being saponified with potash (Paal a. Otten, *B.* 23, 2596). Plates (from water).— $NaA'$  3aq; plates, v. sol. water.

*Imide*  $(C_6H_4NH.CH_2.CO)_2NH$ . [210°]. Got by heating the acid at 200° and adding  $NH_3Aq$  to the product. Needles, sl. sol. water and  $NH_3Aq$  (Bischoff).

*Di-o-tolyl-di-amido-acetic acid*

$(C_6H_4NH_2).CH.CO_2H$ . [240°]. Formed by heating di-chloro-acetic acid with *o*-toluidine (P. Meyer, *B.* 16, 925). Needles, insol. water, sl. sol. alcohol, v. sl. aqueous acids and alkalis.

*Reference*.—NITRO-TOLYL-AMIDO-ACETIC ACID.

*p*-TOLYL-AMIDO-ACETOPHENONE

[1:4]  $C_6H_4Me.NH.CH_2.CO.C_6H_5$ . *Phenacyl-p-toluidine*. [184°]. Formed from *p*-toluidine and bromo-acetophenone in alcohol (Lellmann a. Donner, *B.* 23, 167). Tables, v. sol. benzene, m. sol. alcohol. Yields, on nitration, [1:3:4]  $C_6H_4Me(NO_2).NH.CH_2.Bz$  [165°] and a di-nitro-derivative [156°]. Forms  $B'HNO_3$  and  $B'HCl$ .

*p*-TOLYL-AMIDO-ACRYLIC ETHER

[1:4]  $C_6H_4Me.NH.CH_2.CO_2Et$ . [116°]. Formed from *p*-toluidine and formyl-acetic ether (Von Pechmann, *B.* 25, 1053). Yellow plates, insol. water and ligroin. Alcoholic potash yields plates [144°].  $Ac_2O$  forms acetyl-toluidine.

*Tri-p*-TOLYL-TRI-AMIDO-BENZENE

$C_6H_4N_3$ , i.e.  $C_6H_3(NH.C_6H_5)_3$ . [187°]. Formed by heating phloroglucin with *p*-toluidine at 210° (Minunni, *B.* 21, 1984). Needles, v. sl. sol. cold alcohol. Conc.  $H_2SO_4$  forms a bluish-green solution, turning black on heating.— $B'''HCl$ : amorphous; decomposed by water.— $B'''2HCl$ : small needles.— $B'''H_2PtCl_6$ .

*Tri-acetyl derivative* [193°]. Plates.

*Tri-benzoyl derivative* [282°]. Minute prisms.

*p*-TOLYL-AMIDO-BENZOYL-(a)-NAPHTHO-QUINONE  $C_6H_4.CO.C_6H_4<\frac{CO.C_6H_4.NH.C_6H_5}{CO.CH}$ 

[197°]. Formed by boiling *p*-toluidine with benzoyl-(a)-naphthoquinone in alcoholic solution for 15 minutes (Kegel, *A.* 247, 185). Red needles (from  $HOAc$ ), v. sl. sol. alcohol.

*p*-TOLYL-*o*-AMIDO-BENZYL-AMINE

[4:1]  $C_6H_4Me.NH.CH_2.C_6H_4NH_2$ . [1:2]. [80-55°]. Got by reducing *p*-tolyl-*o*-nitro-benzyl-amine (Söderbaum a. Widman, *B.* 23, 2187). Thin leaflets (from alcohol).  $Ac_2O$  yields a di-acetyl derivative [186°]. The mono-acetyl derivative  $C_6H_4.NAc.CH_2.C_6H_4NH_2$  [99°] may be got by reducing  $C_6H_4.NAc.CH_2.C_6H_4NO_2$ .

*o*-TOLYL-*a*-AMIDO-*n*-BUTYRIC ACID

$C_6H_4.NH.CHEt.CO_2H$ . [84°]. Long prisms. Forms an acetyl derivative [116°] and yields propyl-*o*-toluidine on distillation.

*Ethyl ether EtA'*. [278°]. S.G.  $\frac{25}{4}$  1.019. Got by heating *o*-toluidine with *a*-bromo-butyric ether at 100° (Bischoff a. Mintz, *B.* 25, 2314).

*o*-Tolyl-*a*-amido-isobutyric acid

$C_6H_4NH.CMe.CO_2H$ . [62°]. Formed together with the  $\beta$ -isomeride [110°] by the action of  $KOH$  and a current of steam on the ether [57°], which is got by heating *o*-toluidine with *a*-bromo-isobutyric ether (Bischoff a. Mintz, *B.* 25, 2334). The acid [110°] yields an acetyl derivative [219°], sl. sol. ether. On distillation it forms a lactone [95°].

*p*-Tolyl-*a*-amido-*n*-butyric acid

$C_6H_4NH.CHEt.CO_2H$ . [153°-156°]. Got from the ether  $EtA'$  (279°) S.G.  $\frac{25}{4}$  1.011, which is produced when *p*-toluidine is heated with *a*-bromo-*n*-butyric acid at 105°. Leaflets. Yields propyl-*p*-toluidine on distillation.

*Acetyl derivative*  $C_6H_4.NAc.CHEt.CO_2H$ 

[149°].

*p*-Tolyl-*a*-amido-isobutyric acid

[1:4]  $C_6H_4Me.NH.CMe.CO_2H$ . [150°]. Formed, together with the  $\beta$ -isomeride, by the action of hot potash in a current of steam on the ether  $EtA'$  [36°], which is got by heating *p*-toluidine with *a*-bromo-isobutyric acid. Yields an acetyl

derivative [146°]. Forms isopropyl-*p*-toluidine on distillation.

*p*-Tolyl-*β*-amido-isobutyric acid  
 $C_6H_4NH.CH_2.CHMe.CO_2H$ . [196°]. Formed as above. Gives an acetyl derivative [206°] and decomposes on distillation into *p*-toluidine and a lactone  $C_6H_4N<\frac{CH_2.CHMe}{CO}.CMe_2.O>CO$  (?) [170°].

***o*-TOLYL-AMIDO-CROTONIC ACID**

[1:2]  $C_6H_4Me.NH.CMe.CH.CO_2H$ .  
*Methyl ether* MeA'. [31°]. Formed by the action of *o*-toluidine on methyl aceto-acetate (Conrad a. Limpach, *B.* 21, 523). Prisms (from alcohol).

*Ethyl ether* EtA'. Yellowish oil.

*p*-Tolyl-amido-crotonic acid.

*Methyl ether* MeA'. [60°]. Prisms.

*Ethyl ether* EtA'. [29°]. Formed from acetoacetic ether and *p*-toluidine.

**TOLYL-AMIDO-CYANURIC ACID** *v.*  
*Cyanuric acid*, described under CYANIC ACIDS.

***p*-TOLYL-AMIDO-METHENYL-BENZAMID-  
 OXIM**  $C_6H_4N<\frac{N.O}{N}>C.NH.C_6H_4Me$  [1:4]. [135°].

Formed by heating *p*-tolyl-thiocarbimide with benzamidoxim (Koch, *B.* 24, 398). Plates (from alcohol), *v. sol.* ether.

**DI-*p*-TOLYL-AMIDO-METHYLENE-*o*-PHE-  
 NYLENE DIAMINE**  $C_6H_4N_2$ , *i.e.*

$C_6H_4<\frac{NH}{NH}>C<\frac{NH.C_6H_4}{NH.C_6H_4}>$  [186°]. (above 400°).

Formed by heating  $C(NC_6H_4)_2$  with *o*-phenylenediamine at 135° (Moore, *B.* 22, 1639; 3188). Tables (from alcohol), *v. sol.* boiling water.

—Salts:  $B^+3HCl^-$ . Needles. — $B^+3H_2PtCl_6.8aq.$  — $B^+HSO_4^-$ . Needles, *insol.* ether, *v. sol.* hot Aq.

*Nitrosamine*

$C_6H_4<\frac{N(NO)}{N(NO)}>C(NC_6H_4)_2$ . [130°]. Yellow needles, *v. sol.* alcohol.

*Di-acetyl derivative* [143°]. Needles.

*Di-benzoyl derivative* [185°]. Prisms.

*Tetra-benzoyl derivative* [274°].

**Tetra-*p*-tolyl-tetra-amido-*di*-methylene-*o*-phenylene-diamine**  $C_{12}H_8N_4(C(NHC_6H_4)_2)_2$  [116°]. Formed by heating  $C(NC_6H_4)_2$  with *o*-phenylenediamine at 200° (Moore, *B.* 22, 3195). Needles, *v. sol.* alcohol. Decomposed by dilute  $HClAq$  at 150° into *di-p*-tolyl-urea and *o*-phenylenediamine. — $B^+2HSO_4^-$ . Needles, *sl. sol.* cold water. — $B^+3HCl^-$ . — $B^+3H_2PtCl_6.15aq.$

*Tetra-acetyl derivative* [115°].

*Tetra-benzoyl derivative* [146°].

**DI-*p*-TOLYL-AMIDO-METHYLENE-*o*-PHE-  
 NYLENE-PHENYL-GUANIDINE**

$C_6H_4<\frac{N}{N}>C(NPh)>C(NHC_6H_4)_2$  [187°]. Formed

by boiling  $C(NC_6H_4)_2$  with *o*-phenylene-phenyl-guanidine (Keller, *B.* 24, 2508). Needles (from boiling alcohol), *sl. sol.* ether.

**DI-*p*-TOLYL-AMIDO-METHYLENE-*o*-  
 PHENYLENE-*p*-TOLYL-GUANIDINE**

$C_6H_4N_2(CNC_6H_4).C(NHC_6H_4)_2$  [188°]. Formed by heating *o*-phenylene-*p*-tolyl-guanidine with  $C(NC_6H_4)_2$  at 220° (Keller, *B.* 24, 2513). Prisms (from benzene).

**DI-*p*-TOLYL-AMIDO-METHYLENE-*o*-  
 TOLYLENE-*p*-TOLYL-GUANIDINE**

$C_6H_4N_2(CNC_6H_4).C(NHC_6H_4)_2$  [210°]. Formed by heating tolylene-tolyl-guanidine together

with  $C(NC_6H_4)_2$  at 220° (Keller, *B.* 24, 2521). Needles, *sl. sol.* alcohol.

***o*-TOLYL-AMIDO-METHYL-MALONAMIC  
 ETHER**  $CO_2Et.CMe(NHC_6H_4).CO.NH_2$ . Formed by dissolving *α*-cyano-tolyl-*α*-amido-propionic ether in *con.*  $H_2SO_4$  (Gerson, *B.* 19, 2966). Long needles, *sol.* hot water. Converted by boiling  $NaOHAlq$  into tolyl-amido-propionic acid.

***p*-TOLYL-AMIDO-*p*-METHYL-OXINDOLE**

$C_{10}H_9N_2O$  *i.e.*  $C_6H_4Me<\frac{NH}{CH(N)C_6H_4}>CO$ .

[167°]. Formed by heating dichloro- (or dibromo-) acetic acid with *p*-toluidine (Duisberg, *B.* 18, 190). Needles, *v. sol.* hot alcohol. Reduces ammoniacal  $AgNO_3$ , forming a mirror. Readily absorbs oxygen from the air, forming

$C_6H_4Me<\frac{NH}{C(NC_6H_4)}>CO$ . Alcoholic  $KOH$  forms a blood-red solution. — $BTICl$ : crystalline powder.

*Di-acetyl derivative*  $C_{10}H_9Ac_2N_2O$ . [117°].

**Nitrosamine**  $C_{10}H_9N_2O_2$ . [c. 220°].

***p*-TOLYL-AMIDO-METHYL-THIAZOLE**

$S<\frac{CH}{C(NHC_6H_4)}>CMe$ . [125°]. Formed from oxy-methyl-thiazole and *p*-toluidine (Hantzsch a. Weber, *B.* 20, 3130).

**TRI-*p*-TOLYL-TRI-AMIDO-NAPHTHALENE**

$C_{12}H_8<\frac{C(NHC_6H_4).C(NHC_6H_4).C(NHC_6H_4)}{C(NHC_6H_4).CH}>$  [160°]. Formed

by heating nitroso-ethyl-(*α*)-naphthylamine with *p*-toluidine at 150° (Fischer a. Hepp, *A.* 256, 244). Needles (from alcohol). Readily oxidised to di-methyl-phenyl-rosinduline.

***o*-TOLYL-AMIDO-(*α*)-NAPHTHOQUINONE**

$C_{12}H_8NO_2$ , *i.e.*  $C_{10}H_6O(NHC_6H_4)_2$ . [142°]. Formed from *o*-toluidine and (*α*)-naphthoquinone (Elsbach, *B.* 15, 689). Red needles, *sol.*  $NaOHAlq$ .

***p*-Tolyl-amido-(*α*)-naphthoquinone**

$C_{12}H_8O_2(NHC_6H_4)_2$ . [202°]. Formed from (*α*)-naphthoquinone and *p*-toluidine in hot alcoholic solution (Plimpton, *C. J.* 37, 638). Formed also by the action of *p*-toluidine on (*β*)-oxy-(*α*)-naphthoquinone, and by heating *p*-tolyl-amido-(*β*)-naphthoquinone with  $HOAc$  at 150° (Elsbach, *B.* 15, 687). Red needles. Forms a crimson solution in *con.*  $H_2SO_4$ . *Insol.*  $NaOHAlq$ .

**Di-toluide**  $C_{12}H_8<\frac{C(NC_6H_4).C(NHC_6H_4)}{C(NC_6H_4).CH}>$

[142°]. Formed by oxidation of tri-*p*-tolyl-amido-naphthalene (Fischer a. Hepp, *A.* 256, 240). Orange plates.

***o*-Tolyl-amido-(*β*)-naphthoquinone**

$C_{10}H_6O_2(NHC_6H_4)$  or  $C_{10}H_6(OH)O(NC_6H_4)_2$ . [240°]. Formed from (*β*)-naphthoquinone and *o*-toluidine (Elsbach, *B.* 15, 689). Red needles, *sol.* dilute  $NaOHAlq$ . Not affected by heating with  $HOAc$  at 150°. On heating with dilute  $HClAlq$  it yields (*β*)-oxy-(*α*)-naphthoquinone and *o*-toluidine.

***p*-Tolyl-amido-(*β*)-naphthoquinone** [246°].

Formed from (*β*)-naphthoquinone and *p*-toluidine (Elsbach, *B.* 15, 686). Red needles, *sol.* hot alcohol and  $NaOHAlq$ . On heating with  $HClAlq$  at 130° it is split up into *p*-toluidine and (*β*)-naphthoquinone.

*Methyl ether* MeA'. [150°]. Red crystals (Zircke a. Brauns, *B.* 15, 1969).

*Ethyl ether* EtA'. [137°].

*Isopropyl ether* PrA'. [139°].

*p*-Toluide  $C_6H_4(NHC_6H_4)O(NC_6H_4)$ . [188° cor.]. Formed by heating di-bromo-(*a*)-naphthol with *p*-toluidine (Meldola, *C. J.* 45, 159). Formed also from (*S*)-naphthoquinone oxim, *p*-toluidine, and HOAc (Bromme, *B.* 21, 891). Orange crystals with green lustre.

#### DI-*o*-TOLYL-DI-AMIDO-OIAZTHIOLE

$C_{16}H_{16}N_4S$  i.e.  $S \begin{smallmatrix} C(NHC_6H_4)_2N \\ C(NHC_6H_4)_2N \end{smallmatrix}$ . [185°]. Formed by boiling an alcoholic solution of *o*-tolyl-thio-urea with dilute HClAq and  $H_2O_2$  (Hector, *B.* 23, 368). V. sol. alcohol. Cyanogen passed into its alcoholic solution forms  $C_{16}H_{16}N_4SCy_2$  [89°].— $B'HClAq$ . [219°].— $B'_2H_4P_2Cl_4$ . [192°].— $B'AgNO_3$ . White pp.— $B'_2H_4HgCl_2$ . [232°]. Needles.—Picrate:  $B'C_6H_4N_4O_6$ . [201°].

*Acetyl derivative*  $C_{16}H_{14}AcN_4S$ . [221°].

*Benzoyl derivative*  $C_{16}H_{12}BzN_4S$ . [214°].

*Nitrosamine*  $C_{16}H_{14}(NO)_2N_4S$ . [135°].

Di-*p*-tolyl-di-amido-oiazthiole  $C_{16}H_{16}N_4S$ . [127°]. Formed in like manner from *p*-tolyl-thio-urea (Hector, *B.* 23, 364). Thick yellowish prisms, v. sol. alcohol. Cyanogen forms  $B'Cy_2$  [190°].— $B'HCl$ . [233°]. White needles, becoming reddish in air.— $B'_2H_4P_2Cl_4$  1.1 aq. [109°].— $B'AgNO_3$  1.1 aq. [177°].— $B'_2H_4HgCl_2$ . [114°–119°].—Picrate [238°]. Yellow prisms, sl. sol. alcohol.

*Acetyl derivative*  $C_{16}H_{14}AcN_4S$ . [166°].

*Benzoyl derivative*  $C_{16}H_{12}BzN_4S$ . [186°].

*Nitrosamine*  $C_{16}H_{14}(NO)_2N_4S$ . [247°].

*o*-TOLYL-*m*-AMIDO-PHENOL  $C_{12}H_{10}NO$  i.e.  $C_6H_4NH_2C_6H_4OH$ . (c. 373° cor.). Formed from resorcin, *o*-toluidine, and  $CaCl_2$  at 270° (Philip, *J. pr.* [2] 84, 70). Oil. Reduced by hot zinc-dust to hydro-acridine and acridine.

*Formyl derivative*. [169°]. Tables.

*o*-Tolyl-*p*-amido-phenol  $C_6H_4NH_2C_6H_4OH$ . [90°]. (367° cor.). Formed from hydroquinone, *o*-toluidine and  $CaCl_2$  at 240° (Philip, *J. pr.* [2] 84, 57). White laminae (from light petroleum). Reduced by distilling with zinc to hydro-acridine and acridine. Converted by heating with conc. HCl into hydroquinone and *o*-toluidine.

Salt.— $B'HCl$ : crystalline powder.

*Mono-formyl derivative* [136–5°].

*Di-acetyl derivative* [106°]: needles.

*Di-benzoyl derivative*. [171°].

*p*-Tolyl-*m*-amido-phenol  $C_{12}H_{10}NO$  i.e.  $C_6H_4NH_2C_6H_4OH$ . [92°]. (350° cor.). From resorcin, *p*-toluidine and  $CaCl_2$  at 260° for 8 hours (Hatschek a. Zega, *J. pr.* [2] 83, 269). Prisms or needles (from benzene mixed with petroleum ether). Distilled over zinc-dust, it gives  $C_6H_5NHPH$ .

Salts.— $B'HCl$ ; decomposed by water.

*Formyl derivative*.—

$C_6H_4N(CHO)C_6H_4OH$ . [146°]. V. sol. ether.

*Di-benzoyl derivative*.—

$C_6H_4NBzC_6H_4OBz$ . [c. 105°]. Gives with fuming  $HNO_3$  a di-nitro-derivative. [110°].

*Nitrosamine*.— $C_6H_4N(NO)C_6H_4OH$ . *Oxy-phenyl-tolyl-nitrosamine*. [103°]. Yellow needles (from dil. alcohol).

*p*-Tolyl-*p*-amido-phenol  $C_6H_4NH_2C_6H_4OH$ . [122°]. (350°–360°). From hydroquinone, *p*-toluidine, and  $CaCl_2$  8 hours at 260° (Hatschek a. Zega, *J. pr.* [2] 33, 224). Plates. Heated with zinc-dust it gives phenyl-*p*-tolyl-amine.

Salt.— $B'HCl$ . Powder, decomposed by Aq.

*Di-acetyl derivative*. [101°]. Tables.

*Di-benzoyl derivative*. [169°].

*Nitroso-derivative*  $C_6H_4N(NO)C_6H_4OH$  [180°]; needles. Very unstable.

*o*-TOLYL-*a*-AMIDO-PHENYL-ACETIC ACID

$NHC_6H_4CHPh.CO_2H$ . [148°]. Formed from *a*-bromo-phenyl-acetic acid and *o*-toluidine (Stöckenius, *J.* 1878, 781). Plates, almost insol. water.

*p*-Tolyl-*a*-amido-phenyl-acetic acid. Formed in like manner, using *p*-toluidine. Insol. water.

*Ethyl ether* EtA'. [90°]. Yellowish prisms.

*o*-TOLYL-AMIDO-TRI-PHENYL-METHANE

$CPh_3.NHC_6H_4$ . [142°]. Formed from  $CPh_3Br$  and *o*-toluidine (Wittich, *B.* 17, 705). Prisms (from ether).

*p*-Tolyl-amido-tri-phenyl-methane [177°]. Crystals (from ether).

*Nitrosamine*  $CPh_3.NC_6H_4.NO$ . [145°–148°].

*p*-TOLYL-AMIDO-DI-PHENYL-NAPHTHO-

QUINOXALINE. *Phenylchloride*

$C_6H_4 \begin{smallmatrix} C(NH.C_6H_4.Me) \\ C.N=CPh \end{smallmatrix} \begin{smallmatrix} C.N=CPh \\ C.NPhCl.CPh \end{smallmatrix}$

Got by heating  $C_{10}H_7(OEt) \begin{smallmatrix} C.N=CPh \\ C.NPhCl.CPh \end{smallmatrix}$  with *p*-toluidine at 120° (Witt a. Schmidt, *B.* 25, 2005). Bronzed plates, v. sol. alcohol, forming a crimson solution. Contr.  $H_2SO_4$  forms a slate-blue solution, becoming first blue and then violet on dilution.

TRI-*p*-TOLYL-TRI-AMIDO-DI-PHENYL-

TOLYL-CARBINOL  $C_{12}H_8N_6O$ . *Tri-tolyl-rosaniline*. The salts are formed by heating rosaniline salts with *p*-toluidine (Hofmann, *A.* 132, 290).— $C_{12}H_{18}N_6Cl$ . Small blue crystals (from alcohol), insol. water.

TOLYL-AMIDO-PIPIITZAHIC ACID.

*Toluido-PIPIITZAHIC ACID*.

*o*-TOLYL-*a*-AMIDO-PROPIONIC ACID

$CH_3.CH(NHC_6H_4).CO_2H$ . [116°]. Formed by saponification of the nitrile (Tiemann a. Stephan, *B.* 15, 2038; *C. C.* 1886, 470). Got also by boiling *o*-tolyl-amido-methyl-malonie acid with NaOH Aq (Gerson, *B.* 19, 2963). White crystals.

*Ethyl ether* EtA' [278°]. S.G. 1.047. Formed from *a*-bromo-propionic ether and *o*-toluidine (Bischoff a. Hausdörfer, *B.* 25, 2298).

*Acetyl derivative*  $C_6H_4NAc.CHMe.CO_2H$ . [177°]. Leaflets.

*Amide*. [125°]. Minute needles.

*Nitrile*  $CH_3.CH(NHC_6H_4).CN$ . [78°]. Formed by digesting the cyanhydrin of acetic aldehyde (lactonitrile) with *o*-toluidine.

*p*-Tolyl-*a*-amido-propionic acid. [153°]. Formed in like manner. Plates, sl. sol. water and ether. May be sublimed.

*Ethyl ether* EtA'. [35°]. Tables.

*Acetyl derivative* [166°].

*Amide*. [145°]. Needles, sol. hot Aq.

*Nitrile*. [82°]. Plates, sl. sol. hot Aq.

*p*-Tolyl-*B*-amido-propionic acid  $C_6H_4Me.NH.CH_2.CH.CO_2H$ . [86°]. Formed from *B*-iodo propionic acid and *p*-toluidine (Bischoff a. Mintz, *B.* 25, 2352). Pearly scales, v. e. sol. ether.

Reference. — DI-BROMO-TOLYL-AMIDO-PROPIONITRILE.

*o*-TOLYL-AMIDO-PYROTARTRIMIDE

$CH_2.CO—NH \begin{smallmatrix} C(NHC_6H_4).CO \\ C.NH \end{smallmatrix}$ . [181°]. Obtained by saponi-

Reaction of *o*-tolyl-amido-pyrotartramic ether, which is formed by the action of  $\text{H}_2\text{SO}_4$  upon the  $\alpha$ -cyano- $\alpha$ -*o*-toluidio-butyric ether (Schiller-Wechler, *B.* 18, 1050). White needles. V. sol. alcohol and benzene, sl. sol. ether and hot water, insol. cold water and ligroin. Has both acid and basic properties.

**DI-*p*-TOLYL-DI-AMIDO-SUCCINIC ACID**  
 $\text{CO}_2\text{H}.\text{CH}(\text{NH}_2\text{C}_6\text{H}_4)_2.\text{CH}(\text{NH}_2\text{C}_6\text{H}_4)_2.\text{CO}_2\text{H}$ . [c, 200°]. Formed, together with 'di-tolil succin',  $\text{C}_{12}\text{H}_{12}\text{N}_4\text{O}_8$  [228°], by boiling di-bromo-succinic acid with *p*-toluidine (Junglahn a. Reissert, *B.* 26, 1766). V. sol. alcohol, insol. water. Yields a di-nitroso-derivative [125°], and a di-acetyl derivative  $\text{C}_{22}\text{H}_{22}\text{N}_4\text{O}_8$  aq. which yields  $\text{CaA}''$  aq,  $\text{BaA}''$  aq, and anhydrides  $\text{C}_{22}\text{H}_{22}\text{N}_4\text{O}_8$  [232°], and  $\text{C}_{22}\text{H}_{22}\text{N}_4\text{O}_8$  [222°]. -  $\text{Na}_2\text{A}''$ . -  $\text{CaA}''$ . -  $\text{CuA}''$ .  
*Ethyl ether*  $\text{Et}_2\text{A}''$ . [169°]. Needles.

**DI-*p*-TOLYL-TRI-AMIDO-TOLUENE**  
 $\text{C}_{12}\text{H}_9\text{Me}(\text{NH}_2\text{C}_6\text{H}_4)_3(\text{NH})_2$  [1:2:5:4]. [166°]. Formed by reducing amido-toluquinone ditoluido with zinc dust and  $\text{HOAc}$  (Green, *C. J.* 63, 1403; cf. Barslowsky, *B.* 6, 1209). Plates (from dilute  $\text{HOAc}$ ). A very feeble base.

**DI-*p*-TOLYL-DI-AMIDO-TOLUQUINONE**  
 $\text{C}_{12}\text{H}_9\text{MeO}_2(\text{NH}_2\text{C}_6\text{H}_4)_2$  [1:2:5:4:6]. [178°]. Formed from azotoline,  $\text{MeOH}$ , and conc.  $\text{H}_2\text{SO}_4$  (Fischer a. Hepp, *A.* 262, 251). Brownish-red needles.

**DI-*p*-TOLYL-DI-AMIDO-TOLUQUINONE**  
 $\text{C}_{12}\text{H}_9\text{MeO}_2(\text{NH}_2\text{C}_6\text{H}_4)_2$  [1:2:5:4:6]. [241°]. Formed by boiling toluquinone with *p*-toluidine and alcohol (Fischer a. Hepp, *A.* 256, 259). Yellow needles.

**DI-*p*-TOLYL-DI-AMIDO-TOLUQUINONE** *p*-toluide  
 $\text{C}_{22}\text{H}_{22}\text{N}_4\text{O}_8$ . [191°]. Claret-red plates (Fischer a. Hepp, *B.* 21, 676).

**TOLYLAMINE** is **TOLUIDINE** (*q.v.*).  
**DI-*o*-TOLYL-AMINE**  $\text{NH}(\text{C}_6\text{H}_4)_2$  [1:2]. [312° i.v.], at 728 mm. (Graebe, *A.* 238, 363). Obtained, together with diphenylamine by heating *o*-toluidine with aniline hydrochloride at 280° (Girard a. Willm, *B.* [2] 25, 248). Formed also by heating *o*-cresol with  $\text{ZnBr}_2$ , ammonia, and  $\text{NH}_4\text{Cl}$  at 335° (Merz a. Müller, *B.* 20, 547). Oil.

**DI-*m*-TOLYL-AMINE**  $\text{NH}(\text{C}_6\text{H}_4)_2$ . [3:2:2°]. Formed in like manner (Cosack, *B.* 13, 1091; Merz a. Müller, *B.* 20, 549). Oil, volatile with steam. Sl. sol. acids, v. sol. alcohol.

**Acetyl derivative**  $\text{N}(\text{Ac})(\text{C}_6\text{H}_4)_2$ . [42°].

**Nitrosamine**  $(\text{C}_6\text{H}_4)_2\text{N}.\text{NO}$ . [103°].

**DI-*p*-TOLYL-AMINE**  $\text{NH}(\text{C}_6\text{H}_4)_2$ . [79°]. [3:3:1° i.v.], (Graebe, *A.* 238, 363). Formed by heating *p*-toluidine with its hydrochloride (Girard, *A.* 140, 346; Gerber, *B.* 6, 446). Formed also by heating *p*-cresol with  $\text{ZnCl}_2$ , ammonia, and  $\text{NH}_4\text{Cl}$  at 335° (Merz a. Müller, *B.* 20, 546). White needles. Its salts are decomposed by water.

**Nitrosamine**  $(\text{C}_6\text{H}_4)_2\text{N}.\text{NO}$ . [103°]. Yellow, trimetric crystals (Lehne, *B.* 13, 1514; Cosack).

**Acetyl derivative**  $(\text{C}_6\text{H}_4)_2\text{N}.\text{Ac}$ . [85°].

**Benzoyl derivative**  $(\text{C}_6\text{H}_4)_2\text{N}.\text{Bz}$ . [125°].

**References.**—Tetra-bromo- and Nitro- Di-

**TOLYL-AMINE.**  
**DI-*p*-TOLYL-ISOBUTYL-AMINE**  $\text{C}_{12}\text{H}_{17}\text{N}$  *i.e.*  $(\text{C}_6\text{H}_4)_2\text{N}.\text{C}_4\text{H}_9$ . (290°-300° at 15 mm.). Formed by heating di-*p*-tolyl-amine with isobutyl alcohol and  $\text{HCl}$  in sealed tubes (Girard, *B.* [2] 24, 120).

**TOLYL-ANILINE** v. **PHENYL-TOLUIDINE**.  
**VOL. IV.**

**TOLYL-ARSINE** v. **ARSENIC**.

**TOLYL-ARABINE**  $\text{C}_7\text{H}_7\text{N}_2$  *i.e.*  $\text{O}_2\text{H}_2\text{Me}.\text{N}.\text{C}(\text{C}_6\text{H}_4\text{NMe}_2)_2$ . Formed from auramine hydrochloride and *p*-toluidine (Fehrmann, *B.* 20, 2853). Decomposed by  $\text{H}_2\text{S}$  in alcoholic solution at 50° into  $\text{CS}(\text{C}_6\text{H}_4\text{NMe}_2)_2$  and *p*-toluidine. —  $\text{B}^{1/2}\text{H}_2\text{PtCl}_6$ . Red flakes, v. sl. sol. water.

**TOLYL-AZIMIDO-TOLUENE** v. **AZIMIDO-COMPOUNDS**.

**DI-*p*-TOLYL-TETRAZINE**  $\text{C}_{16}\text{H}_{16}\text{N}_4$  *i.e.*

$\text{C}_6\text{H}_4\text{Me}.\text{N} < \text{N}=\text{CH} > \text{N}.\text{C}_6\text{H}_4\text{Me}$ . [185°]. Mol. w. 269 (obs.). Formed by the action of chloroform and alcoholic potash on *p*-tolyl hydrazine (Ruhemann, *C. J.* 55, 218; 57, 51). Yellow plates (from hot alcohol). Yields a nitro-derivative  $\text{C}_{16}\text{H}_{16}(\text{NO}_2)_2\text{N}_4$  [144°].

**TOLYL-DISAZO** compounds v. **DISAZO-COMPOUNDS**.

**TOLYL BENZAMIDE** v. **Benzoyl derivative** of **TOLUIDINE**.

***p*-TOLYL-BENZAMIDINE**  $\text{C}_{12}\text{H}_{11}\text{N}_2$  *i.e.*

$\text{C}_6\text{H}_4\text{N}.\text{C}(\text{NH}_2\text{C}_6\text{H}_4)_2\text{NH}_2$ . [99°]. Formed from benzonitrile and toluidine hydrochloride (Bernthsen, *B.* 8, 1319; 9, 429). Forms a crystalline nitrate and oxalate.

**Di-*p*-tolyl-benzamidine**

$\text{C}_6\text{H}_4\text{N}.\text{C}(\text{NH}_2\text{C}_6\text{H}_4)_2\text{NH}_2$ . [131°]. Formed by the action of *p*-toluidine on benzonitrile, and on  $\omega$ -chloro-benzylidene-*p*-toluidine  $\text{C}_6\text{H}_4\text{N}:\text{CCl}.\text{C}_6\text{H}_4$  (Bernthsen; Just, *B.* 19, 981). May be sublimed.

**Reference.**—AMIDO-TOLYL-BENZAMIDINE.

***p*-TOLYL-BENZAMIDOXIM**  $\text{C}_{12}\text{H}_{11}\text{N}_3\text{O}$  *i.e.*

$\text{C}_6\text{H}_4\text{N}.\text{C}(\text{NOH})\text{NH}(\text{C}_6\text{H}_4)_2$ . [176°]. Formed by heating hydroxylamine hydrochloride with  $\text{C}_6\text{H}_4\text{N}.\text{CS}.\text{NH}(\text{C}_6\text{H}_4)_2$  and  $\text{Na}_2\text{CO}_3$  at 100° (H. Müller, *B.* 22, 2406). White needles, sl. sol. hot water. —  $\text{B}^1\text{HCl}$ : white needles, sl. sol. water.  $\text{ClCO}.\text{Et}$  converts it into  $\text{C}_6\text{H}_4\text{N}.\text{C} < \text{N} > \text{CO}$ . [163°].

**TOLYL-BENZENE** v. **METHYL-DIPHENYL**.

**Tri-*p*-tolyl-benzene**  $\text{C}_{21}\text{H}_{21}$  *i.e.*  $\text{C}_6\text{H}_4(\text{C}_6\text{H}_4)_3$ .

[171°]. Formed by passing dry  $\text{HCl}$  into *p*-tolyl methyl ketone for some days (Claus, *J. pr.* [2] 41, 402). Needles. Oxidised by  $\text{CrO}_3$  to  $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_3$ . Yields  $\text{C}_6\text{H}_4\text{Br}_3$  [212°].

***p*-TOLYL-BENZIMIDO PHENYL ETHER**

$\text{C}_6\text{H}_4\text{N}.\text{C}(\text{NH}_2\text{C}_6\text{H}_4)_2\text{OPh}$ . [120°]. Formed from  $\text{C}_6\text{H}_4\text{N}.\text{CCl}.\text{NC}_6\text{H}_4$  and  $\text{NaOPh}$  (Hantzsch, *B.* 26, 927).

***o*-TOLYL-BENZOIC ACID**

[1:3]  $\text{C}_6\text{H}_4\text{Me}.\text{C}_6\text{H}_4\text{CO}_2\text{H}$  [1:3]. [204°]. Formed by oxidation of [1:3]  $\text{C}_6\text{H}_4\text{Me}.\text{C}_6\text{H}_4\text{Me}$  [1:3] with dilute  $\text{HNO}_3$  (Perrier, *C. R.* 114, 484). Silky needles, sol. alcohol, m. sol. Aq.

***pp*-Tolyl-benzoic acid**

[1:4]  $\text{C}_6\text{H}_4\text{Me}.\text{C}_6\text{H}_4\text{CO}_2\text{H}$  [1:4]. [244°]. Formed by oxidation of *pp*-ditolyl by  $\text{CrO}_3$  and  $\text{HOAc}$  (Carmelley, *J.* 1877, 384). Sl. sol. hot water. —  $\text{AgA}''$ .

***op*-Tolyl-benzoic acid**. [180°]. Formed by oxidation of [1:2]  $\text{C}_6\text{H}_4\text{Me}.\text{C}_6\text{H}_4\text{Me}$  [1:4] (Carmelley, *C. J.* 37, 707). Insol. water, sol. hot alcohol.

**TOLYL-BENZYL-AMINE** v. **BENZYL-TOLUIDINE**.

***p*-TOLYL-BENZYL-ISOBUTYL-UREA**

$\text{O}_2\text{H}_2\text{N}.\text{N}.\text{O}$ . [41°]. Got from *p*-tolyl-benzyl-carbamic chloride and isobutylamine (Hamme-rich, *B.* 25, 1824). Crystals (from ligroin).

**p-TOLYL-BENZYL-CARBAMIC CHLORIDE**  $(C_6H_5Me)N(CH_2Ph).COCl$ . Formed from *p*-tolyl-benzyl-amine and  $COCl_2$  (Hammerich, *B.* 25, 1822). \*Oil.

**p-TOLYL-BENZYL-CARBINOL**  $C_{11}H_{13}O$  *i.e.*  $C_6H_5Me.CH(OH).CH_2Ph$ . [66°]. (above 360°). Formed by reducing *p*-tolyl benzyl ketone in alcoholic solution by Na (Mann, *B.* 14, 1646). Small concentric needles, sol. alcohol and ether.

**p-TOLYL-BENZYLENE-ACETAMIDINE**  $C_{16}H_{18}N_2$  *i.e.*  $C_6H_5 \begin{array}{c} \diagup CH_2.NC.H \\ \diagdown N = CMe \end{array}$ . [79°]. Formed by reduction of the acetyl derivative of *o*-nitro-benzyl-*p*-toluidine in acetic acid solution with tin and HCl (Lellmann a. Stöckel, *B.* 19, 1610). Small glistening plates. V. sol. alcohol, ether, and chloroform.

**p-TOLYL BENZYL KETONE**  $C_{11}H_{12}O$  *i.e.*  $C_6H_5Me.CO.CH_2Ph$ . [109°]. (above 360°). Formed by the action of  $AlCl_3$  on a mixture of phenyl-acetyl chloride and toluene (Mann, *B.* 14, 1646; Strassmann, *B.* 22, 1229). Plates, sol. alcohol and ether. Na added to its alcoholic solution forms the carbinol and an acid  $C_{10}H_{12}O_2$  [73°].

*Oxim* [131°]. Plates, insol. water.

**p-TOLYL BENZYL OXIDE**  $C_{11}H_{12}O$  *i.e.*  $[1:2] C_6H_5Me.O.CH_2Ph$ . (285°-290°). Oil (Staedel, *B.* 14, 899). Converted by  $HNO_3$  (S.G. 1:5) into a tri-nitro-derivative [145°].

**m-Tolyl benzyl oxide**. [43°]. (300°-305°). Tables (from alcohol), v. sol. ether.

**p-Tolyl benzyl oxide** [41°]. Formed from  $C_6H_5Me.OK$  and  $CH_2PhCl$  (Frische, *A.* 224, 154). Crystals. Converted by  $HNO_3$  (S.G. 1:5) into di-nitro-*p*-cresol [84°].

**TOLYL-BENZYL-ISOPHOSPHINE**  $C_{11}H_{12}P$  or  $C_6H_5P_2$  [187°]. An indifferent body formed by the action of zinc on a mixture of benzyl chloride and  $C_6H_5MePCl_2$  (Michaelis a. Gleichmann, *B.* 15, 1963).

**p-TOLYL BENZYL SULPHONE**  $C_{11}H_{12}Me.SO_2.CH_2Ph$ . [145°]. Formed by the action of benzyl chloride on sodium toluene *p*-sulphinate (Otto, *B.* 13, 1278). Needles, sol. hot alcohol.

**p-TOLYL-BENZYL-THIO-SEMICARBAZIDE**  $C_{11}H_{12}N_2S$ . [121°]. Formed from benzyl thiocarbimide and *p*-tolyl-hydrazine (Dixon, *C. J.* 61, 1022). Prisms, sl. sol. cold alcohol.

**o-TOLYL-BENZYL-THIO-UREA**  $C_{11}H_{12}N_2S$  *i.e.*  $C_6H_5MeNH.CO.SNHCH_2Ph$ . [139°]. Formed by boiling *o*-tolyl-thiocarbimide with benzylamine in alcohol (Dixon, *C. J.* 59, 556). Tufts of prisms, m. sol. hot alcohol.

**m-Tolyl-benzyl-thio-urea**. [114°]. Formed from benzyl-thiocarbimide and *m*-toluidine. Vitreous crystals, v. sl. sol. hot Aq.

**p-Tolyl-benzyl-thio-urea** [121°]. Crystals.

**p-TOLYL-BENZYL-UREA**  $CH_2Ph.NH.CO.NHC_6H_5Me$ . [181°]. Formed from *p*-tolyl cyanate and benzylamine (Kühn a. Henschel, *B.* 21, 506).

**p-Tolyl-di-benzyl-urea**  $C_{22}H_{24}N_2O$  *i.e.*  $(CH_2Ph)_2N.CO.NHC_6H_5Me$ . [169°]. Got from  $(CH_2Ph)_2N.COCl$  and *p*-toluidine (Hammerich, *B.* 25, 1820). Needles (from alcohol), insol. ether.

**p-Tolyl-di-benzyl-urea**  $C_{22}H_{24}N_2O$  *i.e.*  $CH_2Ph.N(C_6H_5Me).CO.NH.CH_2Ph$ . [85°]. Formed from tolyl-benzyl-carbamic chloride and benzylamine (H.). Prisms, v. sol. alcohol.

**Di-p-tolyl-benzyl-urea**  $C_{26}H_{28}N_2O$ . [115°].

Formed from *p*-tolyl-benzyl-carbamic chloride and *p*-toluidine. Needles, v. sol. hot alcohol.

**Di-p-tolyl-di-benzyl-urea**  $(CH_2PhN(C_6H_5Me))_2CO$ . [93°]. Got from *p*-tolyl-benzyl-carbamic chloride and *p*-tolyl-benzyl-amine. Crystalline, sol. alcohol.

**DI-p-TOLYL-BIURET**  $(C_6H_5MeNH.CO)_2NH$ . [c. 220°]. Formed from *p*-tolyl-urea and *p*-tolyl cyanate at 160° (Kühn a. Henschel, *B.* 21, 506). White needles (from alcohol).

**Tri-p-tolyl-biuret**  $(C_6H_5MeNH.CO)_3NC_6H_5Me$ . [156°]. Formed from di-*p*-tolyl-urea and *p*-tolyl cyanate.

**p-TOLYL-BORIC ACID**  $C_6H_5Me.B(OH)_2$ . [240°]. Formed by the action of water on boron-*p*-tolyl-dichloride (v. vol. i. p. 531). Needles, sol. hot water.  $HgCl_2$  gives a white pp. of  $C_6H_5HgCl$ .

**TOLYL-BROMO-ETHYLENE** *v.* **BROMO-TOLYL-ETHYLENE**.

**TOLYL BROMO-METHYL KETONE**  $C_6H_5Me.CO.CH_2Br$ . [55°]. Formed by the action of hot water on di-*exo*-bromo-*exo*-methyl-atrolactic acid (Böttiger, *B.* 14, 1598). Crystals, volatile with steam, sol. water and ether.

**p-TOLYL BROMO-METHYL SULPHONE**  $C_6H_5Me.SO_2.CH_2Br$ . [92°]. Formed by the action of bromine on an aqueous solution of  $C_6H_5SO_2.CH_2CO_2H$  (Otto, *J. pr.* [2] 40, 544). Formed also from  $C_6H_5SO_2Na$  and  $CH_2Br_2$ . Thin monoclinic needles, sol. hot alcohol.

**p-Tolyl di-bromo-methyl sulphone**  $C_6H_5Me.SO_2.CHBr_2$ . [117°]. Formed from tolyl-sulphono-acetic acid and Br (O.). Monoclinic prisms, v. sol. hot alcohol.

**TOLYL-BUTANE** *v.* **BUTYL-TOLUENE**. **m-TOLYL-BUTYLENE**  $C_{11}H_{14}Me.CH_2C_6H_5$ . (195°). Formed from  $C_6H_5Me.CH_2Cl$ , allyl iodide, and Na (Aronheim, *B.* 9, 1790). Oil. Yields a liquid dibromide.

**p-TOLYL-p-BUTYL-PHENYL-THIO-UREA**  $C_6H_5Me.NH.CS.NH.C_6H_5C_4H_9$ . [137°]. Formed from isobutyl-phenyl-amine and *p*-tolyl-thiocarbimide (Mainzer, *B.* 16, 2024). Plates, sol. alcohol and ether.

**DI-p-TOLYL-ISOBUTYL-UREA**  $C_{11}H_{14}N_2O$ . [119°]. Formed from  $(C_6H_5)_2N.COCl$  and isobutylamine (Hammerich, *B.* 25, 1822). Prisms, v. sol. alcohol and ether.

**m-TOLYL-ISOBUTYRIC ACID**  $C_6H_5Me.CH_2CHMe.CO_2H$ . [92°]. Formed by oxidation of *m*-isobutyl-toluene by dilute  $HNO_3$  (Kelbe, *B.* 16, 620). Needles (from ligroin).—AgA': pp.

**Reference.**—**NITRO-TOLYL-ISOBUTYRIC ACID**. **o-TOLYL-CARBAMIC ACID**  $C_6H_5NO_2$  *i.e.*  $C_6H_5Me.NH.CO_2H$ .

*Ethyl ether* EtA'. [42°] (O.); [46°] (L.). Formed from *o*-toluidine and  $ClCO_2Et$  (Cosack, *S.* 12, 1450; Neville a. Winther, *B.* 12, 2324). Formed also from  $C_6H_5Me.CCl.NCl$  and alcoholic potash (Lachmann, *B.* 12, 1349). Tables, sol. alcohol and benzene. Volatile with steam.

Yields *o*-tolyl cyanate on distilling with  $P_2O_5$ . **Isobutyl ether**  $C_6H_5A'$ . (275°-280°). Oil (Mylius, *B.* 5, 974). Partially decomposed on distillation into tolyl cyanate and isobutyl alcohol.

**Benzyl ether**  $CH_2PhA'$ . [84°]. Formed from *o*-tolyl cyanate and benzyl alcohol (Gattermann a. Cantaler, *B.* 25, 1097). Needles

**Phenyl ether PhA'.** [92°]. Formed by boiling di-*o*-tolyl-urea with di-phenyl carbonate for some hours (Eckenroth a. Rückel, *B.* 23, 699). Crystals (from ligroin).

***m*-Phenylene ether C<sub>6</sub>H<sub>4</sub>A'. [154°].** Formed by heating *o*-tolyl cyanate with resorcin at 120° (G. a. C.). Colourless plates.

***p*-Phenylene ether C<sub>6</sub>H<sub>4</sub>A'. [206-5°].** Formed by heating *o*-tolyl cyanate with hydroquinone at 150°.

***o*-Tolyl ether C<sub>6</sub>H<sub>4</sub>A'. [126°].** Formed from *o*-tolyl cyanate and *o*-cresol (G. a. C.). Needles.

**(*β*)-Naphthyl ether C<sub>10</sub>H<sub>7</sub>A'. [149°].** Formed by heating *o*-tolyl cyanate with (*β*)-naphthol at 160° (G. a. C.). Plates.

**Di-phenyl-ethylene ether C<sub>6</sub>H<sub>5</sub>PhA'. [234°].** Formed by heating *o*-tolyl cyanate with hydrobenzoin at 100° (Auwers, *B.* 21, 1778). Needles. An isomeric [163°] is obtained from isohydrobenzoin.

***m*-Tolyl-carbamic acid**

[1:3]C<sub>6</sub>H<sub>4</sub>Me.NH.CO.H.

**Ethyl ether C<sub>10</sub>H<sub>11</sub>NO<sub>2</sub>.** Prepared from *m*-toluidine and chloro-formic ether (Cosack, *B.* 13, 1090). Oil, v. sol. alcohol and ether.

***p*-Tolyl-carbamic acid**

[1:4]C<sub>6</sub>H<sub>4</sub>Me.NH.CO.H.

**Ethyl ether EtA'. [52°].** Formed from *p*-toluidine and ClCO<sub>2</sub>Et (Hofmann, *Pr.* 19, 108; *B.* 3, 656). Monoclinic prisms, v. sol. alcohol (Levin, *J.* 1882, 381).

**Phenyl ether PhA'. [115°].** Formed by distilling di-*p*-tolyl-urea with di-phenyl carbonate (Eckenroth a. Rückel, *B.* 23, 698). Needles (from hot ligroin).

**Di-*p*-tolyl-carbamic acid (C<sub>6</sub>H<sub>4</sub>)<sub>2</sub>N.CO<sub>2</sub>H.**

**Ethyl ether EtA'. [62°].** Formed from (C<sub>6</sub>H<sub>4</sub>)<sub>2</sub>N.COCl and NaOEt (Hammerich, *B.* 25, 1824). Large plates, v. sol. alcohol and ether.

**Chloride (C<sub>6</sub>H<sub>4</sub>Me)<sub>2</sub>N.COCl. [103°].**

Formed from COCl<sub>2</sub>, a solution of di-*p*-tolyl-amine in benzene, and conc. NaOH aq (Hammerich, *B.* 25, 1821). Needles (from alcohol), v. e. sol. ether. AgCy forms the compound (C<sub>6</sub>H<sub>4</sub>)<sub>2</sub>N.CO.CN(AgCy)<sub>2</sub> crystallising in needles which begin to melt at 103°.

***o*-TOLYL-CARBAMINE [1:2]C<sub>6</sub>H<sub>4</sub>Me.N:C.**

[184°]. S.G. 24° 968. Formed by the action of alcoholic potash on *o*-toluidine and chloroform (Nef, *A.* 270, 309). Oil, volatile with steam. When heated at 245° for 3 hours it changes to the isomeric *o*-toluic nitrile. Heated with S in CS<sub>2</sub> at 130° it yields *o*-tolyl thiocarbimide. H<sub>2</sub>S at 100° forms C<sub>6</sub>H<sub>4</sub>Me.NH.CHS [101°].

**Chloride C<sub>6</sub>H<sub>4</sub>Me.N:CCl<sub>2</sub>. (215°).** Formed by passing chlorine into a chloroform solution of the carbamine.

***p*-Tolyl-carbamine C<sub>6</sub>H<sub>4</sub>Me.N:C. (99° at 36 mm.).** Formed in like manner from *p*-toluidine (Nef). Oil.

**Chloride C<sub>6</sub>H<sub>4</sub>Me.N:CCl<sub>2</sub>. (226°).** Converted by *p*-toluidine into tri-*p*-tolyl-guanidine.

***o*-TOLYL-SEMI-CARBAZIDE C<sub>6</sub>H<sub>4</sub>N<sub>2</sub>O i.e. NH<sub>2</sub>.CO.N<sub>2</sub>H.C<sub>6</sub>H<sub>4</sub>. [160°].** Formed by heating *o*-tolyl-hydrazine with urea (Pinner, *B.* 21, 1219). Flat needles, m. sol. water.

***p*-Tolyl-semi-carbazide C<sub>6</sub>H<sub>4</sub>N<sub>2</sub>O. [158°].** Sl. sol. cold water. Reduces Fehling's solution.

**Di-*p*-tolyl-carbazide CO(NH.NHC<sub>6</sub>H<sub>4</sub>)<sub>2</sub>. [201°].** Formed from *p*-tolyl-hydrazine and

carbamic ether (Preund, *B.* 24, 4197). Tables, insol. water, v. sol. hot alcohol.

**TOLYL-CARBIMIDE v. TOLYL ISOCYANATE,** vol. ii. p. 816.

***o*-TOLYL-CARBINOL C<sub>6</sub>H<sub>4</sub>O i.e.**

[1:2]C<sub>6</sub>H<sub>4</sub>Me.CH<sub>2</sub>OH. *o*-Oxy-*o*-xylene. Mol. w. 122. [34°]. (223° i.v.). S.G. 19° 102. Sl. in the cold; 1:5 at 100°. Formed by boiling *o*-bromo-*o*-xylene with KOH aq (Colson, *Bl.* [2] 43, 8; *A. Ch.* [6] 6, 116). Formed also by reducing the aldehyde C<sub>6</sub>H<sub>4</sub>Me.CHO (Raymann, *Bl.* [2] 27, 498), by the action of HNO<sub>3</sub> on the amine C<sub>6</sub>H<sub>4</sub>Me.CH<sub>2</sub>NH<sub>2</sub> (Kröber, *B.* 23, 1028), and by reducing *o*-toluic amide in acid solution by sodium-amalgam (Hutchinson, *B.* 21, 174). Needles, v. sol. alcohol and ether, sol. hot water. Oxidised by alkaline KMnO<sub>4</sub> to *o*-toluic acid [103°].

***m*-Tolyl-carbinol [1:3]C<sub>6</sub>H<sub>4</sub>Me.CH<sub>2</sub>OH. (217°). S.G. 2° 1036 (C.); 12° 916° (R. a. W.). S. 5 in the cold. Formed by boiling the bromide C<sub>6</sub>H<sub>4</sub>Me.CH<sub>2</sub>Br with alkalis (C). Liquid, v. sol. alcohol and ether, sl. sol. cold water. Yields *m*-toluic acid [108°] on oxidation.**

**Phenyl ether C<sub>6</sub>H<sub>4</sub>CH<sub>2</sub>OEt. (202°) at 740 mm. S.G. 12° 93. Oil.**

**Acetyl derivative C<sub>6</sub>H<sub>4</sub>CH<sub>2</sub>OAco. (226°).** Formed from C<sub>6</sub>H<sub>4</sub>CH<sub>2</sub>Br and KOAc (Radziszewski a. Wispek, *B.* 15, 1747). Oil.

***p*-Tolyl-carbinol [1:4]C<sub>6</sub>H<sub>4</sub>Me.CH<sub>2</sub>OH. [59°]. (217°). Formed from *p*-toluic aldehyde and alcoholic potash (Cannizzaro, *C. R.* 54, 1225; *A.* 124, 255). Needles, sl. sol. cold water.**

**Ethyl ether C<sub>6</sub>H<sub>4</sub>CH<sub>2</sub>OEt. (203°) at 740 mm. S.G. 12° 93. Formed from *o*-bromo-*p*-xylene and alcoholic potash (Radziszewski a. Wispek, *B.* 15, 1745). Oil.**

**Di-*o*-tolyl-carbinol (C<sub>6</sub>H<sub>4</sub>Me)<sub>2</sub>CH.OH. [69°] (W.); [62°] (Ador a. Crafts, *B.* 10, 2175). Formed by reducing di-*o*-tolyl ketone with sodium-amalgam (Weller, *B.* 7, 1184). Needles (from alcohol), insol. water.**

**Reference.—OXY-TOLYL-CARBINOL.**

**TOLYL-CARBINYL-AMINE v. METHYL-BENZYL-AMINE.**

**DI-*p*-TOLYL-CARBINYL AMINE**

(C<sub>6</sub>H<sub>4</sub>)<sub>2</sub>CH.NH<sub>2</sub>. [93°]. Formed by reducing the oxim of di-*p*-tolyl ketone in alcoholic solution with sodium-amalgam and HOAc at 60° (Goldschmidt a. Stöcker, *B.* 24, 2798). Tables. —B'HC<sub>2</sub> [235°]. White needles.

**Acetyl derivative [159°].** Needles.

**•TOLYL-CARBINYL-UREA v. METHYL-BENZYL-UREA.**

**Di-*p*-tolyl-carbinyl-urea**

NH<sub>2</sub>.CO.NH.CH(C<sub>6</sub>H<sub>4</sub>)<sub>2</sub>. [152°]. Formed from the hydrochloride of the amine and KCyO (Goldschmidt, *B.* 24, 2799). Needles.

**DI-*p*-TOLYL-CARBONATE (C<sub>6</sub>H<sub>4</sub>O)<sub>2</sub>CO.**

[115°]. Formed, together with di-ethyl carbonate, by heating *p*-tolyl ethyl carbonate at 800° (Bender, *B.* 19, 2268). V. sl. sol. cold alcohol.

**DI-TOLYL DICARBOXYLIC ACID**

[3:4]C<sub>6</sub>H<sub>4</sub>Me(CO<sub>2</sub>H)<sub>2</sub>C<sub>6</sub>H<sub>4</sub>Me(CO<sub>2</sub>H) [1:3:4] [over 300°]. Formed by heating its nitrile with dilute H<sub>2</sub>SO<sub>4</sub> (Löwenherz, *B.* 25, 1086). Plates, insol. water, sl. sol. hot alcohol.

**Nitrile C<sub>6</sub>H<sub>4</sub>Me(CN)<sub>2</sub>. [190°].** Formed from di-amido-ditolyl by Sandmeyer's diazo-reaction. Needles, m. sol. cold alcohol.

**Reference.—OXY-DITOLYL DICARBOXYLIC ACID. TOLYL CHLORIDE v. *o*-CHLORO-XYLENE.**

**p-TOLYL CHLORO-BENZYL SULPHONE**

$C_6H_4Me.SO_2.CHCl.C_6H_5$ . [203°]. Formed by heating sodium toluene *p*-sulphinate with benzyldiene chloride (Otto, *J. pr.* [2] 40, 519). Needles (from HOAc).

**p-TOLYL CHLORO-ETHYL SULPHONE**

$[1:4]C_6H_4Me.SO_2.CHCl.CH_3$ . [48°]. Formed by boiling  $CH_3.CCl_2.CO_2Na$  (1 mol.) with  $C_6H_4SO_3Na$  (2 mols.) in aqueous solution. Formed also by heating ethyldiene chloride (2.5 g.) with sodium toluene *p*-sulphinate (4.5 g.) and alcohol at 150° (Otto, *J. pr.* [2] 40, 515, 534). Trimetric tables, v. sol. hot alcohol. Does not act upon  $C_6H_4SO_3Na$  even at 200°.

**p-Tolyl chloro-ethyl sulphone**

$C_6H_4Me.SO_2.CH_2.CH_2.Cl$ . [79°]. Formed from  $C_6H_4Me.SO_2.CH_2.CH_2.OH$  and  $PCl_5$  (Otto, *J. pr.* [2] 30, 357). Needles or plates, v. sol. hot alcohol.

**p-TOLYL CHLORO-METHYL SULPHONE**

$C_6H_4Me.SO_2.CH_2.Cl$ . [84°]. Formed by heating an aqueous solution of  $CHCl_2.CO_2Na$  (1 mol.) with  $C_6H_4SO_3Na$  (2 mols.) on the water-bath (Otto, *J. pr.* [2] 40, 528). Tables (from benzene), v. sol. hot alcohol.

**p-Tolyl di-chloro-methyl sulphone**

$C_6H_4Me.SO_2.CHCl_2$ . [114°]. Formed by passing chlorine into a warm aqueous solution of  $C_6H_4SO_3CH_2.CO_2H$  (Otto, *J. pr.* [2] 40, 544). Crystals, insol. water, v. sol. hot alcohol.

**TOLYL-CRESOL**

$C_6H_4Me.CH_2.C_6H_4.OH$ . (250°-255° at 10 mm.). Formed by heating *o*-chloro-xylene with phenol and zinc filings (Mazzara, *G.* 9, 421). Oil, sol. alcohol, ether, and alkalis. Not coloured by  $FeCl_3$ .

*Acetyl derivative* (250° at 9 mm.). Decomposed in moist air into HOAc and tolylcresol.

**p-TOLYL-CUMINYL-AMINE**

$C_6H_4Me.NH.CH_2.C_6H_4.N$  *i.e.*  $C_6H_4Me.NH.CH_2.C_6H_4.Br$ . [36°]. (above 200°). Formed by the reduction by sodium-amalgam of the product of the action of cuminal on *p*-toluidine (Uebel, *A.* 245, 293). Plates or prisms.— $B'HCl$ . Plates or needles, sl. sol. hot Aq.

**Nitrosamine**

$C_6H_4Me.N.NO$ . [67°]. Prisms. **p-TOLYL-CUMINYL-UREA**  $C_6H_4Me.N_2O$  *i.e.*  $C_6H_4Me.NH.CO.NHC_6H_4Me$ . [150°]. Formed from cuminyllamine and *p*-tolyl cyanate (Goldschmidt a. Gessner, *B.* 22, 928). Needles, v. sol. alcohol.

**p-TOLYL-CUMYLIDENE-AMINE**

$C_6H_4Me.N:CH.C_6H_4.Pr$ . [51°]. Formed from cuminaldehyde (cuminal) and *p*-toluidine in alcoholic solution (Uebel, *A.* 245, 292). Yellowish plates (from alcohol). Decomposed into the parent substances by heating with acids and alkalis.

**p-TOLYL-ψ-CUMYL-UREA**

$C_6H_4Me.NH.CO.NH.C_6H_4Me$ . [218°]. Formed from *ψ*-cumidine and *p*-tolyl cyanate (Goldschmidt a. Bardach, *B.* 25, 1361). Needles.

**o-TOLYL-CYANAMIDE**

$C_6H_4Me.NH.CN$ . [77°]. Formed by heating  $C_6H_4NH.CS.NH.OH$  or by the action of hydroxylamine on *o*-tolyl thiocarbimide (Tiemann, *B.* 22, 1940; Voltmer, *B.* 24, 881). Tables, v. sol. alcohol and KOH aq, m. sol. water.

**DI-o-TOLYL-CYANAMIDE**

$C_6H_4N_2$ . *i.e.*  $C(CN)_2H_4$ . *Carboditolymide*. (above 300°). Formed by heating the alkyl derivatives of di-*o*-tolyl-thio-urea (Will a. Bielschowski, *B.* 15,

1817). Amorphous, v. sol. benzene. Converted by dilute HCl aq into di-*o*-tolyl-urea.

**Di-p-tolyl-cyanamide**  $C_6H_4N_2SO$  or  $C(NC_6H_4)_2$ . [60°]. (above 230°). Formed by the action of HgO on a benzene solution of di-tolyl-thio-urea (Will, *B.* 14, 1488). Thick prisms, sol. benzene and ether. On heating with aniline it gives phenyl-di-tolyl-guanidine. Acids and alkalis convert it into di-*p*-tolyl-urea. On distillation it yields compounds melting at 49° to 60° and at 149° (Schall a. Paschkowetzky, *B.* 25, 2892). Phenyl-hydrazine at 190° forms  $C_{10}H_{10}N_4$  [163°], which crystallises from alcohol in plates, and yields  $B'AlCl$  and  $B'2H.PtCl_4$ . On heating with phenyl-hydrazine at 165° there is formed  $N.PH_2C(CN.C_6H_4)_2$  [138°], crystallising in pale-red needles, yielding  $B'2H.PtCl_4$  (Wessel, *B.* 21, 2274). Tolylene-*o*-diamine at 140° forms  $C_{12}H_{12}N_4$  [196°], which yields  $B'3HCl$  [143°] (Dahm a. Gasiorowski, *B.* 19, 3057).

**TOLYL CYANATE**

*v. CYANIC ACID.*

**TOLYL CYANIDE**

*v. Nitrile of TOLUIC ACID.*

**TOLYL-CYANURIC ACID**

*v. CYANIC ACIDS.*

**TOLYLENE ALCOHOL**

*v. DI-*o*-XYLYLENE.*

**TOLYLENE-DI-ALLYL-DI-THIO-DI-UREA**

$[1:2:3] C_6H_4Me(NH.CS.NHC_6H_4)_2$ . [152°].

Formed from *c*-tolylene-*o*-diamine and oil of mustard (Lellmann, *A.* 228, 246). Needles (from alcohol), decomposed on fusing into tolylene-thio-urea and di-allyl-thio-urea.

**Tolylene-di-allyl-di-thio-di-urea**

$[1:3:4] C_6H_4Me(NH.CS.NHC_6H_4)_2$ . [150°].

Formed from *i*-tolylene-*o*-diamine and oil of mustard (Lellmann, *A.* 221, 24). Decomposed by heat like the preceding isomeric; melting a second time at 210°-230°.

**Tolylene-di-allyl-di-thio-di-urea**

$[1:2:5] C_6H_4Me(NH.CS.NHC_6H_4)_2$ . [175°-5°].

Formed from tolylene-*p*-diamine and allyl thiocarbimide (Lellmann a. Wüthner, *A.* 228, 209). Plates or prisms, nearly insol. ether.

**Tolylene-di-allyl-di-thio-di-urea**

Formed from tolylene-*m*-*p*-diamine and allyl thiocarbimide. Prisms (from alcohol), insol. ether, v. sol. HOAc. Melts without decomposition.

**TOLYLENE-DI-AMIDO-DI-ACETIC ETHER**

$[1:2:4] C_6H_4Me(NH.CH_2.CO.Et)_2$ . [70°]. Formed from tolylene-*m*-diamine and chloro-acetic ether (Zimmermann a. Khyrim, *B.* 16, 516). Needles (from water).

**c-TOLYLENE-*o*-DIAMINE**

$C_6H_4N_2$  *i.e.*  $C_6H_4Me(NH_2)_2$ . [1:2:3]. Mol. w. 122. [62°].

(255°). Formed from  $C_6H_4Me(NH_2)(NO_2)$  [1:2:3] by reducing with Sn and HCl (Lellmann, *A.* 228, 243). Reddish crystals, smelling of acetamide. — $B'2HCl$ . Sol. water, ppd. by HCl.

**c-Tolylene-*m*-diamine**

$C_6H_4Me(NH_2)_2$ . [1:2:6].

[104°]. Formed by reduction of nitro-toluidine [32°], or of liquid di-nitro-toluene (Ullmann, *B.* 17, 1960). Prisms, sol. hot water. Gives a brown colour with nitrous acid.  $CrO_3$  and  $FeCl_3$  give a brown colour. — $B'HCl$ : crystals, v. e. sol. water.

**i-Tolylene-*m*-diamine**

$C_6H_4Me(NH_2)_2$ . [1:2:4].

[99°]. (c. 280°). Formed by reducing di-nitro-toluene (Hofmann, *Pr.* 11, 518) by reducing (4:1,2)-nitro-toluidine (Nölting a. Collin, *B.* 17, 268), and by the action of  $SnCl_2$  on amido-toluene-azo-amido-cresol (Graeff, *A.* 229, 348). Needles (from water), v. sol. alcohol, ether, and

hot water. Chloroformic ether,  $\text{ClCO.Et}$ , forms [1:2:4]  $\text{C}_6\text{H}_5\text{Me}(\text{NH}_2)(\text{NH.CO.Et})$  [91<sup>o</sup>], and chiefly  $\text{C}_6\text{H}_5\text{Me}(\text{NH.CO.Et})$ , [137<sup>o</sup>] (Schiff, A. 268, 314). Phenyl-thio-carbimide yields  $\text{CO.Et.NH.C}_6\text{H}_5\text{Me.NH.CS.NHPh}$  [155<sup>o</sup>]. Heated alone in the cold forms  $\text{C}_6\text{H}_5\text{N}_2(\text{C}_6\text{H}_5)_2$ , but when heated it yields an orange mass which forms a highly fluorescent solution (Schiff, A. Vanni, A. 253, 319). Benzoyl aldehyde forms  $\text{C}_6\text{H}_5(\text{N.C}_6\text{H}_5)_2$ , [122<sup>o</sup>-128<sup>o</sup>], while cinnamic aldehyde gives  $\text{C}_6\text{H}_5(\text{NC}_6\text{H}_5)_2$ , [162<sup>o</sup>] (Schiff, A. 140, 98; 239, 384).  $\text{Cl.CO.CO.Et}$  forms  $\text{C}_6\text{H}_5\text{Me}(\text{NH.CO.CO.Et})$  [e. 260<sup>o</sup>] and [1:2:4]  $\text{C}_6\text{H}_5\text{Me}(\text{NH}_2)(\text{NH.CO.CO.Et})$  [70<sup>o</sup>], which yields an acetyl derivative [192<sup>o</sup>]. Phenyl-thio-carbimide forms the compound  $\text{NHPh.CS.NH.C}_6\text{H}_5\text{Me.NH.CO.CO.Et}$  [155<sup>o</sup>] and  $\text{C}_6\text{H}_5\text{Me}(\text{NH.CO.CO.Et})_2$   $\text{NPh}$  [198<sup>o</sup>] (Schiff, A. 268, 307). Toluylene-n-diamine heated with citric acid at 125<sup>o</sup> forms  $\text{C}_6\text{H}_4\text{N}_2\text{O}_2$ , crystallising from boiling alcohol in minute octahedra, decomposing at about 187<sup>o</sup> (Schneider, B. 21, 665). Acetyl-acetone at 100<sup>o</sup> forms a syrup, which when heated with  $\text{H}_2\text{SO}_4$  yields  $\text{C}_6\text{H}_5\text{N}_2$  [191<sup>o</sup>] (Combes, C. R. 108, 1252).— $\text{B}^+\text{HCl}$ .— $\text{B}^+\text{2HCl}$ .— $\text{B}^+\text{2HBr}$ .— $\text{B}^+\text{H}_2\text{SO}_4$ , 2aq: prisms. S. 5-6 at 19-5 (Beilstein, A. Kuhlberg, A. 158, 351).— $\text{B}^+\text{H}_2\text{PtCl}_6$ .— $\text{B}^+\text{2HClS}$ . Prisms (Lussy, B. 7, 1265).

*o*-Acetyl derivative  
 $C_6H_4Me(NHAc)NH_2$  [1:2:1]. [140]. Formed from  $C_6H_4Me(NH_2)(NO_2)$  [107<sup>u</sup>] by acetylation and reduction (Wallach, A. 234, 350). Needles.  $-B^+H.PtCl_2$ .

*p*-Acetyl derivative  
 $C_6H_4Me(NH_2)(NHAc)$  {1:2:4}. [160°]. Formed by acetylating the diamine, and got also by reducing  $C_6H_4Me(NO_2)(NHAc)$  {1:2:4} (Tiemann, *B.* 3, 221; Wallach, *B.* 15, 2826, 2831). Long white needles.

*Di-acetyl derivative*  $C_6H_5Me(NHAc)_2$ , [224°]. Got by boiling the base with  $Ac_2O$  or  $HOAc$  (Koch, *A.* 153, 132; Tiemann, *B.* 3, 8; Ladenburg, *B.* 8, 1211). Needles.

*Benzoyl derivative*  
 $C_6H_5Me(NO_2)(NHIBz)$  [1:2:4]. [142°]. Got by  
 reducing  $C_6H_5Me(NO_2)(NHIBz)$  (Boll.) *B* 7 1505

*Di-benzoyl derivative* [224']. Tables, sol. sol. alcohol (Ruhemann, *B.* 14, 2656).

*Thiobenzoyl derivative*  
 $C_6H_5Me(NH_2)NH.CSPh$ . [197°] (Bernthsen &  
 Trompeter, *B.* 11, 1760).

**Phthalyl derivative**  
 $C_6H_5Me \langle \begin{smallmatrix} NH.CO \\ NH.CO \end{smallmatrix} \rangle C_6H_5$ . [192°]. Formed from the base and phthalic anhydride (Biedermann, *B.* 10, 1161). Needles, split up by dilute HCl into phthalic acid and a base  $C_{13}H_{11}N_2O_4$ .

*Di-phthalyl derivative*  
 $C_6H_5Me(NC_6H_4O_2)_2$ . [233°]. Crystals, insol.  
 water and alcohol.

**s-Tolylene-*m*-diamine**  $C_6H_4Me(NH_2)_2$  [1:3:5]. (284°). Formed by reducing *s*- $\alpha$ -nitro-toluene (Staedel, A. 217, 202). Syrup.— $B''H_2SO_4$ .— $B''H_2SnCl_4$ ; crystals,  $\frac{1}{2}$  sol. water.

**Tolylene-*p*-diamine**  $C_6H_4Me(NH_2)_2$  [1:2:5], [64°]. (274°). Formed by reducing (5,1,2)- and (2,1,5)-nitro-toluidines (Beilstein *A.* Kuhlberg, *A.* 158, 352; Fileti *A. Croda, G.* 18, 306), and  $C_6H_4Me.N_2.C_6H_4Me.NH_2$  [2:1:5] or [5:1:2]

(Nietzki, *B.* 10, 832, 1158). Plates (from benzene), v. sol. water, alcohol, and ether. Forms toluquinone on oxidation.  $\text{FeCl}_3$  added to a solution of polyene-*p*-diamine hydrochloride mixed with *o*-toluidine gives an intense green colour.— $\text{B}''\text{HCl}$ . Plates.— $\text{B}''\text{H}_2\text{SO}_4$ . S. 84 at  $11:5^\circ$

*Di-acetyl derivative*  $C_6H_5Me(NHAc)_2$ .  
[220]. Poisons (from dilute alcohol) (Nietzki,  
*B.* 10, 1157; 12, 2237).

**Tolylene-o-diamine**,  $C_6H_4Me(NH_2)_2$  [1:3:4], [88-5], (265°). • Formed by reducing (3,1,4)-nitro-*p*-toluidine (Beilstein a. Kuhlberg, A. 158, 351; Graeff, A. 229, 343). Plates, m. sol. cold water. Its aqueous solution quickly blackens when exposed to air.  $FeCl_3$  forms by oxidation  $C_{11}H_{10}N_2O$ , crystallising from wood spirit in brownish-red plates [247°] (O. Fischer a. Sieder, B. 23, 3802).

Reactions.—1. Benzoic aldehyde at 140° forms  $C_{21}H_{15}N_7$  or  $C_7H_5 \begin{smallmatrix} N(C_7H_7) \\ N \end{smallmatrix} \gg CPh$  [195.5°]

(fadesburg, B. 11, 591, 1656; Hinsberg, B. 19, 2026; 20, 1585), which yields B'Mel [209°], B'EtI [181°], and B'EtI<sub>2</sub> [125°], and is oxidized by KMnO<sub>4</sub> to an acid C<sub>21</sub>H<sub>17</sub>N<sub>3</sub>O<sub>2</sub> [254°].—2. *Purified hydrazide*, acting on the hydrochloride, forms C<sub>21</sub>H<sub>17</sub>N<sub>3</sub>O<sub>4</sub> [128.5°], which yields B'Mel [195.6°], B'Mel<sub>2</sub> [128°], and B'Mel<sub>3</sub> [109°].—3. *Acetic aldehyde* (2 mols.) added to a cold solution of the base (1 mol.) in glacial acetic acid forms  $\text{C}_6\text{H}_5 \cdot \overset{\text{NEt}}{\underset{\text{N}}{\text{C}}} \text{CO} \text{Me}$  (Hinsberg).—4. *Anisic aldehyde*

hydric, added to a dilute aqueous solution of tolylene-*o*-diamine hydrochloride containing a little alcohol, forms  $C_{11}H_{12}N_2O_3$  [152°-156°], which separates on addition of ammonia (1:1). -5. *Salicylic aldehyde* at 110° forms  $C_{11}H_{12}N_2O_3$  [108°-110°], and at 135° it forms azurine  $C_{12}H_{12}N_2O_3$  [250°-5°], which exhibits blue fluorescence in

alkaline solutions. -6. *Glucose* (2 mols.) added to an alcoholic solution of tolylene-*o*-diamine forms  $C_{10}H_8(N:C_6H_{12}O_6)_2$ , crystallising in satiny needles, v. sol. water [ $\alpha_D^{20}$  160], which gives a red colour

with  $\text{FeCl}_3$ . Glucose converts tolylene-*o*-diamine acetate into amorphous 'glycodiamidotoluene'  $\text{C}_{14}\text{H}_{18}\text{N}_2\text{O}_5$ , m. sol. water (Hinsberg, *B.* 20, 495; Griess a. Harrow, *B.* 20, 2209). Glucose  $\text{C}_6\text{H}_{12}\text{O}_6$  acts in aqueous solution on

phenylene-*o*-diamine, forming  $C_{12}H_{10}N_2O_4$  [c. 180°] (E. Fischer, *B.* 22, 93). —7. *Arabinose* forms  $C_{12}H_{10}N_2O_4$  [238°] (G. a. H.). —8. *Acrolein*

n boiling aqueous solution forms tolylene-*o*-diamine across on [185°] (Fischer a. Tafel, *B.* 22, 99). -- 9. *Formic aldehyde* forms  $C_{10}H_{12}N_4$  [222°] (Fischer a. Wreżinski, *B.* 25, 2713). -- 10. *Butyric aldehyde* forms tolylene-butenyl-diamine

$$\text{C}_7\text{H}_9 \leftarrow \text{N} \begin{array}{c} \text{NaI} \\ \bullet \end{array} \text{CPr} \text{ [158}^\circ\text{], and the compound}$$

20, 1590).—11. *Nitrous acid* or, better, *amyl nitrite* acting on a salt of *tolylene-o-diamine* forms *azimido-toluene*  $C_6H_4N_3$ ,  $[84^\circ]$  ( $323^\circ$ ), which is v. sol. alcohol and hot toluene (Zinke

Azimidazole-toluene forms the salts  $\text{C}_6\text{H}_5\text{N}_3\text{H}_2\text{Cl}$ ,  $\text{NaC}_6\text{H}_5\text{N}_3$ ,  $\text{Hg}(\text{C}_6\text{H}_5\text{N}_3)_2$  [235 $\gamma$ ], and  $\text{AcCl}$  converts azimidazole-toluene into

the ( $\beta$ )-acetyl derivative  $C_6H_4\langle\begin{smallmatrix} N \\ N \end{smallmatrix}\rangle NAc$  [94°], while the isomeric ( $\alpha$ )-acetyl derivative  $C_6H_4\langle\begin{smallmatrix} N \\ N \end{smallmatrix}\rangle N$  [182°] is formed by the action of nitrous acid on the acetyl derivative of tolylene- $\alpha$ -diamine.—12. Boiling chloro-acetic ether forms oxytoluinoxaline dihydride and a compound  $C_{10}H_{16}N_2O_4$  (?) [147°], whence  $HNO_3$  forms a compound [248°] (Hinsberg, A. 237, 365).—13. *Isatin* yields  $C_{10}H_{11}N_3$  [290°], sl. sol. alcohol (Hinsberg, A. 237, 344).—14. Equal mols. of tolylene- $\alpha$ -diamine and *acetoacetic ether* when gently warmed together eliminate  $H_2O$ , and form a condensation product  $C_{10}H_{14}N_2O_2$  [82°]; if this is heated at 100°–120° acetic ether is evolved, and a tolylene-ethenyl- $\alpha$ -diamine  $C_6H_4Me\langle\begin{smallmatrix} NH \\ N \end{smallmatrix}\rangle C_2CH_3$  is produced (Ladenburg a. Rügheimer, B. 12, 953; Witt, B. 19, 2977, 3299).—15. *Chloro-acetoacetic ether* forms  $C_6H_4(NH)CMe.CHCl.CO_2Et$  [110°], crystallising in needles (Autenrieth a. Hinsberg, B. 25, 606).—16. *Oxydehydroacetic acid* forms  $C_6H_4O(C_2H_4Me(NH_2))_2$  [147°] (Feist, B. 25, 325).—17. *o-Aldehydo-benzoic acid* in hot water forms  $q\ H_2Me\langle\begin{smallmatrix} N \\ NH \end{smallmatrix}\rangle C_6H_4.CO_2H$  [258°] (Bistrzycki, B. 23, 1043).—18. *Di-oxy-quinone* forms di-oxy-methyl-phenazine  $C_{10}H_{10}N_2O_2$  [c. 265°], which yields a di-acetyl derivative [160°].—19. *Opianic acid* gives, in alcoholic solution at 0°, the acid  $C_6H_4Me(NH)C.C_6H_4(OMe)_2.CO_2H$ , crystallising in needles, decomposing at 234° (Bistrzycki, B. 24, 627).—20. *Di-bromo-pyruvic acid* (1 mol.) forms, on boiling,  $C_6H_4\langle\begin{smallmatrix} N \\ N \end{smallmatrix}\rangle C.CHBr_2$  [235°].

**Salts.**— $B''HCl$ . Needles (Hübner, A. 209, 364).— $B''H_2SO_4$ , 1:1 aq. Scales. S. 9.29 at 19.5°.

— $B''H_2C_2O_4$ , aq (Hinsberg, B. 16, 1532). Compound with *pyrocatechin*  $B''C_6H_3O_7$  [78°]. Needles (from ligroin) (Merz, B. 19, 726).

Compound with cyanogen  $B''Cy_2$ , aq. [c. 244°]. Formed by passing cyanogen into an alcoholic solution of the base (Bladin, B. 18, 666). Crystals, m. sol. alcohol and ether. Converted by heating with water into  $NH_3$  and two isomeric compounds  $C_6H_4N_2O$ , one melting at 290°, the other beginning to decompose at 230°–240°.  $B''Cy_2$  yields the salts  $B''Cy_2.HCl$  1:1 aq.,  $B''Cy_2.2HCl$ ,  $B''Cy_2.H_2PtCl_6$  2aq, minute needles, ( $B''Cy_2$ ),  $H_2PtCl_6$  2aq, and  $B''Cy_2.H_2SO_4$ , aq; minute tables.

**p-Acetyl derivative**  
 $C_6H_4Me(NH_2)(NHAc)$  [1:3:4]. [131°]. Formed by reducing  $C_6H_4Me(NO_2)(NHAc)$  with iron and dilute  $HOAc$  (Boessneck, B. 19, 1757). Plates (from water). Converted by nitrous acid into acetyl-azimido-toluene. On distillation it yields tolylene-acetamidine  $C_6H_4Me\langle\begin{smallmatrix} N \\ NH \end{smallmatrix}\rangle OMe$  [203°] (Niemętowski, B. 25, 861).

**Di-acetyl derivative**  $C_6H_4Me(NAcH)_2$  [216°]. Formed by boiling the base with  $Ac_2O$  (Bistrzycki, B. 23, 1878). Thin prisms (from water). Yields  $HOAc$  and tolylene-acetamidine on distillation.

**Di-propionyl derivative**  
 $C_6H_4Me(NH.CO.Et)_2$  [133°]. Formed in like

manner (B.). Yields tolylene-propenyl-amine [166°] on distillation.

#### Benzoyl derivative

$C_6H_4Me(NH_2)(NHBz)$  [1:3:4]. [194°]. Formed by reduction of  $C_6H_4Me(NO_2)(NHBz)$  with tin and  $HCl$  aq (Hübner, A. 208, 314). Crystals, split up by distillation into water and tolylene-benzamidine [240°].

**Di-benzoyl derivative**  $C_6H_4Me(NHBz)_2$  [264°]. Got by shaking tolylene- $\alpha$ -diamine with  $BzCl$  and  $NaOHAq$  (Hinsberg, A. 254, 255), by the action of  $Bz_2O$  on the diamine (Bistrzycki, B. 23, 1879; 24, 631), and by the action of  $BzCl$  on the benzoyl derivative (Hübner, A. 208, 314). Needles (from  $HOAc$ ).

#### o-Chloro-benzoyl derivative

$C_6H_4Me(NH_2).NH.CO.C_6H_4Cl$  [153°] (Schreib, B. 13, 467). Converted by benzoyl chloride into  $C_6H_4Me(NHBz).NH.CO.C_6H_4Cl$  [178°].

#### Di-cinnamyl derivative

$C_6H_4Me(NH.CO.C_6H_5)_2$  [206°]. Formed from tolylene- $\alpha$ -diamine and cinnamic anhydride (B.). Groups of small needles (from dilute alcohol).

**Oxalyl derivative**  $C_6O_2(NH.C_6H_4Me.NH_2)_2$  [above 300°]. Obtained by the reduction of  $C_6O_2(NH.C_6H_4Me.NO_2)_2$  (Hinsberg, B. 15, 2691). Small needles (from alcohol-ligroin). On fusion it splits up into  $Aq$  and  $C_{10}H_8N_4$  [193°].—Salts.— $B''H_2Cl_2$ , aq.— $B''H_2PtCl_6$ .— $B''H_2SO_4$ , 5aq. Colourless needles.

#### Phthalyl derivatives.

The compounds  $C_6H_4Me.NH_2.C_6H_4O_2$  [104°] and  $C_6H_4Me(NC_6H_4O_2)_2$  [272°] are known (Biedermann, B. 10, 1165; Ladenburg, B. 10, 1125).

#### Benzene-sulphonyl derivative

$C_6H_4Me(NH_2).NH.SO_3Ph$ . The hydrochloride,  $B''HCl$ , is formed by the action of benzene sulphonic chloride on tolylene- $\alpha$ -diamine in benzene (Bistrzycki a. Cybulski, B. 24, 633; cf. Lellmann, A. 221, 18).

#### Phenyl-acetyl derivative

$C_6H_4Me(NH_2).NH.CO.CH_2Ph$  [195°]. Formed from tolylene- $\alpha$ -diamine and phenylacetyl chloride (B. a. C.). Needles, v. sol. hot alcohol.

#### Di-phenylacetyl derivative

$C_6H_4Me(NH.CO.CH_2Ph)_2$  [176°]. Needles, insol. ether, v. sol. hot alcohol.

**References.**—Bromo-, Chloro-, and Nitro-TOLYLENE-DIAMINE.

#### TOLYLENE-DIAMINE SULPHINIC ACID v.

DI-AMIDO-TOLUENE SULPHINIC ACID.

#### TOLYLENE- $\alpha$ -DIAMINE SULPHONIC ACID

$C_6H_4Me(NH_2)_2.SO_3H$  [1:2:3:5]. Formed by reducing nitro-toluidine sulphonic acid (Nietzki a. Pollini, B. 23, 139). Needles. Forms azines with  $\alpha$ -diketones.

#### c-Tolylene-m-diamine sulphonic acid

$C_6H_4N_2SO_3$ , i.e.  $C_6H_4Me(NH_2)_2SO_3H$  [1:2:6:4]. S. 107 at 14°. Formed from toluene *p*-sulphonic acid by nitration and reduction (Schwahrer, A. 166, 360; Marekwald, A. 274, 349). Prisms, not melted at 280°.— $BaA'$ , 4aq.— $HA'HCl$  2aq.— $HA'HBr$  2aq.— $HA'HNO_3$ , aq; needles, sl. sol. alcohol.—( $HA'$ ) $_2H_2SO_4$ , aq; plates.

#### Tolylene-m-diamine a sulphonic acid

$C_6H_4Me(NH_2)_2SO_3H$  [1:2:4:5]. S. 1054 at 10°. Got by reduction of  $C_6H_4Me(NO_2)(NH_2).SO_3H$  [1:2:4:5] with  $SnCl_2$  (Limpricht a. Foth, B. 18, 2185; A. 230, 309). Small prisms.— $KA'$ , aq.— $BaA'$ , 5 $\frac{1}{2}$ aq.— $HA'HCl$ , aq.— $HA'HBr$ , aq; prisms.

**Tolylene-*m* diamine sulphonic acid**  
 $C_6H_4Me(NH_2)_2 \cdot SO_3H$  [1:2:4:2]. Formed from tolylene-*m*-diamine and fuming  $H_2SO_4$  (Wiesinger, *B.* 7, 464). Small prisms. —  $NaA'$  4aq. —  $KA'$  aq. —  $MgA'$  5aq. —  $CaA'$  6½aq. —  $SrA'$  7aq. —  $BaA'$  6½aq. —  $MnA'$  3aq.

**TOYLENE-DIAMINE THIOSULPHONIC ACID** *v. vol.* i. p. 188.

**TOYLENE-BENZAMIDINE** *v.* BENZENYL-TOLYLENE-DIAMINE.

**TOYLENE-BENZENYL-DIAMINE** *v.* BENZENYL-TOLYLENE-DIAMINE.

***p*-TOYLENE-BENZYL-DIAMINE**  
 [1:2:5]  $C_6H_4Me(NH_2)_2 \cdot NHCH_2Ph$ . Got by reducing *p*-nitroso-benzyl-*o*-toluidine by alcoholic ammonium sulphide (Boeddinghaus, *A.* 263, 809). —  $B''^2HCl$ . Needles, sl. sol. alcohol.

**TOYLENE BLUE**  $C_{15}H_{11}N_3HCl$ . Formed by mixing solutions of nitroso-dimethyl-aniline hydrochloride and (1,2,4)-tolylene-*m*-diamine (Witt, *C. J.* 35, 358; *B.* 12, 931). Prisms (containing aq) with coppery lustre, forming blue solutions in water and alcohol. Acids turn the solutions reddish-brown. Alkalis pp. the base as a tarry mass. Tin and  $HClAq$  reduce it to the leuco- base, which forms a deliquescent hydrochloride and crystalline  $(C_6H_4N_3)HSnCl_3$ . On boiling tolylene-blue with water for some time part is reduced to leuco-tolylene blue and part oxidised to tolylene red  $C_{15}H_{11}N_3$ . Tolylene blue heated in aqueous solution containing  $HOAc$  for 12 hours at  $40^\circ$  forms tolylene violet  $C_{15}H_{11}N_3$ , characterised by an insoluble sulphate. Hydrated tolylene-violet  $C_{15}H_{11}N_3$  aq is a scarlet powder which dissolves in alcohol and in ether, forming solutions with orange fluorescence.

**Tolylene red**

$[1^3] C_6H_4(NMe)_2 < \overset{N}{\underset{N}{\text{C}}} > C_6H_4Me(NH_2) [3:6:1]$   
 (Bernthsen a. Schweitzer, *A.* 236, 332; Andersen, *B.* 19, 2217). Orange-red needles (containing 4aq). Forms a red fluorescent solution in alcohol. Its neutral salts are red, its acid salts are blue. By elimination of  $NH_2$  by the diazo-reaction it is converted into di-methyl-amido-methyl-phenazine.

**Isomeride of tolylene red**

$[1^3] C_6H_4(NMe)_2 < \overset{N}{\underset{N}{\text{C}}} > C_6H_4Me(NH_2) [3:5:1]$   
 Formed from chloro-di-nitro-toluene and di-methyl-*p*-phenylene-diamine and reduction of the product (Witt, *B.* 25, 3008). Coppery needles, sol. warm water.

**TOYLENE-BUTENYL-DIAMINE** *v.* BUTENYL-TOLYLENE-DIAMINE.

**TOYLENE-DICARBAMIC ETHER** *v.* *i*-TOLYLENE-*m*-DIAMINE.

**TOYLENE DICYANATE**  $C_6H_4N_4O_2$  *i.e.* [1:2:4]  $C_6H_4Me(NCO)_2$ . [94°]. Formed from tolylene *m*-diamine and  $COCl_2$  (Snape, *C. J.* 43, 258). Needles, sol. ether. When heated with phenol at  $130^\circ$  it yields  $C_6H_4Me(NH.CO)_2Ph$ , [147-5°] crystallising in needles.

**TOYLENE-ETHENYL-DIAMINE**  $C_6H_4N_2$  *i.e.*  $C_6H_4Me < \overset{N}{\underset{NH}{\text{C}}} > CMe$ . [203°] (Niementowski, *B.* 25, 861). [350°] (Nölting a. Witt, *B.* 17, 81). Formed by boiling (1,3,4)-tolylene-*o*-diamine with  $HOAc$  (Ladenburg, *B.* 8, 677) by reducing the acetyl derivative of nitro-*p*-toluidine (Höbner, *B.* 5, 920), and by adding aldehyde to a

solution of tolylene-*o*-diamine in very dilute  $HOAc$  (Hinsberg, *B.* 20, 1589). Tables (from water). Forms with acetone and  $SO_2$  the compound  $(C_6H_4N_2C_2H_5O)_2SO_2$  (Boessneck, *B.* 21, 1909). —  $B''H.PiCl$ . —  $B''HNO_2$ .

**TOYLENE-ETHENYL-ETHYL-DIAMINE**

$C_{11}H_{11}N_2$  *i.e.*  $CMe:CH.CN \Rightarrow CMe$ . [166°]. Formed from [1:3:4]  $C_6H_4Me(NH_2)_2 \cdot NHEt$  and  $Ac_2O$  (O. Fischer, *B.* 26, 200).

**Tolylene-ethenyl-ethyl-diamine**

$CMe:CH.CN \Rightarrow CMe$ . [93°]. Got by ethylation of tolylene-ethenyl-diamine (Hübner, *A.* 210, 351). Formed also by the action of aldehyde (2 mols.) on tolylene-*o*-diamine (1 mol.) (Hinsberg, *B.* 20, 1585) and by heating  $C_6H_4Me(NO)_2NEtAc$  with zinc-dust and  $HOAc$  (Niementowski, *B.* 20, 1884). Needles (containing 3aq). Combines with ethyl iodide, forming  $B'EtI$  and  $B'EtI_2$  [111°], which yield  $B'EtOH$  and  $B'Et_2PiCl$ . Salts. —  $KHlAq$  [143°]. —  $B''HNO_2$  aq. [99°]. Melts at  $95^\circ$  when anhydrous. —  $B''C_2H_5N_2O$ . Crystals, sl. sol. alcohol.

**TOYLENE-ETHYL-DIAMINE**

$CMe:CH.CN \Rightarrow CMe$ . [55°]. Formed by reduction of nitro-ethyl-*p*-toluidine (Gattermann, *B.* 18, 1184; Fischer, *B.* 26, 199). White plates, quickly blackened by light and air. Rotates on water.

**Reactions.**—1. Bisulphide of carbon yields

$C_6H_4Me < \overset{N}{\underset{N}{\text{C}}} > CS_2$  [139°].—2.  $Ac_2O$  forms tolylene-ethenyl-ethyl-diamine [166°].—3. Benzoic aldehyde yields  $C_6H_4Me < \overset{N}{\underset{N}{\text{C}}} > CPh$ ; while *o*- and *p*-nitro- and *o*-oxy- benzoic aldehydes from corresponding bodies [170°], [176°], and [78°].

**Salts.**— $B''HCl$ . [176°]. —  $B''H_2C_2O_4$ . [151°].

**Tolylene-ethyl-diamine**

$C_6H_4Me(NH_2)_2 \cdot NH_2$  [1:2:5]. (264° cor.). Formed by reducing nitroso-ethyl-*o*-toluidine (Koch, *A.* 243, 307). Oil, *v.* sol. ether. —  $B''^2HCl$ . [124°]. Crystals, insol. ether.

**Tolylene-ethyl-diamine**

$C_6H_4Me(NH_2)_2 \cdot NH_2$  [1:2:4]. (282° uncor.). Formed by reduction of nitro-ethyl-*p*-toluidine (Nölting a. Stricker, *B.* 19, 549). Oil. Gives the reactions characteristic of *m*-diamines.

**Tolylene-di-ethyl-diamine**

$C_6H_4Me(NH_2)_2$  [1:3:4]. (265° uncor.). Oil (Hinsberg, *A.* 265, 191). Turns black in air.

**Tolylene-di-ethyl-diamine**

$C_6H_4Me(NH_2)_2 \cdot NH_2$  [1:2:5]. (240° i.v.). Formed by reducing nitro-di-ethyl-*o*-toluidine (Bernthsen, *B.* 25, 3138). Oil.  $FeCl_3$  slowly gives a purple colour in an aqueous solution of the sulphate.  $Na_2S_2O_3$  and  $K_2Cr_2O_7$  added to its solution in  $HOAc$  slowly ppt.  $SO_2H.S.C_6H_4Me(NH_2)_2 \cdot NH_2$  [210°-215°]. —  $B''H_2SO_4$ . Large colourless tables.

**DI-TOLYLENE-ETHYLENE-TETRA-AMINE**

*v.* ETHYLENE-DI-TOLYLENE-TETRA-AMINE.  
**TOYLENE-DI-ETHYL-DI-THIO-DI-UREA**  
 [1:3:4]  $MeC_6H_4(NH.CO.SNH_2)_2$ . [149°]. Got from ethyl mustard oil (5.6 g.) and tolylene-diamine (3 g.) in alcohol (15 c.c.) (Lellmann, *A.* 221, 23). *V.* sol. alcohol, more sol.  $HOAc$ , sl. sol. water. Decomposes when melted into tolylene-thio-urea,  $MeC_6H_4(NH)_2CS$ , and  $CS(NH_2)_2$ .

(1.2.4)-Isomeride [225°]. Formed from tolylene-di-thio-di-urea and EtI at 105° (Lussy, B. 8, 668). Crystals.

#### TOLYLENE-DI-ETHYL-DI-UREA

[1:2.4]  $C_6H_4Me(NH.CO.NHEt)_2$  [175°]. Formed by heating tolylene-urea with EtI at 110° (Lussy, B. 8, 292). Crystals, v. sol. alcohol and ether.

**TOLYLENE HYDRATE** v. PHENYL-BENZYL-CARBINOL.

#### DI-TOLYLENE KETONE OXIDE

[1.3]  $C_6H_4Me \begin{smallmatrix} O \\ \diagup \diagdown \\ CQ \end{smallmatrix} C_6H_4Me$  [3.1]. [166°].

Formed by heating oxytoluic acid with Ac<sub>2</sub>O (Weber, B. 25, 1745). White flakes, sol. alcohol and ether.

**TOLYLENE MERCAPTAN**  $C_6H_4Me(SH)_2$  [1:2.4]. *Dithiocresorcin.* [37°]. (263°) (Klason, B. 20, 355).

#### Di-tolylene mercaptan

$HS.C_6H_4Me.C_6H_4Me.SH$  [113°]. Formed from the diazo-compound of di-amido-o-ditolyl by combination with potassium xanthate at 70°–75° and saponification of the resulting oil with alcoholic potash (Leuckart, J. pr. [27] 41, 214). Yellowish plates, v. sol. alcohol and ether.

*Methyl ether* [118°]. Needles.

#### TOLYLENE METHENYL-AMIDINE $C_6H_4N_2$

i.e.  $C_6H_4Me \begin{smallmatrix} K \\ \diagup \diagdown \\ NH \end{smallmatrix} CH$ . [114°]. Formed by boiling from (1,3,4)-tolylene-diamine with formic acid (Ladenburg, B. 10, 1123; O. Fischer, B. 22, 644). —  $B^*H_2PtCl_6$ . Yellow prisms.

#### TOLYLENE-METHENYL-DIAMINE v.

METHENYL-TOLYLENE-DIAMINE and the preceding body.

#### TOLYLENE METHENYL-METHYL-DIAMINE

$C_6H_4N_2$  i.e.  $CMc:CH.C.N \begin{smallmatrix} CH \\ \diagup \diagdown \\ CH \end{smallmatrix} :CH.C.NMe \geq CH$ . [94°].

Formed by heating  $C_6H_4(NH_2).NHMe$  with formic acid (O. Fischer, B. 26, 195).

**Isomeride**  $CH:CH.C.N \begin{smallmatrix} CMc \\ \diagup \diagdown \\ CH \end{smallmatrix} :CH.C.NMe \geq CH$ . (279°).

Formed by heating tolylene-methenyl-amidine with MeI (O. Fischer, B. 22, 614). Formed also from (1,3,4)-tolylene-diamine and formic aldehyde (Fischer a. Wreszinski, B. 25, 2711). Oil. —  $B^*HI$  aq. —  $B^*HCl$ . Prisms (from  $HCl$  aq.).

#### TOLYLENE-METHYL-DIAMINE

[1:3.4]  $C_6H_4Me(NH_2).NHMe$ . [44°]. Formed by reducing nitro-methyl-*p*-toluidine (Gattermann, B. 18, 1487; O. Fischer, B. 26, 191). Formed also by heating methyl-*p*-amido-toluene- $\alpha$ -benzene sulphonic acid with  $SnCl_4$  and  $HCl$  aq. (Bamberger a. Wulz, B. 21, 2082). Four-sided tables.

**Reactions.** — 1. *Acetic anhydride* yields  $O_2H_4 \begin{smallmatrix} NH \\ \diagup \diagdown \\ NMe \end{smallmatrix} \geq CMc$  [142°]. — 2.  $CS_2$  reacts, forming,  $O_2H_4 \begin{smallmatrix} NH \\ \diagup \diagdown \\ NMe \end{smallmatrix} \geq CS$  [194°]. — 3. *Benzic aldehyde* forms  $C_6H_4 \begin{smallmatrix} N \\ \diagup \diagdown \\ NMe \end{smallmatrix} \geq CPh$  [127°], while *o*-nitro- and *o*-oxy-benzoic aldehyde form corresponding bodies [163°] and [180°].

**Salts.** —  $B^*HCl$ . [175°–180°]. Plates (from alcohol). —  $B^*H_2C_2O_4$ . [124°]. —  $B^*C_6H_5N_3O_7$ . [164°].

#### Tolylene-di-methyl-diamine

$C_6H_4Me(NMe_2)(NH_2)$  [1:5.2]. [28°]. (270°). Formed by reducing nitroso-di-methyl-*m*-toluidine (Wurster a. Riedel, B. 12, 1801; 13,

126). Needles or prisms; v. sol. water, alcohol, and ether. Yields toluquinone on oxidation.

**Acetyl derivative** [158°]. —  $B^*H_2PtCl_6$  4aq.

#### Tolylene-di-methyl-diamine

$C_6H_4Me(NMe_2)(NH_2)$  [1:2.5]. [47°]. (240° i.V.). Formed by reducing nitro-di-methyl-*o*-toluidine (Bernthsen, B. 25, 3134).  $FeCl_3$  gives an intense bluish-red colour in neutral solutions.  $Na_2S_2O_8$  and  $K_2Cr_2O_7$  added to the acetic acid solution ppt.  $C_6H_4Me(NMe_2)(NH_2).S.S.O_3H$  [c. 240°]. Salt. —  $B^*H_2SO_4$ . Needles, v. a. sol. water.

#### Tolylene-tetra-methyl-diamine

$C_6H_4Me(NMe_2)_2$  [1:2.5]. (c. 260°). Formed by heating the preceding body with  $MeOH$  and  $HCl$  at 180° (W. a. R.). Liquid. Coloured blue in aqueous solution by  $FeCl_3$ .

**Methylo-iodide**  $B^*MeI$ . [160°]. Needles.

#### Tolylene-tetra-methyl-diamine

$C_6H_4Me(NMe_2)_2$  [1:3.4]. (226°) at 717 mm. Got by methylation (Niementowski, B. 20, 1888). Liquid, v. sl. sol. water.  $FeCl_3$  at 40° to 50° gives a reddish-brown colour.  $HNO_3$  added to its solution in  $H_2SO_4$  gives a red colouration. —  $B^*H_2PtCl_6$  —  $B^*H_2HgCl_2$  —  $B^*C_6H_5N_3O_7$ . Yellow tables.

**Reference.** — NITRO-TOLYLENE-TETRA-METHYL-DIAMINE.

#### TOLYLENE-METHYL-ETHENYL-AMIDINE

$C_{10}H_{12}N_2$  i.e.  $CMc:CH.C.N \begin{smallmatrix} CH \\ \diagup \diagdown \\ CH \end{smallmatrix} :CH.C.NMe \geq CMc$ . [142°].

Formed, together with  $C_{10}H_{12}N_2O$  [163°], which crystallises with 2aq, by reducing the compound  $C_6H_4Me(NO_2).NMeAc$  (Niementowski, B. 20, 1878), and by acting on tolylene-methyl-diamine with  $Ac_2O$  (O. Fischer, B. 26, 196). Needles (from hot water). —  $B^*H_2PtCl_6$  (dried at 100°). [234°–244°]. —  $B^*HCl$  aq. —  $B^*MeI$ . [221°]. —  $B^*MeOH$ . [115°–135°].

#### TOLYLENE-TETRA-METHYL DI-PYRROLE

**TETRACARBOXYLIC ACID**  $C_{24}H_{22}N_4O_4$  i.e. [1:2.4]  $C_6H_4Me \begin{smallmatrix} N \\ \diagup \diagdown \\ CMc \end{smallmatrix} \begin{smallmatrix} N \\ \diagup \diagdown \\ CMc \end{smallmatrix} \begin{smallmatrix} N \\ \diagup \diagdown \\ CMc \end{smallmatrix} \begin{smallmatrix} N \\ \diagup \diagdown \\ CMc \end{smallmatrix} \begin{smallmatrix} CO_2H \\ \diagup \diagdown \\ CO_2H \end{smallmatrix}$ . [248°]. SL sol. hot alcohol and ether.

**Ethyl ether**  $Et_4A^+$ . Formed by heating di-acetyl-succinic ether with tolylene-*m*-diamine and  $HOAc$  at 150° (Knorr, A. 236, 314). Oil.

#### TOLYLENE-METHYL-THIO-UREA

$CMc:CH.C.NH \begin{smallmatrix} CH \\ \diagup \diagdown \\ CH \end{smallmatrix} :CH.C.NMe \geq CS$ . [194°]. Formed from  $C_6H_4(NH_2)(NHMe)$  and  $CS_2$  (Fischer, B. 26, 196). Needles (from alcohol).

#### TOLYLENE-DI-OXAMIC ACID $C_{11}H_{10}N_4O_4$ i.e.

$C_6H_4Me(NH.CO.CO.H)_2$  [1:2.4]. Formed, together with the amide, by the action of alcoholic  $NH_3$  on the ether. Crystalline. Very sweet. Decomposed by warm  $KOH$  aq into oxalic acid and tolylene-diamine. —  $Ag_2A^+$ . —  $PbA^+$ . —  $BaA^+$  2aq.

**Di-amide**  $C_6H_4Me(NH.CO.CONH_2)_2$  [1:2.4]. Formed from the ether and alcoholic ammonia (Schiff, A. 268, 33). White powder, m. sol. alcohol.

#### Ethyl ether [1:2.4]

$C_6H_4Me(NH.CO.CO.Et)_2$ . [130°]. Formed by boiling  $C_6H_4Me(NH_2).NH.CO.CO.Et$  with alcohol and oxalic ether (Schiff a. Vanni, A. 268, 340). Small needles (from ether).

#### Amide ether

$C_6H_4Me \begin{smallmatrix} NH.CO.CO.Et \\ \diagup \diagdown \\ NH.CO.CO.NH \end{smallmatrix} [1:2] [210°]$ . Formed from  $C_6H_4Me(NH_2).NH.CO.CO.NH_2$  by boiling

with alcohol and oxalic ether (Schiff, A. 268, 841).

*Amide ether*

$\text{C}_6\text{H}_4\text{Me} \langle \text{NH.CO.CONH}_2 \rangle_{[12]}^{[4]}$  [c. 220°]. Got by fusing  $\text{C}_6\text{H}_4\text{Me}(\text{NH}_2) \cdot \text{NH.CO.CO}_2\text{Et}$  with oxamic ether.

**TOLYLENE-OXAMIDE**  $\text{C}_6\text{H}_4\text{Me} \langle \text{NH} \rangle_{\text{NH}} \text{C}_6\text{O}_2$  [c. 260°]. Formed from (1,2,4)-tolylene-diamine and chloro-glyoxylic ether, and also by heating tolylene-diamine oxalate to 160° (Schiff a. Vanni, A. 268, 312).

**TOLYLENE-PENTENYL-DIAMINE**

$\text{C}_6\text{H}_4\text{Me} \langle \text{NH} \rangle_{\text{NH}} \text{C}_5\text{H}_9$  [110°]. Formed by reducing the valeryl derivative of nitro-*p*-toluidine (Friederici, B. 11, 1971; Hübnér, A. 209, 365). Prisms (from ligroin), v. c. sol. alcohol.

**TOLYLENE - DI - PHENYL - DI - AMIDO - METHYLENE-DIAMINE**  $\text{C}_{10}\text{H}_8\text{N}_4$ , i.e.

$\text{C}_6\text{H}_4\text{Me} \langle \text{NH} \rangle_{\text{NH}} \text{C}(\text{NPh})_2$  [161°]. Formed from  $\text{C}(\text{NPh})_2$  and (1,3,4)-tolylene-diamine at 130°-149° (Dahm a. Gasiorowski, B. 19, 3057). Needles (from benzene), v. sol. alcohol.— $\text{B}^+\text{HCl}$  [171°].— $\text{B}^+\text{H}_2\text{SO}_4$ . Plates, v. sol. water and alcohol.

**TOLYLENE-PROPENYL-DIAMINE**

$\text{C}_6\text{H}_4\text{Me} \langle \text{NH} \rangle_{\text{NH}} \text{C}_3\text{H}_5$  [166°]. Formed by distilling the dipropionyl derivative of tolylene-diamine (Bistrzycki, B. 23, 1872). Needles, m. sol. water, almost insol. ligroin.

**TOLYLENE RED v. TOLYLENE BLUE.**

**DI-TOLYLENE DISULPHIDE**

$\text{CMe}:\text{CH}(\text{C}_6\text{H}_4\text{Me})_2:\text{CH}:\text{CMe}$  [116°]. Formed by the action of heat at 200°-250° on tolylene diaz-sulphide  $\text{C}_6\text{H}_4\text{Me} \langle \text{N} \rangle_{\text{N}} \text{N}$  [43°], obtained from ethenyl-amido-tolyl mercaptan and  $\text{HNO}_2$  (Jacobsen a. Ney, B. 22, 911). Conc.  $\text{H}_2\text{SO}_4$  gives an intense blue colour.

**TOLYLENE - DI - THIO - DI - CARBAMIC ETHER** [1:3:4]  $\text{C}_6\text{H}_4\text{Me}(\text{N}:\text{C}(\text{SH})\text{OEt})_2$  [129°]. Formed by boiling tolylene-di-thiocarbimide with alcohol (Billeter a. Steiner, B. 20, 230). Plates (from benzene). Yields a yellowish-white silver salt.

**TOLYLENE - DI - THIOCARBIMIDE** [1:2:4]  $\text{C}_6\text{H}_4\text{Me}(\text{N}:\text{CS})_2$  [56°]. (c. 300°). Formed from tolylene-*m*-diamine and  $\text{CSCl}_2$ , and also by heating tolylene-di-thio-di-urea with conc.  $\text{HClAq}$  (Billeter a. Steiner, B. 18, 3292; 20, 230). Needles. Converted by  $\text{NH}_4\text{Aq}$  into tolylene-di-thio-di-urea [206°], by aniline into di-phenyl-tolylene-di-thio-di-urea [168°]. Copper at 250° produces  $\text{C}_6\text{H}_4\text{MeCy}_2$  [141°].

**Tolylene-di-thiocarbimide** [1:3:4]  $\text{C}_6\text{H}_4\text{Me}(\text{N}:\text{CS})_2$  [42°]. Formed from an aqueous solution of tolylene-*o*-diamine hydrochloride and  $\text{CSCl}_2$  in  $\text{CHCl}_3$  (B. a. S.). Plates. Converted by  $\text{HCl}$  at 200° into *o*-tolylene-thio-urea.

**TOLYLENE-DI-THIO-DIGLYCOLIC ACID**  $\text{C}_6\text{H}_4\text{Me}(\text{S}(\text{CH}_2\text{CO}_2\text{H}))_2$  [152°]. Formed from thio-*orein*  $\text{C}_6\text{H}_4\text{Me}(\text{SH})_2$  [35°], chloro-acetic acid, and  $\text{NaOH Aq}$  (Gabriel, B. 12, 1640). Needles, m. sol. hot Aq.

**TOLYLENE THIO-UREA**  $\text{C}_6\text{H}_4\text{Me} \langle \text{NH} \rangle_{\text{NH}} \text{CS}$ . Formed from  $\text{C}_6\text{H}_4\text{Me}(\text{NH}_2\text{HCl})$  [1:2:3] and

excess of  $\text{NH}_4\text{SCN}$  by boiling with water, evaporating, and heating to 120° (Lellmann, A. 228, 245). Small red crystals (from alcohol). Does not melt below 326°; may be sublimed. Insol. water, sl. sol. alcohol, dissolved by warm  $\text{NaOH}$ ; re-precip. by  $\text{HCl}$ . When boiled with lead acetate and excess of  $\text{NaOH}$ , no  $\text{PbS}$  is formed.

**Tolylene-thio-urea**  $\text{C}_6\text{H}_4\text{Me} \langle \text{NH} \rangle_{\text{NH}} \text{CS}$  [281°]. Formed by heating (1,3,4)-tolylene-*o*-diamine sulphocyanide at 130° (Lellmann, A. 221, 10). Formed also by the action of alcoholic  $\text{NH}_3$  on *o*-tolylene-di-thiocarbimide (Billeter a. Steiner, B. 20, 231). Silvery plates, sol. alcohol,  $\text{HOAc}$ , and cold  $\text{NaOH Aq}$ , sl. sol. water and  $\text{CHCl}_3$ .

***m*-Tolylene-thio-urea**  $\text{C}_6\text{H}_4\text{Me} \langle \text{NH} \rangle_{\text{NH}} \text{CS}$  [119°]. Formed from (1,2,4)-tolylene-diamine and alcoholic  $\text{CS}_2$  (Lassay, B. 8, 293). Crystalline powder, v. c. sol. alcohol.

***m*-Tolylene-di-thio-di-urea** [1:2:4]  $\text{C}_6\text{H}_4\text{Me}(\text{NH}:\text{CS}:\text{NH})_2$  [218°] (L.); [206°] (B. a. S.). Formed by heating tolylene-*m*-diamine sulphocyanide (Lassay, B. 7, 1265; Gebhardt, B. 17, 3046; Billeter a. Steiner, B. 18, 3293; 20, 228). Crystalline powder, insol. water and ether, nearly insol. alcohol, m. sol. hot  $\text{HOAc}$ .

**TOLYLENE-TOLENYL-AMIDINE**  $\text{C}_{11}\text{H}_{11}\text{N}_2$ , i.e.  $\text{C}_6\text{H}_4\text{Me} \langle \text{NH} \rangle_{\text{NH}} \text{C}(\text{C}_6\text{H}_4\text{Me})$ . Formed by reducing [1:4]  $\text{C}_6\text{H}_4\text{Me} \cdot \text{CO} \cdot \text{NH} \cdot \text{C}_6\text{H}_4(\text{NO}_2)\text{Me}$  [4:3:1] (Hübner, A. 210, 331). Needles, sl. sol. water.— $\text{B}^+\text{HCl}$ — $\text{B}^+\text{HNO}_3$ — $\text{B}^+\text{H}_2\text{SO}_4$ . Crystals, sl. sol. water.

**TOLYLENE - DI - *p*-TOLYL - DI - AMIDO - METHYLENE-DIAMINE**  $\text{C}_{12}\text{H}_{12}\text{N}_4$ , i.e.

$\text{C}_6\text{H}_4\text{Me} \langle \text{NH} \rangle_{\text{NH}} \text{C}(\text{NH}(\text{C}_6\text{H}_4\text{Me}))_2$  [196°]. Formed by heating  $\text{C}(\text{NC}_6\text{H}_4\text{Me})_2$  with (1,3,4)-tolylene-diamine (Dahm a. Gasiorowski, B. 19, 3059). Needles (from alcohol).— $\text{B}^+\text{HCl}$  [143°]. Deliquescent needles, v. sol. water.

**TOLYLENE-TOLYL-DIAMINE**  $\text{C}_{11}\text{H}_{11}\text{N}_2$ , i.e. [1:3:4]  $\text{C}_6\text{H}_4\text{Me}(\text{NH})_2\text{NH}(\text{C}_6\text{H}_4\text{Me})$  [1:4]. **Amido-di-*p*-tolyl-amine**. [109°]. Formed by reducing nitro-di-*p*-tolylamine (O. Fischer, B. 23, 8798; 26, 187). Prisms (from ligroin), turning brownish-red in air.  $\text{H}_2\text{SO}_4$  forms a blue solution changing to green.  $\text{FeCl}_3$  forms  $\text{C}_{11}\text{H}_{11}\text{N}_2\text{O}$  [188°] crystallising in red plates, yielding  $\text{B}^+\text{H}_2\text{PtCl}_6$ . Boiling with acetic anhydride and sodium acetate produces  $\text{C}_6\text{H}_5 \langle \text{N}(\text{C}_6\text{H}_5) \rangle_{\text{N}} \text{CMe}$  [95°], which forms  $\text{B}^+\text{H}_2\text{PtCl}_6$ . Benzoic aldehyde forms  $\text{C}_6\text{H}_5 \langle \text{N}(\text{C}_6\text{H}_5) \rangle_{\text{NH}} \text{CHPh}$  [166°], which yields  $(\text{C}_6\text{H}_5)_2\text{N}_2$ ,  $\text{B}^+\text{H}_2\text{PtCl}_6$ , and  $\text{C}_{11}\text{H}_{11}\text{N}_2\text{HAnCl}$ .  
• **Salts**.— $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$ . Nearly insol. cold Aq.— $\text{B}^+\text{C}_6\text{H}_5\text{N}_3\text{O}_6$ . Brownish-red crystals.  
• **Acetyl derivative** [126°]. Prisms.

**Tolylene-*p*-tolyl-diamine** [1:4:3]  $\text{C}_6\text{H}_4\text{Me}(\text{NH})_2\text{NH}(\text{C}_6\text{H}_4\text{Me})$  [1:4]. [107°]. Formed from toluene-azo-toluene or 2-di-*p*-tolyl-hydrazine (hydrazo-toluene) in alcoholic solution by the action of  $\text{SnCl}_2$  and  $\text{HCl}$  (Täuber, B. 25, 1022; cf. Melus, B. 8, 554; Goldschmidt, B. 11, 1626). Plates, v. c. sol. alcohol.  $\text{NaNO}_2$  colours its solution in  $\text{H}_2\text{SO}_4$  deep blue (?). Benzoic aldehyde reacts, forming

$C_6H_5 \cdot \begin{smallmatrix} N(C_6H_5) \\ | \\ N \end{smallmatrix} > OPh$  [165°] (cf. Lellmann, *B.* 15, 832). Benzil in alcohol and HCl forms  $C_6H_5 \cdot N_2O$  [173°]. Ethyl nitrite and  $H_2SO_4$  added to its alcoholic solution form the azimide  $C_6H_5 \cdot \begin{smallmatrix} N(C_6H_5) \\ | \\ N \end{smallmatrix} > N$  [93°]. On oxidation together with *p*-toluidine it forms the ditoluide of amido-tolquinone (Green, *C. J.* 63, 1408).

**Tolylene-di-*p*-tolyl-diamine**  $[1:2:5] C_6H_5Me(NHCH_2CH_3)_2$ . [113°]. Formed by heating hydrotolquinone (40 g.) with *p*-toluidine (160 g.) and  $ZnCl_2$  (80 g.) to 200°–280° for 5 hours (Green, *C. J.* 63, 1408). Plates, sol. HOAc, insol. water.

#### TOLYLENE-*p*-TOLYL-GUANIDINE

$C_6H_5Me \cdot \begin{smallmatrix} NH \\ | \\ NH \end{smallmatrix} > C \cdot NC_6H_5$ . [198°]. Formed from tolylene-*o*-diamine and  $C(NC_6H_5)_2$  (Keller, *B.* 24, 2518). Prisms (from alcohol), or tables (from benzene). Phenyl cyanate forms the compound

$C_6H_5 \cdot \begin{smallmatrix} N \\ | \\ N \end{smallmatrix} > C \cdot NC_6H_5 \cdot \begin{smallmatrix} CO \\ | \\ CO \end{smallmatrix} > NPh$  [233°], crystallising from hot alcohol in needles. —  $B^*HCl$ . —  $B^*H_2SO_4$ . —  $B^*H_2SO_4$ , 5aq. Needles, sl. sol. cold water.

**Acetyl derivative**  $C_6H_5 \cdot \begin{smallmatrix} NH \\ | \\ NH \end{smallmatrix} > C \cdot NC_6H_5$ . [149°]. Needles, v. sol. alcohol.

**Di-benzoyl derivative** [201°]. Needles. **Nitrosamine**  $C_6H_5 \cdot N_2 \cdot H(NO) \cdot C \cdot NC_6H_5$ . [c. 140°]. Decomposed on fusion.

#### TOLYLENE-*p*-TOLYL-THIO-UREA

$CH \cdot CH \cdot C(NC_6H_5)_2 > CS$ . [270°]. Formed from  $CMe \cdot CH \cdot C \cdot NH$  tolylene-tolyl diamine and  $CS_2$  in alcohol (Fischer a. Sieder, *B.* 23, 3799). Prisms, insol. water, sl. sol. ligroin. Conc.  $H_2SO_4$  forms a green solution.

#### TOLYLENE-UREA $C_6H_5 \cdot N_2O$ i.e.

$[1:3] C_6H_5Me \cdot \begin{smallmatrix} NH \\ | \\ NH \end{smallmatrix} > CO$ . [292°]. Formed by heating tolylene-*o*-diamine with urea and got also by the action of  $HClAq$  at 140° on  $C_6H_5Me \cdot \begin{smallmatrix} NH \\ | \\ N \end{smallmatrix} > COEt$  [163°], which is formed by the action of  $HN \cdot C(OEt)_2$  on tolylene-*o*-diamine hydrochloride (Sandmeyer, *B.* 19, 2651). Formed also by heating  $C_6H_5(NH_2) \cdot NH \cdot CO \cdot NPh_2$  (Lellmann a. Bonhöffer, *B.* 20, 2124) or the compound  $C_6H_5(NH_2) \cdot NH \cdot CO \cdot NHPh$  (Leuckart, *J. pr.* [2] 41, 324, who states that it melts above 300°), and by heating tolylene-*o*-diamine in benzene with  $COCl_2$  in toluene in sealed tubes at 100° (Hartmann, *B.* 23, 1048). Needles, q. sol. hot water. —  $B^*HCl$ : prisms.

**TOLYLENE-DI-UREA**  $C_6H_5 \cdot N_2O_2$  i.e.  $[1:3:4] C_6H_5Me(NH \cdot CO \cdot NH)_2$ . [282°]. Got from tolylene-diamine hydrochloride and potassium cyanate in aqueous solution (Lellmann, *A.* 22f, 14). Needles, sl. sol. water and chloroform, sol. alcohol and hot conc. HCl; v. sol. HOAc.

**Tolylene-di-urea**  $C_6H_5 \cdot N_2O_2$  i.e.  $[1:2:4] C_6H_5Me(NH \cdot CO \cdot NH)_2$ . [220°]. Formed from tolylene-*m*-diamine sulphate and  $KCyO$  (Strauss, *A.* 148, 157). Formed also from tolylene cyanate and ammonia (Lussy, *B.* 8, 291). Scales, sl. sol. alcohol and hot water. —  $B^*2HCl$ .

#### TOLYLENE-VIOLET v. TOLYLENE BLUE.

##### *s*-DI-TOLYL-ETHANE

$C_6H_5Me \cdot CH_2 \cdot CH_2 \cdot C_6H_5Me$ . (296°). Formed from

$C_6H_5Me \cdot CH_2Cl$  and sodium (Vollrath, *Z.* 1866, 489). Oil.

***u*-Di-*p*-tolyl-ethane**  $CH_3 \cdot CH(C_6H_5Me)_2$ . (295°).  $\delta_g$  2°–974. Formed by shaking paraldehyde with toluene and  $H_2SO_4$  at 0° (O. Fischer, *B.* 7, 1191). Formed also by heating di-*a*-tolyl-propionic acid with lime (Haiss, *B.* 15, 1476) and by the action of ethylidene chloride and  $AlCl_3$  on toluene (Anschütz, *B.* 18, 664; *A.* 235, 315). Oil. Yields tolyl-benzoic acid and di-tolyl ketone on oxidation.

***s*-*mp*-Di-tolyl-ethane**  $C_6H_5(C_6H_5)_2$ . (297°–300°). Formed from ethylene bromide, toluene, and  $AlCl_3$  (Friedel a. Balsohn, *Bl.* [2] 35, 52; *A. Ch.* [6] 1, 487). Yields isophthalic and terephthalic acids on oxidation.

**References.**—AMIDO-, CHLORO-, TRI-CHLORO-, DI-NITRO-, AND OXY-TOLYL-, ETHANES.

#### TOLYL ETHER v. DI-TOLYL OXIDE.

##### *o*-TOLYL-ETHYL ALCOHOL.

Heza

**hydride**  $CH_2 \cdot \begin{smallmatrix} CH_2 \cdot CHMe \\ | \\ CH_2 \cdot CH_2 \end{smallmatrix} > CH \cdot CHMe \cdot OH$ . (195°–200°). Formed, together with the tetrahydride  $CH_2 \cdot \begin{smallmatrix} CH_2 \cdot CMe \\ | \\ CH_2 \cdot CH_2 \end{smallmatrix} > C \cdot CHMe \cdot OH$  (142° at

50 mm.) by reducing  $C_6H_5Me \cdot CO \cdot CH_3$  in moist ethereal solution by sodium (Kipping a. Perkin, jun., *C. J.* 57, 22). Oil. Yields an acetyl derivative (201°–208°).

##### *p*-TOLYL-ETHYL-*m*-AMIDO-PHENOL.

**Ethyl derivative**  $C_6H_5 \cdot NH \cdot C_6H_4 \cdot OH$ . Formed from  $C_6H_5 \cdot NH \cdot C_6H_4 \cdot OH$ , potash, and  $EtI$  (Hatschek a. Zega, *J. pr.* [2] 33, 217). Oil.

***p*-Tolyl-ethyl-*p*-amido-phenol. Ethyl derivative**  $C_6H_5 \cdot NO \cdot i.e. C_6H_5 \cdot NH \cdot C_6H_4 \cdot OEt$ . (c. 340°). From  $C_6H_5 \cdot NH \cdot C_6H_4 \cdot OH$ , potash, and  $EtI$  (H. a. Z.). Oil.

##### TOLYL-ETHYL-AMINE v. ETHYL-TOLUIDINE.

**Di-tolyl-ethyl-amine**  $(C_6H_5Me) \cdot NH \cdot Et$ . (255°–260° at 20 mm.). Formed by heating di-*p*-tolyl-amine with  $EtOH$  and  $HCl$  at 250°–280° (Girard, *Bl.* [2] 24, 120). Oil.

***o*-TOLYL ETHYL CARBONATE**  $C_6H_5 \cdot H_2O_2$  i.e.  $[1:2] C_6H_5Me \cdot O \cdot CO \cdot OEt$ . (236°). Formed from sodium *o*-cresol and  $ClCO_2Et$  (Lender, *B.* 13, 700). Oil.

***m*-Tolyl ethyl carbonate**. (246°). Formed in like manner from *m*-cresol. Oil.

***p*-Tolyl ethyl carbonate**. (245°). Oil. By long heating at 300° it yields di-*p*-tolyl carbonate and di-ethyl carbonate (Bender, *B.* 19, 2268).

**DI-*p*-TOLYL-ETHYLENE**  $C_6H_5 \cdot H_2$  i.e.  $C_6H_5Me \cdot CH \cdot CH \cdot C_6H_5Me$ . **Di-methyl-stilbene**. [179°]. (above 300°). Formed by distilling  $(C_6H_5Me) \cdot CH \cdot CCl_3$  with zinc-dust (Goldschmidt a. Hepp, *B.* 6, 1504; Elbs a. Förster, *J. pr.* [2] 39, 300), and by heating di-*p*-tolyl fumarate,  $CO_2$  being evolved (Anschütz, *B.* 18, 1948). Plates, v. sol.  $CHCl_3$ . Yields a dibromide [204°].

***u*-Di-tolyl-ethylene**  $CH_2 \cdot C(C_6H_5Me)_2$ . (305°). Formed by the action of alcoholic potash on  $GH_2Cl \cdot CH(C_6H_5)_2$  (Hepp, *B.* 7, 1413). Oil. Yields di-tolyl-ketone [94°] on oxidation.

##### Tetra-tolyl-ethylene $C_6H_5 \cdot H_2$ i.e.

$(C_6H_5)_2C \cdot C(C_6H_5)_2$ . [215°]. A product of the action of chloroform and  $AlCl_3$  on toluene (Schwarz, *B.* 14, 1529). Plates, with greenish-yellow fluorescence, sol. benzene.

**References.**—BROMO- AND DI-CHLORO-TOLYL-ETHYLENE.

***o*-TOLYL-ETHYLENE-DIAMINE**

$C_8H_9NH_2.C_6H_4.NH_2$ . (c. 267°). Formed from *o*-tolylamido-ethyl-phthalimide and HCl (Newman, *B.* 24, 2194). Sol. water and alcohol.— $B''H_2Cl$ . [168°-178°].— $B''2C_6H_4N_2O_2$ . [148°]. Green needles.

*Di-benzoyl derivative* [164-5°]. Needles. *p*-Tolyl-ethylene-diamine. Formed in like manner (N.). Liquid.— $B''2HCl$ . [218°].— $B''H_2PtCl_6$ . Yellowish plates.

*Di-acetyl derivative* [107°]. Needles.

*Di-benzoyl derivative* [161°]. Cubes.

*Di-o-tolyl-ethylene-diamine*  $C_8H_9N_2$  i.e.  $C_8H_9NH_2.CH_2.CH_2.NH.C_6H_4$ . [71°]. S. 3 at 100°. S. (cold alcohol) 9. S. (ether) 14. Formed by the action of *o*-toluidine on ethylene bromide in presence of  $Na_2CO_3$  (Bischoff, *B.* 23, 1982, 2031; 25, 3257; cf. Mauthner a. Suida, *M.* 7, 230; Colson, *Dl.* [2] 48, 799). Plates (from ligroin), v. sol. alcohol. Yields indole on heating with zinc-dust.  $CH_3Cl.CO.H$  and  $NaOAc$  from di-tolyl-pyrazine hexahydride [151°].— $B''2HCl$ .— $B''H_2PtCl_6$ .— $B''H_2SO_4$  (dried at 100°).— $B''2HBr$ . [222°]. S. 3 at 100°.

*Acetyl derivative*  $C_8H_9(NAc.C_6H_4)_2$ . [153°].

*Bromo-acetyl derivative*  $C_8H_9(NG.C_6H_4.CO.CH_2Br)_2$ . [205°]. Sl. sol. cold HOAc and ligroin.

*Bromo-propionyl derivative*  $C_{22}H_{29}N_2Br_2O_2$ . [181°].

*Bromo-n-butyl derivative*  $(C_{24}H_{33}N_2Br_2O_2).C_6H_4$  (from benzene). [190°].

*Bromo-isobutyl derivatives*  $C_8H_9NH_2.C_6H_4.NC.H_2.CO.CBrMe_2$  [137°] and  $C_{11}H_{15}N_2Br_2O_2$ . [173°].

*Di-p-tolyl-ethylene-diamine* [97-5°]. Formed by heating *p*-toluidine with ethylene bromide at 150° (Gretflatt, *M.* S. [3] 3, 383; Bischoff, *B.* 25, 3260). Crystals, v. e. sol. alcohol.—Hydrobromide [255°].

*Acetyl derivative*  $C_8H_9(NAc.C_6H_4)_2$ . [139°].

*Bromo-acetyl derivative*  $C_{20}H_{27}N_2Br_2O_2$ . [196°].

*Bromo-propionyl derivative*. [182°].

*Bromo-n-butyl derivative*

$C_{24}H_{33}N_2Br_2O_2$ . [125°].

*Bromo-isobutyl derivative*

$C_{24}H_{33}N_2Br_2O_2$ . [175°].

*Di-o-tolyl-di-ethylene-diamine*  $C_{18}H_{22}N_2$ . [171°]. Formed, together with di-*o*-tolyl-ethylene-diamine, by heating *o*-toluidine with  $C_2H_5Br$  (M. a. S.). Needles, sl. sol. alcohol. Forms indole when distilled with zinc-dust.

*Di-p-tolyl-di-ethylene-diamine* [190°]. (360°). Formed by heating  $C_2H_5Cl.OH$  with *p*-toluidine at 220° (Wurtz, *A. Suppl.* 7, 94; Demole, *A.* 173, 138). Prisms, v. sl. sol. alcohol.— $B''H_2PtCl_6$ .

*Tri-p-tolyl-tri-ethylene-triamine*  $N_3(C_8H_9)(C_6H_4)_3$ . [186°]. Formed by heating *p*-toluidine with  $C_2H_5Br$  (G.). Needles, v. sl. sol. alcohol. Is perhaps identical with the preceding body. Its hydrochloride melts at 189°.

*Reference*.—NITRO-DI-TOLYL-ETHYLENE-DIAMINE.

***p*-TOLYL-ETHYLENE-ETHYL DIOXIDE**  $C_8H_9Me.O.CH_2.CH_2.OEt$ . (244°). Formed from  $C_8H_9.O.C_2H_5Br$  and alcoholic potash (Schreiber, *B.* 24, 195).

**DI-*p*-TOLYL-ETHYLENE DIKETONE**

$C_{18}H_{20}O_2$  i.e.  $C_6H_4(CO.C_6H_4Me)_2$ . *Di-tolyl-ethane*. [159°]. Formed by the action of succinyl chloride and AlCl<sub>3</sub> on toluene (Holleman, *R. T. C.* 6, 70; Claus, *B.* 20, 1877). Needles, v. sl. sol. cold alcohol, insol. alkalis. AcCl converts it into di-*p*-tolyl-furfurane  $C_{18}H_{16}O$  [164°]. Ammonium acetate and HOAc on boiling form di-*p*-tolyl-pyrole [197°].  $P_2S_5$  forms di-*p*-tolyl-thiophene [171°].

**DI-*p*-TOLYL-ETHYLENE-DI-METHYL-DIAMINE**  $C_{18}H_{24}N_2$  i.e.  $C_6H_4(NMe.C_6H_4Me)_2$ . [80°]. Formed by boiling its di-methyl-di-bromide with  $NH_3Aq$  (Hübner, *A.* 224, 337). Tables or prisms (from alcohol), v. sl. sol. water.— $B''H_2HgCl_2$ . [190°].— $B''H_2PtCl_6$ . Orange-yellow powder.

*Methyl-iodide*  $B''MeI$ . Needles. Decomposed at 100°. M. sol. hot water.

*Methyl-bromide*  $B''MeBr$ . Formed by heating di-methyl-*p*-toluidine with  $C_2H_5Br_2$  at 105° for some days. Yields  $B''Me_2HgCl_2$  [159°-162°],  $B''Me_2SnCl_4$ ,  $B''Me_2PtCl_6$ , and  $B''Me_2I_2.MeN_2O_2$ , [197°], which crystallises from alcohol.

**TOLYL ETHYLENE OXIDE v. ETHYLENE**

ETHER OF CRESOL.

**DI-*p*-TOLYL-ETHYLENE<sup>2</sup> DISULPHONE**

$(C_6H_4.SO_2)_2C_6H_4$ . [201°]. Made by boiling sodium toluene *p*-sulphinate with  $C_2H_5Br$  and alcohol (Otto, *J. pr.* [2] 30, 351; 40, 534). Got also by boiling the same salt with  $CH_3.CCl_3.CO_2Na$ . Needles or plates. Dilute KOHAq converts it into toluene sulphonic acid and  $C_6H_4.SO_2.C_6H_4.OH$  [55°], which yields  $C_6H_4.SO_2.C_6H_4.Cl$  [79°],  $C_6H_4.SO_2.C_6H_4.I$  [100°],  $C_6H_4.SO_2.C_6H_4.OBz$  [176°] and  $(C_6H_4.SO_2.C_6H_4)_3S$  [150°-160°]. Ammonia forms  $(C_6H_4.SO_2.C_6H_4)_3NH$ , which yields a hydrochloride [201°].

**DI-*p*-TOLYL-ETHYLENE-UREA**

$CH_3.N(C_6H_4)_2.CO$ . [228°]. Formed from di- $CH_3.N(C_6H_4)_2.CO$ . [228°]. Formed from di-*p*-tolyl-ethylene-diamine and  $COCl_2$  (Michelet a. Keller, *B.* 14, 2184). Needles.

***p*-TOLYL-DI-ETHYL-PHOSPHINE**

$C_6H_4.PEt_2$ . (210°). Formed from  $C_6H_5PCl_2$  and  $ZnEt_2$  (Czimatia, *B.* 15, 2016). Liquid.— $B''MeI$ . [187°].— $B''Me_2PtCl_6$ . Yellow plates.

***p*-TOLYL-ETHYL-SULPHONE**

$C_6H_4.SO_2.C_2H_5$ . [56°]. Formed by oxidation of  $C_6H_4.SET$  and by the action of  $EtBr$  on sodium toluene *p*-sulphinate (Otto, *B.* 13, 1276; 18, 161). Formed also by warming the acid  $C_6H_4.SO_2.CHMe.CO_2H$  with KOHAq. Trimetric plates;  $a:b:c = 526:1:721$ . Sol. alcohol and ether.

***p*-TOLYL-ETHYL-SULPHONE- $\alpha$ -CARBOXYLIC ACID**  $C_6H_4.SO_2.CHMe.CO_2H$ . *Tolyl-sulphono-propionic acid*. [37°]. Formed by heating  $C_6H_4.SO_2Na$  with  $CH_3.CBr.CO_2Et$  and alcohol at 150° and saponifying the product (Otto, *J. pr.* [2] 40, 555). Crystals (from alcohol), converted by Cl into  $CH_3.CHO.SO_2.C_6H_4$ .

**TOLYL-ETHYL-DISULPHOXIDE v. Ethyl ether of Toluene Thiosulphonous Acid.**

**TOLYL-ETHYL THIOBIURET**  $C_{11}H_{12}N_2S$ . [134°]. Formed from tolyl-thiobiuret, alcohol, aqueous  $NH_3$ , and  $EtI$  (Tursini, *B.* 17, 585). Needles (from alcohol).

***o*-TOLYL-ETHYL-THIOSEMICARBAZIDE**

$C_8H_9NH.NH.CO.SNH.Et$ . [180°]. Formed *o*-tolyl-

hydrazine and an alcoholic solution of ethylthiocarbimide (Dixon, *C. J.* 57, 262). Needles, v. sl. sol. cold water.  $\text{CuSO}_4$  colours its alcoholic solution deep blue.

#### TOLYL-ETHYL-DI-THIO-CARBONATES

$\text{CS}(\text{OEt})_2 \cdot \text{S} \cdot \text{C}_6\text{H}_4 \cdot \text{Me}$ . The *o*-, *m*-, and *p*-compounds formed by the action of potassium xanthate on cold solutions of *o*-, *m*-, and *p*-diazo-toluene chloride are oils (Leuckart, *J. pr.* [2] 41, 188). They are converted into tolyl mercaptans by boiling with alcoholic potash.

#### *o*-TOLYL-ETHYL-THIO-UREA

$\text{CS}(\text{NHEt})_2 \cdot \text{NHC}_6\text{H}_4 \cdot \text{Me}$ . [84°]. Formed from *o*-tolyl-thiocarbimide and ethylamine (Staats, *B.* 13, 136). Prisms, insol. water, sol. alcohol and ether.

*p*-Tolyl-ethyl-thio-urea [96°]. Formed in like manner (Weith, *B.* 8, 1530). Tables, v. sol. hot water.

*o*-Tolyl-di-ethyl-thio-urea  $\text{CS}(\text{NEt})_2 \cdot \text{NHC}_6\text{H}_4 \cdot \text{Me}$ . [102°]. Formed from *o*-tolyl-thiocarbimide and  $\text{NHEt}_2$  (Gebhardt, *B.* 17, 3038). Needles or prisms.

*p*-TOLYL-ETHYL-TOLUTRIAZINE. DIHYDRIDE  $\text{C}_{11}\text{H}_{11}\text{N}_3$ , i.e.  $\text{C}_6\text{H}_4\text{Me} \cdot \text{N} \cdot \text{CHEt} \cdot \text{N} \cdot \text{N} \cdot \text{C}_6\text{H}_4 \cdot \text{Me}$ .

[168°]. Formed by heating toluene-azo-toluidine with propionic aldehyde at 140° (Goldschmidt a. Poltzer, *B.* 24, 1009). Needles (from hot benzene). —  $3\text{HCl}$ . [96°]. — Platinochloride [221°]. Small yellow needles.

*p*-TOLYL-ETHYL-UREA  $\text{C}_{10}\text{H}_{11}\text{N}_2\text{O}$ , i.e.  $\text{NHC}_6\text{H}_4 \cdot \text{CO} \cdot \text{NHEt}$ . Formed from *p*-toluidine and ethyl cyanate (Sell, *A.* 126, 162). Crystals, insol. water, v. e. sol. alcohol.

DI-*o*-TOLYL-FORMAMIDINE  $\text{C}_{10}\text{H}_{11}\text{N}_2$ , i.e.  $\text{NHC}_6\text{H}_4 \cdot \text{CH} \cdot \text{NC}_6\text{H}_4$ . [151°]. Formed by boiling the formyl derivative of *o*-toluidine for a long time, or by heating it with *o*-toluidine and  $\text{PCl}_5$  (Ladenburg, *B.* 10, 1260). Formed also by distilling the thioformyl derivative of *o*-toluidine *in vacuo* (Senier, *C. J.* 47, 762). Prisms (from alcohol), insol. dilute  $\text{NaOH}$  aq. Yields crystalline  $\text{C}_{10}\text{H}_{11}\text{N}_2\text{Br}_2$  —  $\text{B}'\text{H}_2\text{PtCl}_6$ .

DI-*m*-tolyl-formamidine  $\text{NHC}_6\text{H}_4 \cdot \text{CH} \cdot \text{NC}_6\text{H}_4$ . [123°]. Formed by boiling *m*-toluidine with formic acid (Niemetowski, *B.* 20, 1893). Needles or plates, insol. water. Br in  $\text{CS}_2$  yields crystalline  $\text{NHC}_6\text{H}_4 \cdot \text{CHBr} \cdot \text{NBr} \cdot \text{C}_6\text{H}_4$  —  $\text{B}'\text{HCl}$ . [214°]. —  $\text{B}'\text{H}_2\text{PtCl}_6$  —  $\text{B}'\text{C}_6\text{H}_4\text{N}_2\text{O}$ . Yellow needles.

DI-*p*-tolyl-formamidine [141°]. Formed by distilling  $\text{C}_6\text{H}_5\text{NH} \cdot \text{CHS}$  *in vacuo* (Senier, *C. J.* 47, 767; *B.* 18, 2296). Prisms. —  $\text{B}'\text{H}_2\text{PtCl}_6$ .

DI-*p*-TOLYL-FURFURANE  $\text{C}_{18}\text{H}_{18}\text{O}$ , i.e.  $\text{CH} \cdot \text{C}(\text{C}_6\text{H}_4) \cdot \text{CH} \cdot \text{O}$ . [164°]. Formed by the action of  $\text{AcCl}$  on  $\text{C}_6\text{H}_5(\text{CO} \cdot \text{C}_6\text{H}_4)_2$  (Follemann, *R. T. C.* 6, 72). Small plates, converted by  $\text{P}_2\text{S}_5$  into di-tolyl-thiophene, and by ammonium acetate into di-tolyl-pyrrole.

*p*-TOLYL-GLYOXAL  $\text{C}_8\text{H}_7\text{Me} \cdot \text{CO} \cdot \text{CHO}$ . [102°]. Formed from the oxim by dissolving in aqueous  $\text{NaHSO}_3$ , stirring the crystalline mass with alcohol and a little  $\text{HOAc}$ , filtering, and boiling with dilute  $\text{H}_2\text{SO}_4$  (Müller a. Pechmann, *B.* 22, 3358). Needles (from hot water), v. sol. alcohol. Reduces cold ammoniacal  $\text{AgNO}_3$ , but not Fehling's solution. When shaken with benzene (containing thiophene) and  $\text{H}_2\text{SO}_4$  it colours the benzene green. Yields *p*-tolyl-glyoxylic acid and *p*-toluic acid on oxidation.

#### Phenyl hydrazide

$\text{C}_6\text{H}_5 \cdot \text{C}(\text{N} \cdot \text{HPh}) \cdot \text{CH}(\text{N} \cdot \text{HPh})$ . [145°]. Yellow needles (from dilute alcohol).

Oxim  $\text{C}_6\text{H}_5 \cdot \text{CO} \cdot \text{CH} \cdot \text{NOH}$ . Tolyl nitroso-methyl ketone. [100°]. Formed from tolyl methyl ketone, amyl nitrite and  $\text{NaOEt}$ . Needles (from benzene).

Acetyl derivative of the syn-oxim  $\text{C}_6\text{H}_5 \cdot \text{CO} \cdot \text{CH} \cdot \text{NOAc}$  [68°]. From the oxim and  $\text{Ac}_2\text{O}$  (Söderbaum, *B.* 25, 3461). Tables (from  $\text{MeOH}$ ). Cold  $\text{NaOH}$  aq splits it up into  $\text{NaCy}$  and *p*-toluic acid. Conc.  $\text{H}_2\text{SO}_4$  acts in like manner.  $\text{Ac}_2\text{O}$  at 100° forms  $\text{C}_6\text{H}_5 \cdot \text{CO} \cdot \text{CN}$  [52°], whence boiling  $\text{NaOH}$  aq forms *p*-toluic acid.

Acetyl derivative of the anti-oxim  $\text{C}_6\text{H}_5 \cdot \text{C}(\text{OH}) \cdot \text{CH} \cdot \text{NOAc}$ . [148°]. From the oxim and  $\text{AcCl}$  at 0°, followed by water. Cold  $\text{NaOH}$  aq forms  $\text{C}_6\text{H}_5 \cdot \text{CH}(\text{OH}) \cdot \text{CO} \cdot \text{H}$  [146°], v. sol. ether. Conc.  $\text{H}_2\text{SO}_4$  converts this acetyl anti-oxim into the oxim. Converted by  $\text{KCy}$  dissolved in dilute alcohol into *p*-tolyl-formoin  $\text{C}_6\text{H}_5 \cdot \text{CO} \cdot \text{CH}(\text{OH}) \cdot \text{CO} \cdot \text{CO} \cdot \text{C}_6\text{H}_5$  [161°] (Söderbaum, *B.* 25, 3473).

*p*-TOLYL-GLYOXALINE  $\text{C}_{10}\text{H}_9\text{N}$ , i.e.  $\text{C}_6\text{H}_5 \cdot \text{N} \cdot \text{CH} \cdot \text{C}(\text{SH}) \cdot \text{N}$ . (285°). Got by warming

$\text{C}_6\text{H}_5 \cdot \text{N} \cdot \text{CH} = \text{CH} \cdot \text{C}(\text{SH}) \cdot \text{N}$  with dilute  $\text{HNO}_3$  (Marckwald, *B.* 25, 2365). Pale-yellow crystals, sl. sol. water. Smells like mushrooms. —  $\text{B}'\text{H}_2\text{PtCl}_6$  —  $\text{B}'\text{AgNO}_3$  — Picrate. [179°]. Golden needles.

#### *p*-TOLYL-GLYOXALYL MERCAPTAN

$\text{C}_6\text{H}_5 \cdot \text{N} \cdot \text{CH} = \text{CH} \cdot \text{C}(\text{SH}) \cdot \text{N}$ . [205°]. Got by action of boiling  $\text{HCl}$  aq on the product of the action of amido-acetal on *p*-tolyl thiocarbimide (Marckwald, *B.* 25, 2363). Silvery leaflets, m. sol. hot water. Yields  $(\text{C}_6\text{H}_5\text{N} \cdot \text{N} \cdot \text{S})_2 \cdot \text{PtCl}_6$ . Mel in alcohol forms  $(\text{C}_6\text{H}_5\text{N} \cdot \text{MeN} \cdot \text{S})\text{HI}$  [95°], which yields the base  $\text{C}_6\text{H}_5 \cdot \text{N} \cdot \text{CH} = \text{CH} \cdot \text{C}(\text{SMe}) \cdot \text{N}$  [90°], which forms a picrate [140°].

*p*-TOLYL-GLYOXYLIC ACID  $\text{C}_8\text{H}_7\text{O}_3$ , i.e.  $\text{C}_6\text{H}_5 \cdot \text{Me} \cdot \text{CO} \cdot \text{CO}_2\text{H}$ . [97°]. Formed by the action of  $\text{AlCl}_3$  on a mixture of toluene and  $\text{Cl} \cdot \text{CO} \cdot \text{CO}_2\text{C}_6\text{H}_5$  (Roser, *B.* 14, 1750). Formed also by oxidising *p*-tolyl methyl ketone with cold alkaline  $\text{K}_2\text{FeC}_6$  (Buehka a. Irish, *B.* 20, 1762, 2213). Needles (from ligroin), sl. sol. hot water, v. sol. alcohol and ether. Yields *p*-toluic and terephthalic acids on oxidation. Benzene (containing thiophene) when shaken with tolyl-glyoxylic acid and  $\text{H}_2\text{SO}_4$  is turned red, and finally bluish-violet.

Salts. —  $\text{KA}'$ . —  $\text{NaA}'$  3aq (Claus a. Krosenberg, *B.* 20, 2018). —  $\text{BaA}'$ . —  $\text{BaA}'$  8aq. —  $\text{CaA}'$  2aq. —  $\text{AgA}'$ . Needles, v. sol. hot water.

Ethyl ether EtA'. (260°–270°).

Amide  $\text{C}_8\text{H}_7\text{NO}$ . [160°]. Prisms.

Phenyl hydrazide [144°].

DI-*o*-TOLYL-GUANIDINE  $\text{C}_{15}\text{H}_{15}\text{N}_3$ , i.e.

$\text{C}(\text{NH})(\text{NHC}_6\text{H}_4)_2$ . [179°]. Formed by the action of  $\text{NH}_3$ , lead acetate, and  $\text{KOH}$  aq on di-*o*-tolyl-thio-urea (Beyer, *B.* 12, 1855). Crystals, sol. ether. Cyanogen passed into its alcoholic solution forms the dicyanide  $\text{C}_6\text{H}_4 \cdot \text{N}_3$  [174°] which is converted by  $\text{HCl}$  into the oxaly derivative  $\text{C}_6\text{H}_4 \cdot \text{N}_3 \cdot \text{O}_2$  [207°], whence boiling with alcoholic  $\text{HCl}$  forms  $\text{CO} \cdot \text{N} \cdot \text{C}_6\text{H}_4 \cdot \text{CO}$  [214°].

The dicyanide is converted by boiling with an-

line into  $C_6H_5N_3$ , which yields crystalline  $B'HCl$  aq.— $B'_2H_2PtCl_6$ : yellow pp.

Di-*p*-tolyl-guanidine  $NH.C(NHC.H_5)_2$ . [168°]. Formed by passing cyanogen chloride into fused *p*-toluidine (W. Wilson, C. J. 8, 154; A. G. Perkin, C. J. 37, 696). Formed also by desulphuration of di-tolyl-thio-urea in presence of  $NH_3$  (Hofmann, B. 7, 1739). Needles (from ligroin). Nitric acid (S.G. 1.5) gives a di-nitro-derivative [197°], which forms crystalline  $B'HNO_3$ . Alcohol and  $HNO_3$  (S.G. 1.4) produce di-nitro-*p*-tolyl-urea. Cyanogen passed into its ethereal solution forms  $C_{12}H_{17}N_3Cy_2$ , crystallising from ether in prisms, converted by dilute  $HCl$  aq into  $NH.C \begin{smallmatrix} N(C_6H_5)_2.CO \\ N(C_6H_5)_2.CO \end{smallmatrix}$  [188.5°] (Landgrebe, B. 10, 1587). The cyanide is converted by boiling in alcoholic solution with aniline hydrochloride into  $C_{22}H_{21}N_3$  aq [110°–115°].—Salt  $B'_2H_2PtCl_6$ .

Tri-*o*-tolyl-guanidine  $C_{24}H_{23}N_3$ , i.e.  $C(NC_6H_5)(NHC.H_5)_3$ . [131°]. Formed by the action of *o*-toluidine in alcoholic solution in presence of lead oxide on di-*o*-tolyl-thio-urea (Berger, B. 12, 1857; cf. Girard, B. 6, 415). Formed also when di-*o*-tolyl-thio-urea is boiled for a long time (Barr, B. 19, 1769). Minute prisms. Yields a dicyanide  $C_{12}H_{11}N_3$  [141°], converted by conc.  $HCl$  aq in alcoholic solution into  $C_{22}H_{21}N_3O_2$  [179°].— $B'_2H_2PtCl_6$ : yellow prisms.

Tri-*p*-tolyl-guanidine  $C_{24}H_{23}N_3$ . [123°]. S. (alcohol) 7.4 at 0°. Formed by heating di-*p*-tolyl-thio-urea with copper (Merz a. Weith, Z. 1868, 610), or, in alcoholic solution, with *p*-toluidine and  $PbO$  (Hofmann, B. 2, 459). Got by heating *p*-toluidine with  $PCl_5$  and *p*-tolyl-cyanate (Weith, B. 9, 820). Formed also when di-*p*-tolyl-urea is boiled for a long time (Barr, B. 19, 1769), and likewise by the action of *p*-toluidine on the product of the action of chlorine on tolyl cyanate (Nef, A. 270, 322). Needles (from ligroin). Yields a dicyanide  $C_{12}H_{11}N_3$  [184°], which forms  $B'HCl$  aq and  $B'_2H_2PtCl_6$ , and is converted by boiling with alcoholic  $HCl$  into di-tolyl-parabanic acid.

Salts.— $B'HCl$  aq. S. 6 at 0°.— $B'_2H_2PtCl_6$ . S. 0.45 at 0°.— $B'HNO_3$ . S. 0.7 at 0°.— $B'_2H_2SO_4$ . Plates (from hot water). Neutral in reaction.

*p*-TOLYL HEPTADECYL KETONE [1.4] $C_{21}H_{42}Me.CO.C_{17}H_{35}$ . [67°]. (278° at 15 mm.). Formed from toluene, stearyl chloride, and  $AlCl_3$  (Kraft, B. 21, 2265). Oxidised by  $HNO_3$  (S.G. 1.12) to *p*-toluic acid.

*p*-TOLYL-HEXYL-TOLUTRIAZINE DI-HYDRIDE  $C_{21}H_{33}N_3$ , i.e.

$C_6H_5Me \begin{smallmatrix} N.C_6H_5.H_2 \\ N.N.C_6H_5.Me \end{smallmatrix}$  [165°]. Formed by heating  $\alpha$ -naphthol with toluene-*o*-azo-toluidine at 175° (Goldschmidt a. Poltzer, B. 24, 1010). Needles, sol. hot benzene.— $B'HCl$ . [96°].— $B'_2H_2PtCl_6$ . [171°]. Yellow crystalline pp.

*o*-TOLYL-HYDANTOIN  $C_{10}H_{11}N_3O_2$ . [176°]. Formed by heating *o*-tolyl-amido-acetic acid with urea at 180° (Ehrlich, B. 16, 742). Light-yellow plates, sol. alcohol and hot water. On boiling with baryta-water it gives *o*-tolyl-hydantoic acid, which, when set free from its salts, at once splits up into water and *o*-tolyl-hydantoin.

*p*-Tolyl-hydantoin  $C_{10}H_{11}N_3O_2$ , i.e.  $2O \begin{smallmatrix} NH \\ N(C_6H_5)_2.CO \end{smallmatrix}$ . [210°].

Formed, together with *p*-tolyl-hydantoic acid  $CO(NH_2).N(C_6H_5).CH_2.CO.H$ , by fusing *p*-tolyl-amido-acetic acid with urea (Schwebel, B. 11, 1128). Needles (from water), v. sol. alcohol. *p*-Tolyl-hydantoic acid is crystalline, sl. sol. hot alcohol and hot water.

Di-*o*-tolyl-hydantoin  $CO \begin{smallmatrix} N(C_6H_5)_2.CO \\ N(C_6H_5)_2.CH_2 \end{smallmatrix}$ . [275°]. Got from *o*-tolyl-amido-acetic toluidide and  $COCl_2$  (Bischoff, B. 25, 2275).

Di-*p*-tolyl-hydantoin  $CO \begin{smallmatrix} N(C_6H_5)_2.CO \\ N(C_6H_5)_2.CH_2 \end{smallmatrix}$ . [175°]. Formed from *p*-tolyl-amido-acetic toluidide and  $COCl_2$  (Bischoff, B. 25, 2280). Plates (from alcohol), sl. sol. ligroin.

TOLYL-HYDRAZIDO-METHYL-THIAZOLE DIHYDRIDE  $C_{11}Me.S \begin{smallmatrix} CH_2 \\ CH_2 \end{smallmatrix} N \begin{smallmatrix} C.NH.NHC.H_5 \\ C.NH.NHC.H_5 \end{smallmatrix}$ . Formed by heating tolyl-allyl-thio-semicarbazide with conc.  $HCl$  aq at 100° (Avenarius, B. 24, 270). The *p*-compound melts at 133°. Both the *o*- and the *p*-compounds form crystalline hydrochlorides.

$\alpha$ -TOLYL-HYDRAZIDO-PROPIONIC ACID  $C_6H_5Me.NH.NH.CHMe.CO.H$ . [143°]. Formed by the action of sodium-amalgam on the *o*-tolyl-hydrazide of pyruvic acid (Japp a. Klingemann, C. J. 53, 519). Small needles (from  $MeOH$ ).

*o*-TOLYL-HYDRAZINE  $C_{10}H_{11}N_3$ . [53°] (P.); [56°] (P.); [59°] (Gallinek a. Richter, B. 18, 3175). Prepared from *o*-toluidine in the same manner as phenyl-hydrazine is obtained from aniline (Fischer a. Böslar, A. 212, 338; Preund, B. 24, 4200). Glittering plates, slowly oxidised by air, forming a brown oil.— $B'HCl$  aq: needles.  $B'HNO_3$ : plates. With  $SOCl_2$  and ether it forms  $C_{10}H_{11}N_3.SO$ , a yellow oil smelling like geraniums (Michaelis, A. 270, 119). Glucose yields *o*-tolyl-glucoazone  $C_{20}H_{25}N_3O$  [201°] (Kaschen, A. 239, 229). Di-methyl diketone forms  $CH_3.C(N_2HC.H_5).C(N_2HC.H_5).CH_3$  [198°] (Japp a. Klingemann, A. 247, 221).

Formyl derivative  $C_{10}H_{11}Me.NH.NHCHO$ . [121°]. Formed from *o*-tolyl hydrazine and formamide. Needles (Gattermann, B. 25, 1078).

Acetyl derivative  $C_{10}H_{11}N_3.HAc$ . [104°]. Formed from *o*-tolyl-hydrazine and  $Ac_2O$  (G.).

Propionyl derivative  $C_{10}H_{11}N_3.H.C_2H_5O$ . [84°]. Formed from *o*-tolyl-hydrazine and propionic acid (G.). Colours: tables.

Benzoyl derivative  $C_{10}H_{11}N_3.HBz$ . [180°]. Got from the hydrazine and  $BzCl$  in  $Et_2O$  (G.). Needles. Gives off all its nitrogen in the free state on boiling with Fehling's solution (Strache a. Iritzer, M. 14, 38).

*m*-Tolyl-hydrazine  $C_{11}H_{13}N_3$ . [242°] (Buchka a. Schachtelbeck, B. 22, 841; cf. V. Meyer a. Lecoq, B. 16, 2976). Oil.— $B'HCl$ . Needles, v. sol. water and alcohol.

*p*-Tolyl-hydrazine  $C_{10}H_{11}N_3$ . [61°]. [242°]. Obtained from *p*-toluidine (Fischer, B. 8, 589; 9, 890). White plates (from ether), sl. sol. water.

Reactions.—1. With  $SOCl_2$  and ether it forms  $C_{10}H_{11}N_3.SO$  [112°], crystallising in yellow needles (Michaelis a. Kuhl, A. 270, 118).—2.  $C_6H_5.PCl_5$  forms  $C_{16}H_{19}N_3.PC_6H_5$  [162°], crystallising in prisms.—3.  $POCl_3$  forms  $C_{16}H_{19}N_3.PO$  [189°].—4. Acetone forms  $OMe_2(N_2HO.H_5)$  [52°].—5. Acetoacetic ether.

forms  $C_6H_5N_2O$ , [198°] (Knorr, B. 17, 550).—6. *Oxalic ether* forms  $NHC_6H_4NH.CO.CO.Et$ . [139°] (Preund, B. 24, 4198).—7. *Di-methyl diketone* yields  $CH_3C(NHC_6H_4)C(NHC_6H_4)CH_3$ , [280°], and  $CH_3C(NHC_6H_4)Ac$  [161°] (Japp, C. J. 53, 544).

Salt.— $B'C_6H_4PH_2O_2$ . [148°] (Michaelis, A. 270, 134).

Toluene-*p*-phosphinate  $P'C_6H_4PH_2O_2$ . [161°].

#### Formyl derivative

$C_6H_5Me.NH.NH.CHO$ . [164°]. Formed by heating the alcoholic solution of *p*-tolyl-hydrazine with chloroform and potash. Formed also by heating *p*-tolyl-hydrazine with formamide at 130° (Ruhemann, C. J. 55, 248). Plates (from water), v. sol. alcohol.

Acetyl derivative  $C_6H_5Me.NH.NH.Ac$ . [121°]. Formed from *p*-tolyl-hydrazine and  $AcOH$  (Gattermann, B. 25, 1080). Plates.

Propionyl derivative [170°]. Needles.

Dibenzoyl derivative [188°] (Fischer).

#### Di-*o*-tolyl-hydrazine.

Formyl derivative  $(C_6H_5)_2N.NH.NH.O$ . [139°]. Formed from  $C_6H_5NH.NH.CHO$  and  $CuSO_4$  (Gattermann, B. 25, 1073). Plates.

Acetyl derivative  $(C_6H_5)_2N.NH.NH.Ac$ . [191°]. Formed in like manner from acetyl-*o*-tolyl-hydrazine and  $CuSO_4$ . Needles.

Propionyl derivative [167°]. Needles.

Benzoyl derivative [209°]. Needles.

*u*-Di-*p*-tolyl-hydrazine  $(C_6H_5)_2N.NH.NH$ . [172°]. Formed by reduction of di-*o*-tolyl-nitrosamine with zinc-dust and  $HOAc$  (Lehne, B. 13, 1546). Plates, v. sol. alcohol and benzene.— $B'HCl$ .

Formyl derivative  $(C_6H_5)_2N.NH.NH.CHO$ . [146°]. Formed from formyl-*p*-tolyl-hydrazine and  $CuSO_4$  (Gattermann, B. 25, 1079). Plates.

Acetyl derivative. [170°]. Needles.

Propionyl derivative [171-5°]. Needles.

Benzoyl derivative. [187°]. Needles.

*s*-Di-*o*-tolyl-hydrazine  $C_6H_5NH.NHC_6H_4$ . *o*-Hydrazo-toluene. [165°] (P); [146°] (S). Formed by reduction of *o*-toluene-azo-toluene by sodium amalgam (Patrieff, B. 6, 557; Schultz, B. 17, 467). Converted into di-amido-ditolyl  $[3:4:1]C_6H_5Me(NH_2).C_6H_5Me(NH_2)$  [1:3:4] [123°] by heating with  $HCl$ . The di-amido-derivative  $C_6H_5(NH_2).NH.NH.C_6H_4(NH_2)$  [180°] is a product of the action of sodium-amalgam on nitro-*p*-toluidine (Buckney, B. 11, 1453).

*s*-Di-*m*-tolyl-hydrazine  $C_6H_5NH.NHC_6H_4$ . Formed by reducing *m*-toluene-azo-toluene by alcoholic ammonium sulphide (Goldschmidt, B. 11, 1626; Barsilowsky, A. 207, 116). Liquid, converted by  $H_2SO_4$  into di-amido-ditolyl.

*s*-Di-*p*-tolyl-hydrazine  $C_6H_5NH.NHC_6H_4$ . [126°]. Formed in like manner from *p*-toluene-azo-toluene (Melms, B. 3, 553) and by the action of zinc-dust and  $NaOHAq$  on *p*-nitro-toluene (Janovsky, M. 9, 829). Tables or needles, v. a. sol. alcohol. In alcoholic solution it is readily oxidised by air to  $C_6H_5N_2.C_6H_4$ . Dilute  $H_2SO_4$  converts it into toluidine and toluene-azo-toluene. On treatment in alcoholic solution with hydrochloric acid it changes to tolylene-tolyl-diamine. The di-amido-derivative  $[1:2:4]C_6H_5Me(NH_2).NH.NH.C_6H_5Me(NH_2)$  [4:1:2] obtained from  $C_6H_5Me(NH_2).N_2.C_6H_5Me(NH_2)$  by reducing with sodium-amalgam, is crystalline

and yields  $B'H_2SO_4$ ,  $B''2HCl$ ,  $B'''2HBr$ , and  $B''H.PtCl_5$  (Graef, A. 229, 852).

#### Reference.—OXY-TOLYL-HYDRAZINE.

#### *o*-TOLYL-HYDRAZINE SULPHONIC ACID

$C_6H_5Me(NH_2).SO_3H$  [1:2:4]. Formed by adding *o*-diazotoluene *p*-sulphonic acid to a cold solution of  $SnCl_2$  (Limpricht, B. 18, 2193). Colourless needles, v. sol. hot water, nearly insol. alcohol.— $KA'$  2aq: orange-red prisms.— $BaA'$ : yellow crystalline powder.

#### *o*-Tolyl-hydrazine sulphonic acid

$C_6H_5Me(NH_2).SO_3H$  [1:2:2]. Formed by heating *o*-tolyl-hydrazine (1 pt.) with conc.  $H_2SO_4$  (5 pts.) at 100° (Gallinek a. Richter, B. 18, 3175). Thin needles (containing 3aq). By boiling with aqueous  $CuSO_4$  it is quantitatively decomposed into a toluene sulphonic acid and nitrogen.— $NaA'$  3½aq.— $BaA'$  4aq.— $ZnA'$  3aq.— $PbA'$  6aq.— $PbA'$  (OH). Sparingly soluble needles.

#### *p*-Tolyl-hydrazine-*o*-sulphonic acid

$C_6H_5Me(NH_2).SO_3H$  [1:4:2]. [274°]. Formed by reducing *p*-diazotoluene *o*-sulphonic acid with  $Na_2SO_3$  (Brackett a. Hayes, Am. 9, 401) or  $HCl$  and  $SnCl_2$  (Pasche, B. 21, 3416). Tables, sl. sol. cold water. Decomposed by fusion. Not attacked by warm  $H_2SO_4$ .

#### *p*-Tolyl-hydrazine *m*-sulphonic acid

$C_6H_5Me(NH_2).SO_3H$  [1:3:4]. Obtained by reducing *p*-diazotoluene *m*-sulphonic acid by cooled  $SnCl_2$  (Limpricht, B. 18, 2193). Slender prisms, sol. hot water.  $FeCl_3$  evolves nitrogen in the cold. Conc.  $H_2SO_4$  at 80° forms a red amorphous substance (Schneider, Ann. 8, 271).

#### *p*-Tolyl-hydrazine disulphonic acid

$C_6H_5Me(NH_2)(SO_3H)_2$ . Formed by adding *p*-diazotoluene disulphonic acid to a cold solution of  $SnCl_2$  (Limpricht, B. 18, 2193). Nodules, v. sol. water.— $BaHA'$  2½aq: tables.

#### Di-*o*-tolyl-hydrazine disulphonic acid

$C_6H_5Me(SO_3H).NH.NH.C_6H_5Me(SO_3H)$ . A product of the reduction of the corresponding azo-compound by  $SnCl_2$  (Neale, A. 203, 72). Crystalline powder (containing 2½aq), sl. sol. water.— $BaA'$  5aq.— $CaA'$  3½aq: monoclinic efflorescent prisms.

#### Reference.—NITRO-TOLYL-HYDRAZINE SULPHONIC ACID.

#### *o*-TOLYL-IMIDO-DIACETIC ACID

$[1:2]C_6H_5Me.N(CH_2.CO_2H)_2$ . [c. 160°]. Formed by heating *o*-tolyl-amido-acetic acid (1 mol.) with chloroacetic acid (1 mol.),  $Na_2CO_3$  (1½ mols.) and a little water at 140° (Bischoff, B. 23, 1994; 25, 2270). White crystals, insol. ligroin, sl. sol. ether, m. sol. alcohol.— $NH_4A'$ . [160°]. V. sol. Aq.

Amide  $C_6H_5N(CH_2.CO.NH_2)_2$ . [164°]. Plates. Di-*o*-toluide  $C_6H_5N(CH_2.CO.NHC_6H_4)_2$  [150°].

*s* Imide  $C_6H_5N<\frac{CH_2.CO}{CH_2.CO}>NH$ . [146°].

Prisms (from alcohol), sl. sol. water.

#### *o*-Tolylamic acid

$C_6H_5N(CH_2.CO_2H).CH_2.CO.NHC_6H_4$ . [148°]. Crystals (from alcohol).

#### *p*-Tolylimido-diacetic acid

$[1:4]C_6H_5Me.N(CH_2.CO_2H)_2$ . Diglycotolylamic acid. [c. 140°]. Formed by the action of  $Cl_2.Cl.CO_2H$  on *p*-tolyl-glycocol (Meyer, B. 14, 1323; Bischoff, B. 23, 2000). Needles (from water). Very unstable.— $CuA'$  aq: green needles.— $Ag_2A'$  (NO<sub>3</sub>): needles.—*p*-Toluidine

salt  $(C_6H_5NH_2)HA'$ . [119°]. Crystals, sol. hot water.

**Mono-amide.** [222°]. A product of the action of  $Ac_2O$  on the compound [168°] got from chloro-acetic acid and *p*-toluidine (Bischoff, *B.* 25, 2280).

**Di-amide**  $C_6H_5N(CH_2CO.NH_2)_2$ . [250°]. *Di-p-toluide*  $C_6H_4N(CH_2CO.NHC_6H_4)_2$ . [251°]. Long needles (from alcohol).

**Amide p-toluide**  
 $C_6H_5N(CH_2CO.NH_2)CH_2CO.NHC_6H_4$ . [210°]. *p-Tolylamic acid*  
 $C_6H_5N(CH_2CO_2H)CH_2CONHC_6H_4$ . [222°].

Needles, insol. water, sol. hot alcohol.

**p-TOLYL-IMIDO-DIACRYLIC ETHER**  
 $C_6H_5MeN(CH_2CH.CO_2Et)_2$ . [73°]. Formed from *p*-toluidine and formyl-acetic ether (Von Pechmann, *B.* 25, 1053). Yellow needles (from dilute alcohol).

**o-TOLYL-β-IMIDO-BENZYL-MALONIC ETHER**  $C_6H_5NO$ , i.e.  $C_6H_5C(NC_6H_5)CH(CO_2Et)_2$ . [95°]. Formed by the action of *o*-chloro-benzylidene-*o*-toluidine upon sodium-malonic ether (Just, *B.* 19, 985). Crystals, v. sol. ether. Split up by dilute  $HClAq$  at 120° into acetophenone and *o*-toluidine. The *p*-isomeride is liquid.

**o-TOLYL-β-IMIDO-BUTYRIC ACID**  
 $C_6H_5MeN:CMc.CH_2CO_2H$ . [112°]. Formed by heating acetoneacetic ether with *o*-toluidine at 150° (Knorr, *B.* 17, 512; Pawlewski, *B.* 22, 2203). Needles (from hot water), converted by conc.  $H_2SO_4$  into (*Py.* 1)-oxy-(*B.* 4, *Py.* 3)-dimethyl-quinoline.

**p-Tolyl-β-imido-butyric acid.** Formed in like manner from *p*-toluidine. Crystals. Converted by  $H_2SO_4$  into (*Py.* 1)-oxy-(*B.* 2, *Py.* 3)-dimethyl-quinoline.

**p-TOLYL IODO-ETHYL SULPHONE**  
 $C_6H_5SO_2CH_2CH_2I$ . [100°]. Formed from tolyl oxy-ethyl sulphone and  $HIAq$  at 160° (Otto, *J. pr.* [2] 30, 357). Crystals, v. sol. hot alcohol.

**TOLYL IODO-METHYL SULPHONE**  
 $C_6H_5SO_2CH_2I$ . [126°]. Formed by heating sodium toluene sulphinate with  $CH_3I$  and alcohol (Otto, *B.* 21, 655). Small needles, v. c. sol. hot alcohol.

**DI-p-TOLYL KETONE**  $CO(C_6H_5Me)_2$ . [92°]. (333°) at 725 mm. Formed by oxidation of di-tolyl-methane (Weiler, *B.* 7, 1183), of *u*-di-tolyl-ethane (O. Fischer, *B.* 7, 1195), and of *u*-di-tolyl-ethylene (Hepp, *B.* 7, 1414) by chromic acid mixture.

**Preparation.**—50 g.  $AlCl_3$ , 65 c.c. toluene, 50 c.c.  $CS_2$ , and 11 c.c. of a solution of  $COCl_2$  in  $CS_2$  saturated at 0° are put into a corked half-litre flask and gently warmed. After 20 minutes  $HCl$  is allowed to escape and a second 11 c.c. of  $CS_2$  saturated with phosgene is added. The operation is repeated 2 or 3 times; the yield is 50 p.c. of the calculated (Eibs, *J. pr.* [2] 35, 467; cf. Ador a. Crafts, *B.* 10, 2174).

**Properties.**—Crystals (from alcohol). Converted by  $HNO_3$  at 250° into benzoyl-terephthalic acid. Reduced by  $H$  and  $P$  to di-tolyl-methane (Ador a. Billiet, *B.* 12, 2303).

**Oxim**  $(C_6H_5)_2C=NOH$ . [163°]. Prisms (Goldschmidt, *B.* 23, 2746). Decomposes on keeping with sudden evolution of nitrous fumes. Conc.

$H_2SO_4$  at 100° forms the *p*-toluide of *p*-toluic acid.

**Di-p-tolyl diketone**  $C_6H_4CO.OO.C_6H_4$ . *p-Tolil*. [105°]. Formed by boiling toluoin (1 pt.) with  $HNO_3$  (2 pts.) (Stierlin, *B.* 22, 381). Yellow plates (from warm alcohol). Gives a violet colour when boiled with alcoholic potash.

(a)-*Oxim*  $C_6H_4C(NO)(OH).C(NO)(OH).C_6H_4$ . [217°]. Plates or needles, sl. sol. alcohol. Yields a diacetyl derivative [134°].

(B)-*Oxim* [225°]. Formed, together with the (a)-oxim, by the action of hydroxylamine hydrochloride on the ketone. Needles, v. sol. alcohol. Yields a diacetyl derivative [141°].

**Di-p-tolyl tetra-ketone**  
 $C_6H_4.CO.C(OH).CO.CO.C_6H_4$ . [88°]. Formed by the action of nitric acid (S.G. 1-3) on  $C_6H_4.CO.CH(OH).CO.CO.C_6H_4$  (Söderbaum, *B.* 25, 3171). Prisms (containing  $(C_6H_5O)_2CS_2$ ) (when crystallised from  $CS_2$ ).

**Di-oxim**  
 $C_6H_4C(NO)(OH).CO.CO.C(NO)(OH).C_6H_4$ . [181°]. Plates (containing  $EONH$ ) (from alcohol).

**Bi-oxim**  
 $C_6H_4.CO.C(NO)(OH).C(NO)(OH).CO.C_6H_4$ . So called '(β)-nitro-cymene'. [125°]. Mol. w. 324 (by Raoult's method). Formed by the action of nitric acid on cymene and on *p*-tolyl methyl ketone (Hollmann, *R. T. G.* 6, 60; cf. Landolph, *B.* 6, 937; Fittica, *A.* 172, 311). Needles, v. sol. warm alcohol. Converted by  $NaOH$  into *p*-toluic acid. Zinc-dust and  $HOAc$  reduce it to  $C_6H_4.CO.CH_2CH_2.CO.C_6H_4$ . [159°]. Alcoholic  $NH_3$  forms *p*-toluic amide and  $C_6H_4N_2O$ . [162°]. Boiling  $Ac_2O$  forms  $C_6H_4N_2O.Ac_2O$ . [167°].

**Reference.**—OXY-DI-TOLYL KETONE.

**TOLYL-MALONAMIC ACID** v. MALONIC ACID.

**TOLYL-MELAMINE** v. Cyanuramide in the article on CYANIC ACIDS.

**o-TOLYL-MERCAPTAN**  $[1:2]C_6H_4Me.SH$ . [15°]. (188) (H.); (193°) (V.). Formed by reducing (4,1,2)-bromo-tolyl mercaptan (Hübner, *A.* 169, 30; Vallin, *B.* 19, 2953). Prepared by boiling *o*-tolyl ethyl dithiocarbonate with alcoholic potash, the yield being 70 p.c. of the theoretical amount (Leuckart, *J. pr.* [2] 41, 188). Plates. —  $Pb(SC_6H_4)_2$ . Brick-red pp., turning white in air.

**m-Tolyl mercaptan**  $[1:3]C_6H_4Me.SH$ . [c. 200°]. Formed by reducing toluene *m*-sulphonic chloride with tin and  $HCl$  (Hübner, *A.* 169, 51) and by boiling *m*-tolyl ethyl xanthate with alcoholic potash (L.). Colourless liquid with intense odour of mercaptan. Volatile with steam. In ammoniacal alcoholic solution it is oxidised by air to *m*-tolyl disulphide.

**p-Tolyl mercaptan**  $[1:4]C_6H_4Me.SH$ . [43°]. (188°) (J.). (191°) (Crafts, *B.* 19, 3130; Otto, *B.* 19, 3129); (194°) (Vallin, *B.* 19, 2953). Formed by reducing toluene *p*-sulphonic chloride with tin and  $HCl$  (Mäcker, *A.* 136, 79; Javorsky, *Z.* 1865, 222). Formed also by heating *p*-tolyl ethyl xanthate with alcoholic potash (L.). Formed also from di-*p*-tolyl disulphide, alcohol, and  $H_2S$  (Otto a. Rössing, *B.* 19, 3180). Unctuous *laines* (from ether), volatile with steam. Conc.  $H_2SO_4$  forms a blue solution. Readily oxidised to di-*p*-tolyl disulphide [46°]. Chloro-acetone forms  $C_6H_4S.CH_2CO.CH_3$  (151° at 15 mm.); S.G. 1.0986 which yields a phenyl-hydrazide

[62°] (Dellisle, *A.* 260, 268).— $\text{Hg}(\text{SC}_6\text{H}_5)_2$ .— $\text{C}_6\text{H}_5\text{S.HgCl}$ . Plates.

*Ethyl ether*  $\text{C}_6\text{H}_5\text{SEt}$ . (221°). S.G. 1.10016. Colourless oil (Otto, *B.* 13, 1277).

*References*.—AMIDO- and BROMO- TOLYL MERCAPTAN.

**O-TOLYL-MESITYL-THIO-UREA**

$\text{C}_6\text{H}_5\text{NH.CS.NHC}_6\text{H}_3\text{Me}_3$ . [167°]. Formed from *o*-toluidine and mesityl thiocarbimide (Eisenberg, *B.* 15, 1014). Needles, insol. Aq.

**DI-TOLYL-METHANE**  $\text{CH}_2(\text{C}_6\text{H}_5)_2$ . [23°]. (286°).

*Formation*.—1. From formic aldehyde (or methylal), toluene, and  $\text{H}_2\text{SO}_4$  (Weiler, *B.* 7, 1181).—2. By reducing di-tolyl ketone with  $\text{HI}$  and  $\text{P}$  (Ador a. Rilliet, *B.* 12, 2302).—3. A product of the action of  $\text{AlCl}_3$  and toluene on  $\text{CH}_3\text{Cl}$ , on  $\text{CH}_3\text{Cl}$ , or on  $\text{CCl}_4\text{NO}_2$  (Friedel a. Crafts, *A. Ch.* [6] 11, 266; *Bl.* [2] 43, 50; Ellis a. Wittich, *B.* 18, 347).

*Properties*.—Prisms, v. sol. ether. Oxidised by chromic acid mixture to di-tolyl ketone, toluyl-benzoic acid, and  $\text{C}^6(\text{C}_6\text{H}_5\text{CO}_2\text{H})_2$ . Yields a di-nitro-derivative [164°].

**Tri-tolyl-methane**  $\text{CH}(\text{C}_6\text{H}_5)_3$ . [73°]. (377°). Obtained from tri-amido-tri-tolyl-carbinol (Rosenstiehl a. Gerber, *A. Ch.* [6] 2, 353). Crystalline.

*References*.—DI-BROMO- and DI-CHLORO- DI-TOLYL-METHANE.

**O-TOLYL-METHYL-p-AMIDO-PHENOL**

*Methyl derivative*  $\text{C}_6\text{H}_5\text{NMe.C}_6\text{H}_4\text{OMe}$ . (336° cor.). From  $\text{C}_6\text{H}_5\text{NH.C}_6\text{H}_4\text{OH}$ ,  $\text{KOH}$ , and  $\text{MeI}$  (Philip, *J. pr.* [2] 34, 59). Oil.

**TOLYL-METHYL-AMINE** v. METHYL-TOLUIDINE, METHYL-BENZYL-AMINE, and AMIDOXYLENE.

**Di-p-tolyl-methyl-amine**  $(\text{C}_6\text{H}_4)_2\text{NMCH}_3$ . (235°–240° at 20 mm.). Formed from di-tolylamine,  $\text{MeOH}$ , and  $\text{HCl}$  at 250°–280° (Girard, *Bl.* [2] 24, 120). Does not combine with acids.

**DI-TOLYL-DI-METHYL-DI-TRIAZYL**

$\text{N}(\text{C}_6\text{H}_5)_2 \gg \text{C} \equiv \text{N}(\text{C}_6\text{H}_5)_2 \text{N} \text{CMe} \text{N}$ . (259°–260°).

Formed by boiling *p*-tolyl-hydrazine cyanide ( $\text{C}_6\text{H}_5\text{NHNH.Cy}_3$  with  $\text{Ac}_2\text{O}$  (Blatin, *B.* 22, 3114). Crystals (from alcohol), m. sol. alcohol.

**p-TOLYL-METHYL-BENZYL KETONE**

$\text{C}_6\text{H}_5\text{Me.COCH}_2\text{C}_6\text{H}_4\text{Me}$ . [102°]. Got by reducing *p*-toluoin with zinc and alcoholic  $\text{HCl}$  (Stierlin, *B.* 22, 383). Needles, insol. water, v. sol. benzene.

**O-TOLYL-METHYLENE-AMINE**

$\text{C}_6\text{H}_5\text{N.CH}_2$  (?). Formed by adding *o*-toluidine to a solution of formic aldehyde (Wellington a. Tollens, *B.* 18, 3307). Colourless syrup.

**p-Tolyl-methylene-amine**  $\text{C}_6\text{H}_4\text{N.CH}_2$  (?). [c. 122°]. Formed, together with a polymeric solid sol. benzene and alcohol, by adding *p*-toluidine to a solution of formic aldehyde (W. a. T.). Crystals, v. sol. benzene.

**Di-o-tolyl-methylene-diamine**  $(\text{C}_6\text{H}_5\text{NH})_2\text{CH}_2$ . (over 350°). Formed, together with the following solid isomeride, by heating *o*-toluidine with  $\text{CH}_2\text{Cl}_2$  at 110°–115° (Grünhagen, *A.* 256, 305). Liquid, v. sol. ether and alcohol.— $\text{B}^1\text{H}_5\text{PtCl}_6$ : brown amorphous powder.

*Isomeride* [c. 115°]. Crystalline powder, sl. sol. cold alcohol.—Salts:  $\text{B}^2\text{HCl}$ .— $\text{B}^3\text{HBr}$ .— $\text{B}^4\text{H}_2\text{SO}_4$ .— $\text{B}^5\text{H}_2\text{PO}_4$ .— $\text{B}^6\text{H}_2\text{C}_2\text{O}_4$ .— $\text{B}^7\text{H}_2\text{C}_2\text{O}_4$ . Radiating aggregates.

**Di-p-tolyl-methylene-diamine**

$(\text{C}_6\text{H}_4\text{NH})_2\text{CH}_2$ . (above 350°). Formed, together with the solid isomeride, by heating *p*-toluidine with  $\text{CH}_2\text{Cl}_2$  (G.). Oil, v. sol. ether.— $\text{B}^1\text{HCl}$ .— $\text{B}^2\text{H}_5\text{PtCl}_6$ .— $\text{B}^3\text{H}_5\text{AuCl}_4$ .

*Isomeride*  $\text{C}_6\text{H}_4\text{N}_2$ . [c. 156°]. (over 350°). Amorphous, sl. sol. ether.— $\text{B}^2\text{HCl}$  (?).— $\text{B}^3\text{H}_5\text{PtCl}_6$ .— $\text{B}^4\text{H}_2\text{AuCl}_4$ .— $\text{B}^5\text{H}_2\text{C}_2\text{O}_4$ . Crystalline crusts.

**Di-p-tolyl-di-methylene-diamine**

$\text{C}_6\text{H}_4\text{N} \langle \text{CH}_2 \rangle \text{NC}_6\text{H}_4$ . [90°]. A product of the action of  $\text{CH}_2\text{Cl}_2$  on *p*-toluidine at 100° (Grünhagen, *A.* 256, 296). Granules, sol. hot alcohol! Converted by nitrous acid into a crystalline nitroso-derivative  $(\text{C}_6\text{H}_4\text{N})_2\text{C}_6\text{H}_4(\text{NOH})$  (?)— $\text{B}^2\text{HCl}$ .— $\text{B}^3\text{H}_2\text{AuCl}_4$ .— $\text{B}^4\text{HBr}$ .— $\text{B}^5\text{H}_2\text{SO}_4$ .

**o-Tolyl-trimethylene-diamine**

$\text{C}_6\text{H}_5(\text{NH})_2\text{NH.C}_6\text{H}_5$ . (281°). Formed by reducing *o*-tolyl-pyrazole dihydride in alcoholic solution by sodium (Balbiano, *G.* 18, 354). Oil.

**p-Tolyl-trimethylene-diamine**

$\text{C}_6\text{H}_5(\text{NH})_2\text{NH.C}_6\text{H}_4$ . [c. –15°]. (287°). A product of the action of Na on an alcoholic solution of *p*-tolyl-pyrazole (Balbiano). Liquid. Oxalate. [208°]. Spherical groups of minute needles.

**p-TOLYL METHYLENE METHYL SULPHONE KETONE**  $\text{C}_6\text{H}_4\text{SO}_2\text{CH}_2\text{CO.C}_6\text{H}_4$ . [51°]. Formed from chloro-acetone and sodium toluene *p*-sulphinate (Otto, *J. pr.* [2] 36, 401). Silky needles. Yields a bromo-derivative [130°].

**m-TOLYL-METHYLENE-PHTHALIDE**

$\text{C}_6\text{H}_4 \langle \text{C}(\text{CH}_3\text{CO}) \rangle \text{O}$ . [153°]. Formed by heating *m*-tolyl-acetic acid with phthalic anhydride and a little  $\text{NaOAc}$  (Heilmann, *B.* 23, 3157). Needles (from ligroin), sl. sol. ether.

**p-Tolyl-methylene-phthalide**  $\text{C}_6\text{H}_4\text{O}_2$

*p-Xylal-phthalide*. [151°]. Formed in like manner from *p*-tolyl-acetic acid (Ruhemann, *B.* 24, 3965). Yellow needles (from alcohol), sl. sol. ether. Nitrous acid passed into its solution in chloroform forms  $\text{C}_6\text{H}_4 \langle \text{C}(\text{C}(\text{NO}_2)\text{C}_6\text{H}_5) \rangle \text{O}$  [140°], which may be reduced to the compound  $\text{C}_6\text{H}_4 \langle \text{CH:C}_6\text{H}_4 \rangle \text{O}$ . [116°].

*Reference*.—NITRO-TOLYL-METHYLENE-PHTHALIDE.

**m-TOLYL-METHYLENE-PHTHALIMIDINE**

$\text{C}_6\text{H}_4 \langle \text{C}(\text{CH}_3\text{CO}) \rangle \text{NH}$ . [165°]. Formed by heating *m*-tolyl-methylene-phthalide with alcoholic ammonia (Heilmann, *B.* 23, 3161). Yellowish needles.

**p-Xylal-methylene-phthalimidine**  $\text{C}_6\text{H}_4\text{NO}$ . [204°]. Formed by heating *p*-tolyl-methylene-phthalide with alcoholic  $\text{NH}_3$ , the compound  $\text{NH}_2\text{CO.C}_6\text{H}_4\text{CO.CH}_2\text{C}_6\text{H}_5$ , being first formed (Ruhemann, *B.* 24, 3968). Converted by passing nitrous acid through its solution in chloroform into  $\text{C}_6\text{H}_4 \langle \text{C}(\text{C}(\text{NO}_2)\text{C}_6\text{H}_5) \rangle \text{NH}$  [227°].

**Isomeride**  $\text{C}_6\text{H}_4 \langle \text{CH:C}_6\text{H}_4 \rangle \text{O}$ . [228°]. Formed

by heating  $\text{C}_6\text{H}_4 \langle \text{CH:C}_6\text{H}_4 \rangle \text{O}$  with alcoholic ammonia (*R.*).

*Reference*.—NITRO-TOLYL-METHYLENE-PHTHALIMIDINE.

**DI-*p*-TOLYL TRIMETHYLENE DISULPHONE**  $C_6H_4(SO_2CH_2)_2$ . [125°]. Formed from trimethylene bromide and sodium toluene *p*-sulphinate (Otto, *B.* 24, 1834). Plates. Converted by alcoholic potash at 120° into the compound  $O(CH_2CH_2CH_2SO_2C_6H_4)_2$  [80°].

**TOLYL-METHYL-IMESATIN** *v. Toluidine of Methyl-Isatin*.

***m*-TOLYL METHYL KETONE**  $C_6H_4CO.OH$ , *Methyl-acetophenone*. (219°). Formed by distilling calcium *m*-toluate with calcium formate (Buchka & Irish, *B.* 20, 1766).

**Tolyl methyl ketone**. (225°). S.G. 22.9891. *VD.* 4.58. Formed, together with the *p*-compound, by the action of  $AlCl_3$  on toluene and  $AlCl_3$  (Essner & Gossin, *Bl.* [2] 42, 95). This is perhaps the *o*-compound.

***p*-Tolyl methyl ketone**. (217°) (*M.*); (230° *cor.*) (*W.*). Formed by the action of  $AlCl_3$  on a mixture of toluene and  $Ac_2O$  or  $AcCl$  (Michaelis, *B.* 15, 185; Claus, *B.* 19, 234). Formed also by heating toluene with  $HOAc$ ,  $ZnCl_2$ , and  $POCl_3$  (Frey, *J. pr.* [2] 43, 114) and as a by-product in the oxidation of (*o*)-nitro-cymene (Widman, *B.* 19, 587). Oil. Yields a dibromide  $C_6H_4Br_2O$  [100°].  $KMnO_4$  forms terephthalic acid. Alkaline  $K_2FeC_4$  forms *p*-toluic and *p*-tolyl-glyoxylic acids (*B. A. K.*).  $HNO_3$  forms  $C_6H_4N_2O_4$  [125°], which is reduced by zinc-dust and  $HOAc$  to  $C_6H_4(CO_2C_2H_5)_2$  (Holleman, *Z. T. C.* 10, 211).

*Oxim* [88°]. Crystals (from ligroin).

*Phenyl-hydrazide* [97°]. Prisms.

*Reference*.—AMIDO-, IODO-, and OXY-, TOLYL METHYL KETONE.

***o*-TOLYL METHYL KETONE TETRAHYDRIDE**  $CH_2<\frac{CH_2.CMe}{CH_2.CH_2}>C.CO.CH_2$ . (206°).

Formed from *ac*-di-acetyl-pentane by treatment with conc.  $H_2SO_4$  (Kipping & Perkin, *jun.*, *C. J.* 57, 18). Oil, smelling like peppermint. Does not combine with  $NaHSO_3$ . In moist ether it is reduced by  $Na$  to the hexahydride.

*Oxim*  $C_6H_4NO$ . Liquid.

*Phenyl hydrazide*  $C_6H_4H_2N_2$ . Oil.

*Tolyl methyl ketone hexahydride v. METHYL-*

**HEXAMETHYLENYL METHYL KETONE**.

***m*-TOLYL-METHYL-MALONIC ACID**

$[1.3]C_6H_4Me.CH_2CH(CO_2H)_2$ . [133°]. Formed by saponification of the ether (Poppe, *B.* 23, 110). Rhombohedra, sl. sol. water.— $K_2A''$ : needles.

*Methyl ether*  $Me.A''$ . (c. 300°).

*Ethyl ether*  $Et.A''$ . (320°). Formed from *o*-bromo-*m*-xylene and sodium malonic ether. Oil. Converted by alcoholic  $NH_3$  at 150° into  $C_6H_4Me.CH_2CH(CO_2Et).CO.NH_2$  [186°], which on warming with water forms the ammonium salt  $C_6H_4Me.CH_2CH(CO_2Et).CO.NH_4^+$  [77°].  $Et.A''$  is converted by methylamine into the methylamide  $C_6H_4Me.CH_2CH(CO_2Et).CONHMe$  [120°], and by aniline into  $C_6H_4Me.CH_2CH(CO_2NHPh)_2$  [188°].

***Di-m*-tolyl-di-methyl-malonic ether** ( $C_6H_4Me.OH)_2C(CO_2Et)_2$ . [122°]. A product of the action of *o*-bromo-*m*-xylene on sodium malonic ether (Poppe, *B.* 23, 109).

***o*-TOLYL-METHYL-OXAZOLINE**  $C_6H_4NO.i.e.$   $CHMe.O>C.CO.H$ . (258°). Formed by boiling  $C_6H_4.CO.NH.OH.CHO$  with alcoholic potash (Salomon, *B.* 26, 1323). Oil.— $B'C_6H_4N_2O$ . [129°].— $B'H.PtCl_4$ .

VOL. IV.

***p*-Tolyl-methyl-oxazoline**  $C_6H_4NO$ . (265°). Formed from the bromopropyl-amide of *p*-toluic acid (Salomon, *B.* 26, 1326). Oil.—Picrate  $B'C_6H_4N_2O$ . [188°].— $B'H.PtCl_4$ . [184°].

***p*-TOLYL-DI-METHYL-PHOSPHINE**  $C_6H_4PMe_2$ . (210°). Formed from  $C_6H_4PCl_2$  and  $ZnMe_2$  (Czarnatis, *B.* 15, 2014). Oil, oxidised by  $HgO$  to  $C_6H_4PMe_2O$ .  $CS_2$  forms  $C_6H_4PMe_2OS_2$  [110°] crystallising in red plates.

*Methyl-iodide*  $B'MeI$ . [255°]. Needles.

*Benzyl-chloride*. Yields  $B'(C_6H_4).PtCl_4$  [226°], a yellow crystalline pp.

***p*-TOLYL-METHYL-PHTHALIMIDE**  $[4.2.1]C_6H_4Me.CO.O.N.C_6H_4Me$ . [180°]. Formed by distilling (4,2,1)-methyl-phthalic acid with *p*-toluidine (Niemcewiczski, *M.* 12, 630). Crystalline mass, v. e. sol. chloroform, insol. water.

***p*-TOLYL-METHYL-PHTHALIMIDINE**  $C_6H_4<\frac{CH(CH_2C_6H_4Me)}{CO}>NH$ . [149°]. Formed from *p*-tolyl-methylene-phthalimidine,  $HI$  and  $P$  (Ruhemann, *B.* 24, 396). Needles.

**DI-*p*-TOLYL-METHYL-PIPERAZINE**  $C_6H_4N_2$ . [105°]. Formed from di-*p*-tolyl-propylene-diamine, ethylene bromide, and  $Na_2CO_3$ . Needles (from alcohol).—(Bischoff, *B.* 25, 3278).

***o*-TOLYL-METHYL-PROPYLENE- $\psi$ -THIO-UREA**  $CHMe.S>CH_2-N>C.NMe.C_6H_4$ . (c. 295°). Formed from *o*-tolyl-propylene- $\psi$ -thio-urea and  $MeI$  (Frager, *B.* 22, 2999). Yields ( $\beta$ )-methyl-taurine on oxidation.— $B'C_6H_4N_2C_6H_4$ . [138°].— $B'HI$ . [166°].— $B'H_2PtCl_4$ . Decomposes over 200°.

***p*-TOLYL-DI-METHYL-PYRROLE**  $(C_6H_4)N<\frac{CMe:CH}{CMe:CH}>$  [46°]. (255°). Got by heating the di-carboxylic acid (Knorr, *B.* 18, 308). Crystals, volatile with steam.

*Reference*.—AMIDO-TOLYL-DI-METHYL-PYRROLE.

***p*-TOLYL-DI-METHYL-PYRROLE DICARB-**

**OXYLIC ACID**  $(C_6H_4)N<\frac{CMe:C.CO_2H}{CMe:C.CO_2H}>$  Got by saponifying its ether, which is formed by mixing acetic acid solutions of di-acetyl-succinic ether and *p*-toluidine (Knorr, *B.* 18, 304). Needles, decomposes at about 250°, with evolution of  $CO_2$ .— $K.A''$ .— $AgI.A''$ .

*Ethyl ether*  $Et.A''$ . [67°]. Tables.

*Reference*.—AMIDO-TOLYL-DI-METHYL-PYRROLE DICARBOXYLIC ACID.

***p*-TOLYL-DI-METHYL-SULPHAMIDE**  $SO_2(NMe)_2.NH.C_6H_4$ . [91°]. Formed from  $N$  in  $SO_2Cl_2$  and *p*-toluidine (Behrend, *A.* 222, 129). Crystals, v. sol. alcohol and ether.

***p*-TOLYL METHYL SULPHONE**  $C_6H_4.SO_2CH_3$ . [87°]. Formed by the action of conc.  $KOH$  on *p*-tolyl-sulphono-acetic acid (Otto, *B.* 18, 161). Got also from  $C_6H_4.SO_2Na$  and  $MeI$  (Otto). Needles (from very dilute alcohol), v. sol. hot water.

***o*-TOLYL-METHYL-THIAZOLINE**

$CHMe.S>C.CO.H$ . (284°–295°). Formed by heating *o*-toluic bromo-propylamide with  $P_2S_5$  at 150° (Salomon, *B.* 26, 1328). Oil.— $B'C_6H_4N_2O$ . [186°].

***p*-Tolyl-methyl-thiazoline**  $C_6H_4NS$ . (305°). Oil.— $B'C_6H_4N_2O$ . [141°].— $B'H.PtCl_4$ .

• E

**o-TOLYL-METHYL-THIOHYDANTOIN**

$\text{HMe} \begin{smallmatrix} \text{CO} \cdot \text{N}(\text{C}_6\text{H}_5) \\ \text{NH} \cdot \text{CS} \end{smallmatrix}$  [198°]. Formed from

*o*-tolyl-thiocarbimide and alanine (Marckwald, B. 24, 3231). Crystals.

*p*-Tolyl-methyl-thiohydantoin. [197°]. Formed in like manner from *p*-tolyl-thiocarbimide and alanine (Aschan, B. 17, 427). Minute prisms. On heating with alcoholic potash it is converted by hydrolysis into a salt of the oily  $\text{NHOC}_6\text{H}_4\text{CS.NH.CHMe.CO}_2\text{H}$ , which slowly changes, in the free state, back into the hydantoin.

**o-Tolyl-di-methyl-thiohydantoin**

$\text{CMe}_2 \begin{smallmatrix} \text{CO} \cdot \text{N}(\text{C}_6\text{H}_5) \\ \text{NH} \cdot \text{CS} \end{smallmatrix}$  [175°]. Formed from *o*-tolyl-thiocarbimide and  $\alpha$ -amido-isobutyric acid (Marckwald, B. 24, 3284). Needles, v. sol. hot alcohol.

*p*-Tolyl-di-methyl-thiohydantoin. [85°]. Formed in like manner from *p*-tolyl-thiocarbimide. Crystals, v. sol. most solvents.

**o-TOLYL-METHYL-THIO-UREA**

$\text{NHMe} \cdot \text{CS} \cdot \text{NH} \cdot \text{C}_6\text{H}_5$  [153°]. Formed from methyl-thiocarbimide and *o*-toluidine in alcohol (Dixon, C. J. 55, 622). Pearly crystals, m. sol. hot water, sol. alcohol.

*p*-Tolyl-methyl-thio-urea. [126°]. Formed in like manner from *p*-toluidine. Vitreous prisms, v. sol. hot water.

**Reference.**—TOLYL-THIO-UREA.

*o*-TOLYL-( $\alpha$ )-NAPHTHYLAMINE  $\text{C}_{10}\text{H}_7\text{N}$  i.e.  $\text{C}_6\text{H}_4\text{NH.C}_6\text{H}_4\text{Me}$ . [95°]. Formed by heating ( $\alpha$ )-naphthol (1 mol.) with *o*-toluidine (2 mols.) and  $\text{CaCl}_2$  (1 mol.) in sealed tubes at 290°, the yield being 37 p.c. of the theoretical amount (Friedländer, B. 16, 2084). Flat needles, v. sol. alcohol and ether.

*o*-Tolyl-( $\beta$ )-naphthylamine  $\text{C}_{10}\text{H}_7\text{NH.C}_6\text{H}_4\text{Me}$ . [96°]. Formed by heating a mixture of ( $\beta$ )-naphthol with *o*-toluidine and  $\text{CaCl}_2$  at 280°. Silvery plates (from ligroin), v. sol. alcohol.— $\text{B}^2\text{C}_6\text{H}_4\text{N}_2\text{O}_2$  [110°]. Reddish-brown needles.

**Benzoyl derivatives** [118°]. Plates.

*p*-Tolyl-( $\alpha$ )-naphthylamine  $\text{C}_{10}\text{H}_7\text{N}$ . [79°]. (360° at 528 mm.). Formed by heating ( $\alpha$ )-naphthol with *p*-toluidine and  $\text{CaCl}_2$  at 280°, the yield being 50 p.c. Short prisms (from alcohol). Its solutions exhibit blue fluorescence.

*p*-Tolyl-( $\beta$ )-naphthylamine. [104°]. Formed by heating *p*-toluidine hydrochloride with ( $\beta$ )-naphthol for 8 hours at 200° (Witt, B. 20, 578; cf. Friedländer, B. 16, 2078). Plates (from alcohol). Its solutions have violet-blue fluorescence. Dissolved in isoamyl alcohol it is reduced by Na to a hydride [44°] (Jamberger/a. Müller, B. 22, 1309). With nitroso-dimethylaniline hydrochloride and HOAc it yields a saffranine  $\text{C}_{10}\text{H}_7\text{N}_2\text{Cl}(\text{C}_6\text{H}_5) \cdot \text{C}_6\text{H}_4\text{NMe}_2$  (Witt, B. 21, 724). *p*-Tolyl-naphthylamine (10 g.), heated with nitroso-dimethylaniline hydrochloride (4 g.),  $\text{ZnCl}_2$  (10 g.), and HOAc (100 c.c.), forms  $\text{C}_{10}\text{H}_7\text{N}_2(\text{NH} \cdot \text{C}_6\text{H}_4\text{Me})_2$  [225°], which yields an acetyl derivative [225°].

**Acetyl derivatives** [85°]. Needles.**Benzoyl derivatives** [139°]. Needles.

**Reference.**—TETRA-BROMO-TOLYL-NAPHTHYLAMINE.

**DI-p-TOLYL-NAPHTHYLENE-DIAMINE**

$\text{C}_{10}\text{H}_7(\text{NH} \cdot \text{C}_6\text{H}_4)_2$  [237°]. Formed by heating di-*o*-xy-naphthalene with *p*-toluidine and *p*-tolu-

idine hydrochloride (Annaheim, B. 20, 1373. Needles (from xylene). Gives a red colour on heating with solid  $\text{ZnCl}_2$ .

**o-TOLYL-( $\alpha$ )-NAPHTHYL-THIO-UREA**

$\text{CS}(\text{NH} \cdot \text{C}_6\text{H}_5)(\text{NH} \cdot \text{C}_6\text{H}_4)$ . [168°]. Formed by the action of *o*-tolyl thiocarbimide on ( $\alpha$ )-naphthylamine or of ( $\alpha$ )-naphthyl thiocarbimide on *o*-toluidine (Mainzer, B. 15, 1416). Short needles, sol. alcohol. Split up by conc.  $\text{HCl}$  at +150° into *o*-toluidine, ( $\alpha$ )-naphthylamine, *o*-tolyl-thiocarbimide, and ( $\alpha$ )-naphthyl thiocarbimide.

**o-Tolyl-( $\beta$ )-naphthyl-thio-urea** [194°

Formed from *o*-tolyl thiocarbimide and ( $\beta$ )-naphthylamine (M.).

**p-Tolyl-( $\alpha$ )-naphthyl-thio-urea** [168°

Formed from *p*-tolyl thiocarbimide and ( $\alpha$ )-naphthylamine (M.). Slender white needles.

**p-Tolyl-( $\beta$ )-naphthyl-thio-urea** [164°

Formed from *p*-tolyl thiocarbimide and ( $\beta$ )-naphthylamine (M.). Decomposed by  $\text{HCl}$  at +150° into *p*-toluidine, ( $\beta$ )-naphthylamine, *p*-tolyl thiocarbimide, and ( $\beta$ )-naphthyl thiocarbimide.

**p-TOLYL-p-NITRO-BENZYL OXIDE**

$\text{C}_6\text{H}_4\text{Me.O.CH}_2\text{C}_6\text{H}_4\text{NO}_2$ . [91°]. Formed from *p*-nitro-benzyl chloride and alcoholic  $\text{C}_6\text{H}_5\text{ON}$  (Frische, A. 224, 144). Yellowish plates, sol. ether.

**TOLYL NITROSO-METHYL KETONE :**

*Oxim* of TOLYL-GLYOXAL.

**TOLYL-OXAMIC ACID** v. vol. iii. p. 654.**TOLYL-OXAMIDE** v. OXALIC ACID.**o-TOLYL-OXAZOLINE**  $\begin{smallmatrix} \text{CH}_2\text{O} \\ \text{CH}_2\text{N} \end{smallmatrix} \geq \text{C}_6\text{H}_5$ .

(255°). Formed by dissolving *o*-toluic bromoethyl-amide in hot water and adding alkali (Salomon, B. 26, 1322). Oil. Evaporating with aqueous  $\text{HCl}$  (1 mol.) forms the compound  $\text{C}_6\text{H}_4\text{CO.O.CH}_2\text{CH}_2\text{NH}_2$ , while excess of  $\text{HC}$  gives  $\text{C}_6\text{H}_4\text{CO.NH.CH}_2\text{CH}_2\text{Cl}$ . —  $\text{B}^2\text{C}_6\text{H}_4\text{N}_2\text{O}$ , [145°]. —  $\text{B}^2\text{H}_2\text{PtCl}_6$ . [189°].

*p*-Tolyl-oxazoline  $\text{C}_6\text{H}_4\text{NO}$ . [66°]. (265°) Formed by decomposing  $\text{C}_6\text{H}_4\text{CO.NH.CH}_2\text{CH}_2\text{B}$  with alkali. Needles. —  $\text{B}^2\text{C}_6\text{H}_4\text{N}_2\text{O}$ . [188°]. —  $\text{B}^2\text{H}_2\text{PtCl}_6$ . [186°].

**DI-o-TOLYL OXIDE**  $(\text{C}_6\text{H}_4\text{Me})_2\text{O}$ . *Cresyl ether*. (272°–278°). S.G.  $d_4^{20}$  1.047. A product of the distillation of  $\text{Al}(\text{OC}_6\text{H}_4\text{Me})_3$  (Gladstone a. Tribe, C. J. 49, 27). Oil, smelling like geranium leaves.

**Di-m-tolyl oxide**  $(\text{C}_6\text{H}_4)_2\text{O}$ . (284°–288°)  $\mu$ , 1.5576 at 16°. V.D. 193.9. A product of distillation of aluminium thymol  $\text{Al}(\text{OC}_6\text{H}_3)_3$  (Gladstone a. Tribe, C. J. 41, 13). Oil.

**Di-p-tolyl oxide**  $(\text{C}_6\text{H}_4)_2\text{O}$ . [50°]. (270°–800°) Formed by distilling aluminium *p*-cresol (C. a. T.). Prisms (from alcohol).

**Isomeride** [165°]. Formed by heating *p*-cresol with  $\text{ZnCl}_2$  (Busch, B. 17, 2638). Crystals, volatile with steam.

**DI-TOLYL-OXINDOLE**  $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{O}(\text{C}_6\text{H}_4)_2 \\ \text{NH} \end{smallmatrix} > \text{CO}$ 

*Toluisatin*. [200°]. Formed by adding toluene to a solution of isatin in  $\text{H}_2\text{SO}_4$  (Baeyer a. Lazarus, B. 18, 2638). Needles, v. sol. alcohol and ether, sol. aqueous alkalis. Yields an acetyl derivative  $\text{C}_{20}\text{H}_{11}\text{O}(\text{Nac})$  [148°] and an ethyl derivative  $\text{C}_{22}\text{H}_{13}\text{O}(\text{NEt})$  [108°], both being crystalline.

**TOLYL-OXY-ACETIC ACID** *v. TolyI derivative of Glycolic acid and Oxy-tolyl-acetic acid.*

**p-TOLYL OXY-ETHYL SULPHONE**

$\text{C}_6\text{H}_4\text{SO}_2\text{CH}_2\text{CH}_2\text{OH}$ . [55°]. Got from sodium toluene *p*-sulphinate and glycol chlorhydrin (Otto, *J. pr.* [2] 30, 355). Needles (from alcohol) with bitter taste. Heating with KOH aq gives  $\text{C}_6\text{H}_4\text{SO}_2$  [84°].

**Benzoyl derivative**  $\text{C}_6\text{H}_4\text{SO}_2\text{C}_6\text{H}_5\text{OBz}$ . [178°]. Needles, sl. sol. hot alcohol.

**DI-o-TOLYL-PARABANIC ACID**  $\text{C}_{11}\text{H}_{11}\text{N}_2\text{O}_4$

*i.e.*  $\text{CO} < \text{N}(\text{C}_6\text{H}_4)\text{CO}$  [203°]. Formed by boiling an alcoholic solution of oxalyl-di-tolyl-guanidine with conc. HCl aq (Bergner, *B.* 12, 1856). Small needles.

**Di-p-tolyl-parabanic acid** [144°]. Formed by boiling di- (or tri-) *p*-tolyl-guanidinedicyanide with alcohol and HCl (Landgrebe, *B.* 11, 978). Plates. Oxidised by potassium permanganate to  $\text{CO} < \text{N}(\text{C}_6\text{H}_4\text{CO}_2\text{H})\text{CO}$  [159°?].

**p-TOLYL PENTADECYL KETONE**

$\text{C}_{15}\text{H}_{31}\text{CO}_2\text{C}_6\text{H}_4\text{Me}$ . [262° at 15 mm.]. Formed from palmityl chloride, toluene, and  $\text{AlCl}_3$  (Kraft, *B.* 21, 2266). Needles (from alcohol). Yields *p*-toluic acid on oxidation.

**o-TOLYL-PENTHAZOLINE**  $\text{C}_{11}\text{H}_{11}\text{NS}$  *i.e.*

$\text{C}_6\text{H}_4\text{CS} = \text{CH}_2$ . Got by heating trimethylene chlorobromide with thio-*p*-toluic amide (Pinkus, *B.* 26, 1081). Oil, volatile with steam. Its hydrochloride gives a white compound with  $\text{HgCl}_2$ .

**p-Tolyl-pentiazoline** [53°].

**p-TOLYL-PHENYLIAZINE**. *Dihydrate*

$\text{C}_6\text{H}_4\text{N} < \text{CH}_2\text{N} < \text{C}_6\text{H}_5$  [151°]. Formed by the action of  $\text{HNO}_3$  on *o*-amido-benzyl-*p*-toluidine hydrochloride (Busch, *B.* 25, 450). Yellow plates (from alcohol).  $-\text{B}^+\text{HCl}$ .  $-\text{B}^+\text{H}_2\text{PtCl}_6$ . [190°].  $-\text{B}^+\text{C}_6\text{H}_5\text{N}_3\text{O}_4$ . [132°]. Dark-yellow needles.

**p-TOLYL-PHENYL-ACETAMIDINE**  $\text{C}_{15}\text{H}_{15}\text{N}_2$  *i.e.*  $\text{C}_6\text{H}_4\text{CH}_2\text{C}(\text{N} < \text{C}_6\text{H}_5\text{Me})\text{NH}_2$ . [119°]. Formed by heating phenyl-acetonitrile with *p*-toluidine hydrochloride (Bernthsen, *A.* 184, 342). Crystals (from alcohol).  $-\text{B}^+\text{H}_2\text{PtCl}_6$ : yellow prisms.

**DI-p-TOLYL-DIPHENYLACETYLENE-DIAMINE**  $\text{C}_{24}\text{H}_{21}\text{N}_2$  *i.e.*  $\text{C}_6\text{H}_4\text{N} < \text{CPh} < \text{CPh} < \text{NC}_6\text{H}_4$ . [161°]. Formed, together with  $\text{Bz.CPh} < \text{N} < \text{H}$ , [116°], by heating benzil (1 mol.) with *p*-toluidine (2 mols.) at 130° (Blandowski, *M.* 9, 690). Triclinic plates.

**DI-TOLYL-PHENYLENE-DIAMINE** *v.* PHENYLENE-DI-TOLYL-DIAMINE.

**TOLYL PHOSPHATES.**

**Tri-o-tolyl-phosphate**  $(\text{C}_6\text{H}_4\text{O})_3\text{PO}$ . Formed by heating *o*-cresol with  $\text{POCl}_3$ , the yield being 95 p.c. (Heim, *B.* 16, 1767; Rapp, *A.* 224, 173). Oil, sol. alcohol and ether.

**p-Tolyl phosphate**  $\text{PO}(\text{OC}_6\text{H}_4)(\text{OH})_2$ . [116°]. Formed by the action of water on  $\text{PO}(\text{OC}_6\text{H}_4)_3$ , which is a product of the action of  $\text{POCl}_3$  on *p*-cresol (Rapp, *A.* 224, 168). Plates, sol. alcohol, ether, and water.

**Tri-p-tolyl phosphate**  $\text{PO}(\text{OC}_6\text{H}_3)_3$ . [78°]. Formed by heating *p*-cresol with  $\text{POCl}_3$ , the yield being 95 p.c. Colourless tables, insol. Aq.

**p-TOLYL-PHOSPHINE**  $\text{C}_6\text{H}_4\text{NH}_2$ . [4°]. [178°]. Formed by the action of  $\text{AlCl}_3$  on a mixture of toluene and  $\text{PCl}_3$ , the resulting

$\text{C}_6\text{H}_5\text{PCl}_2$  [20°] (245°), being converted by water into  $\text{C}_6\text{H}_5\text{P}(\text{OH})_2$ , which splits up on heating into tolyl-phosphine and toluene phosphonic acid  $\text{C}_6\text{H}_5\text{PO}_2\text{H}_2$  (Michaelis, *B.* 12, 1009; 13, 653; *A.* 212, 230). Oil with strong odour. Rapidly oxidised by air to  $\text{C}_6\text{H}_5\text{P}(\text{OH})_2$ . HI forms  $\text{C}_6\text{H}_5\text{PII}_3$ , crystallising in colourless needles.

**p-TOLYL-PHTHALIDE**  $\text{C}_{11}\text{H}_9\text{O}_2$  *i.e.*  $\text{C}_6\text{H}_4 < \text{CO} < \text{CH}(\text{C}_6\text{H}_5) > \text{O}$ . [129°]. Formed by reducing  $\text{C}_6\text{H}_4\text{CO}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$  in alcoholic solution with Zn and HCl (Gresly, *A.* 234, 235). Needles, sol. hot alcohol, insol.  $\text{NH}_4\text{Aq}$ .

**Di-p-tolyl-phthalide**  $\text{C}_{18}\text{H}_{15}\text{O}_2$  *i.e.*  $\text{C}_6\text{H}_4 < \text{CO} < \text{C}(\text{C}_6\text{H}_4) > \text{O}$ .

[116°]. Formed by heating phthalyl chloride (100 g.) with toluene (450 g.) and  $\text{AlCl}_3$  (Berchem, *Bl.* [2] 42, 168; cf. Friedel a. Crafts, *Bl.* [2] 36, 505). Prisms, sol. alcohol and ether.

**TOLYL-PHTHALIMIDE** *v. TolyImide of PHTHALIC ACID.*

**m-TOLYL-PROPIOLIC ACID**  $\text{C}_9\text{H}_7\text{Cl} < \text{CO}_2\text{H}$ . [109.5°]. Formed by boiling di-bromo-tolyl-propionic acid  $\text{C}_9\text{H}_6\text{Br}_2 < \text{CHBr} < \text{CO}_2\text{H}$  with alcoholic potash (Müller, *B.* 20, 1215).  $\text{AgNO}_3$  gives an explosive white pp.

**o-TOLYL-PROPIONIC ACID**  $\text{C}_9\text{H}_7 < \text{C}_6\text{H}_4\text{O}_2$ . Monoclinic prisms (Young, *B.* 25, 9102).

**m-Tolyl-propionic acid**  $\text{C}_9\text{H}_7 < \text{CH}_2 < \text{CH}_2 < \text{CO}_2\text{H}$ . [43°]. Formed by reducing *m*-tolyl-acrylic acid with sodium-amalgam (Müller, *B.* 20, 9214; von Miller, *B.* 23, 1899). Needles (from ligroin), sol. water, alcohol, and ether. Volatile with steam.

**m-Tolyl-propionic acid** [125°]. Formed by oxidation of *m*-isobutyl-toluene by  $\text{HNO}_3$  (Effront, *B.* 17, 2330). Needles, sl. sol. hot water.  $-\text{Ag}^+$ : crystals, sol. hot water.

**p-Tolyl-propionic acid**. [116°] (Von Miller, *B.* 23, 1898); [120°] (Kröber, *B.* 23, 1033). Formed by reducing *p*-tolyl-acrylic acid. Condensed by hot  $\text{H}_2\text{SO}_4$  to oxy-methyl-indonaphthene.

**Di- $\alpha$ -tolyl-propionic acid**  $\text{CH}_3\text{C}(\text{C}_6\text{H}_4)_2\text{CO}_2\text{H}$ . [152°]. Prepared by adding toluene to a solution of pyruvic acid in  $\text{H}_2\text{SO}_4$  at  $-10^\circ$  (Böttger, *B.* 14, 1596; 15, 1474). Monoclinic crystals, sol. hot alcohol. Give *u*-di-tolyl-ethane on distillation with lime. Oxidised by  $\text{KMnO}_4$  to di-phenyl-ethane tri-carboxylic acid.  $-\text{Ag}^+$ .

**Ethyl ether EtA**. [145°]. Prisms.

**References.** — BIOGEO., NITRO., and OXY.

**TOLYL-PROPIONIC ACIDS.**

**p-TOLYL-PROPIOLIC ALDEHYDE**

$\text{C}_9\text{H}_7 < \text{CH}_2 < \text{CHO}$ . (223°). S.G. 1.9941. Formed by the action of water on the compound of  $\text{CrO}_2\text{Cl}_2$  with the cymene got from camphor and  $\text{P}_2\text{O}_5$  (Richter a. Schüchler, *B.* 17, 1931). Got also by distilling calcium *p*-tolyl-propionate with calcium formate (Miller, *B.* 23, 1082). Oil, smelling like peppermint. Volatile with steam. Yields *p*-toluic and terephthalic acids on oxidation.

**DI-o-TOLYL-PROPYLENE-DIAMINE**

$\text{CHMe}(\text{NHC}_6\text{H}_3)\text{CH}_2\text{NHC}_6\text{H}_3$ . (280° at 120 mm.). Got by heating *o*-toluidine with propylene bromide (Bischoff, *B.* 25, 8276).

**Acetyl derivative**  $\text{C}_{21}\text{H}_{19}\text{N}_2\text{O}_2$ . [126°].

**Di-p-tolyl-propylene-diamine**

$\text{C}_9\text{H}_7(\text{NHC}_6\text{H}_4)_2$ . (277° at 48 mm.) (Bischoff, *B.* 25, 8277). Got from *p*-toluidine and  $\text{C}_6\text{H}_5\text{Br}$ . Oil.

*Acetyl derivative*  $C_{21}H_{22}N_2O_2$ . [114°].

*Benzoyl derivative*  $C_{21}H_{22}N_2O_2$ . [152°].

***o*-TOLYL-PROPYLENE- $\psi$ -THIO-UREA**

$C_9H_{10}N_2O \cdot \frac{8}{N}CHMe$ . [126°]. Formed from

*s*-*o*-tolyl-allyl-thio-urea and HCl (Prager, B. 22, 2999). Tables, sl. sol. hot water.  $-B'_2H_2PtCl_6$ . [178°]. Prisms.  $-B'_2C_6H_5N_2O_2$ . [176°]. Cubes.

***Di*-*o*-TOLYL-PROPYLENE UREA**

$C_9H_{10}N_2O \cdot \frac{N}{N}CH_2 \cdot CO$ . [93°]. Formed from *di*-*o*-tolyl-propylene-diamine and  $COCl_2$  (Bischoff, B. 25, 3276). Prisms (from dilute alcohol).

***Di*-*p*-tolyl-propylene-urea**. [130°].

***d*-TOLYL ISOPROPYL KETONE**

$C_9H_{10}Me.CO.Pr.$  (236°). Formed from toluene, isobutyl chloride and  $AlCl_3$  (Claus, J. pr. [2] 46, 480). Oil, with bitter taste and aromatic odour. Yields *p*-toluic and terephthalic acids on oxidation. Yields an oxim [92°]. May be reduced to *p*-tolyl-isopropyl-carbinol; an oil boiling above 300°.

***Di*-*o*-TOLYL-PYRAZINE HEXAHYDRIDE**

$C_9H_{10}Me.N \cdot \frac{CH_2 \cdot CH_2}{CH_2 \cdot CH_2} \cdot N.C_6H_5Me$ . *Di*-*o*-tolyl-piperazine. [171°]. Formed from ethylene bromide, *o*-toluidine, and  $Na_2CO_3$  at 160° (Bischoff, B. 22, 1781; 23, 1932; cf. Mauthner a. Suida, M. 7, 233). Crystals (from ether).

***Isomeride***. [154°]. Formed by heating *di*-*o*-tolyl-ethylene-diamine with chloro-acetic acid and  $NaOAc$  (Bischoff, B. 23, 2031). Thin needles (from alcohol).

***Di*-*p*-tolyl-pyrazine hexahydride**

$C_9H_{10}N \cdot \frac{CH_2 \cdot CH_2}{CH_2 \cdot CH_2} \cdot N.C_6H_5$ . [188°]. Formed from *p*-toluidine and  $C_6H_5Br_2$  in presence of  $NaOAc$  or  $Na_2CO_3$ . Prisms, sl. sol. alcohol. With  $NaNO_2$  and  $HOAc$  it yields a di-nitroso-derivative [167°].

***o*-TOLYL-PYRAZOLE**  $CH \cdot \frac{CH.N.C_6H_5Me}{CH:N}$

[246.5° cor.]. S.G.  $\frac{1}{4}$  1.0868;  $\frac{1}{2}$  1.0753. Formed by boiling epichlorhydrin (1 mol.) with *o*-tolyl-hydrazine (2 mols.) and benzene, boiling off the benzene, and heating the residue at 150° (Palliano, G. 18, 868). Not reduced by boiling with alcohol and  $Na$ .  $-B'_2H_2PtCl_6$ . [201°].  $-B'EtI$ . [100°]. Needles, v. e. sol. water.

***Dihydrate***  $C_9H_{10}N_2.C_6H_5$ . (271°). S.G.  $\frac{1}{4}$  1.084. Formed from acrolein tolyl-hydrazide and dilute (2 p.c.)  $H_2SO_4$ . Oil. Sol. fuming  $HClAq$ , but reppd. by water.  $K_2Cr_2O_7$  and  $H_2SO_4$  give an indigo-blue colour.

***p*-Tolyl-pyrazole**. [33°]. (259° cor.). Formed, in like manner, from epichlorhydrin and *p*-tolyl-hydrazine. Yellowish plates, sl. sol. hot water.  $-B'_2H_2PtCl_6$  2aq: needles. [184°].  $-B'EtI$ . [105°]. Prisms, v. sol. water.

***Dihydrate***. [60.5°]. (282° i.v.). Formed from acrolein *p*-tolyl-hydrazide and dilute  $H_2SO_4$ . Got also by reducing *p*-tolyl-pyrazole in alcoholic solution by  $Na$ . Iridescent plates, sl. sol. hot water. Its acidified solution is coloured violet-red by  $K_2Cr_2O_7$ .

***o*-TOLYL-PYRIDINE HEXAHYDRIDE**

$C_9H_{10}Me.N.C_6H_5$ . (262°). Formed by heating piperidine with *p*-bromo-toluene at 270° (Lellmann a. Just, B. 24, 2099). V. sol. alcohol and benzene.

***p*-TOLYL-PYRROLE**  $C_9H_9N$  i.e.

$CH:CH \cdot N.C_6H_5Me$ . Got by dry distillation of *p*-toluidine mucate (Lichtenstein, B. 14, 933). Converted by  $AcCl$  into crystalline  $C_9H_9N.CO_2$ .  $-B'_2HgCl_2$ .

***Di*-*p*-tolyl-pyrrole**  $CH:C(O.C_6H_5) \cdot NH$ .

[197°]. Formed by treating *di*-*p*-tolyl-furfurane or  $(C_6H_5.CO)_2C_6H_5$  with  $NH_4OAc$  (Hollemann, R. T. C. 6773). Small plates with bluish lustre. Does not form a K derivative. Boiling  $HClAq$  gives a red resin. With isatin, after several days, it gives an intense red colour.

***o*-TOLYL-QUINAZOLINE DIHYDRIDE**

$C_{15}H_{11}N_2$  i.e.  $C_6H_5 \cdot \frac{N=CH}{CH_2 \cdot N.C_6H_5Me}$ . Formed by reducing the formyl derivative of *o*-nitro-benzyl-*o*-toluidine with tin and  $HClAq$  (Paul a. Busch, B. 22, 2701). Oil.  $-B'HSnCl_4$ .  $-B'HCl$ : amorphous.  $-B'_2H_2PtCl_6$ . [210°]. Needles (from alcohol containing  $HCl$ ).

***p*-Tolyl-quinazoline dihydride**. [120°].

Formed in like manner. Plates, v. sol. alcohol.  $-B'HSnCl_4$ . [165°].  $-B'HCl$  2aq. [85°].  $-B'HCl$ . [251°].  $-B'_2H_2PtCl_6$ . [216°]. Yellow needles.

***Methylo-iodide***  $B'MeI$ . [186°]. Needles.

***p*-Tolyl-quinazoline tetrahydride**

$C_6H_5 \cdot \frac{NH \cdot CH_2}{CH_2 \cdot N.C_6H_5Me}$ . [127°]. Formed by reducing the dihydride in alcoholic solution by sodium. Needles, m. sol. alcohol. Yields a nitrosamine [100°]. Yields a crystalline hydrochloride.

***Reference***.—OXY-TOLYL-QUINAZOLINE.

(*Py*. 3) ***o*-TOLYL-QUINOLINE**  $C_{15}H_{11}N$  i.e.

$C_6H_5 \cdot \frac{CH:CH}{N=C.C_6H_5Me}$ . [77°]. Formed by distilling oxy-tolyl-quinoline (pseudoflavenol) with zinc-dust (Weidel a. Bamberger, M. 9, 108). Silky needles (from benzene).  $-B'_2H_2PtCl_6$  (dried at 105°). Orange tables.

***m*-Tolyl-isoquinoline**  $C_9H_7 \cdot \frac{CH:C_6H_5}{CH:N}$ .

[52°]. Formed by heating (1)-chloro- (3)-*m*-tolyl-isoquinoline with  $HI$  and  $P$  for three hours at 170° (Heilmann, B. 23, 3168). Needles (from  $MeOH$ ).

***p*-Tolyl-isoquinoline**  $C_9H_7 \cdot \frac{CH:C_6H_5}{CH:N}$ .

[78°]. Formed in like manner (Ruhemann, B. 24, 3975). Needles.  $-B'HI$ .  $-B'H_2CrO_4$ .  $-B'_2H_2PtCl_6$ .  $-B'_2C_6H_5N_2O_2$ . Yellow needles.

***Reference***.—OXY-TOLYL-QUINOLINE.

**TETRA-*m*-TOLYL-SILICANE**  $Si(C_6H_5)_4$ .

[151°]. (above 550°). S.G.  $\frac{23}{4}$  1.1188. Formed from *m*-bromo-toluene,  $SiCl_4$ , and sodium (Polis, B. 19, 1021). Prisms (from ether), v. sol. benzene.

**Tetra-*p*-tolyl-silicane**  $Si(C_6H_5)_4$ . [228°]. (above 450°). S.G.  $\frac{23}{4}$  1.0793. Formed from  $SiCl_4$ , *p*-bromo-toluene, ether,  $Na$ , and a little  $EtOAc$  (Polis, B. 18, 1542; 19, 1019). Monoclinic crystals (from chloroform). Decomposed by conc.  $HNO_3$ , forming silica and *di*-*p*-nitro-toluene [72°].

**TETRA-*o*-TOLYL SILICATE**  $Si(OC_6H_5)_4$ . (G. 437°). Formed by heating *o*-cresol with  $SiCl_4$ , the yield being 90 p.c. of the theoretical quantity (Hertkorn, B. 18, 1686). Oil, v. sol.

alcohol. Decomposed by hot water into silica and *o*-cresol.

**Tetra-*m*-tolyl silicate**  $\text{Si}(\text{OC}_6\text{H}_4)_4$ . (445°) at 720 mm. Syrup (H.).

**Tetra-*p*-tolyl silicate**  $\text{Si}(\text{OC}_6\text{H}_4)_4$ . [70°]. (444°). Tables or prisms, v. sol. benzene (H.).

***p*-TOLYL SILICO-CHLORIDE**  $\text{C}_6\text{H}_4\text{SiCl}_2$ . (219°). Formed from  $\text{Hg}(\text{C}_6\text{H}_5)_2$  and  $\text{SiCl}_4$  at 310° (Ladenburg, A. 173, 185). Liquid, converted by dilute aqueous ammonia into  $\text{C}_6\text{H}_4\text{SiO}_2\text{OH}$  (c. 150°), which is converted at 200° into solid  $\text{C}_6\text{H}_4\text{SiO}_2\text{O}$ .

#### • TOLYL SULPHATES.

##### *o*-Tolyl sulphuric acid

[1:2]  $\text{C}_6\text{H}_4\text{Me.O.SO}_3\text{OH}$ . Occurs in small quantity in the urine of horses (Prouesse, H. 2, 355). Prepared from  $\text{C}_6\text{H}_4\text{Me.OK}$  and  $\text{K}_2\text{S}_2\text{O}_8$  (Baumann, B. 11, 1911). The K salt crystallises in plates, m. sol. water.

***m*-Tolyl sulphuric acid**  $\text{C}_6\text{H}_4\text{Me.O.SO}_3\text{OH}$ . Occurs in very small quantity in horses' urine (P.).

***p*-Tolyl sulphuric acid**  $\text{C}_6\text{H}_4\text{Me.O.SO}_3\text{OH}$ . Occurs in the urine of horses and cows (Baumann, B. 9, 1389, 1716; Städeler, A. 77, 18). Formed by boiling potassium *p*-cresol with  $\text{K}_2\text{S}_2\text{O}_8$ . The K salt is sl. sol. cold alcohol.

**DI-*o*-TOLYL-SULPHAZIDE**  $\text{C}_6\text{H}_4\text{N}_2\text{SO}_2$ , *i.e.* [2:1]  $\text{C}_6\text{H}_4\text{Me.NH.NH.SO}_2\text{C}_6\text{H}_4\text{Me}$  [1:2]. ***Tolyl-toluene-sulphazide***. [142°]. Obtained by the action of  $\text{SO}_2$  upon *o*-diazotoluene in alcoholic solution. White glistening needles (Limpriecht, B. 20, 1241). When boiled with baryta-water it decomposes into *o*-toluene-sulphinic acid, toluene, and nitrogen.

**Di-*p*-tolyl-sulphazide**  $\text{C}_6\text{H}_4\text{N}_2\text{SO}_2$ , *i.e.* [4:1]  $\text{C}_6\text{H}_4\text{Me.NH.NH.SO}_2\text{C}_6\text{H}_4\text{Me}$  [1:4]. ***Tolyl-toluene-sulphazide***. [140°]. Formed in like manner from *p*-diazotoluene (L.). Small needles. By boiling with baryta-water it is decomposed into *p*-toluene-sulphinic acid, toluene, and nitrogen.

#### Reference.—NITRO-DI-TOLYL-SULPHAZIDE.

**DI-*p*-TOLYL SULPHIDE**  $\text{S}(\text{C}_6\text{H}_4\text{Me})_2$ . [57°]. (above 300°). Formed by distillation of lead *p*-tolyl-mercaptide (Otto, B. 12, 1175). Small needles, insol. water, sol. alcohol. Yields di-*p*-tolyl sulphone on oxidation by  $\text{KMnO}_4$ .

**Di-*m*-tolyl disulphide**  $\text{C}_6\text{H}_4\text{S}_2$ , *i.e.*  $(\text{C}_6\text{H}_4\text{Me})_2\text{S}_2$ . Formed from *m*-tolyl mercaptan by treatment with dilute  $\text{HNO}_3$  (Hübner a. Post, A. 169, 51). Liquid at -22°. Decomposed on boiling or by atmospheric oxidation of its ammoniacal alcoholic solution (Leuckart, J. pr. [2] 41, 189).

**Di-*p*-tolyl disulphide**  $(\text{C}_6\text{H}_4\text{Me})_2\text{S}_2$ . [43°]. Formed from *p*-tolyl mercaptan by atmospheric oxidation (Märcker, A. 136, 88) or by the action of  $\text{ClSO}_3\text{H}$  (Beckurts a. Otto, B. 11, 2066), or by treatment with  $\text{ICl}$  (Thurnauer, B. 23, 769). Formed also by the action of  $\text{H}_2\text{S}$  on a warm dilute solution of toluene *p*-sulphinic acid in alcohol (Otto, J. pr. [2] 37, 211). Crystals, v. e. sol. ether. Begins to boil at 307° i.v. but decomposes on distillation. Alcoholic K<sub>2</sub>S forms *p*-tolyl mercaptan (Otto a. Rössing, B. 19, 8129).

**Di-*p*-tolyl tetrasulphide**  $(\text{C}_6\text{H}_4\text{Me})_2\text{SO}_4$ . [75°]. Formed by the action of  $\text{H}_2\text{S}$  on a conc. solution of toluene *p*-sulphinic acid (Otto, J. pr.

[2] 37, 211). Small plates, insol. water, v. sol. ether.

#### References.—DI-AMIDO-, DI-BROMO-, and OXY-DI-TOLYL-SULPHIDE.

***o*-TOLYL SULPHOCYANIDE**  $\text{C}_6\text{H}_4\text{Me.S.CN}$ . (c. 245°). Formed by adding cuprous sulphocyanide in KSCy to a solution of *o*-diazotoluene (Thurnauer, B. 23, 770). Yellowish-red oil with unpleasant odour.

***p*-Tolyl sulphocyanide**. (c. 248°). Formed in like manner, and also by passing  $\text{CyCl}$  through alcohol containing lead *p*-tolyl mercaptide. Liquid, solidifying below 0°.

**DI-*p*-TOLYL SULPHONE**  $(\text{C}_6\text{H}_4\text{Me})_2\text{SO}_2$ . [158°]. (405°) at 714 mm. Prepared by the action of  $\text{AlCl}_3$  on a mixture of toluene and toluene *p*-sulphonic chloride (Beckurts a. Otto, B. 11, 2068; 12, 1177; cf. Michael, B. 10, 584). Formed by the action of fuming  $\text{H}_2\text{SO}_4$  or  $\text{SO}_3$  on toluene (Deville, A. 44, 306; Otto a. Grüber, A. 154, 193) and by the action of  $\text{KMnO}_4$  and  $\text{HOAc}$  on di-*p*-tolyl sulphide. Prisms (from benzene), sl. sol. cold alcohol and ether. Potash-fusion yields *p*-cresol and diphenyl (Otto, B. 19, 2426).

#### DITOLYL DISULPHONIC ACID

[1:4:5]  $\text{C}_6\text{H}_4\text{Me}(\text{SO}_3\text{H})\text{C}_6\text{H}_4\text{Me}(\text{SO}_3\text{H})$  [5:1:4]. Formed from di-*o*-amido-ditolyl disulphonic acid by diazotisation followed by boiling with alcohol (Halle, A. 270, 363). Crystals, v. e. sol. water, m. sol. alcohol, insol. ether.—K<sub>2</sub>A'. Hexagonal plates.—KHA': prisms.—BaA' 5aq.

**Chloride**  $\text{C}_6\text{H}_4\text{Me.S}_2\text{O}_2\text{Cl}_2$ . [229°].

**Amide**  $\text{C}_6\text{H}_4\text{Me.S}_2\text{O}_2(\text{NH}_2)_2$ . Needles.

#### *p*-TOLYL-SULPHONO-ACETIC ACID.

$\text{C}_6\text{H}_4\text{Me.SO}_2\text{CH}_2\text{CO}_2\text{H}$ . [118°]. Formed from sodium benzene sulphinate and chloro-acetic acid (Gabriel, B. 14, 834). Crystals (from benzene), sl. sol. hot water. Cl passed into its aqueous solution forms  $\text{C}_6\text{H}_4\text{Me.SO}_2\text{CH}_2\text{CO}_2\text{H}$ . Br forms  $\text{C}_6\text{H}_4\text{Me.SO}_2\text{CHBr}$  and  $\text{C}_6\text{H}_4\text{Me.SO}_2\text{CH}_2\text{Br}$  (Otto, J. pr. [2] 40, 542).—AgA': trimetric tables.

**Ethyl ether EtA'**. Converted by bromine (2 mols.) at 90° into  $\text{C}_6\text{H}_4\text{Me.SO}_2\text{CBr}_2\text{CO}_2\text{Et}$  which on saponification by cold  $\text{NaOHAq}$  yields  $\text{C}_6\text{H}_4\text{Me.SO}_2\text{CHBr}_2$ . [117°].

#### *p*-TOLYL-SULPHONO-ACETONE

$\text{CH}_3\text{CO.CH}_2\text{SO}_2\text{C}_6\text{H}_4\text{Me}$ . [51°]. Formed by heating sodium toluene *p*-sulphinate with chloro-acetone in alcohol (Otto, J. pr. [2] 36, 425). Needles, v. sol. alcohol. Bromine forms  $\text{CH}_3\text{Br.CO.CH}_2\text{SO}_2\text{C}_6\text{H}_4\text{Me}$ . [130°], m. sol. alcohol.

#### Di-*p*-tolyl-di-sulphono-acetone

$\text{CO}(\text{CH}_2\text{SO}_2\text{C}_6\text{H}_4\text{Me})_2$ . Formed by heating  $\text{CH}_3\text{Br.CO.CH}_2\text{SO}_2\text{C}_6\text{H}_4\text{Me}$  with sodium toluene *p*-sulphinate in alcoholic solution. Plates, v. sol. hot  $\text{HOAc}$  and chloroform.

**DI-TOLYL DI-SULPHONO-DI-ETHYL-AMINE**  $\text{NE}(\text{C}_6\text{H}_4\text{Me.SO}_2\text{C}_2\text{H}_5)_2$ . Formed by heating di-tolyl ethylene disulphone with  $\text{NH}_4\text{Aq}$  (Otto, J. pr. [2] 30, 353).—B'HCl. [201°].—B'HAuCl<sub>3</sub>: dark-yellow needles.

**DI-TOLYL-DI-SULPHONO-DI-ETHYL OXIDE**  $\text{O}(\text{C}_6\text{H}_4\text{Me.SO}_2\text{C}_2\text{H}_5)_2$ . [84°]. Formed by the action of conc. KOHAq on  $\text{CH}_3(\text{SO}_2\text{C}_2\text{H}_5)_2$ , and as a by-product in the preparation of  $\text{C}_6\text{H}_4\text{Me.SO}_2\text{C}_2\text{H}_5\text{OH}$  [55°] by the action of dilute KOHAq on the same body (Otto a. Tröger, B. 20, 944; cf. J. pr. [2] 30, 171, 321).

**TOLYL DISULPHOXIDE** *v. Tolyl ether of TOLUENE THIOSULPHONIC ACID.*

**Di-*p*-tolyl sulphoxide**  $\text{SO}(\text{C}_6\text{H}_4\text{Me})_2$ . [92°]. Formed from toluene,  $\text{SOCl}_2$ , and  $\text{AlCl}_3$  (Parker, *B.* 28, 1844). Flat needles (from ligroin), v. s. sol. benzene. Reduced by sodium and alcohol to di-tolyl sulphide [56°].  $\text{KMnO}_4$  in  $\text{HOAc}$  forms di-tolyl sulphone [158°].

**DI-*o*-TOLYL-TETRAZINE**  $\text{C}_{12}\text{H}_{10}\text{N}_4$ , i.e.

$\text{C}_6\text{H}_4\text{N} < \begin{smallmatrix} \text{N:CH} \\ \text{CH:N} \end{smallmatrix} > \text{NC}_6\text{H}_4$ . [141°]. Formed from *o*-tolyl-hydrazine, chloroform, and alcoholic potash (Ruhemann, *C. J.* 57, 52). Crystals. Yields crystalline  $\text{C}_{12}\text{H}_{10}(\text{SO}_3\text{H})_2\text{N}_4$  and  $\text{C}_{12}\text{H}_{10}(\text{NO}_2)_2\text{N}_4$  [207°]. —  $\text{B'HCl}$ : needles.

**Methylo-iodide**  $\text{B'MeI}$ . [198°]. Nodules.

**Di-*p*-tolyl-tetrazine**  $\text{C}_{16}\text{H}_{14}\text{N}_4$ . Formed in like manner.  $\text{B'HCl}$ : very unstable white needles.

**Methylo-iodide**  $\text{B'MeI}$ . [242°]. Needles.

***o*-TOLYL-THIAZOLE DIHYDRIDE**

$\text{C}_6\text{H}_4\text{Me.C} < \begin{smallmatrix} \text{N:CH} \\ \text{S:CH}_2 \end{smallmatrix} >$ . (282°). Formed from thio-*o*-toluic amide and ethylene bromide (Gabriel a. Heymann, *B.* 24, 786). Got also by heating *o*-toluic bromo-ethyl-amide with  $\text{P}_2\text{S}_5$  (Salomon, *B.* 26, 1329). Converted by bromine-water into taurine and *o*-toluic acid. —  $\text{B}'_2\text{H}_2\text{PtCl}_6$ . [199°]. —  $\text{B}'\text{C}_6\text{H}_4\text{N}_3\text{O}$ . [132°].

***p*-Tolyl-thiazole dihydride**. [81°]. Prepared in like manner. Tables.

***p*-TOLYL-THIOBIURET**  $\text{C}_8\text{H}_{11}\text{N}_3\text{S}_2$ . [158°]. Formed by fusing *p*-toluidine (2 pts.) with persulphocyanic acid (1 pt.) (Tursini, *B.* 17, 584). Minute needles, sol.  $\text{NaOH}$  aq. Yields  $\text{C}_8\text{H}_{11}\text{N}_3\text{S}_2\text{Et}$  [134°], crystallising from alcohol in needles, and  $\text{C}_8\text{H}_{11}\text{AsN}_3\text{S}_2$  [166°], crystallising in needles.

***o*-TOLYL- $\beta$ -THIOCARBAMIC ACID**

[1:2]  $\text{C}_6\text{H}_4\text{Me.NH.CS.OH}$ .

**Ethyl ether**  $\text{C}_6\text{H}_4\text{N:C(SH).OEt}$ . *Tolyl-thio-urethane*. Formed by heating *o*-tolyl-thiocarbimide with alcohol at 180° (Liebermann a. Natanson, *B.* 18, 1578; *A.* 207, 161). Oil, sol. alkalis. —  $\text{C}_6\text{H}_4\text{AgNSO}$ : white pp. insol.  $\text{NH}_4\text{Ag}$ . Converted by  $\text{MeI}$  into  $\text{C}_6\text{H}_4\text{N(OEt).SMe}$ , and by  $\text{EtI}$  into  $\text{C}_6\text{H}_4\text{N(OEt).SEt}$ , both being oils boiling above 250°.

***m*-Tolyl- $\beta$ -thiocarbamic acid**

[1:8]  $\text{C}_6\text{H}_4\text{Me.NH.CS.OH}$ .

**Ethyl ether**  $\text{C}_6\text{H}_4\text{N:C(SH).OEt}$ . [68°]. Formed in like manner (L. a. N.). Yields  $\text{C}_6\text{H}_4\text{AgNSO}$  and oily  $\text{C}_6\text{H}_4\text{EtNSO}$ .

***p*-Tolyl- $\beta$ -thiocarbamic acid**. **Ethyl ether**  $\text{C}_6\text{H}_4\text{NC(SH).OEt}$ . [87°]. Formed in the same way (L. a. N.). Triclinic crystals. Ammoniacal  $\text{AgNO}_3$  added to its alcoholic solution ppts.  $\text{C}_6\text{H}_4\text{NC(OEt).SAg}$ , which is converted by  $\text{MeI}$  into  $\text{C}_6\text{H}_4\text{NC(OEt).SMe}$ , and by  $\text{EtI}$  into  $\text{C}_6\text{H}_4\text{NC(OEt).SEt}$ , both being oils boiling above 250°.  $\text{C}_6\text{H}_4\text{NC(OEt).SEt}$  is decomposed by dilute  $\text{H}_2\text{SO}_4$  at 180° into *p*-toluidine and thiocarbonic ether.

***o*-Tolyl- $\alpha$ -thiocarbamic acid**  $\text{C}_6\text{H}_4\text{NH.CO.SH}$ .

**Methyl ether**  $\text{MeA'}$ . [70°]. Formed by heating  $\text{C}_6\text{H}_4\text{NH.C(NC.H).SMe}$  with dilute  $\text{H}_2\text{SO}_4$  at 140° (Will a. Bielschowski, *B.* 15, 1817). Plates.

**Ethyl ether**  $\text{EtA'}$ . [60°]. Tables.

***p*-Tolyl- $\alpha$ -thiocarbamic acid**  $\text{NH.C}_6\text{H}_4\text{CO.SH}$ .

**Methyl ether**  $\text{MeA'}$ . [107°]. Formed by heating  $\text{C}_6\text{H}_4\text{NH.C(NC.H).SMe}$  with dilute  $\text{H}_2\text{SO}_4$  at 170°. Needles, v. sol. alcohol and ether.

**Ethyl ether**  $\text{EtA'}$ . [79°]. Formed from

*p*-toluidine and  $\text{Cl.CO.SET}$ . Needles. Yields  $\text{EtSH}$  and tolyl cyanate on distillation.

**Ethylene derivative**

$\text{CO} < \begin{smallmatrix} \text{N(C}_6\text{H}_4) \\ \text{S} \end{smallmatrix} > \text{C}_6\text{H}_4$ . [88°]. Long slender needles.

***o*-Tolyl-di-thio-carbamic acid**

$\text{C}_6\text{H}_4\text{NH.CS.SH}$ . —  $\text{NIA'}$ . Brown needles, insol. water. —  $\text{BA'}$ . Plates (Losanitsch, *B.* 24, 3027). Forms di-*o*-tolyl-thio-urea on heating.

**Methyl ether**  $\text{MeA'}$ . [132°]. Formed from the Ba salt and  $\text{MeI}$ . White needles.

**Ethyl ether**  $\text{EtA'}$ . [72°]. Formed by heating  $\text{C}_6\text{H}_4\text{NH.C(NC.H).SEt}$  with  $\text{CS}_2$  at 160° (Will a. Bielschowski, *B.* 15, 1817). Prisms.

**Ethylene derivative**  $\text{C}_6\text{H}_4\text{NS}_2$ , i.e.

$\text{CS} < \begin{smallmatrix} \text{N(C}_6\text{H}_4) \\ \text{S} \end{smallmatrix} > \text{C}_6\text{H}_4$ . [129°]. Formed by heating

$\text{C}_6\text{H}_4\text{N.C} < \begin{smallmatrix} \text{S} \\ \text{NC}_6\text{H}_4 \end{smallmatrix} > \text{C}_6\text{H}_4$  with  $\text{CS}_2$  at 200°. Yields

$\text{C}_6\text{H}_4\text{NS}_2\text{MeI}$ , crystallising in prisms [151°].

***m*-Tolyl-di-thio-carbamic acid**

$\text{C}_6\text{H}_4\text{NH.CS.SH}$ .

Salts. —  $\text{BA'}$ . Formed from *m*-toluidine,  $\text{CS}_2$ , and  $\text{Ba(OH)}_2$  in alcohol (Losanitsch, *B.* 24, 3027). Needles, sol. water, insol. cold alcohol. —  $\text{NIA'}$ . Yellowish-brown plates.

**Methyl ether**  $\text{MeA'}$ . [89°]. Needles.

***p*-Tolyl-di-thio-carbamic acid**  $\text{C}_6\text{H}_4\text{NH.CS.H}$ .

Salts. —  $\text{NH}_4\text{A'}$ . Formed from *p*-toluidine,  $\text{CS}_2$ , alcohol, and  $\text{NH}_4\text{Ag}$  (Losanitsch, *B.* 24, 3026). Yellowish prisms, sol. water, insol. alcohol. —  $\text{BA'}$ . Needles. —  $\text{NIA'}$ . Formed from *p*-toluidine,  $\text{CS}_2$ , ammoniacal  $\text{NiSO}_4$ , and alcohol. Brown needles, sol. alcohol, insol. water.

**Methyl ether**  $\text{MeA'}$ . [84°]. Prisms.

**Ethyl ether**  $\text{EtA'}$ . [74°]. Formed by heating  $\text{NH.C}_6\text{H}_4\text{C(NC.H).SEt}$  with  $\text{CS}_2$  at 160° (W. a. B.). Needles, split up by heat into *p*-tolylthiocarbimide and  $\text{EtSH}$ .

**Ethylene ether**  $\text{CS} < \begin{smallmatrix} \text{N(C}_6\text{H}_4) \\ \text{S} \end{smallmatrix} > \text{C}_6\text{H}_4$ .

[126°]. Crystals. Yields a methylo-iodide [107°], which is converted by aniline into  $\text{C}_6\text{H}_4\text{N}_3\text{S}$  [128°], and by *o*-toluidine into  $\text{C}_7\text{H}_7\text{N}_3\text{S}$  [82°].

Reference. — NITRO - TOLYL - THIOCARBAMIC ETHER.

***q*-TOLYL-THIOCARBAZIC ACID** *o*-Tolyl hydrazide

$\text{C}_6\text{H}_4\text{NH.NH.CS.SNH}_2\text{NH.C}_6\text{H}_4$ . Formed from *o*-tolyl-hydrazine, ether, and  $\text{CS}_2$  (Preund, *B.* 24, 4200). Prismatic tables, insol. ether, decomposed by water and alcohol. The *p*-isomeride melts at 109°.

**DI-*o*-TOLYL-THIOCARBAZIDE**  $\text{C}_{12}\text{H}_{10}\text{N}_4\text{S}$ , i.e.  $\text{CS}(\text{NH.NH.C}_6\text{H}_4\text{Me})_2$ . [130°]. Formed from *o*-tolylthiocarbazic acid and *o*-tolyl-hydrazine at 90° (Preund, *B.* 24, 4201). Needles, sol. alcohol, insol. Aq.

**DI-*p*-tolyl-thiocarbazide**. [121°]. Formed in like manner at 110° (Preund, *B.* 24, 4194). Plates, v. sol. hot alcohol.

**Di-*o*-tolyl-thiosemicarbazide**  $\text{C}_{12}\text{H}_{10}\text{N}_4\text{S}$ , i.e.  $\text{NHC}_6\text{H}_4\text{CS.NH.NH.C}_6\text{H}_4$ . [149°]. Formed by heating *o*-tolylthiocarbimide (1 mol.) with *o*-tolyl-hydrazine (1 mol.) in alcohol (Dixon, *C. J.* 61, 1017). Octahedra, pn. sol. hot alcohol, Kisol. Aq.

**Di-*p*-tolyl-thiosemicarbazide**. [154°]. Formed in like manner (D.). Prisms, v. s. sol. hot alcohol.

**op-Di-tolyl-thiosemicarbaside**  
 (4:1)  $C_9H_7Me.NH.CS.NH.NHC_6H_4Me$  [1:2]. [142°].  
 Formed from *p*-tolyl-thiocarbimide and *o*-tolyl-hydrazine (D.). Prisms, sl. sol. hot alcohol.

**Isomeride**  
 [2:1]  $C_9H_7Me.NH.CS.NH.NHC_6H_4Me$  [1:4]. [163°].  
 Formed from *o*-tolyl-thiocarbimide and *p*-tolyl-hydrazine (Dixon, *C. J.* 61, 1015). Prisms, m. sol. hot alcohol.

**Di-*o*-tolyl-thiocarbazone**  $C_{12}H_{10}N_2S_2$  i.e.  $C_6H_4N:N.CS.NH.NHC_6H_4$ . [168°]. Formed from di-*o*-tolyl-thiocarbazide and alcoholic potash (Preund, *B.* 24, 4201). Blue-black needles, v. sol. chloroform, sl. sol. alcohol. Conc.  $H_2SO_4$  forms a bluish-green solution.

**Di-*p*-tolyl-thiocarbazone**. [105°]. Formed in like manner. Dark-blue amorphous flakes.

***o*-TOLYL-THIOCARBIMIDE**  $C_8H_7NS$  i.e. [1:2]  $C_6H_4Me.N:CS$ . (239°). Formed from di-*o*-tolyl-thio-urea by distilling with  $P_2O_5$  (Staats, *B.* 13, 136), by heating with aqueous  $H_3PO_4$  (Hofmann, *B.* 15, 986; Mainzer, *B.* 16, 2017), or by boiling with fuming  $HClAq$  (Girard, *B.* 6, 445). Oil.

**Reactions.**—1. Chlorine forms  $C_8H_7NCl_2SCl$  (218°), which is converted by alcohol into a mixture of di-*o*-tolyl-urea and *o*-tolyl-carbamio ether (Lachmann, *B.* 12, 1349).—2. Chloro-acetic acid and alcohol at 150° form  $C_8H_7N:C<S.C_6H_4CO_2O$  crystallising in needles [120°], decomposed by boiling baryta-water into *o*-toluidine,  $CO_2$ , and thioglycollic acid (Völitzhoff, *B.* 13, 1580).—3.  $PhOMe$  and  $AlCl_3$  on warming form  $C_8H_7NH.CS.C_6H_4OMe$  (95°) (Tust a. Gattermann, *B.* 25, 3528).  $PhOEt$  and  $AlCl_3$  give  $C_{10}H_{11}NSC$  [116°].

***m*-Tolyl-thiocarbimide**  $C_8H_7N:CS$ . (244°) at 732 mm. Formed by boiling di-*m*-tolyl-urea with conc.  $HClAq$  (Weith a. Landolt, *B.* 8, 719). Heavy oil. Converted by copper-powder at 220° into *m*-toluic nitrile.

***p*-Tolyl-thiocarbimide** [1:4]  $C_8H_7Me.N:CS$ . [265°]. (237°). Formed by heating di-*p*-tolyl-thio-urea with  $P_2O_5$  or aqueous  $H_3PO_4$  of S.G. 1.7 (Hofmann, *B.* 1, 173; 15, 986; Staats, *B.* 13, 135). Formed also, together with phenyl-thiocarbimide, by heating  $PhN:C:NC_6H_5$  with  $CS_2$  at 190° (Huhn, *B.* 19, 2409). Needles (from ether), v. sol. alcohol.

**Reactions.**—1. Ammonia forms tolyl-thio-urea, and other bases act in like manner.—2. Bromine forms  $C_8H_7NBr.CSBr$ , which readily gives off  $Br$ , leaving  $(C_8H_7NCS)_2Br_2$  crystallising in plates decomposing at 210° (Helmers, *B.* 20, 790).—3. Chlorine forms  $(C_8H_7NCS)_2Cl_2$ , whence dilute alcohol gives  $(C_8H_7NCS)_2O$  [139°] crystallising in needles.—4.  $CH_3Cl.CO_2H$  and alcohol at 150° form  $C_8H_7N:C<S.C_6H_4CO_2O$  [162°] (Völitzhoff, *B.* 13, 1579).—5. Warmed with toluene and  $AlCl_3$  it gives  $C_8H_7NH.CS.C_6H_5$  [166°].—6. Heated with  $AlCl_3$  it yields  $(C_8H_7N.CS)_2S$  [176°] (Friedmann a. Gattermann, *B.* 25, 3525).—7.  $C_6H_5OMe$  and  $AlCl_3$  react, with formation of  $C_8H_7NH.CS.C_6H_4OMe$  [157°].—8.  $C_6H_5OEt$  and  $AlCl_3$  give  $C_8H_7NH.CS.C_6H_4OEt$  [151°], which may be oxidised to  $C_8H_7NH.CS.C_6H_4NO_2$  [170°].

**Di-*p*-TOLYL DI-THIO-CARBONATE**  
 $CO(SC_6H_4Me)_2$ . [91°]. Formed from *p*-tolyl mercaptan and  $COCl_2$ . It is also a by-product

in the action of *p*-diazotoluene chloride on potassium xanthate (Leuckart, *J. pr.* [2] 41, 190). Needles (from alcohol).

**TRI-TOLYL TRI-THIOCYANURATE**  
 $(C_6H_4Me.SCy)_3$ . [114°]. Formed from sodium *p*-tolyl mercaptan and cyanuric chloride (Klason, *J. pr.* [2] 33, 120). Crystals (from  $HOAc$ ).

***o*-TOLYL-THIOHYDANTOIN**  $C_8H_7NSO_2$  i.e.  $CS<N(C_6H_4Me)>CO$ . [136°]. Formed from *o*-tolyl-thiocarbimide and amido-acetic acid (Marckwald, *B.* 24, 3281). Plates, v. sol. alcohol, sl. sol. ligroin.

***p*-Tolyl-thiohy-lantoïn** [210°] (M.). Formed as above (M.; cf. Aschan, *B.* 17, 426). Flat prisms, sol. alkalis.

**Isomeride** [183°]. Formed by fusing  $CH_3Cl.CO.NHCl$ , with thio-urea (P. Meyer, *B.* 10, 1966). Small crystals.

***p*-Tolyl- $\psi$ -thiohy-dantoic acid**  
 $C_8H_7N:C(NH_2).S.C_6H_4.CO_2H$ . [176° - 182°]. Formed by boiling chloro-acetic acid with ammonium sulphocyanide, *p*-toluidine, and alcohol (Jäger, *J. pr.* [2] 16, 21). Prisms, not attacked by  $Ac_2O$  and  $Hr$ .

**Di-*p*-TOLYL-THIOPHENE**  $C_{12}H_8S$  i.e.  $CH:C(C_6H_4Me)>S$ . [171°]. Formed by heating di-*p*-tolyl-furfurane with  $P_2S_5$  (Holle-mann, *R. T. C.* 6, 74). Small plates (from alcohol). Gives an intense dark-green colour with isatin and  $H_2SO_4$ .

***o*-TOLYL-THIO-UREA**  $NH.CS.NHC_6H_4Me$ . [155°]. Formed from *o*-tolyl thiocarbimide and  $NH_4Aq$  (Staats, *B.* 13, 136). V. sol. hot water and alcohol, sl. sol. ether.

**Acetyl derivative**  $NHAc.CS.NHC_6H_4Me$ . [184°]. Formed from acetyl thiocarbimide and *o*-toluidine in alcohol (Dixon, *C. J.* 65, 804). Pale lemon-yellow prisms, insol. water, sol. alcohol.

**Benzoyl derivative**  
 $NHBz.CS.NHC_6H_4Me$ . [119°]. Formed in Wk<sup>o</sup> manner (Dixon, *C. J.* 55, 623). Pale-yellow prisms, blackened by  $AgNO_3$ .

**Di-*o*-tolyl-thio-urea**  $CS(NH.C_6H_4Me)_2$ . [158°]. Formed from *o*-toluidine and  $CS_2$  (Girard, *B.* 4, 985; Berger, *B.* 12, 1854; Ador a. Rielliet, *B.* 12, 2301). Long needles, v. sol. hot alcohol. Converted by heating with  $MeI$  into the hydroiodide of di-tolyl-methyl-thiourea  $C_{12}H_{10}N_2S_2$ , which may be represented as 'methyl di-*o*-tolyl-imido-thiocarbamate'  $C_8H_7N:C(SMe).NHC_6H_4$ . This body melts at 60°, while the corresponding ethyl derivative melts at 51°. The ethylene derivative [91°] may be represented by the formula  $C_8H_7N:C<S(C_6H_4)>C_6H_4$  (Will a. Bielschowski, *B.* 15, 1316). The isomeric compound [122]  $C_8H_7Me.N:C<N(C_6H_4Me)>S$  [82°] is got by boiling the methyl-iodide of the ethylene derivative of *p*-tolyl-di-thio-carbamio acid with *o*-toluidine.

***m*-Tolyl-thio-urea**  $NHC_6H_4.CS.NH_2$ . [108°]. Formed from *m*-tolyl thiocarbimide and ammonia (Weith a. Landolt, *B.* 8, 719). Prisms, m. sol. hot water, v. sol. alcohol and ether.

**Di-*m*-tolyl-thio-urea**  $CS(NHC_6H_4)_2$ . [122°]. Formed from *m*-toluidine,  $CS_2$ , and alcohol (W.

a. L.). Needles, v. sol. alcohol; nearly insol. hot water.

*p*-Tolyl-thio-urea  $\text{NH}_2\text{C}(\text{NH}_2)\text{CSNH}_2$ . [188°]. (C. a. W.); [182°] (S.). Formed by heating *p*-toluidine hydrochloride with ammonium sulphocyanide (De Clermont a. Wehrin, C. R. 88, 347). Formed also from *p*-tolyl-thiocarbimide ammonia (Staats, B. 18, 136). Plates (from alcohol) with bitter taste, al. sol. cold water, m. sol. alcohol.

*Acetyl derivative*.  $\text{NH}_2\text{C}(\text{NH}_2)\text{CSNHAc}$ . [176°]. Formed from acetyl sulphocyanide and *p*-toluidine (Miguel, Bl. [2] 28, 103). Needles, v. e. sol. hot alcohol, v. sol. ether.

Di-*p*-tolyl-thio-urea  $\text{CS}(\text{NH}_2\text{C}_6\text{H}_4\text{Me})_2$ . [176°]. Formed by boiling *p*-toluidine with  $\text{CS}_2$  and alcohol (Sell, A. 126, 160). It is also a product of the action of allyl-thiocarbimide on an alcoholic solution of *p*-toluidine (Maly, Z. [2] 5, 258). Trimetric prisms (Levin, J. 1882, 384), insol. water, nearly insol. cold alcohol. In alcoholic solution it is converted by  $\text{HgO}$  into di-*p*-tolyl-urea. In benzene solution  $\text{COCl}_2$  forms  $\text{C}_6\text{H}_4\text{N}_2\text{SO}$  [116°] (Will, Yb. 14, 1487).  $\text{CSCl}_2$  forms  $\text{C}_6\text{H}_4\text{N}_2\text{S}_2$  [109°] (Freund a. Wolf, B. 25, 1465).  $\text{MeI}$  forms  $\text{C}_6\text{H}_4\text{N}_2\text{C}(\text{NH}_2\text{C}_6\text{H}_4\text{Me})_2\text{SMe}$  [128°], crystallising in needles, split up by heat into  $\text{C}(\text{NO}_2\text{H}_4)_2$  [60°] and  $\text{HSMe}$ , converted by heating with acids or alkalis into di-*o*-tolyl-urea and  $\text{MeSH}$ , and forming the salts  $\text{B}^+\text{HCl}$  [173°] and  $\text{B}^+\text{HSO}_4$  [156°].  $\text{EtI}$  forms the corresponding  $\text{C}_6\text{H}_4\text{N}_2\text{C}(\text{NH}_2\text{C}_6\text{H}_4\text{Me})_2\text{SEt}$  [87°], while ethylene bromide gives  $\text{C}_6\text{H}_4\text{N}_2\text{C}(\text{NH}_2\text{C}_6\text{H}_4\text{Me})_2$  [112°], which yields  $\text{B}^+\text{H}_2\text{SO}_4$  [194°] and a hydrochloride [219°] (Will a. Bielschowski, B. 14, 1492; 15, 1309).

*References*.—NITRO- and OXY- TOLYL-THIO-UREA.

*p*-TOLYL-TOLUTRIAZINE DIHYDRIDE  $\text{C}_{11}\text{H}_{11}\text{N}_3$ , i.e.  $\text{CH}:\text{CH}.\text{C}_6\text{H}_4\text{CH}_2\text{C}_6\text{H}_4\text{N}_2\text{CH}_2\text{CH}:\text{CH}$ . [178°].

Formed by heating *o*-amido-azo-toluene with formic paraldehyde and alcohol at 140° (Goldschmidt a. Poltzer, B. 24, 1008). Prisms, v. sol. hot alcohol.— $\text{B}^+\text{HCl}$ . [220°].— $\text{B}^+\text{H}_2\text{PtCl}_6$ . [216°]. Yellow crystalline pp.

*o*-TOLYL-URAZOLE  $\text{C}_8\text{H}_7\text{N}_2\text{O}$ , i.e.

$\text{C}_6\text{H}_4\text{N}(\text{NH}_2)\text{CO}\text{NH}_2$ . [170°]. Got by heating *o*-tolyl-hydrazine hydrochloride with urea (Pinner, B. 21, 1219). White leaflets, v. sol. hot water.

*p*-Tolyl-urazole. [274°]. Yellowish needles, v. sl. sol. hot water.

*o*-TOLYL-UREA  $\text{C}_8\text{H}_7\text{N}_2\text{O}$ , i.e.  $\text{NH}_2\text{CO}\text{NH}(\text{C}_6\text{H}_4\text{Me})$  [1:2]. [185°]. Formed from *o*-toluidine hydrochloride and potassium cyanate (Cosack, B. 18, 1089). Plates, sol. alcohol, ether, and hot water.

*Benzoyl derivative*  $\text{CO}(\text{NH}_2\text{C}_6\text{H}_5)\text{NH}(\text{C}_6\text{H}_4\text{Me})$ . [210°]. Formed from *o*-tolyl cyanate and benzamide at 125° (Gattermann a. Cantzler, B. 25, 1088). Needles.

*m*-Tolyl-urea  $\text{NH}_2\text{CO}\text{NH}(\text{C}_6\text{H}_4\text{Me})$  [1:3]. [142°]. Formed from *m*-toluidine hydrochloride and potassium cyanate (Cosack, B. 12, 1450; 13, 1089). Needles or tables (from alcohol) or plates (from water).

*p*-Tolyl-urea  $\text{NH}_2\text{CO}\text{NH}(\text{C}_6\text{H}_4\text{Me})$  [1:4]. [172°] (C.); [180°] (St.; P.). Formed in like manner (C.; cf. Sell, C. J. 16, 190). Formed also by the action of *p*-toluidine on mercuric

fulminate (Steiner, B. 8, 519), and also from *p*-toluamidoxim, benzene sulphonic acid,  $\text{NaOH}$ , and  $\text{CHCl}_3$  (Pinner, B. 24, 1417). Needles, sol. hot water, v. sl. sol. ligroin.

Di-*o*-tolyl-urea  $\text{CO}(\text{NH}_2\text{C}_6\text{H}_4)_2$ . [246°] (B.); [254°] (W.); [256°] (Barr, B. 19, 1769).

*Formation*.—1. By the action of alcohol or water at 100° on the dichloride of *o*-toluic nitrile (Lachmann, B. 12, 1849).—2. From *o*-toluidine hydrochloride and cyanamide (Berger, B. 12, 1859).—3. From tolyl cyanate and water (Neville a. Winther, B. 12, 2325).—4. From *o*-toluidine and  $\text{COCl}_2$  (Girard, B. 6, 444).—5. By heating *o*-toluidine with urea (G.).—6. A product of the distillation of *o*-tolyl-amido-acetic acid (Widman, J. pr. [2] 38, 803).—7. By the action of  $\text{Ac}_2\text{O}$  and benzene on the *o*-toluide of *o*-tolyl-imido-diacetic acid (Bischoff, B. 23, 1995).

*Properties*.—Needles (from  $\text{HOAc}$ ), insol. ether, sl. sol. alcohol. Not volatile with steam.

Di-*m*-tolyl-urea  $\text{CO}(\text{NH}_2\text{C}_6\text{H}_4\text{Me})_2$ . [203°] (G. a. C.); [217°] (C.). Formed from *m*-tolyl cyanate and *m*-toluidine (Gattermann a. Cantzler, 25, 1089), by the action of  $\text{ClCO}_2\text{Et}$  on *m*-toluidine, by heating *m*-tolyl-carbamic ether with water, and by heating *m*-tolyl-urea with *m*-toluidine at 160° (Cosack, B. 12, 1450; 13, 1090). Needles (from alcohol), insol. water.

Di-*p*-tolyl-urea  $\text{CO}(\text{NH}_2\text{C}_6\text{H}_4\text{Me})_2$ . [255°].

*Formation*.—1. By boiling an alcoholic solution of di-*p*-tolyl-thio-urea with  $\text{HgO}$  as long as  $\text{HgS}$  is formed (Sell, C. J. 16, 190; A. 126, 161).—2. By passing  $\text{COCl}_2$  into *p*-toluidine dissolved in chloroform (Miehler, B. 9, 710; Kühn, a. Henschel, B. 21, 605).—3. By heating tolyl-urea with *p*-toluidine at 160° (Weith, B. 9, 821).—4. From *p*-tolyl-cyanate and *p*-toluidine (Gattermann a. Cantzler, B. 25, 1089).

*Properties*.—Needles, insol. water, sl. sol. cold alcohol.

Tri-*p*-tolyl-urea  $\text{C}_{27}\text{H}_{27}\text{N}_3\text{O}$ . [189°]. Got from  $(\text{C}_6\text{H}_4)_3\text{N}.\text{COCl}$  and *p*-toluidine (Hammerich, B. 25, 1822). Needles, sol. warm benzene, insol. ether. Gives a benzoyl derivative [187°].

Tetra-*p*-tolyl-urea  $\text{C}_{36}\text{H}_{36}\text{N}_4\text{O}$ . [80°]. Got from  $(\text{C}_6\text{H}_4)_4\text{N}.\text{COCl}$  and di-*p*-tolyl-amine. Needles, v. e. sol. alcohol.

*References*.—AMIDO-, NITRO-, and OXY-TOLYL-UREA.

TOLYL-XYLIDINE  $\text{C}_{11}\text{H}_{11}\text{N}$ , i.e.  $\text{C}_6\text{H}_4\text{Me}.\text{NH}(\text{C}_6\text{H}_4\text{Me})_2$ . [70°]. (c. 800° at 487 mm.). Silky needles (from alcohol) (Girard a. Vogt, Bl. [2] 18, 69).

*o*-TOLYL *m*-XYLYL KETONE  $\text{C}_{15}\text{H}_{15}\text{O}$ , i.e. [1:2]  $\text{C}_6\text{H}_4\text{Me}.\text{CO}(\text{C}_6\text{H}_4\text{Me})$  [1:2:3]. (830°) at 728 mm. Formed from *o*-toluic chloride and *m*-xylene (Smith, B. 24, 4060). Oil. Converted by hydroxylamine at 120° into a mixture of anilides.

'TONKA BEANS, the fruit of *Dipteris odorata*, contains coumarin (q. v.) (Boullay a. Boutron-Charlard, J. Ph. 11, 426; [3] 7, 160).

'TRAGACANTH GUM. Exudes from *Astragalus verus*, a tree growing in Armenia and the north of Persia. It swells up in water, about one-half of it dissolving. It contains arabic, bassorin, starch, and water.

TRANSPIRATION. Graham, in 1846 and 1849, applied the term 'transpiration' to the passage of gases through capillary tubes into a

vacuum (v. T. 1846, 578; 1849, 849). The rates of transpiration of different gases bear constant relations to each other; but these rates have not been connected in any definite ways with the compositions of the gases. M. M. P. M.

#### TREE GUM v. XYLAN.

#### TREHALOSE v. SUGAR.

**TREHALUM**  $C_{12}H_{22}O_{11}$ . S. -06 at 17°; 1.8 at 100°.  $[a]_D = +179^\circ$ . Occurs in *Trehala manna* (Scheibler a. Mittelmeyer, B. 26, 133\*). Tasteless, minute prisms. Very hygroscopic. Does not reduce Fehling's solution. Does not react with phenyl-hydrazine. Boiling dilute  $H_2SO_4$  forms glucose. At 180° it slowly forms trehalin, which is v. sol. water and ptd. by alcohol. Trehalin dissolves in phenyl-hydrazine. Iodine colours trehalum and trehalin violet. Diastase, yeast, and invertin have no action.  $Ac_2O$  and  $NaOAc$  yield an acetyl derivative [above 210°].

**TRI-** In the alphabetical arrangement of this dictionary the prefix 'tri,' when indicating the presence of three radicles, is treated as if it did not form part of a name, except where the entire name is numerical, as in 'tridecane.'

**TRIANOSPHERMIN.** A crystalline substance occurring in *Trianosperma ficifolia*, a climbing plant of Brazil (Peckholt, *Ar. Ph.* [2] 113, 104; Parodi, *Ph.* [3] 10, 667). It has a pungent taste, is alkaline in reaction, sol. water, alcohol, and ether, and is ptd. by  $Pb(OAc)_2$  and  $PtCl_4$ .

#### TRIAZOLE $N \leq \begin{smallmatrix} CH \\ \diagup \quad \diagdown \\ CH \end{smallmatrix} N$ Pyrroliazole.

[120-5°]. (260°). V.D. 2.39 (calc. 2.49). Formed by heating its carboxylic acid alone or with boiling water (Andreocci, B. 25, 229; Bladin, B. 25, 745). Needles (from ether), v. sol. water and alcohol, may be sublimed. The di-oxy-derivatives of alkyl-triazoles  $N \leq \begin{smallmatrix} C(OH) \\ \diagup \quad \diagdown \\ C(OH) \end{smallmatrix} N$ , named by Pinner 'urazoles,' are obtained by heating hydrazines with urea (Pinner, B. 20, 2358).

#### TRIAZOLE CARBOXYLIC ACID

$N \leq \begin{smallmatrix} CH \\ \diagup \quad \diagdown \\ C(COOH) \end{smallmatrix} NH$  [137°]. Obtained by oxidising methyl-triazole (Andreocci, B. 25, 229) or amido-phenyl-triazole carboxylic acid and alkaline  $KMnO_4$  (Bladin, B. 25, 744). Amorphous powder. — $CuA'$ , aq. Green crystalline powder.

#### TRICARBALLYLIC ACID v. vol. i. p. 679.

#### TRICOSANE v. TRI-COSANE.

**TRIDECANE**  $C_{13}H_{28}$ . [-6°]. (234°). S.G. 2.771;  $\gamma$  0.761. Formed by reduction of methyl dodecyl ketone or of tridecoic acid by  $H_2$  and  $P$  (Kraft, B. 15, 1699). Formed also by distilling barium myristate with  $NaOMe$  (Mai, B. 22, 2184).

**TRIDECOIC ACID**  $C_{13}H_{26}CO_2H$ . [41°]. (236° at 100 mm.). Formed by oxidation of methyl tridecyl ketone (Kraft, B. 12, 1669). Crystals. — $AgA'$ .

**Amide**  $C_{13}H_{26}CO.NH_2$ . [98-5°]. Formed by digesting the nitrile with conc.  $H_2SO_4$  and pouring into water (Lutz, B. 19, 1439). Plates (from alcohol).

**Nitrile**  $C_{13}H_{25}CN$ . (275°). Formed from tridecylamine,  $Br$ , and  $NaOH$ . Oil, v. sol. alcohol and ether.

**TRIDECYL ALCOHOL**  $(C_{13}H_{27})_n.CH.OH$ . [42°]. Formed by reducing di-hexyl ketone (Kipping, O. J. 57, 536). Plates (from dilute alcohol),

insol. water. May be distilled.  $HBr$  forms  $(C_{13}H_{27})_n.CHBr$  [89°].

#### TRIDECYLAMINE $C_{13}H_{27}NH_2$ . [87°]. (265°).

Formed by boiling myristyl-tridecyl-urea with  $KOH$ aq (Lutz, B. 19, 1437). Unctuous mass, v. sol. alcohol and ether. Absorbs water and  $CO_2$  from the air. — $B'HCl$ : needles, decomposing at 100°. — $B'_2H_4PtCl_4$ . — $B'_2H_4SO_4$ : needles, insol. cold water.

#### TRIDECYLENE $C_{13}H_{26}$ . (233° cor.). S.G.

2.8445. Occurs in petroleum from Burmah (Warren a. Storer, Z. 1868, 232).

#### TRIDECYL-UREA. Myristyl derivative

$C_{13}H_{27}N_2O_2$ , i.e.  $C_{13}H_{27}NH.CO.NH_2$ ,  $H_2O$ . [103°]. Formed by the action of  $Br$  and  $KOH$ aq on the amide of myristic acid (Reimer a. Will, B. 18, 2016). Crystals (from alcohol), almost insol. cold water, sol. ether.

#### TRIGENIC ACID v. ETHYLIDENE-MURMET.

#### TRIGONELLIN $C_8H_{12}N_2O$ , i.e.

$CH \begin{smallmatrix} \diagup \quad \diagdown \\ \diagdown \quad \diagup \end{smallmatrix} \begin{smallmatrix} CH \\ \diagup \quad \diagdown \\ CH \end{smallmatrix} \begin{smallmatrix} CO \\ \diagup \quad \diagdown \\ O \end{smallmatrix}$ . Occurs in the seeds of

*Trigonella Fenum-graecum* (Jahns, B. 18, 2518; 20, 2840). It is also produced by saponification of the product of the reaction of  $MeI$  on potassium pyridine ( $\beta$ )-carboxylate (Hantzsch, B. 19, 31). Colourless prisms (containing aq.), converted by  $HCl$ aq at 265° into pyridine ( $\beta$ )-carboxylic acid (q. v., Reaction 4). — $B'HOL$ . — $B'_2H_4PtCl_4$ . — $B'_2H_4AuCl_4$  [198°]. — $B'_2H_4AuCl_4$ . [186°]. Slender needles.

#### n-TRI-COSANE $C_{30}H_{62}$ . [48]. (234° at 15 mm.).

E.G. 2.7785;  $\gamma$  0.7570. Formed from laurone ( $C_{12}H_{24}O$ ) by treatment with  $PCl_5$  and reduction of the resulting  $(C_{12}H_{25})_n.CCl_2$  with  $H_2$  add  $P$  at 240° (Kraft, B. 15, 1712). Obtained also by fractional distillation of paraffin oil from brown coal (Kraft, B. 21, 2263). Glittering plates (from ether-alcohol), sl. sol. alcohol.

#### TRI-COSANE DICARBOXYLIC ACID

$C_{30}H_{60}(CO_2H)_2$ . [102-5°]. Formed by heating di-oxy-penta-icosylene with soda-lime (Stärcke, A. 223, 300). Flocculent pp. (from ligroin-ether). — $PbA'$ .

#### TRI-COSYL ALCOHOL $(C_{12}H_{25})_n.CH.OH$ .

[76°]. Formed by reducing laurone with  $Na$  and water (Kipping, C. J. 57, 983). Plates (from ether), insol. water. Yields an acetyl derivative ( $C_{12}H_{25})_n.CH.OH$  [35°].

#### TRI-COSYL ALCOHOL $C_{30}H_{62}.OH$ . [82°]. A

wax-like body extracted by hot alcohol from flax fibres (Cross a. Boyan, C. N. 59, 135). Yields an acetyl derivative [65°].

#### TRIMELLITIC ACID v. vol. iii. p. 204.

#### TRIMESIC ACID v. vol. iii. p. 230.

**TRIMESITIC ACID**, v. PYRIDINE TRICARB-XYLIC ACID.

#### TRIMETHYLENE v. vol. iii. p. 304.

**TRITICIN**  $C_{12}H_{22}O_{11}$ .  $[a]_D = -43.6^\circ$  (Beide-meister, J. Th. 1881, 69). Extracted by dilute alcohol from the root of couch-grass (*Triticum repens*) (H. Müller, *Ar. Ph.* [3] 2, 500; 8, 1). Tasteless hygroscopic powder, v. sol. water, insol. alcohol and ether. Laboratory. On boiling with water, especially in presence of acid, it changes into levulose. Its solutions are not ptd. by metallic salts, nor coloured by iodine.

#### TROPEOLINES v. AZO-COMPOUNDS.

**TROPEINES**. A name given by Ladenburg to alkyl derivatives of tropine (q. v.).

**TROPIC ACID** *v.* **OXY-PHENYL-PROPIONIC ACID.**

**TROPIDINE** *v.* **METHYL-ETHYLENE PYRIDINE TETRAHYDRIDE.**

(a)-Methyl-tropidine  $C_8H_{11}N$  *i.e.*  
 $CH_3 \cdot CH \cdot CH \cdot CH \cdot CH \cdot CH \cdot CH \cdot CH \cdot CH_2 \cdot NMe_2$  (Ladenburg)  
 or  $CH \cdot \begin{smallmatrix} CH:CH \\ \backslash / \\ CH:CH \end{smallmatrix} \cdot CH \cdot CH_2 \cdot NMe_2$  (Merling).

Formed by distilling tropidine methylo-hydroxide with water (Roth, *B.* 17, 157; Meiling, *B.* 24, 8118). Oil. HClAq forms 'hydrochloro-(a)-methyl-tropidine' which gradually changes into the isomeric 'tropidine methylo-chloride. —  $B'_2H_3PtCl_6$  [174°]. —  $B'HAuCl_4$ : golden-yellow pp. *Methylo-iodide*  $B'MeI$ . [162°]. Needles.

(b)-Methyl-tropidine  $C_8H_{11}N$ . (205°). S.G. 1.222. Formed by heating (a)-methyl-tropidine at 150°–200°. Oil. Converted by HCl into tropilene.

**TROPIGENIN**  $C_8H_{11}NO$ . [161°]. Got by oxidation of tropine by alkaline  $KMnO_4$  (Merling, *B.* 15, 287). Got also by boiling 'homohydro-apotropine' with baryta-water (Pesci, *C.* 12, 329). Needles, sol. water and alcohol. Reconverted by  $MeI$  into tropine. Oxidised by chromic acid mixture to ecgonic acid and a small quantity of tropic acid (Liebermann, *B.* 24, 615). —  $B'HI$ . —  $B'_2CO_3$ : crystalline pp. —  $B'_2H_3PtCl_6$  aq. —  $B'HAuCl_4$ : golden-yellow plates, sol. alcohol.

**TROPILENE**  $C_8H_{10}$  *i.e.*  
 $CH_2 \cdot \begin{smallmatrix} CH:CH \\ \backslash / \\ CH:CH \end{smallmatrix} \cdot CH \cdot CHO$  (?) (Merling) (182°)

(L); (187°) (M.). S.G. 1.0091. V.D. 102.3 (calc. 110). Formed by distilling tropidine methylo-iodide with  $KOH$  (Ladenburg, *B.* 14, 2403; 15, 1028; *A.* 217, 138). Formed also from (b)-methyl-tropidine and cold HClAq (Merling, *B.* 24, 8123). Oil, smelling like oil of bitter almonds and acetone, sol. dilute HClAq, v. sol. alcohol and ether. Reduces warm ammoniacal  $AgNO_3$ , forming a mirror. Reduces Fehling's solution and  $KMnO_4$  in the cold. Not attacked by  $AcCl$ . Combines with  $NaHSO_4$  (M.). Nitric acid forms an adipic acid  $C_8H_{10}O_4$ . Slowly combines with methylamine, forming (b)-methyl-tropine.

**TROPILIDENE**  $C_8H_8$  *i.e.*

$CH \cdot \begin{smallmatrix} CH:CH \\ \backslash / \\ CH:CH \end{smallmatrix} \cdot C \cdot CH_2$ . (114°). S.G. 1.223.

Formed by distilling methyl-tropine methylo-iodide with  $KOH$  (Ladenburg, *A.* 217, 133; *B.* 14, 2408; 26, 1067). Formed also, together with methylamine, by distilling tropine with soda-lime. Oil, smelling somewhat like toluene, but combining readily with bromine, forming  $C_8H_8Br_2$ . Gives no pp. with ammoniacal  $Cu_2Cl_2$ . Oxidised by  $CrO_3$  to benzoic aldehyde and acid (Merling, *B.* 24, 8122).

**TROPINE**  $C_8H_{11}NO$  *i.e.*

$CH_3 \cdot CH_2 \cdot CH \cdot CH \cdot CH_2 \cdot CH_2 \cdot OH$  (Ladenburg) or  $CH_3 \cdot CH_2 \cdot NMe$

$CH_3 \cdot CH \cdot \begin{smallmatrix} CH:CH \\ \backslash / \\ CH:CH \end{smallmatrix} \cdot CH_2 \cdot OH$  (Merling). *Methyl-oxy-*  
 1142 *pyridine tetrahydride*. [62°] (229°).  
 not a base, together with tropic acid, by hydro-  
 (alk). Needles, or hyoscyamine by baryta or  
 Formeau, *A.* 128, 281; 133, 87; Laden-  
 burg, *B.* 217, 115; *B.* 18, 608; 20,  
 HClAq (Kraut, *B.* 26, 1067). Hygroscopic tables  
 burg, *A.* 206, 21. Sol. water and alcohol. Does  
 1653; 23, 1780. from the air. Its aqueous solu-  
 (from ether), v.  
 not absorb  $CO_2$ .

tion ppis. metallic oxides from their salts. Not attacked by nitrous acid. Not volatile with steam. According to Eykman (*B.* 26, 1400) the refractive index agrees best with Merling's formula.

*Reactions.*—1. Decomposed by distilling with soda-lime into tropilidene, methylamine, and  $H_2O$ .—2. Loses  $H_2O$ , being converted into tropidine by heating with fuming  $HCl$  and  $HOAc$  at 180° or by heating with  $H_2SO_4$  (1 pt.) and water (1½ pts.) at 230°.—3. Conc. HIAq and red P at 150° form tropidine and tropidine periodide, but at 140° they form 'tropine iodide'  $C_8H_9NI$ , which crystallises from water in prisms [118°], whence silver chloride followed by  $PtCl_4$  give  $(C_8H_9NI)_2PtCl_4$  crystallising in red octahedra. By treatment with  $Ag_2O$  followed by  $HCl$  and  $PtCl_4$  very soluble  $(C_8H_9NI)_2PtCl_4$  is got.—4. Alkaline  $KMnO_4$  forms tropigenin and, finally, oxalic acid and  $NH_3$  (Merling, *A.* 216, 341).—5.  $CrO_3$  forms tropinic acid  $C_8H_9N(CO_2H)$ .—6. Aqueous  $HOCl$  yields prisms [111°], whence alcohol produces  $C_8H_9NCl \cdot CH_3OH$  [108°], which forms a hydrochloride [102°] crystallising in plates (Einhorn *a.* Fischer, *B.* 25, 1391).

*Salts.*— $B'HI$ . —  $B'_2H_3PtCl_6$ . Orange-red monoclinic crystals. [200°] (Schmidt, *A.* 208, 214). —  $B'HAuCl_4$ . [212°]. —  $B'HCi_6HgCl_4$ . [246°] (Ladenburg, *B.* 24, 1631). —  $B'_2C_8H_9N_2O_4$ .

*Nitro-oxyl derivative*  $C_8H_9(ONO_2)N$ . *Nitro-tropine*. Formed by warming tropine (2 g.) with  $HNO_3$  (12 g. of S.G. 1.25) at 100° (Ladenburg, *B.* 15, 1025). Alkaline liquid, sol. water, alcohol, and ether. Yields  $KNO_3$  on boiling with  $KOH$ . —  $B'_2H_3PtCl_6$ . Needles. —  $B'HI$ . Prisms.

*Benzoyl derivative*  $C_8H_9(OBz)N$ . *Benzoyl-tropine*. Formed by heating tropine hydrochloride with benzoic acid and dilute  $HCl$  (Ladenburg, *B.* 13, 1083; *A.* 217, 96). Crystallises as  $C_8H_9NO_2 \cdot 2aq$  [58°],  $C_8H_9NO_2 \cdot 3aq$  [37°], or anhydrous [42°]. Sl. sol. water, v. sol. alcohol and ether. —  $B'HI$ . —  $B'_2H_3PtCl_6$  2aq. —  $B'_2C_8H_9N_2O_4$ .

*o-Oxy-benzoyl derivative*  $C_8H_9(O \cdot CO \cdot C_6H_4 \cdot OH)N$ . *Salicyl-tropine*. Formed in like manner, using salicylic acid (Gaebbe *a.* Caro, *B.* 13, 106; L.). Silky plates. Feeble poison, .025 g. killing a frog in a few hours. Has no apparent effect on the pupil. —  $B'HI$ . —  $B'_2H_3PtCl_6$ . —  $B'HAuCl_4$ : yellow plates.

*o-Oxy-benzoyl derivative*  $C_8H_9NO_2$ . [226°]. Small plates, v. sl. sol. water. Acts slightly on the pupil of the eye. —  $B'HI$ . —  $B'_2H_3SO_4$  4aq. —  $B'_2H_3PtCl_6$ : orange plates.

*p-Oxy-benzoyl derivative*  $C_8H_9NO_2$ . [227°]. Trimetric plates (containing 2aq). —  $B'HI$ . —  $B'_2H_3PtCl_6$  2aq. Orange plates.

*Phenyl-acetyl derivative*  $C_8H_9NO_2$  *i.e.*  $C_8H_9N(O \cdot CO \cdot CH_2Ph)$ . *Phenylacetotropine*. Aromatic oil. —  $B'HI$ . —  $B'_2H_3PtCl_6$ . —  $B'HAuCl_4$ . —  $B'_2H_3SO_4$ . Soluble tables.

*Mandelyl derivative*  $C_8H_9WO_2$  *i.e.*  $C_8H_9N(O \cdot CO \cdot CHPh \cdot OH)$ . *Homatropine*. Formed by heating tropine with mandelic acid,  $HCl$  (1 pt.), and water (40 pts.), the yield being 50 p.c. of the theoretical amount (Ladenburg, *C.* 8, 90, 921; *A.* 217, 82). Deliquescent prisms (from ether), sl. sol. water. A solution of its hydrochloride is ppd. by potassium-mercuric iodide, but not by tannin. It enlarges the pupil of the eye almost as energetically as atropine, but the enlargement passes off much more rapidly (Völkers,

**A. 217, 86; Bartheau, Berl. Klin. Wochenschrift, 1880, No. 41; Tweedy & Ringer, Lancet, 1880, No. 21).**—B'HB. Trimetric crystals;  $a:b:c = 414:1:472$ .—B'C<sub>2</sub>H<sub>5</sub>N<sub>3</sub>O<sub>6</sub>. Yellow plates.—B'HAuCl<sub>4</sub>.—B'H<sub>2</sub>SO<sub>4</sub>. Needles.

**Cinnamoyl derivative** C<sub>17</sub>H<sub>15</sub>NO<sub>3</sub>. [70°]. Small plates (from dilute alcohol). Gives pps. with tannin, picric acid, potassio-mercuric iodide, and I in KI. Strong poison, .03 g. killing a frog in three minutes. Has little action on the pupil.—B'HCl.—B'H<sub>2</sub>PtCl<sub>6</sub>.—B'HAuCl<sub>4</sub>. Needles.

**Atropyl derivative** C<sub>17</sub>H<sub>15</sub>NO<sub>3</sub>. Atropine. Oil.—B'HAuCl<sub>4</sub>. Small needles.

**Atrolactyl derivative** C<sub>17</sub>H<sub>15</sub>NO<sub>3</sub>. Pseudo-atropine. [120°]. Formed from atropic acid, tropine, and dilute HCl (1:400) by repeated evaporation (Ladenburg, A. 217, 87). Needles (from water). Resembles atropine in physiological action, two drops of a 1 p.c. solution expanding the pupil and paralysing accommodation for a week.—B'HAuCl<sub>4</sub>. [114°].

**Phthalyl derivative** C<sub>17</sub>H<sub>15</sub>N<sub>3</sub>O<sub>4</sub>. [70°]. Formed, in very small quantity, by evaporating phthalic acid with tropine and dilute HCl. Mass of silky needles.—B'H<sub>2</sub>PtCl<sub>6</sub>.

**Methylo-iodide** C<sub>8</sub>H<sub>9</sub>NOMeI. Small crystals, nearly insol. alcohol. Yields B'MeOH and B'Me<sub>2</sub>PtCl<sub>6</sub> (Merling, B. 14, 1829; Ladenburg, A. 217, 131).

**Ethyl-iodide** B'EtI. Crystalline. Yields B'Et<sub>2</sub>PtCl<sub>6</sub>, a yellow crystalline powder.

(a)-Methyl-tropine C<sub>8</sub>H<sub>9</sub>MeNO. (243°). Formed by distilling tropine methylo-iodide. Liquid, v. sol. water and alcohol. Strongly alkaline. Its hydrochloride, distilled with solid KOH, yields dimethylamine.—B'HAuCl<sub>4</sub>. Very unstable.

**Methylo-iodide** (C<sub>8</sub>H<sub>9</sub>MeNO)MeI. Deliquescent needles, decomposed by distilling with solid KOH into tropilidene and trimethylamine.—(C<sub>8</sub>H<sub>9</sub>MeNO)Me<sub>2</sub>PtCl<sub>6</sub>. Orange crystals.

(b)-Methyl-tropine C<sub>8</sub>H<sub>9</sub>NO. (198–205°). Formed by shaking tropine with an aqueous solution of dimethylamine (Ladenburg, B. 14, 2404). Liquid, split up by gaseous HCl into tropilene and NMe<sub>2</sub>H.—B'HAuCl<sub>4</sub>. Prisms.

(γ)-Methyl-tropine C<sub>8</sub>H<sub>9</sub>NO. Formed in small quantity by distilling the methylo-hydroxide of (a)-methyl-tropine (Merling, B. 15, 288). V. sl. sol. Aq.—B'H<sub>2</sub>PtCl<sub>6</sub>. V. sl. sol. Aq.

**Metatropine** C<sub>8</sub>H<sub>9</sub>NO. (238°). Formed by shaking tropine iodide with water and Ag<sub>2</sub>O. Not solid at –30°.—B'HCl. tables.

**Hydrotropidine** C<sub>8</sub>H<sub>9</sub>N. (168°). S.G. 2.937; 15.926. Formed by reducing tropine iodide C<sub>8</sub>H<sub>9</sub>NI<sub>2</sub> with zinc-dust and HClAq (Ladenburg, B. 16, 1408). Liquid, m. sol. water.—B'HCl; deliquescent crystals.—B'H<sub>2</sub>PtCl<sub>6</sub>. Tables.

**Norhydrotropidine** C<sub>8</sub>H<sub>9</sub>N. (60°). (161°). Formed by distilling hydrotropidine hydrochloride in a current of HCl (Ladenburg, B. 20, 1649). Crystalline.—B'HCl. [28°].—B'H<sub>2</sub>PtCl<sub>6</sub>.—B'HHgCl<sub>2</sub>.—B'C<sub>2</sub>H<sub>5</sub>N<sub>3</sub>O<sub>6</sub>. Needles.

**Nitrosamine** C<sub>8</sub>H<sub>9</sub>N<sub>2</sub>O. [117°]. Cubes. **Paratropine** C<sub>8</sub>H<sub>9</sub>NO. (202°). Formed from hydrotropine and K<sub>2</sub>FeCy<sub>4</sub> (Ladenburg, B. 24, 1626).—B'H<sub>2</sub>PtCl<sub>6</sub>. [197°].—B'HAuCl<sub>4</sub>. [182°].—B'HCuH<sub>2</sub>Cl<sub>2</sub>. [225°]. V. sol. water.

**ψ-Tropine** C<sub>8</sub>H<sub>9</sub>NO. [108°]. (242°). Formed, together with tropic acid, by warming hyoscyne with baryta-water (Ladenburg, B. 13, 1551; 17,

151; Liebermann, 24, 2687). Formed also by dissolving its benzoyl derivative in hot conc. HClAq (Hesse, A. 271, 210). Hygroscopic prisms (from chloroform), v. s. sol. water. Yields tropine and ecgonic acids on oxidation.—B'H<sub>2</sub>SO<sub>4</sub>. Hygroscopic crystals.—B'HAuCl<sub>4</sub>. [198°] (Ladenburg); [302°] (H); [225°] (Liebermann).—B'H<sub>2</sub>PtCl<sub>6</sub> 4aq. [206°, anhydrous]. Trimetric prisms;  $a:b:c = 702:1:879$ .

**Methylo-iodide** B'MeI. [270°]. Rhombohedra. Yields B'MeCl and B'Me<sub>2</sub>PtCl<sub>6</sub>. [216°] crystallising from water.

**Benzoyl derivative** C<sub>12</sub>H<sub>11</sub>NO<sub>3</sub>. [48°]. Occurs in the leaves of Java coca (Liebermann, B. 24, 2336; Llesse, A. 271, 208). Colourless plates (from ether).—B'HCl. [270°].—B'H<sub>2</sub>PtCl<sub>6</sub>. Pale-yellow needles.—B'MeI.—B'MeCl.—B'MeAuCl<sub>4</sub>.—B'Me<sub>2</sub>PtCl<sub>6</sub> 2aq.

**Mandelyl derivative** C<sub>8</sub>H<sub>9</sub>NO(CO.CH(OH).C<sub>2</sub>H<sub>5</sub>). **ψ-Iomatropine**. Formed by heating ψ-tropine with mandelic anhydride at 200° (Liebermann & Limpach, B. 25, 931).—B'HCl.—B'H<sub>2</sub>PtCl<sub>6</sub>.—B'HAuCl<sub>4</sub>.

**Tropyl derivative** C<sub>8</sub>H<sub>9</sub>NO(C<sub>2</sub>H<sub>5</sub>O<sub>2</sub>). Isomeride of hyoscyne. [88°]. [α]<sub>D</sub> = –4.9°. Nodules, insol. water, sol. alcohol.—B'HCl. [183°].—B'H<sub>2</sub>PtCl<sub>6</sub>.—B'HAuCl<sub>4</sub>. [185°].

**Atropyl derivative**. [129°]. Formed from tropide and ψ-tropine at 200°. Crystals, sol. water. Split up by HClAq into atropic acid and ψ-tropine.

#### Oxy-tropine carboxylic acid

(H<sub>2</sub>C<sub>2</sub>CH<sub>2</sub>CH(OH).CH(OH).CO<sub>2</sub>H. **Dioxyan-**

**hydroecgonine**. Formed by oxidising hydroecgonine with KMnO<sub>4</sub> and aqueous Na<sub>2</sub>CO<sub>3</sub> at 1° (Einhorn & Rassoff, B. 25, 1395). Decomposes at 280°. V. s. sol. water and MeOH, insol. EtOH.—B'HCl. [251°].—B'C<sub>2</sub>H<sub>5</sub>N<sub>3</sub>O<sub>6</sub>.—KA'.

**Methyl ether** MeA'. [139°]. Tables, v. s. sol. CHCl<sub>3</sub>. Yields B'H<sub>2</sub>PtCl<sub>6</sub>. [210°].

**Benzoyl derivative of the methyl ether** C<sub>12</sub>H<sub>11</sub>MeN.CH(OH).CH(OBz).CQ<sub>2</sub>H. [108°]. Needles.—B'HNO<sub>3</sub>. [216°].—B'HCl. [203°].—B'HAuCl<sub>4</sub>. [173°].—B'H<sub>2</sub>PtCl<sub>6</sub>. [208°].

**Di-benzoyl derivative of the methyl ether** C<sub>12</sub>H<sub>11</sub>MeN.CH(OBz).CH(OBz).CO<sub>2</sub>H. Needles.—B'HNO<sub>3</sub>. [196°].—B'HCl. [280°].—B'H<sub>2</sub>PtCl<sub>6</sub>. [205°].—B'HAuCl<sub>4</sub>. [203°].

#### Reference.—OXYTROPINE.

#### TROPINE DIHYDRIDE C<sub>8</sub>H<sub>9</sub>NO 1.5.

CH<sub>2</sub>.CH<sub>2</sub>.CH<sub>2</sub>.CH<sub>2</sub>.OH. **Hydrotropine.**

CH<sub>2</sub>.CH<sub>2</sub>.NMe. **Methyloxyethylpyridine hexahydrate.** (288°). Formed from oxy-ethyl-piperidine and KMeSO<sub>4</sub> (Ladenburg, B. 24, 1622). V. sol. water and alcohol.—B'HCl 514gCl<sub>2</sub>. [214°].—B'HAuCl<sub>4</sub>. [170°]. Crystals.

**TROPIC ACID** C<sub>8</sub>H<sub>9</sub>NO<sub>3</sub>. [253°] (L); [220°] (M). A product of oxidation of tropine and of ecgonine by chromic acid mixture (Merling, M. 216, 348; Liebermann, B. 23, 2519). Needles, v. sol. water, sl. sol. alcohol, insol. benzene. Gives off CO<sub>2</sub> when heated. Forms salts with acids and bases.—BaA'. Very hygroscopic.—CaA'.—AgA'. Readily reduced.—(HA)<sub>2</sub>PtCl<sub>6</sub>.—HA'IAuCl<sub>4</sub>. Golden prisms.—HA'HCl aq.

#### TROPYLENE v. TROPILENE.

**TRUXENE** (C<sub>8</sub>H<sub>7</sub>). Formed by heating truxone with red P and HIAq (S.G. 1.7) at 180°

(Liebmann & Bergami, *B.* 22, 786; 28, 317). Formed also by heating hydridone with conc.  $\text{HClAq}$ , and by heating phenyl-propionic acid with  $\text{P}_2\text{O}_5$  (Hausmann; Kipping, *C. J.* 65, 269). Needles or plates, melting above  $860^\circ$ , insol.  $\text{CHCl}_3$ . Oxidised by boiling  $\text{HOAc}$  and  $\text{CrO}_3$  to crystalline 'tri-benzoylene-benzene,' which is not melted at  $860^\circ$ .  $\text{HNO}_3$  forms (4,2,1)-nitro-phthalic acid.

(a)-TRUXILLIC ACID  $\text{C}_{11}\text{H}_{10}\text{O}_4$ , *is.*

$\text{CHPh.CH.CHO.H}$  (?) ( $\gamma$ )-Isotropic acid.  
 $\text{CO}_2\text{H.CH} - \text{CHPh}$ .

[274°]. Formed, together with ( $\beta$ )-truxillic acid, by the action of boiling  $\text{HClAq}$  on isatropylcocaine, which is a by-product in the preparation of cocaine (Liebmann, *B.* 21, 2342; 22, 124, 783, 2242). Small needles (from alcohol), sol. hot  $\text{HOAc}$ . Yields cinnamic acid on distillation. Nitric acid (S.G. 1.52) forms two di-nitro-derivatives, [229°] and [290°]. Yields two isomeric sulphonic acids.— $\text{Na}_2\text{A}''$  10aq (Drory, *B.* 22, 2256).— $\text{BaA}''$  8aq. Crystalline, v. sol. water.— $\text{CaA}''$  aq.— $\text{AgA}''$ . Flocculent pp., sol.  $\text{NH}_4\text{Aq}$ .

Methyl ether  $\text{MeA}''$ . [174°]. (c. 300°).

Ethyl ether  $\text{EtA}''$ . [146°]. H.C.p. 2,720,900 (Liebmann, *B.* 25, 92). Yields  $\text{C}_{11}\text{H}_{10}(\text{NO}_2)_2\text{Et}_2\text{O}$  [138°] (Homans, *B.* 24, 2590). Isoamyl ether ( $\text{C}_5\text{H}_{11}$ ) $\text{A}''$ . [83°]. Prisms.  $\text{Ac}_2\text{O}$  at  $150^\circ$  forms (a)-truxillic anhydride, while at  $170^\circ$  the product is ( $\gamma$ )-truxillic anhydride. Di-amide  $\text{C}_{11}\text{H}_8\text{O}_4(\text{NH}_2)_2$ . [265°]. Needles, v. sl. sol. hot water, sl. sol. alcohol (Drory, *B.* 22, 2261).

Di-piperidide  $\text{C}_{11}\text{H}_{11}(\text{CO.NC}_5\text{H}_{10})_2$ . [259°]. Got from the chloride and piperidine (Horstein, *B.* 22, 2264). Crystalline powder, sol. alcohol.

Mono-piperidide  $\text{C}_{11}\text{H}_{11}(\text{CO}_2\text{H})(\text{CO.NC}_5\text{H}_{10})$ . [250°]. Yields  $\text{MeA}''$  [151°] crystallising from ether in needles.

Anhydride  $(\text{C}_{11}\text{H}_9\text{O}_4)_2$ . [191°]. Mol. w. 1712 (1703 obs. by Raoult's method). Formed by heating the acid with  $\text{Ac}_2\text{O}$  and  $\text{NaOAc}$  at  $100^\circ$ . Needles (from benzene-ligroin). Gives no fluorescein. When heated for an hour at  $200^\circ$  it changes to ( $\gamma$ )-truxillic anhydride.

( $\beta$ )-Truxillic acid  $\text{C}_{11}\text{H}_{10}\text{O}_4$ , *is.*

$\text{CHPh.CH.CHO.H}$

$\text{CHPh.CH.C}^*\text{O}_2\text{H}$  (?)

( $\beta$ )-Isotropic acid. [206°]. Formed at the same time as the (a)-acid (Liebmann, *B.* 21, 2342; 22, 783, 2243; 25, 90; 26, 837). More sol. water than the (a)-isomeride. Yields benzil on oxidation. Nitric acid (S.G. 1.52) forms a di-nitro-derivative [216°] (Homans, *B.* 24, 2590). Forms cinnamic acid on distillation.— $\text{Na}_2\text{A}''$  2aq.— $\text{BaA}''$  2aq. Sl. sol. water.— $\text{CaA}''$  8aq.— $\text{AgA}''$ .

Methyl ether  $\text{MeA}''$ . [76°]. Mol. w. 509 (by Raoult's method); calc. 324. H.C.p. 2,422,900. Monoclinic prisms;  $a:b:c = 826:1:2.019$ ;  $\beta = 89^\circ 22'$ .

Ethyl ether  $\text{EtA}''$ . [47°].

Chloride  $\text{C}_{11}\text{H}_9\text{O}_4\text{Cl}$ . [96°]. Tabular prisms, v. sol. ether (Drory, *B.* 22, 2260).

Mono-piperidide  $\text{C}_{11}\text{H}_{11}(\text{CO}_2\text{H})(\text{CO.NC}_5\text{H}_{10})$ . [224°]. Formed from ( $\beta$ )-truxillic anhydride and piperidine (Horstein, *B.* 22, 2264). Needles, sl. sol. cold alcohol.

Dipiperidide  $\text{C}_{11}\text{H}_{11}(\text{CO.NC}_5\text{H}_{10})_2$ . [180°]. Formed from the chloride and piperidine. Prisms, v. sol. alcohol.

Phenylimide  $\text{C}_{11}\text{H}_9\text{O}_4\text{NPh}$ . [180°].

Mol. w. 351 (obs.). Got by heating the anhydride with aniline. Colourless needles (from alcohol). Cold alcoholic potash forms the compound  $\text{CO}_2\text{H.C}_{11}\text{H}_9\text{O}_4\text{N.NHPh}$  [197°].

Phenyl hydrazide  $\text{C}_{11}\text{H}_9\text{O}_4\text{NPh}$ .

[218°]. Formed from the acid, phenyl-hydrazine, and  $\text{HOAc}$  on warming. Crystals (from  $\text{HOAc}$ ).

Fluorescein  $\text{C}_{11}\text{H}_9\text{O}_4\text{N}(\text{C}_6\text{H}_4(\text{OH})_2)_2\text{O}$ .

Formed by heating the acid or its anhydride, with resorcin at  $240^\circ$ . Amorphous brownish-red powder, sol. alkalis forming fluorescent solutions, v. sol. alcohol, insol. benzene.

Anhydride  $\text{C}_{11}\text{H}_9\text{O}_4$ . [116°]. Mol. w. 278 calc., 289 obs. by Raoult's method. Does not change to an isomeride when heated.

( $\gamma$ )-Truxillic acid  $\text{C}_{11}\text{H}_{10}\text{O}_4$ , *isotropic acid*. [228°]. Formed by heating the anhydride of the (a)-isomeride with  $\text{HCl}$  at  $160^\circ$ . Needles (from dilute alcohol), v. sl. sol. hot water, v. sol. ether. Yields cinnamic acid on distillation. Gives the same anhydride as the (a)-isomeride (Ladenburg, *B.* 22, 124). Heated with  $\text{HClAq}$  at  $260^\circ$  it is changed to ( $\alpha$ )-truxillic acid.  $\text{HNO}_3$  (S.G. 1.52) forms a di-nitro-derivative [293°].

Salts.— $\text{BaA}''$  11aq.— $\text{CaA}''$  3½aq.—

$\text{CaA}''$  6½aq.— $\text{AgA}''$  2aq.: crystalline pp. Methyl ether  $\text{MeA}''$ . [126°]. Needles. Mol. w. 332 (calc. 324).

Mono-ethyl ether  $\text{C}_{11}\text{H}_{11}(\text{CO}_2\text{H})(\text{CO}_2\text{Et})$ . [172°]. Formed, together with the di-ethyl ether, by saturating an alcoholic solution of the acid with  $\text{HCl}$  (Liebmann, *B.* 22, 2240). Needles, yielding  $\text{AgA}''$ . At  $320^\circ$  it is converted into a mixture of (a)-truxillic acid and (a)-truxillic ether.

Di-ethyl ether  $\text{EtA}''$ . [98°]. Needles, v. sol. alcohol (Drory, *B.* 22, 2260).

Mono-piperidide  $\text{C}_{11}\text{H}_{11}(\text{CO.NC}_5\text{H}_{10})(\text{CO}_2\text{H})$ . [261°]. Plates (from water or dilute alcohol). Yields  $\text{MeA}''$  [201°] and a piperidine salt  $(\text{C}_5\text{H}_{11}\text{N})\text{HA}''$  8aq [218°], which crystallises (with 3aq) from alcohol (Horstein, *B.* 22, 2262).

Di-piperidide  $\text{C}_{11}\text{H}_{11}(\text{CO.NC}_5\text{H}_{10})_2$ . [248°]. Needles, insol. water, sol. alcohol.

Mono-anilide  $\text{C}_{11}\text{H}_9\text{O}_4\text{NPh}$ . [220°]. Formed by heating the acid with aniline (Liebmann, *B.* 25, 836). Needles (from dilute alcohol).

Aniline  $\text{C}_{11}\text{H}_9\text{O}_4\text{N.NHPh}$ . [255°].

Anhydride  $\text{C}_{11}\text{H}_9\text{O}_4$ . Mol. w. 282 (calc. 278). Gives no fluorescein.

( $\beta$ )-Truxillic acid  $\text{C}_{11}\text{H}_{10}\text{O}_4$ . [174°]. Formed by fusing ( $\beta$ )-truxillic acid with potash. Needles (from water), v. sol. alcohol (Liebmann, *B.* 22, 2250; Hesse, *A.* 271, 205). Yields a di-nitro-derivative [226°]. Yields cinnamic acid on distillation.— $\text{CaA}''$ : rosettes of needles.— $\text{BaA}''$  4aq: prisms, sl. sol. Aq.— $\text{CuA}''$  2aq.— $\text{AgA}''$ .

Methyl ether  $\text{MeA}''$ . [77°]. Needles.

Reference.— $\alpha$ -TRUXILLIC ACID.

TRUXONE  $(\text{C}_9\text{H}_6\text{O})_2$ ,  $\alpha = 29.8$ . [289°]. Formed from (a)-truxillic acid and fuming  $\text{H}_2\text{SO}_4$  (S.G. 1.96) at  $15^\circ$  (Liebmann & Bergami, *B.* 22, 784; 23, 320). Plates (by sublimation), insol. water, acids, and bases. Not attacked by  $\text{HNO}_3$ . Yields  $(\text{C}_9\text{H}_6\text{Cl}_2)_2$  [178°]. Aniline and  $\text{HOAc}$  on

boiling form the anilide ( $C_6H_5.NPH_2$ ), crystallising in needles,  $[270^\circ]$ , decomposed by fusion.

**Phenyl-hydrasides** ( $C_6H_5.N.HPH_2$ ). [c.  $270^\circ$ ]. Needles, v. sl. sol. alcohol.

**Oxim** ( $C_6H_5.NOH$ ). Very unstable, easily changing to an anhydride. Boiling  $Ac_2O$  yields ( $B.H_2.NQAe$ ),  $[261^\circ]$ , m. sol. HOAc.

**TULUCUNIN**  $C_{10}H_{14}O_4$ . Occurs in the bark of *Tarapa Tulucuna* (Caventou, *J. Ph.* [3] 35, 189). Light-yellow amorphous resin, with very bitter taste, sl. sol. water, v. sol. alcohol, fusol. ether. Turned blue by cold  $H_2SO_4$ .

**TUNGSTATES**, and derivatives of; v. TUNGSTEN OXYACIDS, SALTS, AND DERIVATIVES OF, p. 802; also TUNGSTEN THIO-ACIDS, AND SALTS OF, p. 810.

**TUNGSTEN**. W. (Wolfram). At. w. 183.6. Mol. w. is unknown.  $\bar{S}G$ . 18-77 (Waddell, *Am.* 8, 280); 18-77 (Moissan, *C. R.* 116, 1225); 19-13 at  $4^\circ$  (Roscoe, *C. J.* [2] 10, 286); for other determinations v. Bernoulli (*P.* 111, 576), Zettnow (*P.* 111, 16).  $\bar{S}H$ .  $6^\circ$  to  $15^\circ$  -035 (De la Rive a. Marcet, *A. Ch.* [2] 75, 113).  $\bar{S}V.S.$  c. 9-7.

**Historical**.—In 1785 a new acid was prepared by J. and F. d'Elhujar from the mineral *wolframite*, and shown to be identical with an acid obtained three years before from *tungstein* by Scheele (*Opusc.* 2, 119). The metal of the new acid was isolated by J. and F. d'E. For many years the new metal was known as *wolfram* or *tungsten* (from Swedish—heavy stone); the latter name has gradually driven out the former in England and France, but the metal is generally called wolfram in Germany; the symbol W is universally employed.

**Occurrence**.—Never uncombined. *Wolframite* (tungstate of Fe and Mn) is found in considerable quantities in Cornwall, Saxony, Bohemia, &c.; *tungstenite*, or *scheelite* (tungstate of Ca), *scheelite* (tungstate of Pb), and some other tungstates occur in various localities; *wolframins* or *wolfram-ochre*,  $WO_3$ , is also found. Some tin ores contain compounds of W, and W is therefore not infrequently found in specimens of tin.

**Formation**.—1. By reducing  $WO_3$  by heating to redness in H (Berzelius, *P.* 4, 147; Wöhler, *A.* 77, 262; Zettnow, *P.* 111, 16; Roscoe, *C. N.* 25, 61, 78).—2. By heating  $WO_3$  with Na and NaCl (*Z.*, *Ac.*).—3. By reducing  $WO_3$  by mixing with 10 p.c. charcoal and 2 p.c. resin, and heating in a closed crucible for some hours to a white heat (Filsinger, *S. U. I.* 1878, 229).—4. By passing vapour of oxychloride of W and H through a red-hot tube (von Uslar, *A.* 94, 255). 5. By heating  $WCl_5$  in H, in a zinc bath (Roscoe, *Ac.*).—6. By strongly heating the salt  $(NH_4)_2WO_4$  in a carbon crucible (Bucholz, *P.* 111, 576).—7. By strongly heating the nitride (*q. v.*, p. 800) in H (Wöhler, *A.* 73, 190).

**Preparation**.—1. Pure  $WO_3$  is heated to bright redness, in a Pt tube, in a stream of pure dry H (*v. Formation*, No. 1).—2. A mixture of pure  $WO_3$  and dry lampblack is heated in an electric furnace (Moissan, *C. R.* 116, 1225).

$WO_3$  is prepared from *wolframite* by heating the very finely powdered mineral with conc.  $HClAq$ , pouring off the solution from time to time and adding more  $HClAq$ , and after some time adding a little  $HNO_3Aq$  until most of the brown solid is changed to yellow  $WO_3.xH_2O$ , washing the residue thoroughly by decantation,

adding a considerable quantity of  $NH_3Aq$  and warming, filtering from quartz, unchanged *wolframite*, &c., evaporating the solution until small lustrous crystals of an acid ammonium tungstate separate, boiling these crystals for a long time with  $HNO_3Aq$ , washing, and heating the residue (Scheibler, *J. pr.* 83, 239; cf. Bernoulli, *P.* 111, 590).

**Properties**.—A steel-grey, hard, brittle, crystalline powder (Riche, *A. Ch.* [3] 50, 5). By reducing the nitride in H, Wöhler (*A.* 78, 190) obtained W as a black powder. By reducing  $WO_3$  by C in an electric furnace, Moissan (*C. R.* 116, 1228) obtained a lustrous, very hard, greyish white solid. As produced by passing the vapour of  $WO_3Cl_2$  mixed with H through a red-hot tube, W forms a shining, dark steel-grey, mirror-like deposit, which can be detached from the tube in hard, brittle crusts (von Uslar, *A.* 94, 255). W can be melted in the O-H flame, part of it burning to  $WO_3$  (Riche, *Ac.*); or by using a current from 600 Bunsen cells, in an atmosphere of N (Desprez, *C. R.* 29, 549). Considerable masses may be melted by employing the current from a dynamo (v. Huntington, *C. N.* 46, 163). W was regarded by Faraday as diamagnetic (*T.* 1846, 49). The emission spectrum is described by Thalén (*A. Ch.* [4] 18, 202). W is unchanged in air, but when the pulverulent metal is heated it burns to  $WO_3$ ; compact W burns in air only at very high temperatures; as obtained by reducing  $WCl_5$  by H, W is said to be pyrophoric. Water is decomposed by W at a red heat. The metal is scarcely acted on by  $HClAq$  or  $H_2SO_4Aq$ ; it is oxidised by  $HNO_3Aq$  to  $WO_3.xH_2O$ ; the pulverulent metal dissolves slowly in caustic alkali solutions. Finely divided W reduces and ppt. many metals from solutions of their salts. W combines directly with Br, Cl, I, or S. W is not acted on by heating in  $NH_3$ , nor in CO (v. Rideal, *C. J.* 55, 45; Smith a. Oberholtzer, *Zeit. f. anorg. Chemie*, 5, 63).

The at. w. of W has been determined (1) by reducing  $WO_3$  in H, and again oxidising W to  $WO_3$  (Berzelius, *P.* 4, 151 [1825]; Schneider, *J. pr.* 50, 158, 161 [1850]; Marchand, *A.* 77, 263 [1850]; von Borel, *J. pr.* 54, 254 [1851]; Riche, *A. Ch.* [3] 50, 10 [1856]; Dumas, *A. Ch.* [3] 55, 143 [1859]; Bernoulli, *P.* 111, 597 [1860]; Persoz, *A. Ch.* [4] 1, 93 [1864]; Roscoe, *C. N.* 25, 61, 73 [1872]; Waddell, *Am.* 8, 280 [1887]); (2) by determining  $H_2O$  in  $BaWO_4.xH_2O$  (Scheibler, *J. pr.* 83, 324 [1861]); (3) by reducing W in H and determining  $H_2O$  produced (Bernoulli, *P.* 111, 597 [1860]); (4) by analysing  $Ag_2WO_4$  and  $FeWO_4$  (Zettnow, *P.* 130, 16, 240 [1877]); (5) by analysing  $WCl_5$  (Roscoe, *C. N.* 25, 61, 73 [1872]); (6) by determining  $\bar{S}H$  of W (De la Rive a. Marcet, *A. Ch.* [2] 75, 113 [1840]); (7) by determining  $V_2O_5$  of  $WCl_5$ ,  $WCl_4$ , and  $WOCl_2$  (v. these compounds). The older determinations gave values for at. w. varying from 186 to 189; the most recent determination (by Waddell) gave 184.04; Roscoe's determinations, made by reducing  $WO_3$  to W and oxidising W again to  $WO_3$ , by finding the ratio of  $WCl_5$  to  $AgCl$  and to  $Ag$ , and by reducing  $WCl_5$  in H, gave values varying from 183.25, to 183.77. The number 183.6 is probably correct to half a unit. The atom of W is pentavalent in the gaseous molecule  $WCl_5$ , and hexavalent in the gaseous molecule  $WCl_6$ .

W is the fourth member (the third is as yet unknown) of the even series, orbromium, family of Group VI. in the periodic arrangement of the elements. W is followed in its family by U, and it succeeds Mo and Cr. W very closely resembles Mo; like that element W is both metallic and non-metallic; the balance of these properties being, however, not quite so evenly maintained in W as in Mo. It is doubtful whether any definite salt has been isolated derived from an oxyacid by replacing H by W. The oxide  $WO_3$  acts as a fairly acidic oxide; like  $MoO_3$ , it is remarkable for the large number of compounds it forms, simultaneously, with oxides that are more basic and oxides that are less basic than itself. The chemical relations of W are discussed in the article CHROMIUM GROUP OF ELEMENTS, vol. ii. p. 168.

**Reactions.**—1. Heated in air burns to  $WO_3$ ; finely divided W burns easily; compact W only at a very high temperature (v. Roscoe, *C. N.* 25, 61, 73).—2. Heated to redness in steam gives H and oxide ( $? WO_3$ ).—3. Reacts with hot nitric acid, or aqua regia, to form  $VO_3$  and  $H_2O$ ; the same product is obtained by heating W with conc. sulphuric or hydrochloric acid, but oxides intermediate between  $WO_3$  and  $WO_2$  are formed at first (Riche, *A. Ch.* [3] 50, 15).—4. Pulverulent W dissolves in boiling conc. potash solution, giving H and a tungstate of K (Riche, *l.c.*).—5. Heated in carbonyl chloride to  $150^{\circ}$ – $200^{\circ}$   $VOCl_3$  is produced, mixed with C (Smith & Oberholtzer, *Zeit. f. anorg. Chemie*, 5, 63).—6. By heating to redness with sulphur chloride a red, crystalline thiochloride, probably  $W_2S_3Cl_2$ , is formed as a sublimate, unstable in air (S. a. O., *l.c.*).—7. Finely divided W reduces solutions of several metallic salts;  $AgNO_3$  and  $AuCl_3$  solutions are reduced to Ag and Au,  $HgCl_2$  to  $HgCl$ , Cu, Pd, Pt and Rh are partially ppd. from solutions; Bi, Cd, and Pb are not ppd. (Smith, *Zeit. f. anorg. Chemie*, 1, 360).

**Combinations.**—1. Heated in oxygen,  $WO_3$  is formed.—2. Combines with chlorine, to form  $WCl_5$ , at c.  $800^{\circ}$ ; with bromine, to form  $WBr_5$ , at a higher temperature; and with iodine, to form  $WI_5$ , when strongly heated.—3. Heated with sulphur, forms  $WS_2$ .—4. The compound  $WP_5$  is said to be formed by strongly heating W in phosphorus vapour (Wöhler & Wright, *A.* 79, 244).

**Detection and Estimation.**—Compounds of W form colourless beads with borax or microcosmic salt in the outer blowpipe flame. The borax bead is yellow in the inner flame if a considerable quantity of a compound of W is present. The microcosmic salt bead is blue in the inner flame in the absence of compounds that themselves form coloured beads; in presence of iron compounds the bead is blood-red, but addition of tin causes it to become blue. Soluble alkali tungstates are formed by fusion with alkali carbonate or nitrate; addition of excess of  $H_2SO_4$ ,  $HClAq$ ,  $H_3PO_4$ ,  $H_2C_2O_4$ , or  $HO_2H_2O_4$  to an aqueous solution of a tungstate, followed by immersion of a piece of zinc in the liquid, produces a blue colour; addition of  $H_2S$  to an acidulated solution of a tungstate gives no pp., but a blue colour. According to Mallet (*C. J.* 28, 1223), the successive addition of small pieces of zinc to the solution obtained

by adding excess of conc.  $HClAq$  to an alkaline tungstate produces various colours, the most marked of which is a brilliant magenta-red. By adding  $KCNSAq$  and then small pieces of zinc to a solution of an alkaline tungstate in excess of conc.  $HClAq$ , a deep green colour is produced; and an amethyst colour is noticed when  $KCNSAq$  is added to the solution of an alkaline tungstate, the solution is then diluted,  $HClAq$  is then added, and lastly zinc is placed in the liquid. Very minute quantities of W can be detected by adding  $SO_4$  and Zn to solution of an alkaline tungstate, whereby a light-blue colour is obtained (M., *l.c.*, p. 1233). W is estimated as  $WO_3$ , obtained by evaporation and strongly heating; for separation from other elements a *Manual of Analysis* must be consulted.

**Tungsten, alloys of.** By reducing mixtures of  $WO_3$  with oxides of Sb, Bi, Co, Cu, Pb, Ni, or Zn, Bernoulli (*P.* 111, 573) obtained alloys of W with these metals, provided there was not more than 10 p.c. of the foreign metal present. An alloy with aluminium, approximately  $WAl_3$ , was obtained by Wöhler & Michel (*A.* 115, 102) by heating a mixture of  $WO_3$ , Al, cryolite, and NaCl and KCl. W alloys with iron; v. Poleck & Grützer (*B.* 26, 35) for an alloy approximately  $W_2Fe$ . An alloy of 9 or 10 p.c. W with steel is extremely hard (v. Bernoulli, *l.c.*; Philipp, *Hofmann's Ber. über chem. Industrien*, 745; Le Guen, *C. R.* 56, 593; 59, 786; 63, 967; 64, 619; 68, 592; Caron, *A. Ch.* [3] 68, 143; Osmond, *C. R.* 104, 985; Gruner, *C. R.* 96, 197).

**Tungsten, amidonitrides of, v. TUNGSTEN NITRIDES, AND ALLIED COMPOUNDS, p. 799.**

**Tungsten, bromides of.** The elements combine when heated together to form  $WBr_5$ , and by partial reduction in H this gives  $WBr_4$ .

**TUNGSTEN PENTABROMIDE  $WBr_5$ .** The formula is probably molecular, from the analogy of  $WCl_5$ . Prepared by heating W in excess of Br vapour, taking care that every trace of water and O are excluded. Dark, violet-brown needles, resembling I; melts at  $276^{\circ}$  and boils at  $333^{\circ}$ , giving off a dark-brown vapour; decomposed on distillation, with separation of Br; moist air or water forms  $HBrAq$  and blue oxide of W; heated to  $850^{\circ}$  in a stream of H,  $WBr_5$  is formed (Roscoe, *C. N.* 25, 73; cf. Borek, *J. pr.* 54, 254; Blomstrand, *J. pr.* 82, 408).

**TUNGSTEN DIBROMIDE  $WBr_4$ .** Obtained, as a bluish-black, velvety solid, when  $WBr_5$  is heated at c.  $350^{\circ}$  (in a bath of  $ZnCl_2$ ) in a stream of dry H;  $WBr_4$ ,  $WOBr_4$ , and Br distil over, and  $WBr_5$  remains. Heated above c.  $400^{\circ}$  in H gives W and HBr; with  $HNO_3$  gives  $WO_3$ ,  $HBrAq$ , and  $NH_4NO_3$  (Roscoe, *l.c.*).

**Tungsten, chlorides of.** When W is heated in Cl the compound  $WCl_5$  is formed, and by reduction in H or CO, this gives  $WCl_4$ ,  $WCl_3$ , and  $WCl_2$ . Great confusion existed about the compositions of the chlorides of W until Roscoe's researches in 1872 established the formulae.

**TUNGSTEN TETRACHLORIDE  $WCl_4$ .** Mol. w. 395.82. Prepared by heating W in Cl (Roscoe, *C. N.* 25, 61). The materials must be perfectly dry, and every trace of air must be excluded, else  $WOCl_2$  is formed; the  $WCl_4$  sublimes on the cooler part of the tube, and is then distilled several times in a stream of dry Cl, and then in

a current of dry H (a small quantity of  $\text{WCl}_5$  is formed, and distils off with the H). Teclu (A. 187, 255) obtained  $\text{WCl}_5$  by heating  $\text{WO}_3$  and  $\text{PCl}_5$  in a sealed tube at  $170^\circ$ .  $\text{WCl}_5$  forms dark-violet crystals; crystallises from  $\text{CS}_2$  in brown, six-sided tablets, from  $\text{POCl}_3$  in steel-blue, metal-like, regular crystals (T., L.c.). Melts, out of contact with air, at  $275^\circ$ , and boils at  $346.7^\circ$  at 760 mm. pressure (R., L.c.). V.D. 190 at  $350^\circ$  (Debray, C. R. 60, 820; Roscoe, L.c.); V.D. 168.8 at  $440^\circ$  (D., L.c.; R., L.c.; Riebt, B. 3, 666). Dissolves readily in  $\text{CS}_2$ , or  $\text{POCl}_3$  (T., L.c.). Distilled in  $\text{CO}_2$  gives  $\text{WCl}_4$  and  $\text{Cl}_2$ ; this fact taken in connection with V.D. at  $440^\circ$  shows that at somewhat above b.p.  $\text{WCl}_5$  probably dissociates to  $\text{WCl}_4$  and  $\text{Cl}_2$ .  $\text{WCl}_5$  is unchanged in air; but if a trace of  $\text{WOCl}_2$  is present,  $\text{HClAq}$  and  $\text{WO}_3$  are formed. Hot water produces  $\text{WO}_3$  and  $\text{HClAq}$ . Heated in air, or in O, forms  $\text{WOCl}_2$  (Roscoe, L.c.; Blomstrand, J. pr. 82, 417).  $\text{WOCl}_2$  is also formed by heating  $\text{WO}_3$  with  $\text{WCl}_5$ .  $\text{WCl}_5$  interacts with  $\text{NH}_3$  at the ordinary temperature, to form  $\text{NH}_4\text{Cl}$  and  $\text{W}_2\text{N}_2$  (Rideal, C. J. 55, 44).

**TUNGSTEN PENTACHLORIDE  $\text{WCl}_5$ .** Mol. w. 360.45. Prepared by repeatedly heating  $\text{WCl}_5$  somewhat above its b.p. ( $346.7^\circ$ ) in a stream of dry H, and when a solid residue has been formed removing the  $\text{WCl}_5$  from less volatile lower chlorides by heating in  $\text{CO}_2$  (Roscoe, C. N. 25, 61). Black, lustrous, needle-shaped crystals; very deliquescent; melts at  $248^\circ$ , and boils at  $275.6^\circ$  (R., L.c.). V.D.  $175.6$  to  $179.9$  at  $350^\circ$ ;  $185.7$  to  $186.4$  at  $440^\circ$  (R., L.c.). Slightly soluble in  $\text{CS}_2$ , forming a blue liquid; forms an olive-green solution in water, but is mostly decomposed to  $\text{HClAq}$  and blue oxide of W. Heated in O forms  $\text{WOCl}_2$  and  $\text{Cl}_2$  (R., L.c.; cf. Blomstrand, J. pr. 82, 425; 89, 230).

**TUNGSTEN TETRACHLORIDE  $\text{WCl}_4$ .** This compound is present in the solid residue obtained by heating  $\text{WCl}_5$  in H in the preparation of  $\text{WCl}_5$  (v. supra); it is prepared by distilling this residue, in a bath of  $\text{H}_2\text{SO}_4$ , in a stream of dry  $\text{CO}_2$ , returning the distillate to the distilling vessel and heating again, and repeating these processes several times (Roscoe, L.c.). A soft, crystalline, greyish-brown powder; very hygroscopic; has not been fused or volatilised; heated strongly, it gives  $\text{WCl}_5$  and  $\text{WCl}_3$ . Heated in H to  $c. 440^\circ$  pyrophoric W is produced. Decomposed by water to  $\text{WO}_3$  and a greenish-brown solution (R., L.c.).

**TUNGSTEN DICHLORIDE  $\text{WCl}_2$ .** Prepared by heating  $\text{WCl}_5$  in a bath of zinc, in a stream of dry  $\text{CO}_2$ ;  $\text{WCl}_2$  distils off and  $\text{WCl}_5$  remains. A loose, grey, amorphous powder; water forms  $\text{WO}_3$  and  $\text{HClAq}$ , with evolution of H; interacts with H which has been passed through  $\text{HNO}_3\text{Aq}$  to form  $\text{WO}_3$ ,  $\text{HCl}$ , and  $\text{NH}_4\text{NO}_3$  (R., L.c.).

**Tungsten, cyanides of.** No cyanides of W have been isolated; according to Wyrnoff (A. Ch. [5] 8, 444; cf. Atterberg, Bl. [2] 24, 355), compounds containing W, K, and  $\text{FeCy}$ , are obtained by adding  $\text{HClAq}$  to a mixture of K tungstates and K ferrocyanide.

**Tungsten, fluorides of.** No fluoride of W has been isolated. According to Berzelius (P. 4, 147), when a solution of  $\text{WO}_3 \cdot \text{H}_2\text{O}$  in  $\text{HFAq}$  is evaporated and the residue is treated with water, a solid remains which is free from F after being

heated in  $\text{NH}_3$ . According to Riche (A. Ch. [3] 50, 41), a solution of tungstic hydroxide in  $\text{HFAq}$  gives crystals of  $\text{WO}_3 \cdot \text{H}_2\text{O}$  on evaporation.

**Tungstoxyfluorides. (Fluotungstates.)** By dissolving tungstates of the form  $\text{M}_2\text{WO}_6$  in  $\text{HFAq}$ , Maignac obtained a series of compounds of the forms  $2\text{M}^+\text{F} \cdot \text{WO}_3 \cdot x\text{H}_2\text{O}$  and  $\text{M}^+\text{F} \cdot \text{WO}_3 \cdot x\text{H}_2\text{O}$ , and also a few compounds of the form  $\text{M}^+\text{F} \cdot \text{WO}_3 \cdot \text{F} \cdot \text{H}_2\text{O}$  (A. Ch. [3] 69, 67). These compounds may be regarded as salts of the hypothetical acids  $\text{H}_2\text{WO}_6$  and  $\text{HWO}_6$ ; they are similar to some classes of the compounds described as *fluomolybdates* (this vol. p. 425).

The *tungstoxyfluorides* etch glass even when dry; they react slowly with acids, giving  $\text{WO}_3 \cdot \text{H}_2\text{O}$ . The salts of the forms  $\text{M}_2^+\text{WO}_6$  and  $\text{M}^+\text{WO}_6$  were prepared by dissolving  $\text{M}_2\text{WO}_6$  and  $\text{M}^+\text{WO}_6$  in  $\text{HFAq}$  and evaporating; in some cases also by dissolving  $\text{WO}_3 \cdot \text{H}_2\text{O}$  in  $\text{HFAq}$ , adding  $\text{MOH}$ , and evaporating. The salts of the form  $\text{M}^+\text{WO}_6$  were formed by dissolving acid tungstate in  $\text{HFAq}$  and evaporating. The following compounds were isolated: (1)  $\text{M}_2^+\text{WO}_6 \cdot x\text{H}_2\text{O}$ ;  $\text{M} = \text{NH}_4$ ,  $x = 0$ ;  $\text{M} = \text{K}$ ,  $x = 1$ ;  $\text{M} = \text{Na}$ ,  $x = 0$ ; (2)  $\text{M}^+\text{WO}_6 \cdot x\text{H}_2\text{O}$ ;  $\text{M} = \text{Zn}$ ,  $x = 10$ ; (3)  $\text{MWO}_6 \cdot x\text{H}_2\text{O}$ ;  $\text{M} = \text{NH}_4$ ,  $x = 1$ ;  $\text{M} = \text{K}$ ,  $x = 1$ . The salts  $(\text{NH}_4)_2\text{WO}_6$ ,  $(\text{NH}_4)_2\text{WO}_6$ , and  $\text{CuWO}_6 \cdot \text{NH}_3$  were also obtained.

By dissolving  $\text{K}_2\text{WO}_6 \cdot \text{H}_2\text{O}$  in 4 p.c.  $\text{H}_2\text{O}_2\text{Aq}$ , and crystallising from dilute  $\text{H}_2\text{O}_2\text{Aq}$  containing a little  $\text{H}_2\text{F}$ , Piccini (Zrit. f. anorg. Chemie, 2, 21) obtained  $\text{K}_2\text{WO}_6 \cdot \text{F} \cdot \text{H}_2\text{O}$ . P. calls this compound *fluoroxypertungstate*; it might also be named *pertungstoxyfluoride*.

**Tungsten, haloid compounds of.** When W is heated in a stream of Cl the compound  $\text{WCl}_5$  is formed, and this by reduction in H gives  $\text{WCl}_4$ ,  $\text{WCl}_3$ , and  $\text{WCl}_2$ . The compound  $\text{WBr}_4$  is formed by heating W in  $\text{Br}$  vapour, and  $\text{WBr}_3$  is obtained by partially reducing  $\text{WCl}_5$  in H. Small quantities of  $\text{W}_2$  are obtained by heating W in vapour of I. No fluoride of W has been isolated. Oxychlorides and oxybromides of the forms  $\text{WOX}$  and  $\text{WO}_2\text{X}$  are obtained by heating W oxides in Cl or Br, and in other ways. The following compounds have been vapourised, and the simplest formulae are molecular:  $\text{WCl}_5$ ,  $\text{WCl}_4$ ,  $\text{WOCl}_2$ . The formulae  $\text{WBr}_4$ ,  $\text{WOBBr}_3$ ,  $\text{WOCl}_3$ , and  $\text{WO}_2\text{Br}_2$  are probably molecular; but if the analogy of the chlorides and bromides of Mo of the form  $\text{Mo}_2\text{X}_5$  is to be followed (v. vol. iii. pp. 427, 428) it is probable that the molecular formulae of the dichloride and dibromide of W are not less than  $\text{W}_2\text{X}_4$ .

**Tungsten, hydroxides of, v. TUNGSTEN OXIDES AND HYDRATED OXIDES (p. 800), also TUNGSTEN OXYACIDS (p. 802).**

**Tungsten, iodide of,  $\text{WI}_5$ .** This, the only iodide of W that has been isolated, is obtained, in very small quantities, by passing I vapour, mixed with  $\text{CO}_2$ , over red-hot W. It forms a metal-like, greenish crust; heated in air it gives off I and leaves  $\text{WO}_3$ ; it is not decomposed by water (Roscoe, C. N. 25, 73).

**Tungsten, nitrides of, and allied compounds.** Compounds of W with N, and probably also with H, are formed by heating  $\text{WCl}_5$  or  $\text{WOCl}_2$  in  $\text{NH}_3$ ; the interaction of  $\text{NH}_3$  and

WO<sub>3</sub> probably produces a compound, or compounds, of W, N, H, and O; and a compound of W, N, and O is perhaps formed by heating WO<sub>3</sub> with NH<sub>4</sub>Cl.

**TUNGSTEN NITRIDES.** By passing dry NH<sub>3</sub> over WCl<sub>5</sub>, and washing away the NH<sub>4</sub>Cl produced, by water, Rideal (*C. J.* 55, 44) obtained a black lustrous powder, agreeing fairly with the composition W<sub>2</sub>N<sub>3</sub>. This substance is insoluble in HNO<sub>3</sub>Aq, dilute H<sub>2</sub>SO<sub>4</sub>Aq, or NaOH Aq; hot conc. H<sub>2</sub>SO<sub>4</sub> produces NH<sub>3</sub> and WO<sub>3</sub>; fusion with NaOH forms Na tungstate; heating in air, or with *aqua regia*, oxidises it to WO<sub>3</sub> (*R., l.c.*).

By continued heating WU<sub>3</sub> in NH<sub>3</sub>, to a temperature difficult to regulate, as slightly too high a temperature produces W, Uhrlaub obtained a black substance to which he gave the formula W<sub>2</sub>N<sub>2</sub> (*Die Verbindungen einiger Metalle mit Stickstoff*, Göttingen, 1859).

**TUNGSTEN AMIDONITRIDES.** By the action of NH<sub>3</sub> on WCl<sub>5</sub>, Wöhler (*A. 73*, 198) obtained a black substance containing from 86.76 to 90.8 p.c. W, and 8.24 p.c. N; W. supposed this substance to be a mixture of two amidonitrides, 2WN<sub>2</sub>.W(NH<sub>2</sub>)<sub>2</sub> and 2WN.W(NH<sub>2</sub>)<sub>2</sub>. W. obtained similar black substances, which he did not analyse, by heating chlorides of W with NH<sub>4</sub>Cl (*A.* 105, 258).

**Compounds of tungsten with N, H, and O.** Wöhler (*A. 73*, 198) obtained a black substance by heating WO<sub>3</sub> to dull redness in dry NH<sub>3</sub>; the percentage of W in this substance varied from 87.65 to 88.47, and it contained 7.15 p.c. N, and c. 2 p.c. H. To this substance W. gave the formula W<sub>2</sub>N<sub>2</sub>H<sub>2</sub>O<sub>4</sub> (= 4WN<sub>2</sub>.W<sub>2</sub>(NH<sub>2</sub>)<sub>2</sub>.2WO<sub>3</sub>). Rideal (*C. J.* 55, 44) passed dry NH<sub>3</sub> over WO<sub>3</sub> heated to a dull redness until the yellow WO<sub>3</sub> was changed to a black, amorphous powder; he allowed to cool, and removed excess of NH<sub>3</sub> by passing a current of dry air through the tube. The black substance thus obtained contained 85.26 p.c. W, and 7.4 p.c. N; assuming c. 3 p.c. H, the numbers agreed fairly with the formula W<sub>2</sub>N<sub>2</sub>H<sub>2</sub>O<sub>4</sub>.

**Compound of tungsten with N and O.** Rideal (*l.c.*) obtained a black powder, agreeing in composition approximately with the formula WN<sub>2</sub>WO<sub>3</sub>, by heating WO<sub>3</sub> with NH<sub>4</sub>Cl until the weight became constant. According to Rideal (*l.c.*) finely divided W does not change when heated in a stream of dry NH<sub>3</sub>, after having been heated to redness in dry H<sub>2</sub>; nor does NH<sub>3</sub> react with the blue oxide of W when heated therewith.

**Tungsten, oxides and hydrated oxides of.** When powdered W is heated in O it combines to form WO<sub>3</sub>; by heating this oxide in H a blue oxide is formed, to which various formulae intermediate between WO<sub>3</sub> and WO<sub>2</sub> have been assigned; by further heating in H, or with C, the dioxide WO<sub>2</sub> is produced. There are indications of an oxide with more O than WO<sub>2</sub>. WO<sub>3</sub> dissolves in acids, but corresponding salts have not been isolated; the blue oxide separates from these solutions; WO<sub>3</sub> is also soluble in alkali solutions. WO<sub>3</sub> is insoluble in acids; it dissolves in alkali and alkaline carbonate solutions, forming tungstates (*v. under* TUNGSTEN OXYGENS, p. 802). WO<sub>3</sub> combines with many acidic oxides to form compounds which react as acids (*v. p.* 801). WO<sub>3</sub> is the anhydride of more than

one tungstic acid (*v. p.* 801). None of the oxides has been vaporized; the mol. w. of none is known.

**TUNGSTEN DIOXIDE WO<sub>2</sub>.** (*Brown oxide of tungsten.*)

**Formation.**—1. By heating a mixture of WO<sub>3</sub> and C to redness (Buchholz, *V.S.* 3, 1).—2. By heating WO<sub>3</sub> to incipient redness in H (Wöhler, *A. 73*, 198; 77, 262).—3. By decomposing WCl<sub>5</sub> or WCl<sub>6</sub> by H<sub>2</sub>O (Roscoe, *C. N.* 25, 61, 73).—4. By the reaction of Zn and HClAq on WO<sub>3</sub> (Wöhler, *P. 2*, 845), or on solution of a metatungstate (Riche, *l.c.*).

**Preparation.**—WO<sub>3</sub> is placed in a porcelain tube closed at one end and provided with a long opening in the middle; this tube is placed inside another porcelain tube which is kept at red heat, while H is passed through as long as water continues to be formed (Wöhler, *A. 77*, 262 *note*); the product is allowed to cool in H, and is kept in H for 24 hours (Riche, *A. Ch.* [3] 50, 29).

**Properties.**—A brown powder with a slight violet sheen; prepared by reducing WO<sub>3</sub> by Zn and HClAq, the oxide is obtained in metal-like lustrous crystals, pseudomorphs of WO<sub>3</sub>. S.G. 12.11 (Karsten, *S.* 65, 394).

**Reactions.**—1. Moist WO<sub>3</sub> oxidises rapidly in air to WO<sub>3</sub>; as prepared by reducing WO<sub>3</sub> in H it is pyrophoric, but if allowed to cool slowly in H the product is not pyrophoric (Berzelius, *P.* 4, 147; 8, 267; Wöhler, *l.c.*; Riche, *l.c.*).—2. Heated strongly in hydrogen gives W.—3. Chlorine forms WO<sub>2</sub>Cl<sub>2</sub> when heated with WO<sub>3</sub> (Roscoe, *l.c.*, p. 63).—4. Heated to dull redness in a stream of ammonia, a compound, or compounds, of W with N, H, and O is formed (*v. Compounds of W with N, H, and O, under* TUNGSTEN NITRIDES, *supra*).—5. By heating with *sal ammoniac*, Rideal (*C. J.* 55, 44) obtained a black powder approximately WN<sub>2</sub>WO<sub>3</sub> (*v. Compound of W with N and O, supra*).—6. Moist WO<sub>2</sub> dissolves easily in warm hydrochloric or sulphuric acid, forming reddish-brown solutions from which blue oxide of W separates. WO<sub>2</sub> prepared in the dry way is scarcely acted on by acids, except *aqua regia*, which oxidises it to WO<sub>3</sub>.—7. WO<sub>2</sub> dissolves in conc. *potash solution*, giving off H<sub>2</sub> and forming K tungstate. 8. Reduces mercuric chloride to HgCl, and ppts. Cu<sub>2</sub>O from solutions of copper salts (Riche, *A. Ch.* [3] 50, 5).—9. Heated in nitric oxide to below 500° gives the blue oxide; oxidised to WO<sub>3</sub> by heating in nitrogen dioxide to c. 800° (Sabatier & Senderens, *C. R.* 114, 1429; 115, 236).

**BLUE OXIDE OF TUNGSTEN.** Blue compounds of W and O are obtained by heating WO<sub>3</sub> with reducing agents; analyses lead to formulae such as W<sub>2</sub>O<sub>5</sub>, W<sub>2</sub>O<sub>4</sub>, or W<sub>2</sub>O<sub>3</sub>, intermediate between WO<sub>3</sub> and WO<sub>2</sub>. Malaguti (*A. Ch.* [3] 60, 278) gave the formula W<sub>2</sub>O<sub>4</sub> to the blue product of heating WO<sub>3</sub> in H to c. 250°; von Uslar (*Beiträge zur Kenntniss des W und Mo* [Göttingen, 1855]) gave the formula W<sub>2</sub>O<sub>4</sub>. Gmelin said that a blue oxide of the composition W<sub>2</sub>O<sub>4</sub> is formed by strongly heating WO<sub>3</sub> in CO.

Blue compounds are also obtained by strongly heating NH<sub>3</sub> tungstates out of contact with air (Malaguti, *l.c.*; von Uslar, *l.c.*). Aqueous solutions of WO<sub>3</sub> or tungstates are coloured blue by the action of very weak reducers, e.g. by exposing moist WO<sub>3</sub> on paper to sunlight (Liesegang).

*C. C.* 1865, 948), or by the action of  $\text{SnCl}_4\text{Aq}$  on tungstates (Bunsen, *A.* 188, 289; v. also Scheibler, *J. pr.* 83, 313). Conc.  $\text{H}_2\text{SO}_4$  or  $\text{HClAq}$  gives a blue colour when heated with W (Riche, *A. Ch.* [3] 50, 15). Tungstates boiled with acetic acid and then electrolysed give blue coloured substances (Smith, *B.* 13, 753).

**PEROXIDES OF TUNGSTEN.** Fairley (*C. J.* 31, 141) obtained indications of an oxide with more O than  $\text{WO}_3$ , by dissolving  $\text{WO}_3 \cdot 2\text{H}_2\text{O}$  in  $\text{H}_2\text{O}_2\text{Aq}$ , and evaporating over  $\text{H}_2\text{SO}_4$  *in vacuo*; the green, transparent, yellow scales thus obtained dissolved in water, forming a solution which could be titrated with  $\text{KMnO}_4\text{Aq}$ , with separation of  $\text{WO}_3 \cdot x\text{H}_2\text{O}$ . Cammerer (*Chem. Zeitung*, 15, 957) found that  $\text{WO}_3$  dissolved in boiling  $\text{H}_2\text{O}_2\text{Aq}$ , with evolution of O; on spontaneous evaporation he obtained a yellow powder, to which he gave the formula  $\text{WO}_3 \cdot \text{H}_2\text{O}_2 \cdot \text{H}_2\text{O}$  (cf. reaction of  $\text{H}_2\text{O}_2\text{Aq}$  with  $\text{CrO}_3\text{Aq}$ , vol. ii. p. 166). According to Pichard (*C. R.* 112, 1060), a salt  $\text{Na}_2\text{O} \cdot \text{W}_2\text{O}_7 \cdot 2\text{H}_2\text{O}$  is formed by boiling Na paratungstate solution with  $\text{H}_2\text{O}_2\text{Aq}$  and evaporating *in vacuo*.

**TUNGSTEN TRIOXIDE  $\text{WO}_3$ .** (*Tungstic anhydride*). Sometimes erroneously called *tungstic acid*.)

**Occurrence.**—As *tungstic ochre* or *wolframite* in Cumberland, Connecticut, North Carolina, &c.

**Formation.**—1. By strongly heating in air tungstate of  $\text{NH}_4$  or of  $\text{Hg}$ .—2. By strongly heating  $\text{WO}_3 \cdot x\text{H}_2\text{O}$ .—3. By burning W in air or O.

**Preparation.**—An aqueous solution of commercial  $\text{Na}_2\text{WO}_4$  is poured into boiling  $\text{HClAq}$  (1:1); the ppd.  $\text{WO}_3$  is washed with  $\text{HClAq}$  until NaCl is completely removed; it is then washed with water to remove all HCl, and dissolved in  $\text{NH}_3\text{Aq}$ ; the solution is evaporated to dryness, and the  $\text{NH}_3$  salt thus obtained is heated in an open crucible until every trace of  $\text{NH}_3$  is driven off (Roscoe, *C.N.* 25, 73). Bernoulli (*P.* 111, 590) recommends to boil the  $\text{NH}_3$  salt for a long time with successive quantities of  $\text{HNO}_3\text{Aq}$  (to remove traces of Na salts), and to wash the residual  $\text{WO}_3$  quite free from acids (cf. Zettnow, *P.* 130, 16, 240).  $\text{WO}_3$  is obtained in crystals by very strongly heating the amorphous oxide (Bernoulli, *P.* 111, 595; Schafarik, *W. A. B.* 47, 246); by dissolving  $\text{WO}_3$  in molten borax (Nordenskjöld, *P.* 114, 612); by strongly heating the oxide in a current of HCl (Debray, *C. R.* 55, 287); or by heating to whiteness a mixture of  $\text{Na}_2\text{WO}_4$  and  $\text{Na}_2\text{CO}_3$  imbedded in NaCl, when crystals of  $\text{WO}_3$  sublime (*D.*, l.c.).

$\text{Na}_2\text{WO}_4$  may be prepared from wolframite by heating a mixture of 150 pts. of the finely powdered mineral with 100 pts. calcined  $\text{Na}_2\text{CO}_3$  and 15 pts.  $\text{NaNO}_3$ , for four or five hours, in an iron vessel, lixiviating with water and crystallising (*g.* Franze, *J. pr.* [2] 4, 238; cf. Huntington, *B.* 17, 203; Scheibler, *J. pr.* 83, 239).

Waddell (*Am.* 8, 380) prepares pure  $\text{WO}_3$  from *tungstentite*, by treating the powdered mineral with *aqua regia*, washing the residue, fusing it with  $\text{KHSO}_4$ , dissolving in water, and fractionally ppg. by  $\text{HgNO}_3\text{Aq}$ ; the first pps. are then decomposed by *aqua regia*, the  $\text{WO}_3$  thus obtained is dried and fused with  $\text{Na}_2\text{CO}_3$ , the fused mass is dissolved in water, tartaric acid is added, and  $\text{H}_2\text{S}$  is passed into the solution; the filtrate

from ppd.  $\text{MnS}$ , &c., is boiled till  $\text{H}_2\text{S}$  is expelled, and is then fractionally ppd. by  $\text{HgNO}_3\text{Aq}$ ; the later pps. are collected, washed, and decomposed by heating in an open vessel. For a method of preparing  $\text{WO}_3$  from *wolframite* v. *Preparation of Tungsten*, p. 797.

**Properties.**—A heavy, canary-yellow powder; becoming orange-coloured when heated (Roscoe, *C. N.* 25, 73). Crystalline  $\text{WO}_3$  is described as wine-yellow, very lustrous, rhombic tablets (Nordenskjöld, *P.* 114, 612). A trace of Na tungstate gives a green colour to  $\text{WO}_3$  (*lk.*, l.c.). S.G.: amorphous, 7.13, to 7.16 (Zettnow, *P.* 130, 16, 240; Karsten, *S.* 65, 391); crystalline, 7.23 at  $17^\circ$  (*Z.*, l.c.); 6.38 (*N.*, l.c.). S.H. ( $8^\circ$  to  $98^\circ$ ) 0.7983 (Regnault, *A. Ch.* [3] 1, 129); ( $22^\circ$  to  $52^\circ$ ) 0.894 (Kopp, *T.* 1865, 71). Melts readily in the blowpipe (Riche, *A. Ch.* [3] 50, 20); can be sublimed by mixing with  $\text{Na}_2\text{CO}_3$ , and heating to whiteness (Debray, *C. R.* 55, 287); also by strongly heating in  $\text{HCl}$  (Schafarik, *W. A. B.* 47, 246). Not decomposed at m.p. of Pt (c.  $1750^\circ$ ) (Read, *C. J.* 65, 313 [1894]). On exposure to light  $\text{WO}_3$  turns greenish, owing to partial reduction (Roscoe, l.c.; cf. Liesegang, *C. C.* 1865, 943).  $\text{WO}_3$  is insoluble in water or acids, even in boiling conc.  $\text{H}_2\text{SO}_4$ ; it dissolves in hot  $\text{KOH Aq}$ ,  $\text{NH}_3\text{Aq}$ , or  $\text{K}_2\text{CO}_3\text{Aq}$ , also in molten  $\text{K}_2\text{CO}_3$ ,  $\text{KHSO}_4$ , or  $\text{K}_2\text{WO}_4$ ; also in molten alkali chlorides, in air, with evolution of Cl (Schultze, *J. pr.* [2] 21, 437, 441).  $\text{WO}_3$  acts as an acid oxide, forming tungstates (v. **TUNGSTEN OXYACIDS**, p. 802).

**Reactions.**—1. Heated in hydrogen,  $\text{WO}_3$  is reduced to the blue oxide, then to  $\text{WO}_2$ , and finally to W (v. **BLUE OXIDE OF TUNGSTEN**, p. 800; **TUNGSTEN DIOXIDE**, p. 800; and **TUNGSTEN**, p. 797).—2. Reduction to  $\text{WO}_2$  or W is effected by heating with carbon.—3. Heated with potassium or sodium,  $\text{WO}_3$  gives W.—4. Reduction to the blue oxide, and then to  $\text{WO}_2$ , is brought about by zinc and hydrochloric acid, by stannous chloride, and also by heating with water and different organic compounds.—5. Heating with carbon in chlorine produces  $\text{WO}_2\text{Cl}_2$  and  $\text{WOCl}_4$ .—6.  $\text{WOCl}_4$  is formed by passing vapour of tungsten hexachloride over heated  $\text{WO}_3$  (Roscoe, *C. N.* 25, 63).—7. A mixture of  $\text{WO}_3$  and calcium chloride heated to redness in carbon dioxide gives  $\text{WO}_2\text{Cl}_2$  (Schultze, *J. pr.* [2] 21, 441).—8. Mixed with carbon and heated in bromine,  $\text{WO}_3$  gives  $\text{WOBr}_4$ ; and  $\text{WO}_2\text{Br}_4$  is formed by passing vapour of tungsten pentabromide over hot  $\text{WO}_3$  (Roscoe, l.c. p. 73).—9.  $\text{WO}_3$  is said to dissolve in molten alkali chlorides, in air, giving off Cl; heated in absence of air (in a stream of  $\text{CO}_2$ ) with chloride of calcium, cobalt, iron, magnesium, or nickel, it is said to give  $\text{WO}_2\text{Cl}_2$  and  $\text{MWO}_2$  (Schultze, l.c.).—10. Heating with phosphorus pentachloride produces  $\text{WCl}_6$  and  $\text{POCl}_3$  (Teclu, *A.* 187, 255); but  $\text{WO}_2\text{Cl}_2$  and  $\text{WOCl}_4$  are also formed, according to the relative masses of  $\text{WO}_3$  and  $\text{PCl}_5$ , and the temperature (Schiff, *A.* 197, 185).—11.  $\text{WO}_2\text{Cl}_2$ ,  $\text{WOCl}_4$ , and  $\text{CO}_2$  are formed by heating  $\text{WO}_3$  in vapour of carbon tetrachloride (Watts & Bell, *C. J.* 33, 442).—12. Compounds of W with N, H, and O (v. p. 800) are formed by heating  $\text{WO}_3$  in ammonia; and a compound of W with N and O is probably produced by heating  $\text{WO}_3$  with sal ammoniac (v. p. 800).—13.  $\text{W}_8\text{S}_8$

is formed by passing sulphur vapour, or hydrogen sulphide, over  $\text{WO}_3$  heated to whiteness (Berzelius); also by heating to redness a mixture of  $\text{WO}_3$  with 6 pts. of mercuric sulphide (B.; Brock, *J. pr.* 54, 254).

**HYDRATES OF TUNGSTEN TRIOXIDE.** Various compounds of the form  $\text{WO}_3 \cdot x\text{H}_2\text{O}$  have been isolated; as these compounds act as acids, they are described under TUNGSTEN OXYACIDS.

**Tungsten oxyacids, salts, and derivatives of.** Several hydrates of  $\text{WO}_3$  that react as acids are known.  $\text{WO}_3$  also combines with many acidic oxides—such as  $\text{Fe}_2\text{O}_3$ ,  $\text{B}_2\text{O}_3$ ,  $\text{SiO}_2$ , &c.—and the compounds so formed combine with basic oxides to form salt-like bodies.

**TUNGSTIC ACIDS.** The hydrates of  $\text{WO}_3$  fall into two classes: *tungstic acids*, which are insoluble, or nearly insoluble, in water; and *metatungstic acids*, which dissolve in water.

**Tungstic acids.** The monohydrate  $\text{WO}_3 \cdot \text{H}_2\text{O}$ , or *orthotungstic acid*  $\text{WO}_3(\text{OH})_2$ , is obtained by dissolving  $\text{WO}_3$  in hot alkali or alkaline carbonate solutions, and boiling these solutions with excess of a mineral acid. It is also said to be obtained by decomposing an ammoniacal solution of  $\text{WO}_3$  by  $\text{OI}$  (Dumas, *A. Ch.* [3] 55, 144); and also by boiling powdered wolframite with *aqua regia*. This acid is a yellow solid; it reddens litmus; is insoluble, or almost insoluble, in water. According to Braun (*J. pr.* 91, 39), it is changed to  $2\text{WO}_3 \cdot \text{H}_2\text{O}$  at  $100^\circ$ ; according to Zettnow (*P.* 130, 16, 240), this change is effected at  $50^\circ$ . The acid is slowly reduced by  $\text{Zn}$  and  $\text{HClAq}$ , the final product being  $\text{WO}_2$  (O. v. d. Pfordten, *B.* 16, 508).

The dihydrate  $\text{WO}_3 \cdot 2\text{H}_2\text{O}$  is said to be formed by adding a mineral acid to a dilute solution of an alkali tungstate  $\text{M}_2\text{WO}_6$ , and drying in the air; also by decomposing  $\text{WCl}_4$ ,  $\text{WOCl}_2$ , or  $\text{WO}_2\text{Cl}_2$  by water (Forcher, *W. A. B.* 44 [2], 173; cf. Riche, *A. Ch.* [3] 50, 36; Anthon, *J. pr.* 9, 6). Forms  $\text{WO}_3 \cdot \text{H}_2\text{O}$  by drying over  $\text{H}_2\text{SO}_4$  (Braun, *J. pr.* 91, 39). This hydrate is described as an amorphous, white solid; reddens litmus; somewhat soluble in water, but insoluble if a little acid is present. By boiling with dilute acids is said to give  $\text{WO}_3 \cdot \text{H}_2\text{O}$ .

The hemihydrate  $2\text{WO}_3 \cdot \text{H}_2\text{O}$ , or *ditungstic acid*  $\text{H}_2\text{W}_2\text{O}_{11}$ , is said by Braun (l.c.) to be formed by heating the monohydrate to  $100^\circ$ ; the change is complete at  $50^\circ$  according to Zettnow (*P.* 130, 16, 240).

**METATUNGSTIC ACIDS.** Acids of the composition  $4\text{WO}_3 \cdot x\text{H}_2\text{O}$  are obtained by decomposing hot conc.  $\text{BaW}_2\text{O}_8\text{Aq}$  by the equivalent quantity of  $\text{H}_2\text{SO}_4$ , filtering from  $\text{BaSO}_4$ , and evaporating (Scheibler, *J. pr.* 83, 310); also by decomposing  $\text{PbW}_2\text{O}_8\text{Aq}$  by  $\text{H}_2\text{S}$ , filtering, and evaporating (Forcher, *W. A. B.* 44 [2], 173). The composition of the acid formed by evaporating *in vacuo* over  $\text{H}_2\text{SO}_4$  is probably  $\text{H}_4\text{W}_4\text{O}_{23} \cdot \frac{1}{2}\text{H}_2\text{O}$  (Scheibler, l.c.; cf. Persoz, *C. R.* 84, 175; Lotz, *A.* 91, 52).  $\text{BaW}_2\text{O}_8$  is obtained by ppg. a hot conc. solution of  $(\text{NH}_4)_2\text{W}_2\text{O}_8$  by  $\text{BaCl}_2\text{Aq}$ ;  $\text{PbW}_2\text{O}_8$  by ppg.  $(\text{NH}_4)_2\text{W}_2\text{O}_8\text{Aq}$  by  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2\text{Aq}$ ;  $(\text{NH}_4)_2\text{W}_2\text{O}_8$  is formed by boiling  $(\text{NH}_4)_2\text{WO}_4$  with  $\text{WO}_3\text{Aq}$  and evaporating.

According to Zettnow (*P.* 130, 16, 240), the pp. obtained by decomposing  $\text{Na}_2\text{W}_2\text{O}_8\text{Aq}$  by a mineral acid has the composition  $4\text{WO}_3 \cdot \text{H}_2\text{O}$  ( $= \text{H}_4\text{W}_4\text{O}_{23}$ ) after drying at  $200^\circ$ .

**Metatungstic acid** crystallises in sulphur-yellow octahedra; the acid is readily soluble in water, forming a very sour, intensely bitter liquid. A conc. solution gives a pp. of  $\text{WO}_3 \cdot 2\text{H}_2\text{O}$  on standing; when a dilute solution is boiled it coagulates and gives a pp. of white  $\text{WO}_3 \cdot 2\text{H}_2\text{O}$ , and then of yellow  $\text{WO}_3 \cdot \text{H}_2\text{O}$ . The heats of neutralisation of  $\text{H}_4\text{W}_4\text{O}_{23}\text{Aq}$  by  $\text{Na}_2\text{OAq}$ ,  $\text{K}_2\text{OAq}$ ,  $\text{BaOAq}$ , and  $\text{SrOAq}$  are given by Péchard (*C. R.* 108, 1167); the values are nearly the same as those for  $\text{HNO}_3\text{Aq}$  and  $\text{H}_2\text{SO}_4\text{Aq}$ . When four equivalents of base are added to  $\text{H}_4\text{W}_4\text{O}_{23}\text{Aq}$ , orthotungstates  $\text{M}_2\text{WO}_6$  are formed (*P.*, l.c.).

By long-continued boiling 2 pts.  $\text{Na}_2\text{WO}_4$  with 1 pt.  $\text{As}_2\text{O}_3$ , evaporating, treating with alkali solution, and repeatedly crystallising, Iefort (*A. Ch.* [5] 25, 205) obtained fine, very lustrous crystals, which were very soluble in water and in alcohol; to this acid L. gave the composition  $\text{H}_4\text{W}_4\text{O}_{23} \cdot 6\text{H}_2\text{O}$ , and the name *luteo-metatungstic acid*.

**Colloidal (meta?) tungstic acid.** By adding to 5 p.c.  $\text{Na}_2\text{WO}_4\text{Aq}$  rather more  $\text{HClAq}$  than sufficed to neutralise the  $\text{Na}$ , and dialysing, with addition from time to time of a little  $\text{HClAq}$ , Graham (*C. J.* 17, 318) obtained a solution in water of tungstic acid. The solution was not gelatinised by acids, salts, or alcohol at the ordinary temperature; it remained clear at  $200^\circ$ . According to Sabanéeff, (*J. R.* 21, 515; Abstract in *C. J.* 58, 1315), determinations of the freezing-point of an aqueous solution of Graham's soluble acid point to the formula  $3\text{WO}_3 \cdot \text{H}_2\text{O}$  ( $= \text{H}_3\text{W}_3\text{O}_{10}$ ). As the values for mol. w. obtained by S. varied from 679 to 996, there seems little reason for adopting the formula  $\text{H}_2\text{W}_2\text{O}_9$  (713) rather than  $\text{H}_2\text{W}_2\text{O}_{10}$  (944).

**TUNGSTATES.** A great many tungstates have been prepared. The proportion of basic to acidic radicle varies much in these compounds. The better studied tungstates have been divided into three classes—*orthotungstates*  $\text{MO}_2\text{WO}_6$ , *paratungstates*  $8\text{MO}_2 \cdot 7\text{WO}_6$ , or perhaps  $5\text{MO}_2 \cdot 12\text{WO}_6$ , and *metatungstates*  $\text{MO}_4\text{WO}_6$ —but as many tungstates are known which do not fit into any of these classes it seems better to adopt a nomenclature and arrangement similar to those employed for the molybdates (cf. vol. iii. p. 423), based on the number of  $\text{WO}_3$  radicles in the salts. Arranging the tungstates on this plan we get the following table.  $\text{R} = \text{divalent metal}$ , or two atoms of a monovalent metal.

(Ortho) *Monotungstates*  $\text{RO}_2\text{WO}_6$ , or  $\text{RWO}_6$ ; derived from the acid  $\text{H}_2\text{WO}_6$ .

*Ditungstates*  $\text{RO}_2\text{WO}_8$ , or  $\text{RW}_2\text{O}_{10}$ ; derived from the acid  $\text{H}_4\text{W}_2\text{O}_{11}$ .

(Para)  $\left\{ \begin{array}{l} 3:7 \text{ tungstates } 3\text{RO}_2 \cdot 7\text{WO}_6 \text{ or } \text{R}_3\text{W}_7\text{O}_{23} \\ 5:12 \text{ tungstates } 5\text{RO}_2 \cdot 12\text{WO}_6 \text{ or } \\ \quad \text{R}_5\text{W}_{12}\text{O}_{31} \end{array} \right.$

2:5 tungstates  $2\text{RO}_2 \cdot 5\text{WO}_6$ , or  $\text{R}_2\text{W}_5\text{O}_{19}$

3:8 tungstates  $3\text{RO}_2 \cdot 8\text{WO}_6$ , or  $\text{R}_3\text{W}_8\text{O}_{26}$

*Tritungstates*  $\text{RO}_3\text{WO}_8$ , or  $\text{RW}_3\text{O}_{11}$ ; derived from Graham's colloidal acid.

(Meta) *Tetratungstates*  $\text{RO}_4\text{WO}_6$ , or  $\text{RW}_4\text{O}_{11}$ ; derived from the acid  $\text{H}_4\text{W}_4\text{O}_{23}$ .

*Pentatungstates*  $\text{RO}_5\text{WO}_6$ , or  $\text{RW}_5\text{O}_{16}$

*Hexatungstates*  $\text{RO}_6\text{WO}_6$ , or  $\text{RW}_6\text{O}_{21}$

*Octotungstates*  $\text{RO}_8\text{WO}_6$ , or  $\text{RW}_8\text{O}_{28}$

The tungstates which have been most thoroughly examined are the monotungstates or orthotungstates; the paratungstates, which

are either 3:7 or 5:12 salts; and the tetra- or metatungstates.

For *thio-tungstates* v. TUNGSTEN, THIO-ACIDS AND SALTS OF, p. 810.

**ORTHOTUNGSTATES** or **MONOTUNGSTATES**,  $\text{RO.WO}_3$  or  $\text{RWO}_4$ . Salts of  $\text{H}_2\text{WO}_4$ , which is the monohydrate of  $\text{WO}_3$ . The alkali orthotungstates are obtained by dissolving  $\text{WO}_3$  or  $\text{WO}_3.\text{H}_2\text{O}$  in alkali or alkali-carbonate solutions; or by fusing  $\text{WO}_3$  with alkalis, alkaline carbonates, or alkali acid sulphates, and dissolving in water. The other orthotungstates are generally obtained from solutions of the alkali salts by ppn.; also by strongly heating  $\text{WO}_3$  with metallic oxides or carbonates; also by fusing the alkali salts with metallic chlorides, and washing with water (Manross, A. 81, 243; 82, 356; Geuther a. Forsberg, A. 120, 268; Schultze, A. 126, 56). The orthotungstates are insoluble in water, except the alkali salts and the Mg salt. Solutions of the alkali salts give pps. of  $\text{WO}_3.\text{H}_2\text{O}$  (yellow) or  $\text{WO}_3.2\text{H}_2\text{O}$  (white), with dilute  $\text{H}_2\text{SO}_4$ ,  $\text{HClAq}$ ,  $\text{HNO}_3$ ,  $\text{H}_3\text{PO}_4$ ; the pp. by  $\text{HClAq}$  dissolves in a considerable excess of conc.  $\text{HClAq}$  (Mallet, C. J. 28, 1228); cold solutions of metatungstates are not ppd. by acids. According to Marignac (A. Ch. [3] 69, 5) the pp. obtained by adding an acid to a solution of an alkali tungstate sometimes contains alkali, and sometimes the ppg. acid, according to the relative quantity of acid used, the dilution, and probably also the temperature. Orthotungstates which are insoluble in water, and the metals of which form carbonates that are insoluble in alkali carbonate solutions, can be brought into solution by fusion with alkali carbonates and treatment with water.

Solutions of orthotungstates give a white pp. with  $\text{HgNO}_3$ ,  $\text{Aq}$ ; a bluish-white pp. with  $\text{Cu(NO}_3)_2$ ,  $\text{Aq}$ ; a brown flocculent pp. on adding  $\text{K}_2\text{FeCy}_3$ ,  $\text{Aq}$ , after adding  $\text{HClAq}$ ; no pp. with tincture of galls until an acid is added, when a copious chocolate-coloured pp. is formed; and a yellow pp. with  $\text{SnCl}_4$ ,  $\text{Aq}$ , which pp. turns blue when it is warmed with a little  $\text{HClAq}$  or  $\text{H}_2\text{SO}_4$ ,  $\text{Aq}$ . For the reactions with Zn and acid, and with  $\text{KCNAsq}$ , Zn and acid, v. TUNGSTEN, DETECTION OF, p. 798.

**Barium orthotungstate**  $\text{BaWO}_4$ . Prepared by fusing 7 parts  $\text{BaCl}_2$  with 4 parts  $\text{Na}_2\text{CO}_3$  and 2 parts  $\text{Na}_2\text{WO}_4$ , and washing with water; white octahedra (Geuther a. Forsberg, A. 120, 270); fusible with difficulty (Zettnow, P. 130, 256); S.G. 5.0035 at  $18.5^\circ$  (Clarke, Am. S. [3] 14, 281). *Hydrates*: (1)  $2\text{BaWO}_4.\text{H}_2\text{O}$ , by ppg. a hot solution of  $3\text{Na}_2\text{O}.7\text{WO}_3$  by  $\text{BaOAg}$  (Scheibler, B. B. 1860, 208); (2)  $\text{BaWO}_4.2\text{H}_2\text{O}$  and  $\text{BaWO}_4.2\text{H}_2\text{O}$ , by adding four equivalents  $\text{BaO}$  in solution to  $\text{H}_2\text{W}_2\text{O}_7$ ,  $\text{Aq}$  (Péchar, C. R. 108, 1167).

**Cadmium orthotungstate**  $\text{CdWO}_4$ . Obtained as a yellow crystalline powder by fusing together 11 parts  $\text{CdCl}_2$ , 16 parts  $\text{NaCl}$ , and 4 parts  $\text{Na}_2\text{WO}_4$  (G. a. F., Lc., p. 268; Z., Lc., p. 240). The *dihydrate*  $\text{CdWO}_4.2\text{H}_2\text{O}$  is obtained by ppg. a solution of a salt of Cd by  $\text{Na}_2\text{WO}_4$ ,  $\text{Aq}$  (Anthon, J. pr. 8, 899; 9, 337; Smith a. Bradbury, B. 24, 2935).

**Calcium orthotungstate**  $\text{CaWO}_4$ . Occurs native as *scheelite*, S.G. 6.02 (Berthoulli, J. 13, 788). Obtained by adding  $\text{K}_2\text{WO}_4$ ,  $\text{Aq}$  to  $\text{CaCl}_2$ ,  $\text{Aq}$ . Quadratic octahedra are formed by fusing

$\text{Na}_2\text{WO}_4$  with excess of  $\text{CaCl}_2$  (Manross, A. 81, 243; 82, 348); also by heating the ppd. salt with  $\text{CaO}$  in a stream of  $\text{HCl}$  (Debray, C. R. 55, 287).

**Chromium orthotungstate**  $\text{Cr}_2(\text{WO}_4)_3.20\text{H}_2\text{O}$ . Obtained as a green pp. by adding  $\text{Na}_2\text{WO}_4$ ,  $\text{Aq}$  to  $\text{CrCl}_3$ ,  $\text{Aq}$ ; loses  $13\text{H}_2\text{O}$  at  $100^\circ$  (Lotz, A. 91, 68).

**Cobalt orthotungstate**  $\text{CoWO}_4.2\text{H}_2\text{O}$ . A violet powder; obtained by ppg. Co salt solutions by  $\text{K}_2\text{WO}_4$ ,  $\text{Aq}$  (Anthon, J. pr. 9, 344).

**Copper orthotungstate**  $\text{CuWO}_4.2\text{H}_2\text{O}$ . A green powder, melting at a red heat and cooling to chocolate-coloured crystals, formed by ppg. Cu salts by  $\text{Na}_2\text{WO}_4$ ,  $\text{Aq}$  (A., Lc.).

**Ferrous orthotungstate**  $\text{FeWO}_4$ . Obtained as opaque crystals by heating  $\text{WO}_3$  and  $\text{Fe}_2\text{O}_3$  in a stream of  $\text{HCl}$  (Debray, C. R. 55, 288); also by fusing 2 parts  $\text{FeCl}_3$ , 2 parts  $\text{NaCl}$ , and 1 part  $\text{Na}_2\text{WO}_4$  (Geuther a. Forsberg, A. 120, 273; Zettnow, P. 130, 30). The *trihydrate*  $\text{FeWO}_4.3\text{H}_2\text{O}$  was obtained by Anthon (J. pr. 9, 343) as a brown powder by ppg. a ferrous salt by  $\text{K}_2\text{WO}_4$ ,  $\text{Aq}$ . *Double compounds* of the form  $m\text{FeWO}_4.n\text{MnWO}_4$ , with the ratios  $m:n = 7:1, 4:1, 3:1, 3:2, 1:2$ , and  $1:7$  were obtained by fusing  $\text{FeCl}_2$ ,  $\text{MnCl}_2$ ,  $\text{NaCl}$ , and  $\text{Na}_2\text{WO}_4$  in varying proportions (G. a. F., Lc. p. 270; cf. Z., Lc. p. 250). *Wolframite* has approximately the composition  $\text{FeO.MnO.WO}_3$ .

**Lead orthotungstate**  $\text{PbWO}_4$ . Occurs native as *scheelite*; obtained, as a white pp., by adding  $\text{K}_2\text{WO}_4$ ,  $\text{Aq}$  to solution of a salt of Pb (A., Lc., p. 342); quadratic octahedra are formed by fusing 10 parts  $\text{Na}_2\text{WO}_4$  with 47 parts  $\text{PbCl}_2$ , S.G. 8.245 (Manross, A. 82, 357).

**Magnesium orthotungstate**  $\text{MgWO}_4$ . Formed, in white octahedra, by fusing 2 parts  $\text{MgCl}_2$  with 2 parts  $\text{NaCl}$  and 1 part  $\text{Na}_2\text{WO}_4$  (G. a. F., Lc. p. 272).

**Manganese orthotungstate**  $\text{MnWO}_4$ . Garnet-brown, lustrous, rhombic crystals; S.G. 6.7; obtained by fusing 2 parts  $\text{MnCl}_2$ , 2 parts  $\text{NaCl}$ , and 1 part  $\text{Na}_2\text{WO}_4$  (G. a. F., Lc.; Z., Lc.).

**Mercurous orthotungstate**  $\text{Hg}_2\text{WO}_4$ . A yellow pp., formed by adding solution of a mercurous salt to solution of an alkali tungstate (A., Lc.).

**Nickel orthotungstate**  $\text{NiWO}_4$ . Formed by fusing 2 parts  $\text{NiCl}_2$  with 2 parts  $\text{NaCl}$  and 1 part  $\text{Na}_2\text{WO}_4$ ; brown, lustrous crystals (Schultze, A. 126, 56); S.G. 6.8845 at  $20.5^\circ$ , 6.8522 at  $22^\circ$  (Clarke, Am. S. [3] 14, 281). The *hexahydrate*,  $\text{NiWO}_4.6\text{H}_2\text{O}$ , is obtained by ppn. (A., Lc.).

**Potassium orthotungstate**  $\text{K}_2\text{WO}_4$ . White, triclinic needles; obtained by boiling  $\text{WO}_3$  with an equivalent weight of  $\text{KOHAg}$  or  $\text{K}_2\text{CO}_3$ ,  $\text{Aq}$ , and evaporating (Marignac, A. Ch. [3] 69, 18; Anthon, J. pr. 8, 399; 9, 837). Decomposes when heated; melts at red heat (M., Lc.), taking up  $\text{CO}_2$  (Ulrich, W. A. B. 56 [2], 148; cf. Knorre, J. pr. 27, 89). Various *hydrates* are obtained by crystallising a solution of  $\text{WO}_3$  in  $\text{K}_2\text{CO}_3$ ,  $\text{Aq}$  under different conditions (M., Lc.; A., Lc.; Riche, A. Ch. [3] 50, 45).

**Silver orthotungstate**  $\text{Ag}_2\text{WO}_4$ . A pale-yellow, amorphous pp. by adding  $\text{Na}_2\text{WO}_4$ ,  $\text{Aq}$  to solution of a salt of Ag; melts below redness, and becomes crystalline on cooling; easily soluble in  $\text{HNO}_3$ ,  $\text{Aq}$ ; soluble in  $\text{NH}_4\text{Aq}$  (Zettnow, P. 130, 30; cf. Muthmann, B. 30, 984; Wöhler a.

*Rautenberg, A. 114, 120.* By evaporating a solution in  $\text{NH}_4\text{Aq}$  over  $\text{CaO}$  and  $\text{NH}_4\text{Cl}$ , Widmann obtained the compound  $\text{Ag}_2\text{WO}_4 \cdot 4\text{NH}_3$ . (*Bk.* [2] 20, 64).

**Sodium orthotungstate**  $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$ . Obtained by crystallising a solution of  $\text{WO}_3$  in the equivalent quantity of  $\text{NaOHAq}$  or  $\text{Na}_2\text{CO}_3\text{Aq}$ . Transparent, colourless, rhombic tablets (Marignac, *A. Ch.* [3] 69, 22). Effloresces *in vacuo*, or in dry air. Loses all  $\text{H}_2\text{O}$  at  $100^\circ$ . S.G. 3.2588 at  $17.5^\circ$ , 3.2314 at  $19^\circ$ ; S.G. of  $\text{Na}_2\text{WO}_4 = 4.1743$  at  $20.5^\circ$ , 4.1833 at  $18.5^\circ$  (Clarke, *Am. S.* [3] 14, 281). Solubility = 41 at  $0^\circ$ , 55 at  $15^\circ$ , 123.4 at  $100^\circ$  (Riche, *J. pr.* 69, 10). For S.G. of  $\text{Na}_2\text{WO}_4\text{Aq}$  of different concentrations, v. Franz (*J. pr.* [2] 4, 238). For E.C. of  $\text{Na}_2\text{WO}_4\text{Aq}$  v. Walden (*Z. P. C.* 1, 529).

**Strontium orthotungstate**  $\text{SrWO}_4$ . Obtained by ppn. (Anthon, *l.c.*); also by fusing 2 parts  $\text{SrCl}_2$ , 2 parts  $\text{NaCl}$  and 1 part  $\text{Na}_2\text{WO}_4$  (Zettnow, *l.c.*; Schultze, *A.* 126, 56).

**Zinc orthotungstate**  $\text{ZnWO}_4$ . Colourless tablets; formed by fusing 2 parts  $\text{ZnCl}_2$  with 2 parts  $\text{NaCl}$  and 1 part  $\text{Na}_2\text{WO}_4$  (Couthner, *A.* Forsberg, *A.* 120, 270; cf. Zettnow, *P.* 130, 240).

**PARATUNGSTATES.** A number of acid tungstates have been isolated, the composition of which is expressed by one of the formulae  $3\text{RO} \cdot 7\text{WO}_3$  or  $5\text{H}_2\text{O} \cdot 12\text{WO}_3$ . The former formula was given by Lotz (*A.* 91, 49) and Scheibler (*J. pr.* 83, 273); the latter formula by Laurent (*A. Ch.* [3] 21, 54) and Marignac (*A. Ch.* [3] 69, 5). The two formulae represent salts of almost identical composition, and no way has been found of deciding which formula is the better (cf. Knorre, *J. pr.* [2] 27, 83). The acid tungstates of this series are more easily formed and crystallise better than the other acid salts; they are generally called *paratungstates*, following the suggestion made by Marignac.

The alkali paratungstates are obtained by saturating hot alkali solutions with  $\text{WO}_3$  and crystallising; most of the other paratungstates are prepared by ppn. from solutions of the alkali salts. The alkali salts are soluble in water, the other salts are insoluble. Solutions of alkali paratungstates give, with dilute  $\text{HClAq}$ , white pps. which become yellow on boiling ( $\text{WO}_3 \cdot x\text{H}_2\text{O}$ ). Metatungstates,  $\text{RO} \cdot 4\text{WO}_3$ , are formed by gradually adding  $\text{HClAq}$  to boiling solutions of paratungstates; meta-salts are also formed by boiling para-salts with  $\text{WO}_3 \cdot \text{H}_2\text{O}$ . Solutions of paratungstates are not ppd. by  $\text{SO}_2\text{Aq}$ ,  $\text{HIAq}$ , bitric, tartaric, or oxalic acid; but the presence of one of these acids does not hinder ppn. by  $\text{HClAq}$ . Solutions of alkali paratungstates give pps. with salts of almost all the heavy metals.  $\text{H}_2\text{S}$  reacts with alkali paratungstates in solution to form solutions of thio-tungstates which give brown pps. with acids, soluble in  $(\text{NH}_4)_2\text{SAq}$ . Paratungstates readily react with  $\text{H}_3\text{PO}_4$ ,  $\text{H}_3\text{AsO}_4$ , &c., to form complex acids (v. p. 807), solutions of which are not ppd. by acids, except these are added in considerable excess; solutions of paratungstates are, therefore, not ppd. by  $\text{HClAq}$  in presence of  $\text{H}_3\text{PO}_4$ ,  $\text{H}_3\text{AsO}_4$ ,  $\text{H}_2\text{B}_4\text{O}_7$ , &c. For the reactions of paratungstates with  $\text{PtO}_2\text{H}$ , v. Rosenheim (*B.* 24, 2897; the reaction is rather indefinite).

If the simpler (3:7) formula is adopted, the

paratungstates are represented as  $3\text{R}^{II} \cdot 0.7\text{WO}_3$ ,  $3\text{R}^{IV} \cdot 0.7\text{WO}_3$ , and  $\text{R}^{IV} \cdot 0.7\text{WO}_3$ , i.e. as salts of the hypothetical acid  $\text{H}_3\text{W}_7\text{O}_{21}$ , wherein 6H are replaced by  $6\text{R}^I$ ,  $3\text{R}^{II}$ , or  $2\text{R}^{IV}$ ; if the less simple formula (5:12) is adopted, the paratungstates of monovalent and divalent metals are regarded as salts of the hypothetical acid  $\text{H}_5\text{W}_{12}\text{O}_{41}$  ( $= 12\text{WO}_3 \cdot 5\text{H}_2\text{O}$ ), wherein 10H are replaced by  $10\text{R}^I$  or  $5\text{R}^{II}$ ; paratungstates of  $\text{R}^{III}$  must be represented in this scheme by the complicated formula  $\text{R}^{III} \cdot 10(\text{W}_{12}\text{O}_{41})$ . In the paratungstates which have been best examined  $\text{R}^I = \text{NH}_4$ , Li, Hg, K, Ag, and Na;  $\text{R}^{II} = \text{Ba}$ , Cd, Ca, Co, Cu, Pb, Mg, Mn, Ni, Sr, and Zn; and  $\text{R}^{III} = \text{Al}$  and Cr. The simpler formulae are employed in the descriptions of the individual salts.

**Aluminium paratungstate**  $\text{Al}_2\text{W}_7\text{O}_{21} \cdot 9\text{H}_2\text{O}$ . A flocculent pp., drying to gum-like lumps; obtained by adding  $(\text{NH}_4)_2\text{W}_7\text{O}_{21}\text{Aq}$  to a solution of a salt of Al (Lotz, *A.* 83, 65; Anthon, *J. pr.* 8, 399; 9, 337).

**Ammonium paratungstate**  $(\text{NH}_4)_2\text{W}_7\text{O}_{21} \cdot 6\text{H}_2\text{O}$ . Obtained by dissolving  $\text{WO}_3 \cdot \text{H}_2\text{O}$  in  $\text{NH}_4\text{Aq}$  and crystallising at the ordinary, or a little above the ordinary, temperature (Lotz, *A.* 91, 55). Crystallises in white, rhombic needles (Marignac, *A. Ch.* [3] 69, 25; Kerndt, *J. pr.* 41, 190); also in rhombic tablets (M., *l.c.*); and is, therefore, dimorphous. Solubility = 2.8 to 4.5 at  $15^\circ$ – $22^\circ$ ; when the solution is boiled the 'very soluble meta-salt'  $(\text{NH}_4)_2\text{W}_7\text{O}_{21}$  is formed. Loses 3.9 p.c.  $\text{H}_2\text{O}$  at  $100^\circ$ ; when heated to redness the blue oxide of W remains mixed with compounds containing N (M., *l.c.*). Marignac (*l.c.*) gave the formula  $(\text{NH}_4)_2\text{W}_7\text{O}_{21} \cdot 11\text{H}_2\text{O}$  to this salt; Berzelius, and Anthon (*l.c.*) gave the formula  $(\text{NH}_4)_2\text{W}_7\text{O}_{21} \cdot \text{H}_2\text{O}$ ; and Riche (v. Marignac, *l.c.*) the formula  $(\text{NH}_4)_2\text{W}_7\text{O}_{21} \cdot 5$  or  $6\text{H}_2\text{O}$ .

Various double salts have been isolated; with  $\text{Na}_2\text{W}_7\text{O}_{21}$  (v. Knorre, *B.* 19, 821; Gibbs, *Am. J.* 236); with  $\text{K}_2\text{W}_7\text{O}_{21}$  (v. Laurent, *A. Ch.* [3] 21, 69; Marignac, *A. Ch.* [3] 69, 55); with  $\text{Mg}_2\text{W}_7\text{O}_{21}$  v. M. (*l.c.*), Lotz (*A.* 91, 61); with  $\text{Zn}_2\text{W}_7\text{O}_{21}$  v. Lotz (*l.c.*); with  $\text{Cd}_2\text{W}_7\text{O}_{21}$  v. L. (*l.c.*); with  $\text{Hg}_2\text{W}_7\text{O}_{21}$  v. Anthon (*J. pr.* 8, 399; 9, 337).

**Barium paratungstate**  $\text{Ba}_2\text{W}_7\text{O}_{21} \cdot 8\text{H}_2\text{O}$ . A white pp. formed by adding  $(\text{NH}_4)_2\text{W}_7\text{O}_{21}\text{Aq}$  to excess of  $\text{BaCl}_2\text{Aq}$ , washing and drying over  $\text{H}_2\text{SO}_4$  (Lotz, *A.* 93, 50; cf. Knorre, *B.* 18, 327; 19, 826). Forms a double salt with  $\text{Na}_2\text{W}_7\text{O}_{21}$  (Scheibler, *J. pr.* 83, 314).

**Cadmium paratungstate**  $\text{Cd}_2\text{W}_7\text{O}_{21} \cdot 16\text{H}_2\text{O}$ ; white needles, obtained by adding  $\text{Na}_2\text{W}_7\text{O}_{21}\text{Aq}$  to excess of solution of a salt of Cd (Gonzalez, *J. pr.* [2] 36, 44).

**Calcium paratungstate**  $\text{Ca}_2\text{W}_7\text{O}_{21} \cdot 18\text{H}_2\text{O}$ ; a crystalline pp. formed by ppg. excess of  $\text{CaCl}_2\text{Aq}$  by  $\text{Na}_2\text{W}_7\text{O}_{21}\text{Aq}$ , and drying in the air (Knorre, *B.* 18, 328). Forms a double salt with  $\text{Na}_2\text{W}_7\text{O}_{21}$  (Gonzalez, *l.c.*).

**Chromium paratungstate**  $\text{Cr}_2\text{W}_7\text{O}_{21} \cdot 9\text{H}_2\text{O}$ ; a grey powder, obtained by heating  $\text{CrCl}_3$  with  $(\text{NH}_4)_2\text{W}_7\text{O}_{21}$ ; insoluble in water, but dissolves in  $\text{CrCl}_3\text{Aq}$  (Lotz, *A.* 91, 66).

**Cobalt paratungstate**  $\text{Co}_2\text{W}_7\text{O}_{21} \cdot 25\text{H}_2\text{O}$  (Gonzalez, *l.c.*); forms a double salt with  $\text{Na}_2\text{W}_7\text{O}_{21}$  (G., *l.c.*).

**Copper paratungstate**  $\text{Cu}_2\text{W}_7\text{O}_{21} \cdot 19\text{H}_2\text{O}$ ; a pale-green pp. formed by adding  $\text{Na}_2\text{W}_7\text{O}_{21}\text{Aq}$  to

excess of  $\text{CuSO}_4\text{Aq}$  (Knorre, B. 19, 826; v. also Gonzalez, J. pr. [2] 86, 44). Forms a double salt with  $\text{Na}_2\text{W}_2\text{O}_7$  (K., l.c.).

Lead paratungstate  $\text{Pb}_2\text{W}_2\text{O}_7$ ; a white pp. formed by adding  $(\text{NH}_4)_2\text{W}_2\text{O}_7\text{Aq}$  to  $\text{Pb}(\text{NO}_3)_2\text{Aq}$  (Lotz, A. 91, 49). Forms a double salt with  $\text{Na}_2\text{W}_2\text{O}_7$  (Gonzalez, l.c.).

Lithium paratungstate  $\text{Li}_2\text{W}_2\text{O}_7 \cdot 19\text{H}_2\text{O}$ . Large prisms, unchanged in air; obtained by boiling the proper quantities of  $\text{WO}_3$  and  $\text{Li}_2\text{CO}_3$  in water, and allowing to crystallise (Scheibler, J. pr. 83, 321).

Magnesium paratungstate  $\text{Mg}_2\text{W}_2\text{O}_7 \cdot 24\text{H}_2\text{O}$ ; obtained by ppn. (Knorre, B. 19, 824). Forms a double salt with  $\text{Na}_2\text{W}_2\text{O}_7$  (K., l.c.).

Manganese paratungstate  $\text{Mn}_2\text{W}_2\text{O}_7 \cdot 34\text{H}_2\text{O}$  (Gonzalez, J. pr. [2] 36, 44). Forms a double salt with  $\text{Na}_2\text{W}_2\text{O}_7$  (K., l.c.).

Nickel paratungstate  $\text{Ni}_2\text{W}_2\text{O}_7 \cdot 14\text{H}_2\text{O}$  (Anthony, J. pr. 9, 344).

Potassium paratungstate  $\text{K}_2\text{W}_2\text{O}_7 \cdot 6\text{H}_2\text{O}$  (Marignac, A. Ch. [3] 69, 33, gave the formula  $\text{K}_2\text{W}_2\text{O}_7 \cdot 11\text{H}_2\text{O}$ ). Prepared by saturating hot  $\text{KOH Aq}$  with  $\text{WO}_3 \cdot x\text{H}_2\text{O}$ , and allowing to cool; by boiling  $\text{K}_2\text{WO}_4$  with  $\text{H}_2\text{O}$ ; or by fusing wolframite with  $\frac{1}{3}$  of its weight of  $\text{K}_2\text{CO}_3$ , boiling the product with water, saturating the aqueous solution with  $\text{CO}_2$ , and crystallising (M., l.c.). White rhombic crystals, isomorphous with the  $\text{NH}_4$  salt (M., l.c.). Decomposed, by melting, to  $\text{K}_2\text{WO}_4$  and  $5\text{K}_2\text{O} \cdot 14\text{WO}_3$ , without forming any meta-salt (Knorre, J. pr. [2] 27, 91). Solubility—2.15 cold water, 6.6 boiling water.

Various hydrates have been obtained (v. Zettnow, P. 130, 211; cf. Lefort, A. Ch. [5] 9, 93; 15, 321; 17, 470; 25, 200). Forms double salts with  $\text{Na}_2\text{W}_2\text{O}_7$  (v. Marignac, A. Ch. [3] 69, 55; Laurent, A. Ch. [3] 21, 54).

Silver paratungstate  $\text{Ag}_2\text{W}_2\text{O}_7$ ; a yellow, crystalline pp. formed by adding  $\text{Na}_2\text{W}_2\text{O}_7\text{Aq}$  to excess of  $\text{AgNO}_3\text{Aq}$  (Gonzalez, J. pr. [2] 36, 44).

Sodium paratungstate  $\text{Na}_2\text{W}_2\text{O}_7 \cdot 16\text{H}_2\text{O}$ . This formula is given by Scheibler (J. pr. 83, 285); the formula  $\text{Na}_2\text{W}_2\text{O}_7$  is given by Laurent (l.c.), Marignac (l.c.), and by Friedheim a. Meyer, (Zeit. f. anorg. Chemie, 1, 81). Prepared by saturating hot  $\text{NaOH Aq}$ , or  $\text{Na}_2\text{CO}_3\text{Aq}$ , with  $\text{WO}_3 \cdot x\text{H}_2\text{O}$  and evaporating to the crystallising point; also by passing  $\text{CO}_2$  into  $\text{Na}_2\text{WO}_4\text{Aq}$  until the reaction is only faintly alkaline. Large, well-formed, white, triclinic crystals (Scheibler, l.c.; Marignac, A. Ch. [3] 69, 30). Effloresces in air; loses c.  $\frac{1}{2}$  of its  $\text{H}_2\text{O}$  over  $\text{H}_2\text{SO}_4$ ; is dehydrated without decomposition at  $300^\circ$  (S., l.c.); heated to dull redness leaves a residue, insoluble in water, containing more than  $5\text{WO}_3$  to  $\text{Na}_2\text{O}$  (M., l.c.; also Knorre, J. pr. [2] 27, 71). Melts above dull redness, giving  $\text{Na}_2\text{WO}_4$  and  $\text{Na}_2\text{W}_2\text{O}_7$  (meta-salt). Heated with water to  $150^\circ$  gives much meta-salt (K., l.c.). Solubility 8 to 9 at  $35^\circ$  to  $40^\circ$ ; for the salts obtainable from an aqueous solution v. M. (l.c.), and also K. (B. 18, 2362). By boiling a solution with  $\text{Na}_2\text{CO}_3$  transformation to  $\text{Na}_2\text{WO}_4$  is complete (v. Schmidt, Am. 8, 16). A hydrate with  $21\text{H}_2\text{O}$  has been obtained (M., l.c.). Forms double salts with  $\text{Sr}_2\text{W}_2\text{O}_7$  (Gonzalez, J. pr. [2] 36, 44), and with  $\text{Zn}_2\text{W}_2\text{O}_7$  (Knorre, B. 19, 829).

Strontium paratungstate  $\text{Sr}_2\text{W}_2\text{O}_7 \cdot 8\text{H}_2\text{O}$  (Knorre, B. 18, 327).

Zinc paratungstate  $\text{Zn}_2\text{W}_2\text{O}_7 \cdot x\text{H}_2\text{O}$  (Gonzalez, J. pr. [2] 86, 44).

METATUNGSTATES OR TETRATUNGSTATES,  $\text{R}^{IV}\text{O}_4\text{WO}_3$ , or  $\text{R}^{IV}\text{W}_2\text{O}_{11}$ . Salts of the acid  $\text{H}_2\text{W}_2\text{O}_{11}$  (v. METATUNGSTIC ACIDS, p. 802). The metatungstates may be obtained by causing metatungstic acid  $\text{H}_2\text{W}_2\text{O}_{11} \cdot x\text{H}_2\text{O}$  (v. p. 802) to interact with carbonates, chlorides, or nitrates; also by the reaction of a weak acid ( $\text{H}_3\text{PO}_4\text{Aq}$  is the best) with orthotungstates, the acid being added as long as the pp. of  $\text{WO}_3 \cdot x\text{H}_2\text{O}$  which is at first formed re-dissolves; also from the alkali salts by double decomposition, or better from the Ba salt by interacting with sulphates; the alkali metatungstates are prepared by boiling solutions of the orthotungstates for some time with  $\text{WO}_3 \cdot x\text{H}_2\text{O}$ .

Most of the metatungstates are very soluble in water and are crystallisable from aqueous solutions; aqueous solutions are not ppd. by acids in the cold, but pps. are obtained after long standing or boiling. Metatungstates are changed to ortho-salts by excess of alkali; when strongly heated, orthotungstates are formed. Solutions of metatungstates are not ppd. by  $\text{H}_2\text{S}$ ;  $(\text{NH}_4)_2\text{SAq}$  gives a blue pp.; pps. are not obtained with salts of the heavy metals except Pb and Hg<sup>+</sup>;  $\text{K}_2\text{FeCl}_6\text{Aq}$  does not form a pp.

Ammonium metatungstate  $(\text{NH}_4)_2\text{W}_2\text{O}_{11} \cdot 8\text{H}_2\text{O}$ . This formula is given by Scheibler (J. pr. 83, 303); more complicated formulae are given by Marguerite (A. Ch. [3] 17, 477), Laurent (A. Ch. [3] 21, 62), and Lotz (A. 91, 65). Obtained by boiling the para-salt  $(\text{NH}_4)_2\text{W}_2\text{O}_7 \cdot x\text{H}_2\text{O}$  with  $\text{WO}_3 \cdot x\text{H}_2\text{O}$  (La gueritte, A. Ch. [3] 17, 477); also by boiling the para-salt with a little  $\text{HNO}_3\text{Aq}$  (Laurent, A. Ch. [3] 21, 62); also by heating the dry para-salt to  $250^\circ$ – $300^\circ$  (Scheibler, J. pr. 83, 804; cf. Persoz, A. Ch. [4] 1, 101; and Marignac, A. Ch. [4] 3, 71). White octahedra; effloresces in air; loses  $7\text{H}_2\text{O}$  at  $100^\circ$ . Solubility in cold water = 120 (Lotz, l.c.), = 286 (Riche, A. Ch. [3] 50, 45). The solution is optically refractive. Insoluble in alcohol or ether. Forms a double salt with  $\text{NH}_4\text{NO}_3$  (Marignac, A. Ch. [3] 69, 61).

Barium metatungstate  $\text{BaW}_2\text{O}_{11} \cdot 9\text{H}_2\text{O}$ . Obtained by adding  $\text{BaCl}_2\text{Aq}$  to a hot conc. solution of  $\text{Na}_2\text{W}_2\text{O}_7$ , acidified by  $\text{HCl Aq}$  (Scheibler, J. pr. 83, 304). Crystallises in large, white, tetragonal octahedra; S.G. 4.298 at  $14^\circ$ ; loses  $6\text{H}_2\text{O}$  at  $100^\circ$ ; easily soluble in hot water, decomposed by much cold water to  $\text{WO}_3$  and  $\text{BaW}_2\text{O}_{11} \cdot 6\text{H}_2\text{O}$ , which dissolve again on heating.

Cadmium metatungstate  $\text{CdW}_2\text{O}_{11} \cdot 10\text{H}_2\text{O}$ . Lustrous, white octahedra; unchanged in air; obtained by decomposing  $\text{BaW}_2\text{O}_{11}\text{Aq}$  by  $\text{CdSO}_4\text{Aq}$  (S., l.c., p. 273).

Calcium metatungstate  $\text{CaW}_2\text{O}_{11} \cdot 10\text{H}_2\text{O}$ . Quadratic octahedra, obtained by dissolving  $\text{CaCO}_3$  in  $\text{H}_2\text{W}_2\text{O}_{11}\text{Aq}$  and crystallising (S., l.c., p. 314).

Cobalt metatungstate  $\text{CoW}_2\text{O}_{11} \cdot 9\text{H}_2\text{O}$  (S., l.c. p. 317).

Copper metatungstate  $\text{CuW}_2\text{O}_{11} \cdot 11\text{H}_2\text{O}$  (S., l.c. p. 317).

Magnesium metatungstate  $\text{MgW}_2\text{O}_{11} \cdot 8\text{H}_2\text{O}$  (S., l.c.).

Manganese metatungstate  $\text{MnW}_2\text{O}_{11} \cdot 10\text{H}_2\text{O}$  (S., l.c. p. 273).

**Mercurous metatungstate**  $\text{Hg}_2\text{W}_2\text{O}_{11} \cdot 36\text{H}_2\text{O}$ . Obtained, as a white pp., by adding  $\text{HgNO}_3\text{Aq}$  to solution of  $\text{H}_2\text{W}_2\text{O}_{11}$  or a meta-salt (S., l.c., p. 319).

**Nickel metatungstate**  $\text{NiW}_2\text{O}_{11} \cdot 8\text{H}_2\text{O}$  (S., l.c., p. 273).

**Potassium metatungstate**  $\text{K}_2\text{W}_2\text{O}_{11} \cdot 8\text{H}_2\text{O}$ . Lustrous octahedra; obtained by boiling  $\text{K}_2\text{W}_2\text{O}_{11}\text{Aq}$  with  $\text{WO}_3 \cdot x\text{H}_2\text{O}$ ; very soluble in hot water, considerably less soluble in cold water (S., l.c., p. 303). A pentahydrate was obtained by Marignac (A. Ch. [4] 3, 71).

**Silver metatungstate**  $\text{Ag}_2\text{W}_2\text{O}_{11}$ . Obtained, as a crystalline crust, by adding  $\text{AgNO}_3\text{Aq}$  to  $\text{Na}_2\text{W}_2\text{O}_{11}\text{Aq}$ , evaporating, separating from  $\text{Ag}_2\text{WO}_4$ , and evaporating again (S., l.c. p. 318).

**Sodium metatungstate**  $\text{Na}_2\text{W}_2\text{O}_{11} \cdot 10\text{H}_2\text{O}$ . Obtained by boiling  $\text{Na}_2\text{W}_2\text{O}_{11}\text{Aq}$  with  $\text{WO}_3 \cdot x\text{H}_2\text{O}$  and allowing to evaporate; white, lustrous octahedra; S.G. 3.8647 at  $13^\circ$ ; very soluble in hot, but less in cold, water (S., l.c. p. 303).

**Strontium metatungstate**  $\text{SrW}_2\text{O}_{11} \cdot 8\text{H}_2\text{O}$  (S., l.c. p. 314).

**Zinc metatungstate**  $\text{ZnW}_2\text{O}_{11} \cdot 10\text{H}_2\text{O}$  (S., l.c. p. 273).

**TUNGSTATES OTHER THAN ORTHO-, PARA-, AND META-SALTS.**

**Ditungstates.** Salts of the form  $\text{R}_2\text{O}_3 \cdot 2\text{WO}_3 = \text{R}_2\text{W}_2\text{O}_7$ . Salts of K and Na of this composition were said by Lefort (A. Ch. [5] 17, 470) to be formed by neutralising cold solutions of  $\text{K}_2\text{WO}_4$  and  $\text{Na}_2\text{WO}_4$  by acetic acid; Knorre (J. pr. [2] 27, 83) obtained only metatungstates,  $\text{R}_2\text{W}_2\text{O}_{11}$  by this method.

**Two to five tungstates.** The existence of salts of the class  $2\text{R}_2\text{O}_3 \cdot 5\text{WO}_3 = \text{R}_5\text{W}_5\text{O}_{17}$  is doubtful. Marignac obtained a salt to which he gave the formula  $\text{Na}_5\text{W}_5\text{O}_{17} \cdot 11\text{H}_2\text{O}$  along with the para-salt  $\text{Na}_2\text{W}_2\text{O}_{11} \cdot 16\text{H}_2\text{O}$  (A. Ch. [8] 69, 50). The same salt seems to have been obtained by Lefort (l.c.; cf. Foreher a. Gibbs, J. 1880, 341) by adding acetic acid and alkali to  $\text{Na}_2\text{WO}_4\text{Aq}$  and allowing to stand for some time (cf. also Schmidt, Am. 8, 16).

**Three to eight tungstates.** A salt  $(\text{NH}_4)_3\text{W}_3\text{O}_{11} \cdot 3\text{H}_2\text{O} = 3(\text{NH}_4)_2\text{O} \cdot 8\text{WO}_3 \cdot 8\text{H}_2\text{O}$  seems to have been prepared by Marignac (A. Ch. [3] 69, 61).

**Tritungstates**  $\text{R}_3\text{O}_3 \cdot 3\text{WO}_3 = \text{R}_3\text{W}_3\text{O}_{11}$ . Lefort (A. Ch. [5] 17, 470) prepared a salt to which he gave the formula  $\text{Na}_3\text{W}_3\text{O}_{11} \cdot 6\text{H}_2\text{O}$ , by pouring a boiling solution of  $\text{Na}_2\text{W}_2\text{O}_{11} \cdot 6\text{H}_2\text{O}$  (obtained by adding acetic acid to  $\text{Na}_2\text{WO}_4\text{Aq}$  until the liquid shows an acid reaction) into boiling acetic acid, allowing to cool, separating the lower syrupy layer, and crystallising it. A corresponding salt  $\text{K}_3\text{W}_3\text{O}_{11} \cdot 2\text{H}_2\text{O}$  was obtained by a similar method; and a series of tritungstates was prepared by mixing equivalent quantities of the Na salt and metallic acetates, in solution, and adding alcohol. L. describes the tritungstates as easily decomposing in aqueous solutions to di- and tetra-salts. The following salts were formed by L.: —  $\text{BaW}_3\text{O}_{11} \cdot 4\text{H}_2\text{O}$ ;  $\text{CdW}_3\text{O}_{11} \cdot 4\text{H}_2\text{O}$ ;  $\text{CaW}_3\text{O}_{11} \cdot 6\text{H}_2\text{O}$ ;  $\text{CoW}_3\text{O}_{11} \cdot 4\text{H}_2\text{O}$ ;  $\text{FeW}_3\text{O}_{11} \cdot 4\text{H}_2\text{O}$ ;  $\text{PbW}_3\text{O}_{11} \cdot 2\text{H}_2\text{O}$ ;  $\text{MgW}_3\text{O}_{11} \cdot 4\text{H}_2\text{O}$ ;  $\text{MnW}_3\text{O}_{11} \cdot 6\text{H}_2\text{O}$ ;  $\text{NiW}_3\text{O}_{11} \cdot 4\text{H}_2\text{O}$ ;  $\text{K}_3\text{W}_3\text{O}_{11} \cdot 2\text{H}_2\text{O}$ ;  $\text{Na}_3\text{W}_3\text{O}_{11} \cdot 4\text{H}_2\text{O}$ ;  $\text{SrW}_3\text{O}_{11} \cdot 6\text{H}_2\text{O}$ . Knorre's experiments led him to regard Lefort's tritungstates as mixtures (J. pr. [2] 27, 83).

**Penta- and octo-tungstates.** Salts

of K and Na of the composition  $\text{R}_5\text{W}_5\text{O}_{17}$  and  $\text{R}_8\text{W}_8\text{O}_{23}$  are said to have been isolated, the former by fusing mixtures of  $\text{R}_2\text{WO}_4$  and  $\text{WO}_3$ , the latter by fusing  $\text{R}_2\text{W}_2\text{O}_{11}$  with  $\text{R}_2\text{WO}_4$  (Knorre, J. pr. [2] 27, 81, 91).

A few tungstates that do not find places in any of the foregoing classes have been described by different observers (v. especially Lefort, A. Ch. [5] 9, 93; 15, 324; 17, 470; 25, 200; also Schreiber, J. pr. 83, 237; Gonzalez, J. pr. [2] 36, 44; Knorre, J. pr. [2] 27, 93; Lotz, A. 91, 49; Feit, B. 21, 133; Cleve, Bl. [2] 43, 170; Högborn, Bl. [2] 42, 2).

**PERTUNGSTATES.** By boiling a solution of the paratungstate  $\text{Na}_2\text{W}_2\text{O}_{11} \cdot 16\text{H}_2\text{O}$  with  $\text{H}_2\text{O}_2\text{Aq}$ , and then evaporating *in vacuo*, Péchard (C. R. 112, 1060) obtained small white crystals of a salt to which he gave the formula  $\text{Na}_2\text{O} \cdot \text{W}_2\text{O}_7 \cdot 2\text{H}_2\text{O} = \text{NaWO}_4 \cdot \text{H}_2\text{O}$ ; and by treating  $(\text{NH}_4)_2\text{W}_2\text{O}_{11} \cdot 6\text{H}_2\text{O}$  in a similar way he isolated the corresponding  $\text{NH}_4$  pertungstate. According to P. these salts are decomposed by alkalis with evolution of  $\text{O}$ ; solutions of them set free  $\text{I}$  from  $\text{KIAq}$ , and react with  $\text{HClAq}$ , giving off  $\text{Cl}$ .

**TUNGSTEN BRONZES.** Bright-coloured, lustrous, metal-like, crystalline solids, obtained by the action of reducers—such as  $\text{H}$ , coal-gas,  $\text{Sn}$ , or  $\text{Fe}$ —on tungstates of  $\text{Li}$ ,  $\text{K}$ , or  $\text{Na}$ ; also by the electrolysis of these tungstates when molten. The composition of these compounds, which are known as bronzes and are used as pigments, is represented by the formula  $\text{M}_x(\text{WO}_3)_y$ , where  $\text{M} = \text{Li}$ ,  $\text{K}$ , or  $\text{Na}$ . The constitutions of the compounds are not known; they may be represented as compounds of tungstates with  $\text{WO}_3$ , by the general formula  $x\text{M}_2\text{O}_3 \cdot y\text{WO}_3$ ; they may also be represented as compounds of  $\text{M}_2\text{O}$  with a radicle composed of  $\text{W}$  and  $\text{O}$  in a ratio greater than  $\text{W}:2\text{O}$  and less than  $\text{W}:3\text{O}$ —that is, as compounds of  $\text{M}_2\text{O}$  with oxides intermediate between  $\text{WO}_3$  and  $\text{WO}_2$ . The tungsten bronzes are insoluble in most acids, also in alkali solutions.

**Sodium tungsten bronzes.** These compounds are formed by the interaction of Na tungstates and  $\text{H}$  (Wöhler, P. 2, 350),  $\text{Sn}$  (Wright, A. 79, 221), coal-gas (Schnitzler, D. P. J. 211, 484),  $\text{Zn}$  or  $\text{Fe}$  (Zettnow, P. 130, 261), or by electrolysis Na tungstates (Scheibler, J. pr. 83, 321). According to Philipp (B. 15, 499), the different processes yield the same bronze if the same tungstate is used, and the more  $\text{WO}_3$  there is in the tungstate employed the richer in  $\text{WO}_3$  is the bronze produced. All the compounds are insoluble in acids or alkalis; they dissolve in  $\text{NaClO}_4\text{Aq}$ ; heated with  $\text{NH}_4\text{Aq}$  and  $\text{AgNO}_3\text{Aq}$  they give  $\text{Ag}$  and  $\text{WO}_3$  (cf. P. a. Schwebel, B. 12, 2234; 15, 500; Knorre, J. pr. [2] 27, 51). These compounds are slowly oxidised to tungstates by heating to redness in air (K., l.c.). Philipp (l.c.) gave S.G. of all the sodium bronzes as 7.2 to 7.8 at  $16^\circ$  to  $18^\circ$ .

**Purple-red bronze**  $\text{Na}_2\text{W}_2\text{O}_{11} = \text{Na}_2\text{O} \cdot 2\text{WO}_3 \cdot \text{WO}_3 = \text{Na}_2\text{O} \cdot \text{W}_3\text{O}_{11} = \text{Na}_2\text{WO}_7 \cdot \text{WO}_3$ . Prepared by fusing for c. half an hour a mixture of 10.9 g.  $\text{Na}_2\text{CO}_3$ , 71.7 g.  $\text{WO}_3$ , and 20 g. tinfoil, and boiling successively with  $\text{H}_2\text{O}$ ,  $\text{NaOHAq}$ , and  $\text{HClAq}$ . Red cubes; the powder transmits green light when suspended in water (P., l.c.).

**Red-yellow bronze**  $\text{Na}_3\text{W}_3\text{O}_{11} = 2\text{Na}_2\text{O} \cdot 3\text{WO}_3 \cdot 2\text{WO}_2 = 2\text{Na}_2\text{O} \cdot \text{W}_5\text{O}_{17}$ . Prepared by

melting 60 to 80 g. of a mixture of  $\text{Na}_2\text{WO}_4$  and  $\text{WO}_3$  in the ratio  $2\text{Na}_2\text{WO}_4:\text{WO}_3$ , adding 80 g. tin-foil, and keeping molten for 1 to 2 hours. Red-yellow cubes; the powder is brownish yellow, and transmits blue light when suspended in water (P., l.c.).

**Gold-yellow bronzes**  $\text{Na}_2\text{W}_2\text{O}_{11} = 5\text{Na}_2\text{O} \cdot 7\text{WO}_3 \cdot 5\text{WO}_2 = 5\text{Na}_2\text{O} \cdot \text{W}_{12}\text{O}_{41}$ . Prepared by heating  $\text{Na}_2\text{W}_2\text{O}_{11}$  to dull redness in H, powdering and again heating in H, and then boiling with  $\text{H}_2\text{O}$ ,  $\text{HClAq}$ , and  $\text{Na}_2\text{CO}_3\text{Aq}$  successively. Golden yellow, crystalline powder (P., l.c.; cf. Wöhler, P. 2, 350; Wright, A. 79, 221).

**Blue bronzes**  $\text{Na}_2\text{W}_2\text{O}_{11} = \text{Na}_2\text{O} \cdot 4\text{WO}_3 \cdot \text{WO}_2 = \text{Na}_2\text{O} \cdot \text{W}_5\text{O}_{16}$ . Prepared by fusing  $\text{Na}_2\text{WO}_4$  with more than  $2\text{WO}_3$ , and adding tin-foil; also by melting  $\text{Na}_2\text{W}_2\text{O}_{11}$  (paratungstate) and electrolyzing with 6 Zn-Pt elements (P., l.c.; Scheibler, J. pr. 83, 321; cf. Knorre, J. pr. [2] 27, 49; and Zettnow, P. 130, 261). Dark-blue cubes, with a red sheen; S.G. 7.28 at  $17^\circ$ .

**Potassium tungsten bronzes.** The compound  $\text{K}_2\text{W}_2\text{O}_{11} = \text{K}_2\text{O} \cdot 3\text{WO}_3 \cdot \text{WO}_2 = \text{K}_2\text{O} \cdot \text{W}_5\text{O}_{16}$  seems to be the only one of this class that has been isolated. Prepared by fusing  $\text{K}_2\text{WO}_4$  with  $\text{WO}_3$  and adding tin-foil; also by fusing  $\text{K}_2\text{CO}_3$  with from  $3\text{WO}_3$  to  $4\text{WO}_3$ , and reducing by H or coal gas; also by electrolyzing a molten mixture of  $\text{K}_2\text{WO}_4$  and  $\text{WO}_3$ . Reddish-violet prisms, giving a blue powder, which transmits greenish light when suspended in water; S.G. c. 7.1 (Laurent, A. Ch. [2] 67, 219; Zettnow, P. 130, 262; Knorre, J. pr. [2] 27, 63).

**Lithium tungsten bronzes.** A compound of this class, probably  $\text{Li}_2\text{W}_2\text{O}_{11}$ , is obtained by fusing  $\text{Li}_2\text{W}_2\text{O}_{11}$  (paratungstate) with tin. Dark blue crystals (Scheibler, J. pr. 83, 321; Knorre, l.c., p. 69; Feit, B. 21, 135).

A **potassium sodium bronze** and a **potassium lithium** bronze have been obtained (Knorre, l.c. p. 66; Feit, l.c.).

**COMPLEX TUNGSTIC ACIDS AND SALTS.** Tungstic oxide  $\text{WO}_3$  combines with several anhydrides, e.g.  $\text{B}_2\text{O}_3$ ,  $\text{P}_2\text{O}_5$ ,  $\text{As}_2\text{O}_3$ ,  $\text{SiO}_2$ , &c., and water, to form acidic compounds, and also with these anhydrides and basic oxides to form salt-like compounds; the whole of these compounds are usually grouped together as **complex tungstic acids** and **complex tungstates**, and they are divided into such classes as **arsenotungstates**, **phosphotungstates**, &c.

**ANTIMONOTUNGSTIC ACIDS AND SALTS.** According to Lefort (A. Ch. [5] 17, 487), the compounds  $\text{Sb}_2\text{O}_3 \cdot 5\text{WO}_3 \cdot 4\text{H}_2\text{O}$  and  $\text{Sb}_2\text{O}_3 \cdot 6\text{WO}_3 \cdot 8\text{H}_2\text{O}$  are formed by dissolving tartar emetic in  $\text{Na}_2\text{O} \cdot 3\text{WO}_3\text{Aq}$  and  $\text{Na}_2\text{O} \cdot 2\text{WO}_3\text{Aq}$  respectively. Gibbs (Am. 7, 392) obtained  $4\text{BaO} \cdot 6\text{Sb}_2\text{O}_3 \cdot 22\text{WO}_3 \cdot 36\text{H}_2\text{O}$  and  $6\text{K}_2\text{O} \cdot 4\text{Sb}_2\text{O}_3 \cdot 12\text{WO}_3 \cdot 25\text{H}_2\text{O}$ .

**ARSENOTUNGSTIC ACIDS AND SALTS.** Compounds of the form  $\text{As}_2\text{O}_3 \cdot 16\text{WO}_3 \cdot x\text{H}_2\text{O}$  have been obtained by Kehrmann (A. 245, 45; cf. Frapery, B. 17, 256); and series of compounds of  $\text{As}_2\text{O}_3$  with  $\text{WO}_3$  and basic oxides ( $\text{Na}_2\text{O}$ ,  $\text{K}_2\text{O}$ ,  $\text{BaO}$  &c.), in which the ratio of  $\text{As}_2\text{O}_3:\text{WO}_3$  is 1:6 and 1:8, have been described by Gibbs (Am. 7, 313). Compounds of  $\text{WO}_3$  with  $\text{As}_2\text{O}_3$  and bases, and also with  $\text{As}_2\text{O}_3$  and  $\text{As}_2\text{O}_5$  and bases, are described by Gibbs (l.c.).

**BOROTUNGSTIC ACIDS AND SALTS.** Two com-

pounds of  $\text{B}_2\text{O}_3$  and  $\text{WO}_3$  have probably been isolated, in which the ratios of the oxides are 1:14 and 1:9 respectively: compounds of each of these with bases are known (Klein, A. Ch. [5] 28, 350).

**Borotungstic acid and salts**

$\text{B}_2\text{O}_3 \cdot 14\text{WO}_3 \cdot x\text{H}_2\text{O}$ . A solution containing  $\text{B}_2\text{O}_3$  and  $\text{WO}_3$  in the ratio 1:14 is obtained by boiling  $\text{Na}_2\text{WO}_4\text{Aq}$  with  $\text{B}_2\text{O}_3\text{Aq}$ , ppg. by  $\text{HgNO}_3\text{Aq}$ , decomposing the pp. by  $\text{H}_2\text{S}$ , and expelling  $\text{H}_2\text{S}$  from the filtrate by warming (for details v. K., l.c.). Compounds of the form  $x\text{MO} \cdot \text{B}_2\text{O}_3 \cdot 14\text{WO}_3 \cdot y\text{H}_2\text{O}$  have been formed, where  $x = 2, 3$ , and 4, and M is Ba, K,  $\text{Ag}$ , Na, and Sr.

**Tungstoboric acid and salts.** The compound  $\text{B}_2\text{O}_3 \cdot 9\text{WO}_3 \cdot x\text{H}_2\text{O}$ , usually known as tungstoboric acid, is obtained in yellowish octahedra by evaporating the solution of borotungstic acid. A considerable number of compounds of bases with  $\text{B}_2\text{O}_3$  and  $\text{WO}_3$ , in the ratio  $\text{B}_2\text{O}_3:9\text{WO}_3$ , has been obtained; most of them are of the form  $2\text{MO} \cdot \text{B}_2\text{O}_3 \cdot 9\text{WO}_3 \cdot x\text{H}_2\text{O}$ ,  $\text{M} = (\text{NH}_4)$ , Ba, Cd, Ca, Co, Cu, Li, Mg, Mn, Hg, Ni, K, Na, Tl; a few salts  $2\text{M}_2\text{O} \cdot \text{B}_2\text{O}_3 \cdot 9\text{WO}_3 \cdot x\text{H}_2\text{O}$  ( $\text{M} = \text{Al}$  or Cr) are also described by Klein (l.c.).

**FLUOROTUNGSTATES and allied compounds; v. TUNGSTOXYFLUORIDES (p. 799).**

**IODOTUNGSTATES.** Bloisstran (J. pr. 40, 327) described a compound  $2\text{K}_2\text{O} \cdot \text{I}_2\text{O}_5 \cdot 2\text{W}_{12}\text{O}_{41} \cdot 3\text{H}_2\text{O}$ , obtained by adding the calculated quantity of  $\text{HIO}_3$  to  $\text{K}_2\text{WO}_4\text{Aq}$ .

**PHOSPHOTUNGSTIC ACIDS AND SALTS.** The oxides  $\text{WO}_3$  and  $\text{P}_2\text{O}_5$  combine in several proportions, in presence of  $\text{H}_2\text{O}$ , to form complex acids which contain large quantities of  $\text{WO}_3$  relatively to the  $\text{P}_2\text{O}_5$ . A great many compounds are known containing  $\text{WO}_3$  and  $\text{P}_2\text{O}_5$  combined with basic oxides.

**Phosphotungstic acids.** Compounds of the form  $\text{P}_2\text{O}_5 \cdot x\text{WO}_3 \cdot y\text{H}_2\text{O}$ ; compounds wherein  $x = 24, 21, 20, 16$ , and 12 seem to have been isolated. The existence of these compounds was made known by Scheibler (B. 5, 802); they have been investigated chiefly by Gibbs (Am. 2, 217, 281; 4, 377; 5, 361, 391; 7, 313, 392; Péchard, C. R. 109, 301; 110, 754; and Kehrmann, B. 20, 1805, 1811; 24, 2326; 25, 1966; A. 245, 45; Zeit. f. anorg. Chemie, 1, 428; also Drechsel, B. 20, 1452; and Brandhorst a. Kraut, A. 249, 373). The phosphotungstic acids are obtained by boiling  $\text{H}_3\text{PO}_4\text{Aq}$  with  $\text{H}_2\text{W}_2\text{O}_{11} \cdot x\text{H}_2\text{O}$  (meta-acid); by decomposing the mercurous salts by  $\text{HClAq}$ ; and by boiling  $\text{Na}_2\text{W}_2\text{O}_{11} \cdot x\text{H}_2\text{O}$  (para-salt) with  $\text{Na}_2\text{HPO}_4\text{Aq}$ , decomposing by  $\text{HClAq}$ , and dissolving the acids thus formed in ether. The phosphotungstic acids are unchanged in solutions in dilute acids; these solutions are scarcely acted on by  $\text{H}_2\text{S}$ , and very slightly by zinc; they give phosphates and tungstates when boiled with alkalis; characteristic pps. are produced with alkaloids, urea, albumen, &c.

**Phosphododecitungstic acid and salts**  $\text{P}_2\text{O}_5 \cdot 24\text{WO}_3 \cdot x\text{H}_2\text{O}$  and  $y\text{MO} \cdot \text{P}_2\text{O}_5 \cdot 24\text{WO}_3 \cdot x\text{H}_2\text{O}$ . The acid is obtained by evaporating a solution of  $\text{H}_3\text{PO}_4$  and  $\text{H}_2\text{W}_2\text{O}_{11} \cdot x\text{H}_2\text{O}$  in the proper proportion (Péchard, l.c.); by boiling a solution of tungstate and phosphate of Na, in the ratio  $24\text{Na}_2\text{WO}_3 \cdot 2\text{Na}_2\text{HPO}_4$ , acidulating with  $\text{HNO}_3\text{Aq}$ , ppg. by  $\text{HgNO}_3\text{Aq}$ , decomposing the Hg salt by  $\text{HClAq}$ , filtering, and evaporating in *vacuo*

(Gibbs, *Am. J.* 2, 217); by boiling  $\text{H}_2\text{PO}_4\text{Aq}$  with  $\text{BaWO}_4$  in the proper proportion, decomposing by a small excess of  $\text{H}_2\text{SO}_4\text{Aq}$ , removing  $\text{H}_2\text{SO}_4$  by  $\text{BaOAc}$ , filtering, and evaporating (Sprenger, *J. pr.* [2] 22, 418). The acid crystallises in white, regular octahedra, or cubes. The value for  $x$  in the formula  $\text{P}_2\text{O}_5 \cdot 24\text{WO}_3 \cdot x\text{H}_2\text{O}$  varies according to different observers, from 40 to 58, 59, and 61. The salts  $y\text{MO} \cdot \text{P}_2\text{O}_5 \cdot 24\text{WO}_3 \cdot x\text{H}_2\text{O}$  are obtained by mixing tungstates (normal or para-salts) with  $\text{H}_2\text{PO}_4\text{Aq}$  or a phosphate, and decomposing by slight excess of  $\text{HClAq}$ ,  $\text{HNO}_3\text{Aq}$ , or  $\text{H}_2\text{SO}_4\text{Aq}$ ; in most cases the salts ppt. as fine, white powders; in some cases it is advisable to evaporate to dryness, extract with alcohol and ether, and evaporate. The salts have been described by Gibbs (*l.c.*); Kehrnmann (*Zeit. f. anorg. Chemie*, 1, 430); K. a. Freinkel (*B.* 24, 2327); Sprenger (*J. pr.* [2] 122, 418); and Brandhorst a. Kraut (*A.* 249, 373). Salts have been obtained wherein  $\text{MO} = (\text{NH}_4)_2\text{O}$ ,  $\text{BaO}$ ,  $\text{CuO}$ ,  $\text{K}_2\text{O}$ ,  $\text{Ag}_2\text{O}$ , and  $\text{Na}_2\text{O}$ , and  $y = 1, 2$ , and 3.

**Phosphotungstic acid and salts.**  
 $\text{P}_2\text{O}_5 \cdot 16\text{WO}_3 \cdot x\text{H}_2\text{O}$  and  $y\text{MO} \cdot \text{P}_2\text{O}_5 \cdot 16\text{WO}_3 \cdot x\text{H}_2\text{O}$ . The acid is obtained by boiling  $\text{Na}_2\text{WO}_4\text{Aq}$  with  $\text{H}_2\text{PO}_4\text{Aq}$ , acidulating with  $\text{HNO}_3\text{Aq}$ , adding  $\text{NH}_4\text{Cl}$  and boiling, crystallising the pp. from  $\text{NH}_4\text{ClAq}$ , evaporating the  $\text{NH}_4$  salt thus produced with *aqua regia*, and crystallising the acid so formed from water (for details v. K. *l.c.*). To an acid obtained by decomposing the K salt by  $\text{H}_2\text{SiF}_6\text{Aq}$ , or the Ag salt by  $\text{HClAq}$ , K. gives the formula  $\text{P}_2\text{O}_5 \cdot 18\text{WO}_3 \cdot x\text{H}_2\text{O}$ ; and he says that the salts are  $y\text{MO} \cdot \text{P}_2\text{O}_5 \cdot 18\text{WO}_3 \cdot x\text{H}_2\text{O}$ . The acid forms citron-yellow, six-sided tablets; it melts by the heat of the hand, and is very soluble in water. According to K. (*B.* 20, 1805; *A.* 245, 45), salts of this series are obtained by boiling any phosphotungstates with excess of  $\text{H}_2\text{PO}_4\text{Aq}$  in presence of an alkali salt. It is probable that two series of salts exist—one with  $16\text{WO}_3$  and another with  $18\text{WO}_3$  (cf. Gibbs, *l.c.*; and Péchard, *l.c.*). Salts have been obtained wherein  $\text{MO} = (\text{NH}_4)_2\text{O}$ ,  $\text{BaO}$ ,  $\text{CaO}$ ,  $\text{CuO}$ ,  $\text{PbO}$ , and  $\text{K}_2\text{O}$ , and  $y = 1, 3, 4$ , and 6.

#### Other phosphotungstic acids and salts.

I. Salts of the form  $y\text{MO} \cdot \text{P}_2\text{O}_5 \cdot 22\text{WO}_3 \cdot x\text{H}_2\text{O}$  have been obtained, wherein  $\text{MO} = (\text{NH}_4)_2\text{O}$ ,  $\text{BaO}$ , and  $\text{K}_2\text{O}$ , and  $y = 2, 3, 4$ , and 7 (v. K. a. F., *B.* 21, 2327; 26, 1966; K., *Zeit. f. anorg. Chemie*, 1, 435; Sprenger, *l.c.*; Gibbs, *l.c.*).

II. An acid of the form  $\text{P}_2\text{O}_5 \cdot 21\text{WO}_3 \cdot x\text{H}_2\text{O}$ , and salts  $y\text{MO} \cdot \text{P}_2\text{O}_5 \cdot 21\text{WO}_3 \cdot x\text{H}_2\text{O}$ , where  $\text{MO} = (\text{NH}_4)_2\text{O}$ ,  $\text{K}_2\text{O}$ , and  $\text{Ag}_2\text{O}$  and  $y = 3$ , have been isolated (K. a. F., *l.c.*; K., *l.c.*).

III. The acid  $\text{P}_2\text{O}_5 \cdot 20\text{WO}_3 \cdot x\text{H}_2\text{O}$  and a salt  $6\text{BaO} \cdot \text{P}_2\text{O}_5 \cdot 20\text{WO}_3 \cdot x\text{H}_2\text{O}$  were obtained by Péchard (*l.c.*) and Gibbs (*l.c.*).

IV. For the acid  $\text{P}_2\text{O}_5 \cdot 12\text{WO}_3 \cdot x\text{H}_2\text{O}$  and the salts  $y\text{MO} \cdot \text{P}_2\text{O}_5 \cdot 12\text{WO}_3 \cdot x\text{H}_2\text{O}$ , where  $\text{MO} = (\text{NH}_4)_2\text{O}$ ,  $\text{BaO}$ ,  $\text{CaO}$ ,  $\text{CuO}$ ,  $\text{PbO}$ ,  $\text{Li}_2\text{O}$ ,  $\text{MgO}$ ,  $\text{Hg}_2\text{O}$ ,  $\text{K}_2\text{O}$ ,  $\text{Ag}_2\text{O}$ ,  $\text{Na}_2\text{O}$ ,  $\text{TiO}_2$ , and  $\text{ZnO}$ , v. Péchard (*C. R.* 110, 754).

V. A few salts of the form  $y\text{MO} \cdot \text{P}_2\text{O}_5 \cdot 7\text{WO}_3 \cdot x\text{H}_2\text{O}$  have been obtained ( $\text{MO} = (\text{NH}_4)_2\text{O}$ ,  $\text{BaO}$ ,  $\text{CaO}$ ,  $\text{Hg}_2\text{O}$ ,  $\text{Na}_2\text{O}$ ;  $y$  doubtful) (Gibbs, *l.c.*; K., *l.c.*).

VI. Compounds of alkali phosphates with  $\text{WO}_3$ , and with phosphoric acids and  $\text{WO}_3$ , have been isolated; also compounds of alkalis with  $\text{H}_2\text{PO}_4$  and  $\text{WO}_3$ , and with  $\text{H}_3\text{PO}_4$  and  $\text{WO}_3$ ,

are described by Gibbs (*Am. J.* 5, 361; 7, 318, 392).

#### PLATINOTUNGSTATES, v. this vol., p. 283.

**SILICOTUNGSTIC ACIDS AND SALTS.** Three compounds of  $\text{SiO}_2$  with  $\text{WO}_3$  and  $\text{H}_2\text{O}$ , which react as acids, have been isolated, and many compounds of bases with  $\text{SiO}_2$  and  $\text{WO}_3$  have been obtained (Marignac, *A. Ch.* [4] 8, 5).

**Silicoduoodecitungstic acid, and salts**  
 $\text{SiO}_2 \cdot 12\text{WO}_3 \cdot x\text{H}_2\text{O}$ ; as most of the salts contain  $4\text{M}_2\text{O}$  (or  $2\text{MO}$ ) the acid is usually written  $4\text{H}_2\text{O} \cdot \text{SiO}_2 \cdot 12\text{WO}_3 \cdot x\text{H}_2\text{O}$  ( $= \text{H}_4\text{SiW}_{12}\text{O}_{40} \cdot x\text{H}_2\text{O}$ ). According to Drechsel (*B.* 20, 1452), the acid is most easily obtained by dissolving  $\text{Na}_2\text{WO}_4$  in boiling water, nearly neutralising with  $\text{HNO}_3\text{Aq}$ , dissolving the crystals that separate in cold water, boiling this solution with gelatinous  $\text{SiO}_2 \cdot x\text{H}_2\text{O}$  until  $\text{HClAq}$  ceases to give a pp., filtering, evaporating, adding a large excess of  $\text{H}_2\text{SO}_4\text{Aq}$ , extracting with ether, separating the lowest layer and evaporating (for details v. D., *l.c.*). Large, colourless, dimetric octahedra (with  $x = 29$ ); loses  $25\text{H}_2\text{O}$  at  $100^\circ$ , and all  $\text{H}_2\text{O}$  at  $350^\circ$ . Very soluble in water and alkali solutions. Most of the salts of this acid have the composition  $4\text{M}_2\text{O} \cdot \text{SiO}_2 \cdot 12\text{WO}_3 \cdot x\text{H}_2\text{O}$ , or  $2\text{MO} \cdot \text{SiO}_2 \cdot 12\text{WO}_3 \cdot x\text{H}_2\text{O}$ ;  $\text{MO} = (\text{NH}_4)_2\text{O}$ ,  $\text{Hg}_2\text{O}$ ,  $\text{K}_2\text{O}$ ,  $\text{Ag}_2\text{O}$ ,  $\text{Na}_2\text{O}$ ;  $\text{MO} = \text{BaO}$ ,  $\text{CaO}$ ,  $\text{MgO}$ ;  $x$  varies from 7 to 28 (Marignac, *l.c.*).

**Tungstosilicic acid, and salts.** This name is generally given to an acid containing  $\text{SiO}_2$  and  $\text{WO}_3$  in the same ratio (1:12) as silicoduoodecitungstic acid. The formula of the acid is generally written  $4\text{H}_2\text{O} \cdot \text{SiO}_2 \cdot 12\text{WO}_3 \cdot 20\text{H}_2\text{O}$ . The acid is obtained by evaporating a solution of silicoduoodecitungstic acid to dryness, taking up with water, filtering from separated  $\text{SiO}_2$ , evaporating to a syrup, and allowing to crystallise. Forms short, white, triclinic prisms; melts under  $100^\circ$ , giving off  $16\text{H}_2\text{O}$  and again solidifying. The salts of this acid are obtained by dissolving carbonates in a solution of the acid, and evaporating; they are more soluble and less easily crystallised than the salts of the duoodecitungstic acid; the salts are of the forms

- (1)  $2\text{MO}(4\text{M}_2\text{O}) \cdot \text{SiO}_2 \cdot 12\text{WO}_3 \cdot x\text{H}_2\text{O}$ , where  $\text{M} = \text{Ca}$ , or  $\text{M}_2 = \text{K}_2$ ;
- (2)  $2\text{M}_2\text{O} \cdot 2\text{H}_2\text{O} \cdot \text{SiO}_2 \cdot 12\text{WO}_3 \cdot x\text{H}_2\text{O}$ , where  $\text{M} = \text{K}$ , or  $\text{Na}$ ; some more complex salts have also been isolated (Marignac, *l.c.*).

**Silico-acetitungstic acid, and salts.** The acid  $4\text{H}_2\text{O} \cdot \text{SiO}_2 \cdot 10\text{WO}_3 \cdot x\text{H}_2\text{O}$  ( $x$  probably = 3) is obtained by decomposing the Ag salt by  $\text{HClAq}$ , filtering, and evaporating *in vacuo*; the Ag salt is prepared by adding  $\text{AgNO}_3\text{Aq}$  to the  $\text{NH}_4$  salt which is obtained by boiling an acid tungstate of  $\text{NH}_4$  with  $\text{SiO}_2 \cdot x\text{H}_2\text{O}$ , filtering, and evaporating. The acid forms a clear, yellowish, glassy solid, which does not wholly dissolve in water; loses  $3\text{H}_2\text{O}$  at  $100^\circ$ ; on boiling with water most of the  $\text{SiO}_2$  separates, and the filtrate contains tungstosilicic acid. A few salts have been obtained; they are difficult to purify from silicotungstic acids and tungstosilicates (Marignac, *l.c.*).

**STANNIOPHOSPHOTUNGSTATES.** Gibbs (*Am. J.* 1892) obtained the salt  $2(\text{NH}_4)_2\text{O} \cdot \text{P}_2\text{O}_5 \cdot 28\text{SnO}_2 \cdot 22\text{WO}_3 \cdot 15\text{H}_2\text{O}$  by the reaction of  $\text{SnCl}_4 \cdot 2\text{NH}_4\text{Cl}$  and  $2\text{Na}_2\text{O} \cdot \text{P}_2\text{O}_5 \cdot 24\text{WO}_3 \cdot x\text{H}_2\text{O}$ .

**TUNGSTIC ACIDS.** Two acids,  $(\text{H}_2\text{O})_2\text{TiO}_3 \cdot 12\text{WO}_3 \cdot x\text{H}_2\text{O}$  and  $(\text{H}_2\text{O})_2\text{TiO}_3 \cdot 10\text{WO}_3 \cdot x\text{H}_2\text{O}$ , are described by Lejarmie (v. Klein, *Bl.* [2] 36, 17).

**VANADOTUNGSTIC ACIDS AND SALTS.** Several compounds of  $\text{WO}_3$  with  $\text{V}_2\text{O}_5$  and  $\text{H}_2\text{O}$  have been described by Gibbs (*Ann.* 4, 377; 5, 361, 391) and Rosenheim (*A.* 251, 197); they belong to the forms  $\text{V}_2\text{O}_5 \cdot 10\text{WO}_3 \cdot x\text{H}_2\text{O}$ ,  $\text{V}_2\text{O}_5 \cdot 18\text{WO}_3 \cdot x\text{H}_2\text{O}$ , and  $\text{V}_2\text{O}_5 \cdot 4\text{WO}_3 \cdot x\text{H}_2\text{O}$ . Compounds of these with  $\text{yM}_2\text{O}$  and  $\text{yMO}$  are also described; and a great variety of compounds coming under the general formula  $x\text{MO} \cdot y\text{V}_2\text{O}_5 \cdot z\text{WO}_3 \cdot x\text{H}_2\text{O}$  have been obtained (cf. Friedheim, *B.* 23, 1505; and Rothenbach, *B.* 23, 3050).

**Tungsten, oxybromides of.** Two oxybromides,  $\text{WO}_2\text{Br}_2$  and  $\text{WOBr}_4$ , are formed by the reaction of Br on  $\text{WO}_3$ , and in other ways. The formula  $\text{WOBr}_4$  is very probably molecular, from the analogy of  $\text{WOCl}_4$ .

**Tungsten dioxidebromide  $\text{WO}_2\text{Br}_2$ .** Obtained by heating  $\text{WO}_3$  in a stream of Br vapour, also by passing vapour of  $\text{WBr}_4$  over heated  $\text{VO}_2$  (Roscoe, *C. N.* 25, 73); also by heating  $\text{VS}_2$  or a mixture of  $\text{WO}_3$  and C in Br (Borck, *J.* pr. 54, 254). Red, transparent, prismatic crystals; appearing black when hot, and giving a yellow powder. Volatilised at red heat with partial decomposition to  $\text{WO}_3$  and  $\text{WOBr}_4$ .

**Tungsten oxytetrafluoride  $\text{WOBr}_4$ .** Obtained by passing Br vapour over a heated mixture of equal parts of  $\text{WO}_3$  and W, and autously distilling from less volatile  $\text{WO}_2\text{Br}_2$  (Roscoe, *C. N.* 25, 73). Also formed by passing Br mixed with some overheated W, or by heating a mixture of  $\text{WO}_3$  and C in Br vapour (Blomstrand, *J.* pr. 82, 430). Brownish black, lustrous, crystalline needles; melts at  $277^\circ$  and boils at  $27^\circ$ . Heated in moist air gives  $\text{WO}_3$  and  $\text{HBr}$ , and is decomposed to the same products by water.

**Tungsten, oxychlorides of.** Two oxychlorides,  $\text{WO}_2\text{Cl}_2$  and  $\text{WOCl}_4$ , are formed by heating W in Cl mixed with some O, and in other reactions.

**Tungsten dioxidechloride  $\text{WO}_2\text{Cl}_2$ .** Obtained by heating  $\text{WO}_3$  in a stream of Cl, and subliming (Roscoe, *C. N.* 25, 63); also by passing  $\text{CO}_2$  over a mixture of  $\text{WO}_3$  and  $\text{CaCl}_2$  heated to redness (Schulze, *J.* pr. [2] 21, 432). Also formed, along with  $\text{WOCl}_4$ , by heating W in Cl mixed with O; by heating  $\text{WO}_3$  and C in Cl; by heating  $\text{WO}_3$  in  $\text{CCl}_4$  (Watts a. Bell, *C. J.* 33, 42); and by heating  $\text{WO}_3$  with  $\text{PCl}_5$  (Schiff, *et.* 97, 185; cf. Tungsten trioxide, *Reactions*, to. 10, p. 801). Yellow, four-sided tablets; sublimes without melting at c.  $266^\circ$ , with partial decomposition to  $\text{WO}_3$  and  $\text{WOCl}_4$ . Not decomposed in moist air, nor by cold water (R., *l.c.*). Heated in dry  $\text{NH}_3$  gives off  $\text{NH}_4\text{Cl}$  and leaves  $\text{VO}_2$  (Rideal, *C. J.* 55, 48); in this reaction  $\text{VO}_2\text{Cl}_2$  behaves like  $\text{CrO}_2\text{Cl}_2$  (R., *C. J.* 49, 367); according to Smith a. Shinn (*Zeit. f. anorg. Chem.*, 4, 381), a black compound  $\text{W}_2\text{O}_5\text{N}_2\text{H}_2$  is formed by heating  $\text{WO}_2\text{Cl}_2$  in dry  $\text{NH}_3$ .

**Tungsten oxytetrafluoride  $\text{WOCl}_4$ .** Mol. r. 341.04. Formed by heating W in Cl containing a little O; also by passing Cl over a hot mixture of  $\text{WO}_3$  and C; by heating  $\text{WO}_3$  in  $\text{CCl}_4$  (Watts a. Bell, *C. J.* 33, 442); by heating  $\text{VCl}_3$  or  $\text{WCl}_5$  in O and Cl; by heating  $\text{WCl}_5$  with

$\text{H}_2\text{O}_2$ ; and by heating  $\text{WO}_2\text{Cl}_2$ . Prepared by passing vapour of  $\text{WCl}_5$  over heated  $\text{WO}_3$  in a current of Cl (Roscoe, *C. N.* 25, 63). Also by heating  $\text{WO}_3$  and  $\text{PCl}_5$  in the ratio  $\text{WO}_3:\text{PCl}_5$  or  $\text{WO}_3:2\text{PCl}_5$ , distilling off  $\text{POCl}_3$ , and the small quantities of  $\text{WCl}_5$  and  $\text{WCl}_4$  that are formed, washing the reddish residue with a little cold  $\text{CS}_2$  (to remove  $\text{WCl}_5$ ), then dissolving in a larger quantity of warm  $\text{CS}_2$ , evaporating, and carefully heating the residue in a stream of  $\text{CO}_2$ , whereby the more volatile  $\text{WOCl}_4$  is separated from  $\text{WO}_2\text{Cl}_2$  (Schiff, *A.* 197, 185).

$\text{WOCl}_4$  forms ruby-red, transparent needles; melts at  $210.4^\circ$ , and volatilises at  $227.5^\circ$ , forming a yellow vapour (R., *l.c.*). V.D. 170.2 to  $175.8$  at  $350^\circ$ , 171.5 at  $440^\circ$  (R., *l.c.*; cf. Debray, *C. R.* 60, 820). Exposure to air produces a crust of yellow  $\text{WO}_2\text{Cl}_2$ . Heated in  $\text{NH}_3$  probably gives  $\text{W}_2\text{N}_2$  (Rideal, *C. J.* 65, 43). Decomposed by water, with a hissing sound, to  $\text{WO}_3$  and  $\text{HCl}$  (Roscoe, *l.c.*).

**Tungsten, oxyfluorides of.** No compound of W with O and F has been isolated, but compounds are known which may be regarded as containing  $\text{WO}_2\text{F}_2$ . These compounds,  $\text{WO}_2\text{F}_2 \cdot 2\text{MF}$  and  $\text{WO}_2\text{F}_2 \cdot \text{MF}$ , and also a compound  $\text{WO}_2\text{F}_2 \cdot 2\text{KF}$ , are described under Tungsten oxyfluorides (p. 799).

**Tungsten, phosphides of.** By heating W in vapour of P, a dark-grey powder was obtained by Wöhler a. Wright (*A.* 79, 244), to which they gave the composition  $\text{W}_2\text{P}_4$ . By heating a mixture of  $\text{WO}_3$  and  $\text{P}_2\text{O}_5$  in a graphite crucible, W. a. W. (*l.c.*) obtained large, dark-grey, lustrous, six-sided prisms; S.G. 5.207; insoluble in acids, including *aqua regia*, soluble in a molten mixture of  $\text{Na}_2\text{CO}_3$  and  $\text{NaNO}_3$ ; unchanged by heating in air, but burns brilliantly in O. From an estimation of the P, W. a. W. gave the formula  $\text{W}_2\text{P}_4$ .

**Tungsten, salts of.** No salts have been isolated by replacing the H of oxyacids by W. Except the halides, the only salts of W that are known are those wherein W forms part of the negative radicle.

**Tungsten, selenides of.** By saturating a solution of  $\text{Na}_2\text{WO}_4$  with  $\text{H}_2\text{Se}$ , and then adding dilute  $\text{H}_2\text{SO}_4$ , Ueismann (*A.* 116, 125) obtained a black pp., to which he gave the formula  $\text{WSe}_2$  (the estimation of W is given); by heating this in a tube a grey solid was obtained, said by U. to be  $\text{WSe}_2$  (no analyses).  $\text{WSe}_2$  is said to be easily soluble in solutions of alkalis, alkali sulphides, or alkali selenides.

**Tungsten, sulphides of.** Two compounds of W and S are known,  $\text{WS}$  and  $\text{WS}_2$ ; the latter is acidic, forming salts  $\text{MWS}_2$ . The V.D. of neither has been determined.

**Tungsten disulphide  $\text{WS}_2$ .** Obtained by heating  $\text{WO}_3$  to whiteness in vapour of S or in  $\text{H}_2\text{S}$  (Berzelius); also by heating W and S; also by heating  $\text{WO}_3$  with 6 pts.  $\text{HgS}$  out of contact with air (Borck, *J.* pr. 54, 254). According to Carnot (*Bl.* [2] 32, 164),  $\text{WS}_2$  is usually formed when a compound of W is heated in a stream of dry  $\text{H}_2\text{S}$  (v. also von Usler, *A.* 94, 256; Combes, *A.* 232, 262). A dark-grey, graphite-like, lustrous, crystalline powder (v. Riche, *et. Ch.* [3] 50, 26). Is said to decompose steam at a full red heat; reduced to W by very long continued heating in H.

**TUNGSTEN TRISULPHIDE**  $WS_3$ . Obtained by fusing powdered wolframite with 2 pts. C, 3 pts. S, and 3 pts.  $Na_2CO_3$ , dissolving in water, decomposing the  $Na_2WS_4$  thus produced by  $HClAq$ , washing the pp. completely out of contact with O, and drying at  $100^\circ$  (von Usler, A. 94, 256; Corleis, A. 232, 264). A black powder; slightly soluble in water, more soluble on boiling, probably with partial decomposition. Soluble in alkali sulphide solutions, forming thio-salts (v. Tungsten, thio-acids and salts of, *infra*). By adding to  $Na_2WS_4$  a little more  $HClAq$  than was needed to combine with the Na, Winsinger (Bt. [2] 49, 452) obtained a colloidal form of  $WS_3$ .

**Tungsten, sulpho-acids and salts of, v. next article.**

**Tungsten, thio-acids and salts of.** By saturating  $(NH_4)_2WO_4$  and  $K_2WO_4$  with  $H_2S$ , Berzelius obtained  $(NH_4)_2WS_4$  and  $K_2WS_4$  (P. 8, 267); these salts were more fully examined by Corleis (A. 232, 258), who also obtained  $Na_2WS_4$ , and also some thio-oxy-tungstates. All the thio-tungstates that have been isolated are ortho-salts, i.e. salts of  $H_2WS_4$ . Very dilute solutions of thiotungstates can be titrated by  $IAq$  in presence of  $KHCO_3$  (C, l.c.). **Ammonium thiotungstate**  $(NH_4)_2WS_4$ . Obtained by passing  $H_2S$  for four or five hours into a solution of 10 g.  $WO_3.H_2O$  in 100 c.c.  $NH_4Aq$  S.G. .94, +20 c.c. water, allowing to stand for some hours in a closed vessel, and washing the crystals that separate with alcohol and ether. Forms orange-yellow prisms, isomorphous with  $(NH_4)_2MoS_4$ ; very easily decomposed "in moist air"; easily soluble in water, slightly soluble in alcohol. Heated in  $CO_2$  gives  $WS_3$  (B, l.c.; C, l.c.).

**Ammonium dithio-oxy-tungstate**  $(NH_4)_2WS_5O_2$ . Obtained by passing  $H_2S$  into a solution of 10 g.  $WO_3.H_2O$  in 40 c.c.  $NH_4Aq$  S.G. .90, +10 c.c. water, until the liquid becomes turbid, and washing the crystals that form with alcohol and ether. Forms yellow, prismatic crystals. When dry, the salt is unchanged in air. Decomposed by re-crystallising from water, giving paratungstate  $(NH_4)_2W_2O_7.6H_2O$  (C, l.c.).

**Potassium thiotungstate**  $K_2WS_4$ . Obtained by warming  $(NH_4)_2WS_4$  with  $KHSO_4$ , adding alcohol, and crystallising from conc.  $KHSO_4$ . Forms yellow, prismatic needles; easily soluble in water. By continued boiling with  $KHSO_4$  paratungstate is formed,  $K_2W_2O_7.6H_2O$  (C, l.c.). Forms a double salt with  $KNO_3$ , with the composition  $K_2WS_4.KNO_3$  (B, l.c.).

**Potassium trithio-oxy-tungstate**  $K_2WS_5O_2.H_2O$ . Obtained in citron-yellow, quadratic tablets, by passing  $H_2S$  for three or four hours into a solution of 10 g.  $K_2WO_4$  in 10 c.c. water, and evaporating *in vacuo*, or precipitating by alcohol (C, l.c.).

**Potassium monothio-oxy-tungstate**  $K_2WSO_4.H_2O$ . Obtained, in almost colourless, very hygroscopic, crystalline masses, by passing  $H_2S$  into a solution of 10 g.  $K_2WO_4$  in 5 c.c. water until the liquid is turbid, filtering, adding 4 to 5 vols. alcohol, separating the under layer of liquid, allowing to crystallise, and washing with alcohol and ether (C, l.c.).

**Sodium thiotungstate**  $Na_2WS_4$ . Obtained,

but not pure, by Corleis (l.c.), by decomposing  $(NH_4)_2WS_4$  by  $NaHSO_4$ .

**Tungsten, thiocloride of.** By heating W to redness with  $S_2Cl_2$ , Smith a. Oberholtzer (Zeit. f. anorg. Chemie, 5, 63) obtained a red, crystalline sublimate, unstable in air, probably  $WS_2Cl_2$ . M. M. P. M.

**TUNGSTEN BRONZES** v. under TUNGSTEN OXYACIDS, p. 806.

**TUNGSTIC ACIDS** v. TUNGSTEN OXYACIDS, p. 802; also TUNGSTEN THIO-ACIDS, *supra*.

**TUNGSTOXYFLUORIDES** v. under TUNGSTEN FLUORIDES, p. 799.

**TUNGSTEN, ORGANIC COMPOUNDS OF.** Tungsten, heated with MeI at  $240^\circ$ , forms  $WMe_4$  [110°], which crystallises in tables, and is converted by  $Ag_2O$  into  $WMe_3O$ , which dissolves in acids (Litche, C. R. 42, 203; Cahours, A. 122, 70).

**TUNICIN** v. ANIMAL CELLULOSE, vol. i. p. 718.

**TURMERIC.** The root of *Amomum Curcuma*.

It contains curcumin (q. v.) and turmerol.

**TURMERIC ACID**  $C_{11}H_8O_6$  [35°]. A product of oxidation of turmerol by cold  $KMnO_4$  (Jackson a. Menke, Am. 6, 77). Needles, sl. sol. water, v. sol. alcohol. —  $CaA'$ , 3aq. S. (of  $CaA'$ ) 1:28 at  $16^\circ$ . White needles. —  $AgA'$ .

**TURMEROL**  $C_{10}H_{12}O$  (?). ( $193^\circ$ – $198^\circ$  at 60 mm.). S.G. 1.1902.  $[a]_D = 33.5^\circ$ . An oil occurring in turmeric. Distils with decomposition at  $285^\circ$ – $290^\circ$  (Jackson a. Menke, Am. 4, 368; G, 77). Dextrorotatory. Does not combine with  $NaHSO_4$ .  $KMnO_4$  oxidises it to acetic, terephthalic, turmeric, and apoturmeric acids.  $PCl_5$  forms  $C_{10}H_8Cl_2$ , which is also got by heating turmerol with conc.  $HClAq$  at  $150^\circ$ . Sodium forms  $C_{10}H_7ONa$ , whence isobutyl iodide forms oily  $C_{10}H_7OC_4H_9$ .

**Apoturmeric acid**  $C_8H_6(CO_2H)_2$  (?). [221°]. Woolly mass, sol. boiling water.

**TURPENTINE.** Semi-fluid resins exuding from coniferous trees. They consist of resin dissolved in oil of turpentine. On distillation oil of turpentine passes over and colophony remains behind. The various oils of turpentine are described under TERPENES. The chief constituent of colophony is abietic anhydride (v. ABETIC ACID and SYLVIC ACID). On oxidation by dilute  $HNO_3$  colophony yields isophthalic, trimesic, and terebic acids (Schreder, A. 172, 93). On the products of distillation of colophony v. RESINS.

**TURPETHIN**  $C_{14}H_{18}O_4$  [c.  $183^\circ$ ]. Occurs in the root of *Convolvulus Turpethum* (*Ipomoea Turpethum*) (Boutron-Charlard, J. Ph. 8, 131; Spirgatis, J. pr. 92, 97; A. 139, 41). Purgative yellowish-brown resin, v. sol. alcohol, insol. ether (difference from jalapin). Conc.  $H_2SO_4$  forms a red solution. Boiling alkalis convert it into turpethic acid. Boiling dilute mineral acids yield glucose (3 mols.) and turpetholic acid (1 mol.).

**Turpethic acid**  $C_{14}H_{18}O_6$ . Amorphous yellowish mass, v. sol. water. Split up by boiling  $HClAq$  into glucose and turpetholic acid. —  $BaA'$ . —  $BaHA'$  (dried at  $100^\circ$ ).

**Turpetholic acid**  $C_{14}H_{18}O_7$  [c.  $88^\circ$ ]. Mipute needles (from dilute alcohol), sl. sol. ether. —  $NaA'$  (dried at  $100^\circ$ ). —  $BaA'$ . Amorphous. —  $AgA'$ . Amorphous pp.

**Ethyl ether** EtA'. [78°]. Plates.

**TYLOPHORINE.** An alkaloid in *Tylophora zanthetica* (Hooper, *Ph.* [3] 21, 617). Crystalline, af. sol. water, sol. alcohol and ether.

**TYPE METAL.** An alloy of 15-20 parts Sb with c. 70 parts Pb, and 10 to 15 parts Sn; v. *LEAD ALLOYS*, vol. iii. p. 124.

**TYPES.** The object of classification is to put together like things, and to put apart things that are unlike. A perfect system of chemical classification would place side by side those elements and compounds that are chemically similar, and it would also indicate the relations that exist between all the elements and all the compounds. Inasmuch as the object of chemistry is the study of the connections between composition and properties, and between changes of composition and changes of properties, a complete scheme of chemical classification must indicate the relations of the substances classified, both as regards composition and also as regards properties. To connect composition with properties necessitates a thorough knowledge of both, and this knowledge can be gained only by comparing one substance with other substances. But, because of the large amount of detailed investigation that is required before the chemical properties of an element or a compound are known, chemists have often forgotten the larger issues of their labours, and have busied themselves rather with the examination of individual bodies than with the comparative study of many bodies. And, because of the imperfection of chemical knowledge at any time, those who have attempted the classification of chemical substances have generally paid chief attention either to the composition or to the properties of the substances to be classified. Hence systems of classification have sometimes prevailed that were founded chiefly on similarities of composition, and at other times classificatory schemes have been in vogue that rested mainly on similarities of properties. But there has always been a desire, and generally an effort, to classify on the bases of composition and properties. To classify satisfactorily demands the recognition of a simple class-mark, which shall also be clear, definable, and invariably applicable. It is probably correct to say that none of the larger classes of chemical compounds has a class-mark of this description. Hence the main difficulty in chemical classification. Take, for instance, the great class of acids. What is the class-mark? What must be known about the composition of a compound before it is put into the class of acids? There is no single and sufficient class-mark to be gained by studying the compositions of acids. What, then, about the properties of acids? Here, too, no simple, definable, and applicable property has been found which serves to distinguish acids from all other compounds. Acids, it is usually said, are compounds containing *replaceable hydrogen*. But the expression *replaceable hydrogen* has not been, and cannot be, exactly defined. Hence, all that can be done is to set up an ideal or typical acid, and to place in the class *acids* those compounds which fairly closely approach this type as regards both properties and composition. And as with acids so with other classes of compounds. A classification by means of types becomes inevitable in such a science as chemistry,

but a typical classification cannot be final in any exact science.

Lavoisier's system of classification rested on oxygen; compounds were regarded as formed by the union of oxygen with other elements or groups of elements; the non-oxygenated part of a compound was called by Lavoisier the *rest* or *radicle*; compounds of oxygen with certain radicles were bases, compounds with other radicles were acids, and salts were formed by the union of bases with acids. Lavoisier used the term *radicle* to include elements and groups of elements.

"J'ai déjà fait observer, que dans le règne minéral presque tous les radicaux oxydables et acidifiables étaient simples; que dans le règne végétal au contraire, et surtout dans le règne animal, il n'en existait presque pas qui ne fussent composés au moins de deux substances, d'hydrogène et de carbone; que souvent l'azote et le phosphore s'y réunissaient, et qu'il en résultait des radicaux à quatre bases."—*Traité élémentaire de Chimie*, [1793], p. 251.

About twenty-four years after Lavoisier made this statement Berzelius repeated it.

"Nachdem wir den Unterschied zwischen den Producten der organischen und der anorganischen Natur, und die verschiedene Art und Weise wie ihre entfernteren Bestandtheile untereinander verbunden sind, näher kennen gelernt, haben wir gefunden, dass dieser Unterschied eigentlich darin besteht, dass in der anorganischen Natur alle oxidierten Körper aus einfachem Radical haben, während hingegen alle organischen Substanzen aus Oxyden mit zusammengesetzten Radical bestehen."—*Lehrbuch der Chemie*, 2. Aufl. (Stockholm, 1817), vol. I. p. 544.

Why do acids and bases unite to form salts? What is the cause of the formation of compounds by the union of radicles, either simple or compound? These questions were answered by Berzelius by appealing to the fact that the electric current very often resolves compounds into two parts, and in many cases also effects the combination of elements or groups of elements. Radicles combine, said Berzelius, because the negative electricity on one is thereby neutralised by the positive electricity on the other. Thus arose the electro-chemical conception of dualism (v. *DUALISM*, vol. ii. p. 416; cf. *RADICALS*, vol. iv. p. 323).

In 1832 Liebig and Wöhler made an exhaustive study of compounds obtained from bitter-almond oil; they showed that the relations of composition and properties of these compounds were brought together, and expressed in a consistent conception by supposing that all the compounds contained a radicle having the composition  $C_{11}H_9O$  ( $C = 12$ ,  $O = 16$ ); this group of elements, common to all the derivatives of bitter-almond oil, they called *benzoyl*. The work of Liebig and Wöhler marked a great advance in chemical classification; it was the actual working out of the connections between composition and properties of a number of compounds, and the expression of these connections in clear and definite language. The term *radicle* became henceforth the expression of a vivifying conception. The compounds derived from bitter-almond oil had certain common properties, and they had also a common composition; they belonged to the same type. The compounds of benzoyl examined by Liebig and Wöhler included such compounds as these:  $C_6H_5.OH$ ,  $C_6H_5.O.H$ ,  $C_6H_5.O.Cl$ ,  $C_6H_5.O.N$ ,  $C_6H_5.O.NO$ . The radicle  $C_{11}H_9O$  is common to all; this radicle is united with  $H$ ,  $Cl$ ,  $NO$ ,  $CN$ , or some other radicle, in the different compounds; nevertheless

less, the properties of the compounds are so similar that all are said to belong to one type. To what extent, then, it was asked, may the properties of one radicle differ from those of another before the replacement of one of these by the other carries with it a change of type? The answer generally given to this question was: If the replacing radicle is chemically similar to the radicle replaced the type will not be destroyed. In 1834 Dumas, from the study of the action of chlorine on various organic compounds, announced the *empirical laws of substitution* as follows: (1) When a compound containing hydrogen is subjected to the dehydrogenating action of chlorine, bromine, iodine, oxygen, &c., one atom of chlorine, bromine, iodine, or oxygen, is taken up for each atom of hydrogen lost by the compound. (2) The same rule applies, without modifications, when the compound contains oxygen. (3) If a hydrogenised compound contains water the hydrogen of the water is given up without replacement, and then another quantity of hydrogen is absorbed, so that the final result is a replacement of hydrogen. A year or so later Laurent propounded a *theory of substitution*, which asserted that when equivalent substitution of hydrogen by chlorine or bromine occurs the chlorine or bromine takes the place of the hydrogen, and to a certain extent plays the same part as the hydrogen, and hence the chlorinated or brominated product must be similar to the compound from which it has been prepared. Laurent's views were much opposed, for a time by Dumas himself; but they gradually prevailed, and chemists became familiarised with the notion of the replacement of such a decidedly electro-positive element as hydrogen by an element so decidedly electro-negative as chlorine, resulting in the production of a compound of the same chemical type as the original substance.

About 1839 Dumas sought to distinguish mechanical types from chemical types. Compounds formed one from the other by the replacement of a certain number of equivalents of one radicle by the same number of equivalents of another radicle, and having their radicles similarly combined, and exhibiting similar properties, were said to belong to the same *chemical type*. Compounds were said to belong to the same *mechanical type* when they were composed of equal numbers of equivalents of radicles, but differed essentially in their properties. Dumas at this time regarded the properties of compounds as conditioned more by the arrangement than by the nature of their parts. He compared compounds to planetary systems, the planets being represented by the atoms of the compounds. One atom, he said, might be replaced by another atom, or an atom by a group of atoms, without destroying the system; if the number of replacing atoms, or radicles, were the same as the number of atoms, or radicles, replaced, and the relative arrangement of all the atoms or radicles were not altered, the compounds belonged to the same type. By some such development as this the theory of types came to include the older theory of radicles.

It is evident that the terms used by Dumas and others to express the conceptions of the theory of types are vague and incapable of

exact definition. The expression 'equivalent radicles' cannot be defined, nor can an exact and invariable connotation be given to the expressions 'radicles similarly combined' and 'compounds having similar properties.' But if it had been possible to classify chemical substances in an ideally perfect way the theory of types would not have arisen. If there is to be a typical classification the language whereby this classification is expressed must be more or less vague. Whether a compound formed from another by replacing equivalents of one kind by an equal number of equivalents of another kind does or does not belong to the same type as the parent compound can be determined only by a careful study of the properties of both compounds and by a comparison of the compounds one with another. The application of the theory of types was possible only when the properties and the compositions of compounds were exhaustively compared. The theory of types produced much fruit, because it suggested and demanded much inquiry into the fundamental problem of chemistry.

In 1849 Wurtz prepared two compounds which resembled ammonia in their prominent characters. These compounds were found to have the compositions  $C_2H_5N$  and  $C_4H_9N$  respectively ( $C=6$ ). The similarities between the properties of these compounds and ammonia led Wurtz to regard them as *substituted ammonias*, and to express this conception by the formulæ  $C_2H_5.NH_2$  and  $C_4H_9.NH_2$ . One method by which these compounds were prepared consisted in treating methyl and ethyl bromides ( $C_2H_5Br$  and  $C_4H_9Br$ ;  $C=6$ ) with ammonia, and then decomposing the products by potash. These reactions suggested the view that the new compounds were derived from methylic and ethylic ethers ( $C_2H_5O$  and  $C_4H_9O$ , according to the notation then used) by substituting  $NH_2$  for  $O$ . Both views agreed in representing the new compounds as  $C_2H_5.NH_2$  and  $C_4H_9.NH_2$  respectively. But the properties of the compounds resembled those of ammonia; hence the view that Wurtz's compounds were derived from ammonia prevailed. This view was expressed by saying that these compounds belonged to the ammonia type, and by comparing the formula of the typical compound with the formulae of the compounds formed after that exemplar; thus:

Type:	Derivatives:
Ammonia $NH_3.H$	Methylamine $NH_2.C_2H_5$
	Ethylamine $NH_2.C_4H_9$

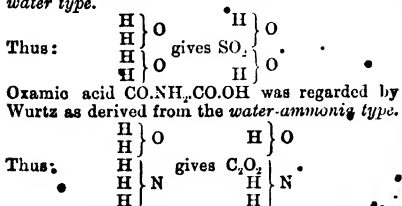

Very soon after Wurtz's preparation of methylamine and ethylamine Hofmann argued that it should be possible to substitute each of the three atoms of hydrogen in  $NH_3$  by the radicles  $C_2H_5$  and  $C_4H_9$ , and so to obtain the compounds  $NH(C_2H_5)_3$ ,  $N(C_2H_5)_2$ ,  $NH(C_4H_9)_3$ , and  $N(C_4H_9)_2$  ( $C=6$ ), all which compounds ought to resemble ammonia in their properties. Hofmann fulfilled his own prophecy by preparing di- and tri-methylamine and di- and tri-ethylamine; and, basing his methods on the conception of the ammonia type, he prepared a large series of ammonia-like compounds derived from  $NH_3$ ,  $2NH_3$ , &c., by substituting for  $H$  various radicles composed of carbon and hydrogen. The ammonia type was thus established.

About the year 1850 Williamson studied the relations of ether to alcohol. The formula of ether was then written  $C_2H_5O$  ( $C=6, O=8$ ), and that of alcohol  $C_2H_5O_2$ . Williamson heated potassium alcoholate ( $C_2H_5KO_2$ ) with ethylic iodide ( $C_2H_5I$ ), expecting to obtain ethylated alcohol ( $C_4H_9(C_2H_5O)_2$ ); but he obtained common ether. Williamson suggested that the formula then accepted for ether should be doubled, and written  $(C_2H_5)_2O_2$ . He also found that by heating common alcohol with sulphuric acid, and adding methylic alcohol to the hot mixture, an ether-like compound was obtained, the simplest formula of which was  $C_3H_8O$  ( $C=6, O=8$ ). Williamson argued that if common ether is  $C_2H_5O$ , then the ether of methylic alcohol must be  $C_3H_8O$ , and that, in the reaction of sulphuric acid with ethylic and methylic alcohols simultaneously, a mixture of these two ethers might be expected to be produced. To account for the facts he had observed Williamson proposed to double the formulae of the two ethers and to write them  $(C_2H_5)_2O_2$  and  $(C_3H_8)_2O_2$ ; and for the formula of the ether formed by the action of sulphuric acid on the two alcohols simultaneously he proposed the formula  $C_4H_{10}(C_2H_5O)_2$  [ $=2C_3H_8O$ ]. Williamson compared the relations between the alcohols and ethers with the relations between water, potash, and potassium oxide. These relations are made clearer if the formulae are expressed in terms of the atomic weights  $C=12$  and  $O=16$ ; thus:

Type:	Derivatives:
Water $H.H.O$	Alcohol $C_2H_5.H.O$
	Ether $C_2H_5.C_2H_5.O$
	Potash $K.H.O$
	Potassium oxide $K.K.O$ .

Thus arose the *water type*. To this were referred such compounds as acetic acid  $C_2H_3O_2.H.O$ , anhydrous acetic acid  $C_2H_3O_2.C_2H_3O_2$ , and many others.

Gradually the greater number of compounds, both organic and inorganic, came to be referred to four fundamental types—the *hydrochloric acid type*  $HCl$ , the *water type*  $HHO$ , the *ammonia type*  $NHHH$ , and the *marsh gas type*  $CHHHH$ . To these were added so-called *condensed types* and *mixed types*; sulphuric acid, for instance,  $SO_2.OH.OH$ , was said to belong to the *double water type*.

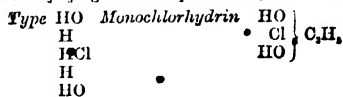

The great danger attending the development of the theory of types was, that careful investigations into the reactions of compounds might easily be abandoned in favour of a superficial examination of a compound, followed by a relegation of it to this or that type. The theory began by being very vague and elastic; the adoption of a few definite types rendered it more exact; but the temptation to manipulate for-

mulae on paper, and to invent condensed types and mixed types, gradually led chemists to see that the theory had done its work, and that it must give place to wider views, which should also be more accurate, regarding the connections between composition and properties.

The conception of types carried with it, from the first, more or less vague notions regarding the arrangements of the atoms in those collocations of atoms that form the reacting units of compounds; at any rate, this conception was bound up with the general conception of atomic arrangement. The reacting units of compounds that showed similar properties were thought of as composed of atoms similarly arranged. Moreover, the type was said to be maintained when an atom, or a group of atoms, in the parent compound was replaced by an equivalent number of atoms, or groups of atoms. These two conceptions, that of equivalency, and that of atomic arrangement, led gradually to the representation of the reacting unit, or molecule, of a compound as a definitely arranged group of atoms held together by actions and reactions between individual atoms; these conceptions led to the wider conception of valency, and to a system of classification based on the notion that each kind of atom is capable of directly combining with a limited, and determinable, number of other atoms. The formula given to chlorosulphonic acid, with the object of connecting the composition with the properties of this compound, and of suggesting relations between this and other compounds, may be taken as an example of the merging of the notion of types into that of valency. This acid was regarded as derived both from water and hydrochloric acid; it was supposed to belong to the mixed *water-hydrochloric acid type*. Hence the formula,  $ClSO_2H$ , was written thus:—

The radicle  $SO_2$  was regarded as equivalent to  $2H$ ; and it was said that the residues of the two parts of the mixed type, i.e.  $Cl$  and  $OH$ , were bound together by the radicle  $SO_2$ . Again, monochlorhydrin,  $C_2H_4ClO$ , was regarded as a derivative of the triple type  $HHO.HCl.HHO$ , and was said to be formed by the binding together of the three residues  $OH$ ,  $Cl$ ,  $OH$  by the radicle  $C_2H_4$ , regarded as equivalent to  $3H$ . Thus:—

The most of the conceptions underlying these formulae, and formulae like these, were expressed in the language of atoms and molecules, the notion of atomic valencies was gained. The group of atoms  $SO_2$  replaces two atoms of hydrogen, one atom in the molecule  $HCl$  and one atom in the molecule  $HHO$ ; and as the atomic group  $SO_2$  is capable of directly combining with two atoms of hydrogen, or such a number of atoms as is equivalent to two atoms of hydrogen, this group binds together the atom  $Cl$  and the atomic group  $OH$ , and so the new molecule

$\text{SO}_3\text{OH.Cl}$  is produced. This statement contains the fundamental conception of atomic valency; it also contains the conception of types, and that of radicles.

The radicles were compared as regards their equivalency, generally in terms of hydrogen; then the elementary atoms were compared, and arranged in classes, such that all in one class were exchangeable, any number of one kind for the same number of another kind.

When the atoms had been classified in accordance with the number of atoms of hydrogen, or atoms equivalent thereto, with which each was capable of combining, the foundations had been laid of a system of classification which was more accurate than that based on the notion of types, and which at the same time included the essential characters of the typical system. The article CLASSIFICATION in the first edition of this *Dictionary* represents the stage which had then (1863) been reached in the process of fusion of the theories of radicles, types, and valency. The system of classification developed in that article is based (1) on the compositions of compounds interpreted by help of the theory of valency, and (2) on the properties of the compounds interpreted by the help of the theory of types; the study of the properties of a compound is used to determine the radicles that the compound contains, and a knowledge of the valencies of these radicles determines the form of the compound, and, taken along with the reactions of the compound, the type to which it is to be referred.

Although the introduction of the principle of atomic equivalency widened the conception of chemical types, it also tended towards a method of classification which was based on too slight a study of the bodies to be classified. A superficial examination of a compound generally sufficed to bring out some similarities between it and a well-known typical substance; the new compound was at once referred to its type; the form of the type determined the form of the compound under examination; it was then only necessary to manipulate the empirical formula by arranging the elements in groups, or radicles, and to assign to each radicle such a valency as satisfied the general rules that had been deduced from the study of a few typical compounds. The conception of types became very mechanical in its applications, so mechanical indeed that it was in danger of becoming metaphysical. New radicles were easily invented, and their valencies were deduced by *a priori* arguments. Kekulé recalled chemists to the study of properties by insisting that the properties of a compound are conditioned by the properties of the atoms which compose the molecule of the compound; and at a later date Mendeléeff made the same demand by asserting that the properties and the compositions of all compounds are periodic functions of the atomic weights of the elements.

The notion of types plays an important part in the classification of elements and compounds that has arisen from the practical examination of the meaning of Mendeléeff's periodic law. The periodic classification of the elements lays considerable stress on the study of the typical oxides, hydrides, hydroxides, &c., of each group of elements; for instance, the highest salt-forming oxide of Group I. belongs to the type  $\text{R}_2\text{O}$ ,

that of Group II. to the type  $\text{R}_2\text{O}_3$ , and so on. But the word *type* is not used here with quite the same connotation as was given to it by the theory of types. All that is implied in statements such as those just made is, that the elements of Group I. combine with oxygen in the ratio of two atoms of element to a single atom of oxygen, that these oxides are salt-forming, and that they are characteristic of the elements of this group. The typical oxide-form of each group expresses the composition of that oxide which contains the greatest number of atoms of oxygen relatively to one atom of the group-element, and which oxide reacts either with acids or with alkalis to form corresponding salts. The oxides that belong to the typical oxide-form of a group may be acidic or basic, or some of them may be acidic and some basic; all that is asserted of their properties is that they are salt-forming. The properties of the typical oxide of any individual element are conditioned by the general character of the group, and the general character of the series, wherein the element is placed; by the special character of the element itself; and by the position of the element in the whole periodic system of classification. The term *type* is used in the nomenclature arising from the comparative study of the elements and compounds based on the periodic law with a wider, and at the same time a more exact, meaning than that which was given to it when the notion of types was made the basis of chemical classification. In the older classification the conception of types was the basis of the system; the conception was of necessity vague, and hence it was necessary sometimes to widen, and sometimes to narrow, the application of the conception. The modern system of classification is based on the relative weights of the atoms of the elements, and the conception of types plays a subsidiary part; the form of the typical oxide, or hydroxide, or other compound, is determined, as the compositions of all the compounds are determined, by the relative masses of the atoms of the elements; and the general character of the typical oxide, hydroxide, &c., of each group is determined, as the special character of each compound of each element is determined, also by the relative masses of the atoms of the elements.

The periodic classification of the elements and compounds makes use of the notion of types in another way, by applying the conception to certain elements. The elements placed in series 1 and 2, viz. H, Li, Be, B, C, N, O, and F, exhibit almost the whole range of properties of all the elements. The properties of the succeeding elements may almost be said to be but variations on the theme announced in the change from hydrogen to fluorine. These eight elements are types of all the others. In a somewhat narrower sense the element lithium summarises the range of properties shown in Group I.; beryllium summarises the range of properties shown in Group II.; boron, the properties of Group III.; carbon, the properties of Group IV.; nitrogen, the properties of Group V.; oxygen, the properties of Group VI.; and fluorine, the properties of Group VII. Each of the seven elements is the typical element of its group. Objections have been raised to this use of the term *typical*, on the ground that each

of the elements in question differs more from any member of its group than any other two members of the group differ from one another. But if an element is to summarise the properties of some ten or eleven other elements, it must differ considerably from each of these, while at the same time it resembles them all. The question of typical elements, and also that of typical oxide-forms, &c., are discussed in the article PERIODIC LAW (vol. iii. p. 806); that article should be consulted.

The older classification by types prepared the way for the wider conception of valency, which took up and utilised the permanent features of the typical arrangements of elements and compounds. The study of valency led chemists to see the importance of examining the properties of the atoms of the elements, and thus made them ready to accept the more elastic, and more exact, generalisation of the periodic law. The theory of types developed into the theory of valency, and the theory of valency has been included in the theory of the periodicity of the connection between the atomic weights of the elements and the compositions and properties of the compounds of the elements. The general conception of types remains; we are still obliged to picture to ourselves a typical acid, a typical base, a typical salt, a typical alcohol, a typical amide, and so on. But this conception is no longer the basis of chemical classification. We have gone deeper down, and laid the foundations of our system on the firmer basis of the atomic weights of the elements. M. M. P. M.

**TYPHOTOXINE**  $C_8H_9NO_2$ . An alkaloid obtained from pure cultures of the typhogen bacillus (Gautier, *Bl.* [2] 48, 13).

**TYROSINE**  $C_9H_9NO_3$ , i.e.  $C_6H_5(OH).CH_2.CH(NH_2).CO_2H$ . *p*-Oxy- $\alpha$ -amido-phenyl-propionic acid. Mol. w. 181. [235°]. S.G. 1.456 (Siber, *B.* 17, 2837). S. 0.4 at 20°; 65 at 100°. S. (90 p.c. alcohol) 0.074 in the cold. H.F. 150,400. H.C.v. 1,070,800. H.C.p. 1,071,200 (Berthelot, A. André, *Bl.* [3] 4, 227).  $[\alpha]_D^{20} = -8^\circ$  in HClAq at 16°;  $-9^\circ$  in KOHAq at 20° (Mauthner, *M.* 3, 843).

**Occurrence.**—Occurs abnormally in the liver and urine (e.g. in cases of poisoning by phosphorus (Frerichs, A. Städel, *J.* 1855, 723; 1856, 702; Blundermann, *H.* 6, 242), in the cutaneous scales in pellagra (Schmetzer, *Dissert.*, Erlangen, 1862), in cochineal (De la Rue, *A.* 64, 35), in sprouting pumpkin seeds (Schulze, *J.* pr. 57, 162; in dahlia bulbs (Leitgeb, *C. O.* 1888, 1397), in alcoholic extract of woad leaves (Sehunc, *C. N.* 37, 223), and in beetroot molasses (Lippmann, *B.* 17, 2835).

**Formation.**—1. By potash fusion from casein (Liebig, *A.* 57, 127; 62, 269), globulin, feathers, hairs (Ley, A. Köller, A. 83, 332), and albumen (Nenoki, *J.* pr. [2] 17, 97).—2. By the action of boiling dilute  $H_2SO_4$  on ox-horn (Hinterberger, *A.* 71, 72), on fibrin (Städel, *A.* 111, 12; 116, 57), and on silk (Weyl, *B.* 21, 1529).—3. By putrefaction of yeast (A. Müller, *J.* pr. 57, 162; Béchamp, *C. R.* 74, 115, 184), albumen and gelatin (Jeanneret, *J.* pr. [2] 15, 353).—4. In small quantity by heating conglutin with HClAq (Siegfried, *B.* 24, 419).—5. From  $\gamma$ -amido-

phenyl-alanine and  $HNO_3$  (Friedländer, A. Mahly, *B.* 16, 854; Erlenmeyer, A. Lipp, *A.* 219, 161).

**Properties.**—Stellate groups of slender silky needles (from water), insol. alcohol and ether, insol.  $NH_4Aq$  and KOHAq. Levorotatory. Its solution is not pptd. by lead acetate or subacetate until  $NH_4Aq$  is added. Boiling  $Hg(NO_3)_2$ , containing  $HNO_3$ , turns its solution red, forming a brownish-red pp. (R. Hoffmann, *A.* 87, 123; L. Meyer, *A.* 132, 156). After warming with conc.  $H_2SO_4$ , diluting with water, and neutralising with  $BaCO_3$ , the solution is turned violet by  $FeCl_3$ . Tyrosine gives off less  $N_2$  when its solutions are decomposed by  $NaOH$  and  $H_2$  in presence of  $NH_3$  than when the  $NH_3$  is absent.

**Reactions.**—1. At 270° it splits up into  $CO_2$  and  $C_6H_5(OH).CH_2.CH_2.NH_2$  (Schmitt, A. Nasse, *A.* 133, 211).—2. Potash-fusion forms *p*-oxybenzoic and acetic acids (Barth, *A.* 136, 110; Ost, *J.* pr. [2] 12, 159; Baumann, *IL.* 4, 804). 3.  $KClO_4$  and  $HClAq$  form tetra-chloroquinone.—4. By putrefactive fermentation it is converted into hydro-*p*-coumaric acid, and finally into *p*-cresol and phenol (Weyl, *B.* 12, 1450).—5.  $HIAq$  and  $P$  at 150° from  $NH_3$  and *p*-oxy-phenyl-propionic acid (Häfner, *Z.* [2] 4, 391; 6, 113). Conc.  $HClAq$  and  $HBrAq$  at 240° have no action.—6. Conc.  $H_2SO_4$  (4 pts.) at 100° forms crystalline  $C_9H_9(SO_3H)NO_3$ , v. sl. sol. cold water, which also occurs in a hydrated amorphous form (containing 2aq).  $H_2$  yields  $(NH_4)H_2A^+aq$ ,  $Ba(H_2A^+)aq$ , and  $Ca(H_2A^+)aq$  (Städeler, *A.* 116, 57).  $BaC_2H_4NO_3aq$  is obtained from the product of the action of  $H_2SO_4$  (10 pts.) on tyrosine (1 pt.).—7.  $MeOH$ , potash, and  $MeI$  yield crystalline  $C_9H_9NIO_3K$ , sol. water, decomposed by warm KOHAq into  $NMe$ , and the methyl derivative of *p*-coumaric acid (Körner, A. Menozzi, *G.* 11, 550).—8. Potassium cyanate added to boiling water containing tyrosine forms tyrosine-hydantoic acid  $C_9H_9(OH).CH_2.CH(NH.CO.NH_2).CO_2H$ , crystallising from water in needles, insol. ether (Jaffé, *H.* 7, 310). This body begins to melt at 152°, being decomposed above 170°. It gives a red colour and pp. on warming with Millon's reagent. It forms  $KA^+aq$ , crystallising from alcohol-benzene.—9. Tyrosine administered to a dog appears in the urine as tyrosine-hydantoic  $C_9H_9(OH).CH_2.CH(NH.CO.NH_2).CO.NH$  [275°-280°], which crystallises from water in needles, and is decomposed by heating in sealed tubes with baryta-water into  $CO_2$ , ammonia and tyrosine. Other products found in the urine of a rabbit after a dose of tyrosine are hydro-*p*-coumaric and *p*-oxy-phenyl-acetic acids and phenols (Blundermann, *H.* 6, 251).

**Salts.**— $Na_2C_9H_9NO_3$ .— $CaC_9H_9NO_3$ .— $BaC_9H_9NO_3$  2aq. Prisms, more sol. cold than hot water.— $Cu(C_9H_9NO_3)_2$ . S. 0.98 in the cold; 4 at 100°. Got by adding  $Cu(OH)_2$  to a boiling solution of tyrosine (Hofmeister, *A.* 189, 6). Insol. alcohol. Deposits black cupric oxide on boiling with water.— $C_9H_9NO_3(HgO)_2$  2aq.— $C_9H_9NO_3(HgO)_2$  aq.— $C_9H_9NO_3(HgO)_2$  aq (Vintschgau, *J.* 1869, 985).— $AgC_9H_9NO_3$  aq; amorphous pp.— $AgO_2H_9NO_3$  2aq; crystalline powder.— $B^+HCl$  2aq; needles, decomposed by water.— $B^+H_2P_2Cl_4$  (Gintl, *Z.* [2] 5, 704).— $B^+H_2SO_4$ . Slender needles, not coloured by  $FeCl_3$ .

**Di-bromo-tyrosine**  $C_6H_4Br_2NO_2$ , 2aq. S. 46 at 16°; 4 at 100°. Formed from dry tyrosine and Br vapour (Gorup-Besanez, A. 125, 281). Needles or tables (from water), sl. sol. alcohol.  $Ag_2C_6H_4Br_2NO_2$ , 2aq. —  $B'HCl$  1½aq. —  $B'HB$ . —  $B'_2H_2SO_4$ . Prisms, sol. water and alcohol.

**Nitro-tyrosine**  $C_6H_4N_2O_5$ , i.e.  $C_6H_4(NO_2)NO_2$ . Formed from tyrosine (1 pt.), water (4 pts.), and nitric acid (4 pts. of S.G. 1.3) in the cold (Strecker, A. 73, 70; Städeler, A. 116, 77). Pale-yellow needles, sl. sol. cold water. — Salts:  $Ba(C_6H_4N_2O_5)_2$  (dried at 100°). Blood-red amorphous mass. —  $Ag_2C_6H_4N_2O_5$ , aq. orange pp. changing to a red powder. —  $B'HCl$  ½aq. Tufts of lemon-yellow needles. —  $B'ONO$ . S. 20.

**Lemon-yellow needles.** —  $B'_2H_2SO_4$ . Yellow needles or granules.

**Di-nitro-tyrosine**  $C_6H_2(NO_2)_2NO_2$ , [115°]. Formed by warming nitro-tyrosine with dilute  $HNO_3$ . Golden plates (from water). — Salts:  $CaC_6H_2N_3O_7$ , 3aq. Golden six-sided tables. —  $BaC_6H_2N_3O_7$ , 2aq. Ruby-red prisms with yellow reflex, exploding when heated.

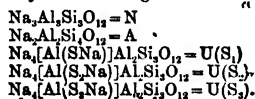

**Reference.** — AMIDO-TYROSINE.

**TYROTOXICON.** A poisonous substance formed in milk, containing the butyric acid ferment, which has stood for some days. Occurs also sometimes in cheese (Vaughan, Ph. [3] 18, 479; H. 10, 146). When its alcoholic solution is mixed with  $PtCl_4$  and evaporated violent explosion takes place.

## U

**ULEXINE**  $C_{22}H_{21}N_3O_5$ , [151°]. An alkaloid in the seeds of common furze (*Ulex europaeus*) (Gerrard & Symons, Ph. [3] 17, 104, 229; 19, 1029; 20, 978, 1017). Deliquescent crystals, v. sol. chloroform, insol. ether. Poison, paralyzing respiration (Bradford, J. Physiol. 8, 79). Possibly identical with uytisine. —  $B'HCl$ . Deliquescent. —  $B'H_2PtCl_6$ . —  $B'2HAuCl_4$ .

**ULTRAMARINE.** The blue-coloured material contained in *lapis-lazuli*. Until 1828 ultramarine was obtained by powdering and washing *lapis-lazuli*; but since that year it has been manufactured by heating to bright redness mixtures of Al silicate (*china clay*),  $Na_2CO_3$  (carbonated soda ash), S, and charcoal, and washing, powdering, drying, and sifting the product. (For details of the manufacture v. DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 891.) The constituent elements of ultramarine are Al, Na, Si, S, and O. Treated with  $HCl$  aq, ultramarine gives off  $H_2S$ ; the solution contains  $NaCl$ ,  $AlCl_3$ , and  $SiO_2$ , and the residue consists of  $SiO_2$ , S, and some  $Al_2O_3$ ; these reactions point to ultramarine being a compound of silicates and polysulphides. Much work has been done on the constitution of ultramarine, but the results obtained have not finally settled the question. From analyses and investigations made in 1891, Brögger & Bäckström (W. J. 1891. 454) conclude that the composition of the essential colouring compound in natural ultramarine is represented by the formula  $Na_4[Al(S,Na)]_3Al_3(SiO_3)_6$ . They also conclude that artificial ultramarines may be expressed by the following formulae:—

The main constituents of the different varieties of blue ultramarine are N, A, and  $U(S_1)$ ; of green ultramarine  $U(S_2)$  and N; and  $U(S_1)$  is the main constituent of white ultramarine, according to B. A. B. Formulae more or less approaching those given above have been assigned to ultramarine by other observers; thus Silber in 1880 represented blue ultramarine as  $Si_3Al_3Na_4S_3O_{12}$  (B. 13, 1854). On the other hand,

some chemists have regarded the essential constituent of ultramarine as a sodium thiosilicate; for instance, Rieckmann (B. 11, 2013 [1878]) gives  $Na_4Si_3(ONa)_6$  as the composition of 'ideal ultramarine blue'; and he regards artificial ultramarine as a mixture, the only essential part of which is sodium thiosilicate. Clarke (Am. 10, 126) suggested a formula for ultramarine which should indicate the relations of this body to various natural silicates; in this respect Clarke's formula is important (v. this vol. p. 451).

**White ultramarine** is obtained by completely cutting off air during the roasting of the materials; it is changed to blue by heating in  $O$ ,  $SO_2$ , or  $Cl$  (v. Ritter, W. J. 1160. 226; cf. Philipp, B. 9, 1109; 10, 1227; Böttlinger, A. 182, 311; R. Hoffmann, A. 194, 1).

**Red ultramarine** was observed by Scheffer, in 1873, to be formed in preparing the ordinary substance in a muffle furnace very strongly heated and freely exposed to the air; it contains less Na and more Al than the blue variety (B. 6, 1450; v. also Bächner, D. P. J. 231, 446; Zettner, B. 8, 259, 353).

**Yellow ultramarine** is formed by heating the red variety in the air a little above 360°, for a short time (R. Hoffmann, A. 194, 1). According to Büchner (B. 7, 990), both the yellow and red forms are produced by heating blue ultramarine to 300°–400° in  $O$  or  $SO_2$ ; the colour changes to red and then to yellow. If  $Cl$  is passed over ultramarine before the formation of the blue variety is completed, at 410°, the colour goes green, and then reddish-yellow (Zettner, B. 8, 259, 353); by heating the product with alkali, all  $Cl$  is removed and a **violet ultramarine** is produced. This variety goes to the red form when heated in vapour of  $HNO_3$  or  $HCl$  at 130°–150° (Zettner, l.c.).

**Green ultramarine** is formed when a little  $SiO_2$  is used in the roasting process; it is converted into the blue substance by roasting with S. This form seems to be intermediate between white and blue ultramarine. According to Philipp (B. 9, 1109), S is not taken up in the change from green to blue; by heating the green form in sealed tubes with water, at 100°, he obtained the blue, the water removing a very small quantity of sodium compounds.

**Substituted ultramarines.** Blue to green, and reddish-grey, substances have been formed by heating ultramarine with  $\text{AgNO}_3$  aq. and by treating the product of this reaction with  $\text{KI}$ ,  $\text{LiI}$ ,  $\text{BaI}_2$ ,  $\text{ZnI}_2$ , &c. These substances, known as *silver ultramarine*, *potassium ultramarine*, &c., probably contain Ag, K, Li, Ba, &c., in place of Na (v. Unger, *D. P.* 212, 224, 301; Philipp, *B.* 10, 1227; Heumann, *A.* 199, 253; 201, 262; Forcrand a. Ballin, *Bl.* [2] 30, 112). By heating silver ultramarine with various alcoholic iodides, Forcrand (*C. R.* 88, 30) obtained ultramarines containing alcoholic radicles, such as *ethyl ultramarine*, *amyl ultramarine*, &c. *Selenion* and *tellurium ultramarines* have also been produced, wherein S is substituted by Se or Te (v. Leykauf, *W. J.* 1876, 555; Guimet, *A. Ch.* [5] 13, 102; Plicque, *Bl.* [2] 28, 518; Morel, *Bl.* [2] 28, 522). Various substituted ultramarines have been examined by Wunder (*Chem. Zeit.* 1890, 1119). M. M. P. M.

**ULMIC ACID.**  $\text{C}_6\text{H}_4\text{O}_2$ ;  $\text{H}$  4.6-4.5;  $\text{O}$  29.31-5.  $\text{C}_6\text{H}_4\text{O}_2$  or  $\text{C}_{10}\text{H}_8\text{O}_2$ . H.C. 1983, 200. H.F. 266, 200. Formed by action of  $\text{HCl}$  on cane sugar. Is an anhydride or mixture of anhydrides  $\text{C}_6\text{H}_4\text{O}_2$  (humic anhydride) (Berthelot a. André, *Bl.* [3] 7, 441, 451). Turns yellow in air and sunlight, giving off  $\text{CO}_2$ . The same thing happens with the humic acid extracted from vegetable mould by  $\text{KOH}$  aq. and  $\text{ppd}$ . by  $\text{HCl}$ . Dilute alkalis cause it to swell up, forming insoluble salts and a small quantity of a soluble basic salt. When conc.  $\text{KOH}$  aq. is used a salt is formed, from which two-thirds of the alkali can be removed by washing, leaving  $\text{KC}_6\text{H}_4\text{O}_2$  aq. and as reconverted into the acid,  $\text{C}_6\text{H}_4\text{O}_2$ , by  $\text{HCl}$  aq. Ammonia converts humic anhydride (ulmic acid) into an amido-acid  $\text{C}_6\text{H}_4\text{NO}_2\text{NH}_2$ , whence  $\text{HCl}$  sets free  $\text{C}_6\text{H}_4\text{NO}_2$ . Salts.— $\text{KC}_6\text{H}_4\text{O}_2$  aq. Hard, black, insoluble mass, yielding a brown powder. The 'ulmin' of Malaguti. Formed by shaking the anhydride with  $\text{KOH}$  (1 pt.) and water (120 pts.).— $\text{NaC}_6\text{H}_4\text{O}_2$  aq.— $\text{NaC}_6\text{H}_4\text{O}_2$  aq.

**References.**—HUMIC, SACCHARUMIC, and SACULMIC ACIDS.

**UMBELLIC ACID**  $\text{C}_6\text{H}_4\text{O}_2$ , i.e. [4:2:1]  $\text{C}_6\text{H}_4(\text{OH})_2\text{CH}:\text{CH}:\text{CO}_2\text{H}$ . Mol. w. 132. Di-oxy-cinnamic acid. Formed by warming its lactone, umbelliferone with  $\text{KOH}$  aq. (Tiemann a. Reimer, *B.* 12, 994; Posen, *B.* 14, 2745). Yellowish powder. Turns brown at  $240^\circ$ , and decomposes below  $260^\circ$ . Sol. alcohol and warm water, insol. ether. Resinified by boiling its aqueous solution. Reduces warm ammoniacal  $\text{AgNO}_3$ , forming a mirror.  $\text{FeCl}_3$  gives a brown  $\text{pp}$ .

**Methyl derivative**  $\text{C}_6\text{H}_4\text{O}_2$ . [180°-185°]. Got by heating herniarin with alcoholic potash at  $160^\circ$  (Barth a. Herzig, *M.* 10, 165). Needles (from water).

**( $\beta$ )-Di-methyl derivative**  $\text{C}_6\text{H}_4(\text{OMe})_2\text{CH}:\text{CH}:\text{CO}_2\text{H}$ . [138°]. Formed by the action of  $\text{MeI}$  and  $\text{KOH}$  in  $\text{MeOH}$  on the methyl derivative of umbelliferone in the cold (W. Will, *B.* 16, 2115; 19, 1777). Needles, v. sol. alcohol and ether. Converted into the ( $\beta$ )-isomeride by boiling alone or with  $\text{HCl}$  aq. Both isomerides are reduced by sodium-amalgam to the same  $\text{C}_6\text{H}_4(\text{OMe})_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$ , and are oxidized by  $\text{KMnO}_4$  to the same  $\text{C}_6\text{H}_4(\text{OMe})_2\text{CO}_2\text{H}$ .— $\text{CaA}$ , 2aq: crystals.— $\text{BaA}$ , 2aq: needles.

Vol. IV.

**( $\beta$ )-Di-methyl derivative.** [184°]. Formed as above, and also by saponification of its methyl ether  $\text{C}_6\text{H}_4(\text{OMe})_2\text{CH}:\text{CH}:\text{CO}_2\text{Me}$  [87°], which is got by evaporating methyl-umbelliferone (1 mol.) with  $\text{NaOH}$  (2 mols.) nearly to dryness, and digesting the residue with  $\text{MeI}$  and  $\text{MeOH}$  (Tiemann a. Will, *B.* 15, 2079). Needles, sol. alcohol and ether. Sl. sol. cold water.

**( $\alpha$ )-Di-ethyl derivative** [4:2:1]  $\text{C}_6\text{H}_4(\text{OEt})_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ . *Di-ethyl-umbelliferic acid*. [107°]. Formed by mixing ethyl-umbelliferone (5 g.) with  $\text{KI}$  (10 g.) and a solution of  $\text{KOH}$  (4 g.) in alcohol (Will a. Beck, *B.* 19, 1780). Small plates, v. sol. alcohol, ether, and benzene.

**( $\beta$ )-Di-ethyl derivative.** [200°]. Formed by boiling the ( $\alpha$ )-isomeride for some time, and also by heating ethyl-umbelliferone (10 g.) with  $\text{KI}$  (9 g.) and a solution of  $\text{Na}$  (2 g.) in alcohol for six hours at  $150^\circ$ . Crystals, m. sol. alcohol, sl. sol. water.

**UMBELLIFERONE**  $\text{C}_6\text{H}_4\text{O}_2$ , i.e.

$\text{C}_6\text{H}_4(\text{OH})_2\text{CH}:\text{CH}:\text{CO}_2\text{H}$ . Mol. w. 162. [224°]. S. 1 at  $100^\circ$ . Formed by the dry distillation of various resins, chiefly those derived from umbelliferous plants, e.g. galbanum, sagapenum, and asafetida (Sommer a. Zwenger, *A.* 116, 15; Mössner, *A.* 119, 260; Hlasiwetz a. Grabowski, *A.* 139, 100; Hirschsohn, *C. C.* 1877, 182). Formed by heating malic acid (1 mol.) with resorcin (1 mol.) and  $\text{H}_2\text{SO}_4$  (Pechmann, *B.* 17, 932). Prepared by distilling the alcoholic extract of gum galbanum (Tiemann a. Reimer, *B.* 12, 993). Needles, sl. sol. cold water and ether, v. sol. alcohol. Dissolves in acids, without change. Alkalis above  $50^\circ$  form umbelliferic acid. Its solution in dilute alkalis shows blue fluorescence.  $\text{H}_2\text{SO}_4$  forms a solution with green fluorescence. Reduces  $\text{AgNO}_3$  on boiling. Yields (4,2,1)-di-oxy-benzoic acid on oxidation (Tiemann a. Parrisius, *B.* 13, 2354). Fuming  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$  form  $\text{C}_6\text{H}_4(\text{NO}_2)_2\text{O}_2$  [216°] (Posen, *B.* 14, 2744).

**Acetyl derivative**  $\text{C}_{11}\text{H}_8\text{O}_4$ . [140°]. Formed by acetylation, and also by boiling di-oxy-benzoic aldehyde with  $\text{Ac}_2\text{O}$  and  $\text{NaOAc}$  (Tiemann, *B.* 10, 2216; 12, 995). Needles, sl. sol. water.

**Methyl derivative**  $\text{C}_6\text{H}_4\text{O}_2$ , i.e.  $\text{C}_6\text{H}_4(\text{OMe})_2\text{CH}:\text{CH}:\text{CO}_2\text{H}$ . [114°]. Formed by heating umbelliferone with  $\text{KMe}$  and  $\text{MeI}$  (T. a. R.). Leaflets, nearly insol. water. Appears to be identical with herniarin [118°], which is extracted by alcohol from *Herniaria hirsuta* (Barth a. Herzig, *M.* 10, 161).

**Ethyl derivative**  $\text{C}_6\text{H}_4\text{O}_2$ . [88°]. Plates, v. sol. alcohol (Will a. Beck, *B.* 19, 1779).

**Oxim of the methyl derivative** [4:2:1]  $\text{C}_6\text{H}_4(\text{OMe})_2\text{CH}:\text{CH}:\text{C}(\text{NOH})_2$ . [138°]. Formed from the methyl derivative of thio-umbelliferone and hydroxylamine (Aldringen, *B.* 24, 8465). Needles, v. sol. hot water and alcohol.  $\text{FeCl}_3$  colours its solution brownish-red.

**Phenyl-hydrazide of the methyl derivative**  $\text{C}_6\text{H}_4(\text{OMe})_2\text{CH}:\text{CH}:\text{C}(\text{NHPh})_2$ . [115°]. Yellow needles, giving a blue colour with  $\text{H}_2\text{SO}_4$ .

8 G

**Thio-umbelliferone. Methyl derivative**  
 $C_6H_3(OMe) \cdot \begin{smallmatrix} CH:CH \\ O-CS \end{smallmatrix}$  [114°]. Formed by heating the methyl derivative of umbelliferone with  $P_2S_5$  (Aldringen, B. 24, 3465). Needles, sol. alcohol, v. sl. sol. water.

**References.**—BROMO- and METHYL-UMBELLIFERONE.

**UMBELLOL**  $C_8H_{10}O$ . (216°). V.D. 4-29. Occurs in the volatile oil of the Californian laurel (Stillmann, B. 13, 629). Oil, sol.  $H_2SO_4$  with red colour, becoming black. Attacked by Na.

**UMBELLULIC ACID** v. HENDECOIC ACID.

**UNDECANE** v. HENDECAN.

**UNDECOIC ACID** v. HENDECOIC ACID.

**UNDECOLIC ACID** v. HENDECINOIC ACID.

**UNDECYLENE** v. HENDECYLENE.

**UNDECYLENIC ACID** v. HENDECENOIC ACID.

**UNDECLIC ACID** v. HENDECOIC ACID.

**URACIL**  $CO \cdot \begin{smallmatrix} NH.CH \\ NH.CO \end{smallmatrix} > CH$ . *Di-oxy-pyrimidine*. Derivatives of this compound are formed by the action of acetone, citric ether on urea, thio-urea, and guanidine (Behrend, A. 229, 1; 240, 6; List, A. 236, 1; Jäger, A. 262, 365; Warrington, J. pr. [2] 47, 201).

**Amido-uracil**  $C_4H_4N_2O_2$ . Formed, together with oxuracil  $C_4H_4N_2O_4$ , by reducing nitro-uracil (Behrend), and by boiling di-bromo-pyruvamide with baryta-water (Fischer, A. 239, 193). Yellow needles, sol. water. Converted by cyanic acid into oxanthine  $C_4H_4N_2O_4$ , which crystallises in needles, sl. sol. water, sol. alkalis, gives with Cl the murexide reaction, may be oxidised to alloxantin, and gives some alloxan with bromine-water.

**Acetyl derivative**  $C_4H_4N_2O_5$  3aq. Prisms.

**Nitro-uracil** v. NITRO-DI-OXY-PYRIMIDINE.

**Bromo-nitro-oxy-uracil. Dihydrate**

$C_4H_4N_2O_3Br$  i.e.  $CO \cdot \begin{smallmatrix} NH.CH(OH) \\ NH.CO \end{smallmatrix} > CBr(NO_2)$ .

Formed by adding Br to nitro-uracil suspended in water (Behrend, A. 240, 11). Crystalline mass, sl. sol. cold water and alcohol. Boiling with water produces brominated nitro-methanes and a crystalline compound  $C_4H_4N_2O_3$ , formed by the action of urea upon nitro-uracil. Tin and HCl reduce it to amido-uracil.

**Methyl-uracil** v. DI-OXY-METHYL-PYRIMIDINE.

**Nitro-methyl-uracil**  $C_4H_4N_2O_4$ . Prepared by nitrating methyl-uracil with  $HNO_3$  (S.G. 1.5) mixed with an equal volume of  $H_2SO_4$  (S.G. 1.84) (Behrend, A. 240, 3). Prisms or tables (from water), sl. sol. hot alcohol.

**Isomeride** v. NITRO-DI-OXY-METHYL-PYRIMIDINE.

**Nitro-di-methyl-uracil** v. NITRO-DI-OXY-METHYL-PYRIMIDINE.

**Di-chloro-oxy-methyl-uracil. Dihydrate**

$C_4H_4Cl_2N_2O_3$  i.e.  $CO \cdot \begin{smallmatrix} CMe(OH).NH \\ CO \end{smallmatrix} > CO$ .

Formed by the action of chlorine on methyl-uracil suspended in water (Behrend, A. 236, 59). Tables (from water); slowly decomposed by boiling water. M. sol. alcohol; not decomposed by boiling alcohol. M. sol. ether. A solution of  $SnCl_4$  in  $HCl$  at 100° reduces it to chloro-methyl-uracil  $C_4H_4ClN_2O_3$ , which crystallises from water in needles. Fuming  $HNO_3$  gives di-chloro-barbituric acid.

**Di-bromo-oxy-methyl-uracil**  $C_4H_4N_2Br_2O_3$  i.e.

$CBr \cdot \begin{smallmatrix} CMe(OH).NH \\ CO \end{smallmatrix} > CO$ . From methyl-uracil (or bromo-methyl-uracil), and bromine-water (Behrend, A. 229, 18; 236, 57). Cubes (from hot water). Boiling alcohol converts it into bromo-methyl-uracil  $C_4H_4N_2BrO_3$ . Fuming  $HNO_3$  forms di-bromo-barbituric acid.

**Di-chloro-oxy-tri-methyl-uracil. Dihydrate**

$CO \cdot \begin{smallmatrix} NMe.CO \\ NMe.CMe(OH) \end{smallmatrix} > CCl_2$ . [144°]. Formed by passing Cl into an aqueous solution of tri-methyl-uracil (Hagen, A. 244, 14). Crystals, sl. sol. hot water. Reduced by boiling with  $SnCl_4$  to chloro-tri-methyl-uracil, which crystallises in prisms, m. sol. hot water.

**Nitro-ethyl-uracil** v. NITRO-DI-OXY-ETHYL-PYRIMIDINE.

**Methyl-ethyl-uracil** v. DI-OXY-METHYL-ETHYL-PYRIMIDINE.

**Nitro-methyl-ethyl-uracil** v. NITRO-DI-OXY-METHYL-ETHYL-PYRIMIDINE.

**Amido-uracil carboxylic acid** v. DI-OXY-AMIDO-PYRIMIDINE CARBOXYLIC ACID.

**References.**—THIO-METHYL-URACIL and URAMIDO-CROTONIC ACID.

**URAMIDO-ACETIC ACID** v. HYDANTOIC ACID.

**p-URAMIDO-BENZENE SULPHONIC ACID**

$NH_2.CO.NH.C_6H_4.SO_3H$ . Formed by evaporating a solution of p-amido-benzene sulphonic acid and potassium cyanate (Pellizzari, A. 248, 156), and also by heating dry p-amido-benzene sulphonic acid (1 mol.) with urea (1½ mols.) (Friedel, C. R. 112, 868). Pearly plates (from dilute alcohol), v. sol. water. — BaA, 3aq; monoclinic prisms, sol. Aq.

**o-URAMIDO-BENZOIC ACID**  $C_8H_6N_2O_4$  i.e.

$NH_2.CO.NH.C_6H_4.CO_2H$ . Formed from potassium cyanate and the hydrochloride of o-amido-benzoic acid (Griess, J. pr. [2] 5, 371; B. 11, 1730).  $HNO_3$  yields only one di-nitro-derivative.

**m-Uramido-benzoic acid**  $C_8H_6N_2O_4$ . S. 1 at 100°. S. (96 p.c. alcohol) 72 at 16°. S. (ether) 127 at 16°. Occurs in urine after a dose of m-amido-benzoic acid (E. Salkowski, H. 7, 113).

**Formation.**—1. By adding potassium cyanate to a boiling saturated solution of the sulphate of m-amido-benzoic acid (Menschutkin, A. 153, 84; Z. [2] 4, 275).—2. By fusing m-amido-benzoic acid with urea (Griess, Z. [2] 5, 312; B. 2, 47). 3. By boiling m-cyanamido-benzoic acid with  $HCl$ aq (Traube, B. 15, 2122).

**Properties.**—Small prisms (containing aq), v. sl. sol. hot water. At 200° it yields  $CO(NH_2.C_6H_4.CO_2H)_2$ . On distilling m-uramido-benzoic acid (4 pts.) with  $P_2O_5$  (1 pt.) m-amido-benzoic nitrile [54°] is formed (Griess, B. 8, 224). Boiling KOHAq splits it up into m-amido-benzoic acid,  $CO_2$ , and  $NH_3$ .

**Salts.**— $NH_4A$ aq. —  $KA$ . —  $CaA$ , 4aq. —  $PbA$ , 2aq. —  $AgA$ : curdy pp., becoming crystalline.

**Ethyl ether**  $EtA$ . [176°]. Formed from m-amido-benzoic ether and  $KCyO$  (Griess, J. pr. [2] 4, 293). Plates, sl. sol. hot water.

**Amide**  $C_8H_6N_4O_3$ . Formed from m-amido-benzamide and  $KONC$  (Menschutkin). Scales (from water), decomposed by fusion, sl. sol. alcohol.

**p-Uramido-benzoic acid**  $C_9H_7N_3O_4$ . Formed in like manner (Griess, *J. pr.* [2] 5, 369). Plates, almost insol. cold water, v. sl. sol. hot water, m. sol. hot alcohol. Yields some *p*-amido-benzonitrile [86°] on distilling with  $P_2O_5$ .— $BaA'$ . Plates, v. e. sol. cold water.

**Di-uramido-benzoic acid**  $C_{10}H_{10}N_4O_4$  i.e.  $(NH_2.CO.NH).C_6H_4.CO_2H$ . Formed by fusing di-amido-benzoic acid with urea (Griess, *B.* 2, 47). Small granules, v. sl. sol. hot water.— $BaA'$ , (dried at 130°). Nodules, v. sol. hot water.

**References.**—AMIDO-, NITRO-, and OXY-URAMIDO-BENZOIC ACIDS.

**URAMIDO-BENZOYL v. OXY-QUINAZOLINE.**

**p-URAMIDO-BENZYL-UREA**  $C_{10}H_{11}N_3O_2$  i.e.  $NH_2.CO.NH.C_6H_4.CH_2.NH.CO.NH_2$ . [197°]. *p*-**Di-uramido-toluene**. Formed by heating together *p*-amido-benzyl-amine hydrochloride (1 mol.) and KCNO (2 mols.) in aqueous solution (Amsel & Hofmann, *B.* 19, 1289). Small needles. Sol. hot water.

**URAMIDO-ISOBUTYRIC ACID v. ACETON-URAMIC ACID.**

**o-URAMIDO-CINNAMIC ACID**  $C_{11}H_{11}N_3O_4$  i.e.  $NH_2.CO.NH.C_6H_4.CH=CH.CO_2H$ . Formed from *o*-amido-cinnamic acid and aqueous KCNO (Rothschild, *B.* 23, 3341). Sol.  $NH_4Aq$  and hot  $HClAq$ .

**(B)-URAMIDO-CROTONIC ACID**  $C_8H_7N_3O_4$  i.e.  $CH_3.C(NH_2.CO.NH).CH.CO_2H$ . The ether is converted by  $NaOH$  into the salt  $NaA'$ , which crystallises in needles, v. sol. water; but on adding acids to this salt di-oxy-methyl-pyrimidine  $C_4H_5N_2O_2$  is produced. Methyl-uracil is reconverted by  $NaOH$  into sodium uramido-crotonate (Behrend, *A.* 229, 5).

**Ethyl ether EtA'**. [166°]. Formed from acetoacetic ether and urea. Needles, v. sol. ether, m. sol. alcohol. Decomposed by warm  $HClAq$  into urea, acetone,  $CO_2$ , and alcohol. Alcohol forms  $CH_3.C(NH.CO_2Et).CH.CO_2Et$  [29°] (Meister, *A.* 244, 234).

**Amide**  $CH_3.C(NH.CO.NH_2).CH.CO.NH_2$  [131°]. Crystals (containing  $EtOH$ ) (Meister).

**Amido-uramido-crotonic acid. Lactam.**

$C_6H_5(NH_2)_2O_2$  i.e.  $CO < \begin{smallmatrix} NH.CMe \\ NH.CO \end{smallmatrix} > C.NH_2$  (?).

**Amido-methyl-uracil.** Methyl-uracil (v. Di-oxy-methyl-pyrimidine) is converted by Br in  $CS_2$  into crystalline bromo-methyl-uracil  $C_4H_5N_2O_2$ , whence conc.  $NH_4Aq$  at 150° forms amido-methyl-uracil (Behrend, *A.* 231, 250). Satiny plates (from water), melting near 250°. Sol. alcohol. The hydrochloride is converted by potassium cyanate into oxy-methyl-xanthine  $C_4H_5N_3O_2$ , 2aq, crystallising from water in prisms.— $BHCl$  aq. Monoclinic crystals;  $a:b:c = 1.629:1.2345$ ;  $\beta = 52^\circ 57'$ .— $BH_2I_2PtCl_4$ , 2aq: needles, v. sol. water.

**Acetyl derivative**  $C_8H_9(NHAc)_2N_2O_2$  3aq. Formed from oxy-methyl-xanthine and  $Ac_2O$  at 170°. Thick trimetric prisms (from water). Decomposes near 210° without melting. Sol. alkalis and reppd. by acids.

**URAMIDO-ETHANE SULPHONIC ACID**

$NH_2.CO.NH.CH_2.CH_2.SO_3H$ . **Taurocarbamie acid.** Occurs in small quantity in urine after a dose of taurine (E. Salkowski, *B.* 6, 744, 1901). Formed by evaporating a solution of taurine with  $KCyO$ . Formed also by the action of bromine-water on ethylene- $\psi$ -thio-urea (Gabriel,

*B.* 22, 1142). Dimetric plates, v. sol. water, sl. sol. alcohol, insol. ether. Decomposed by baryta-water at 140° into  $CO_2$ , taurine, and  $NH_3$ .— $BaA'$ : tables (from alcohol).— $AgA'$ . Radiating tufts of crystals.

**URAMIDO-HEXOIC ACID**  $C_{11}H_{13}N_3O_4$  i.e.  $NH_2.CO.NH.CH(C_2H_5).CO_2H$ . [200°]. Formed by boiling isobutyl-hydantoin with baryta-water (Pinner & Spilker, *B.* 22, 696). Needles, v. sol. alcohol and hot water.— $BaA'$ : nodular groups of prisms.

**Ethyl ether EtA'**. [135°]. Formed by heating isobutyl-hydantoin with  $KOH$  and  $EtBr$ . Needles, v. sol. alcohol and hot water.

**Nitrile**  $NH_2.CO.NH.CH(C_2H_5).CN$ . Formed by heating the cyanhydrin of isovaleric aldehyde with urea (Pinner & Lifschütz, *B.* 20, 2351). Oil, sol. alcohol and ether. On warming with  $HClAq$  it yields isobutyl-hydantoin  $C_4H_9CH < \begin{smallmatrix} CO.NH \\ NH.CO \end{smallmatrix} < NH.CO$  [210°].

**Amide**  $NH_2.CO.NH.CH(C_2H_5).CO.NH_2$  [170°]. Formed from the nitrile (1 pt.) and conc.  $H_2SO_4$  (3 pts.) in the cold. Crystals, v. sol. water and alcohol.

**URAMIDO-HIPPURIC ACID**  $C_{10}H_{11}N_3O_4$ . Formed by fusing *m*-amido-hippuric acid with urea (Griess, *J. pr.* [2] 1, 235). Nodules, v. e. sol. hot water. Decomposed by boiling conc.  $HClAq$  into glycocholl and *m*-uramido-benzoic acid.— $AgA'$ . Crystalline pp.

**URAMIDO-NITRO-AMIDO-PHENOL**  $C_8H_7N_5O_4$  i.e.  $C_6H_3(NO_2)(NH_2)(NH.CO.NH_2).OH$ . Formed by reducing di-nitro-oxy-phenyl-urea with ammonium sulphide (Griess, *J. pr.* [2] 5, 1). Reddish-brown needles, sl. sol. hot water and alcohol.— $BHCl$ : white scales.— $BaA'$ , 3aq: steel-blue needles, v. sol. hot water. Boiling  $HClAq$  converts it into amidocarboxamid *p*-nitrophenol  $C_6H_4N_2O_6$ , which yields  $BaA'$ , 2aq and  $BHCl$  aq, and is reduced by tin and  $HClAq$  to diamidocarboxamidophenol  $C_6H_4N_4O_6$ , which yields  $BHCl$ , crystallising in plates.

**URAMIDO-DI-NITRO-PHENOL v. Di-NITRO-OXY-PHENYL-UREA.**

**p-URAMIDO-PHENYL-ACETIC ACID**  $NH_2.CO.NH.C_6H_4.CH_2.CO_2H$ . [174°]. Formed by boiling *p*-cyanamido-phenyl-acetic acid with  $HClAq$  (Traube, *B.* 15, 2122). Small crystals (containing 1 aq), sol. water, alcohol, and ether.

**$\alpha$ -Uramido-phenyl-acetic acid. Ethyl ether**  $NH_2.CO.NH.CHPh.CO_2Et$ . [189°]. Formed by the action of aqueous  $KCyO$  on the hydrochloride of  $\alpha$ -amido-phenyl-acetic ether (Kossel, *B.* 21, 4150). V. sol. alcohol and hot water.

**Nitrile**  $NH_2.CO.NH.CHPh.CN$ . [170°]. Formed by heating the cyanhydrin of benzoic aldehyde with urea (Pinner & Lifschütz, *B.* 20, 2351). Converted by acids into  $C_8H_7N_3O_2$  [182°], crystallising in scales, v. sol. alcohol and hot water.

**$\alpha$ -URAMIDO-PHENYL-CROTONIC ACID.**

**Nitrile**  $CHPh.CH.CN(NH.CO.NH_2).CN$ . [160°]. Formed by heating urea with the cyanhydrin of cinnamic aldehyde (Pinner & Lifschütz, *B.* 20, 2351). Needles, v. sol. hot alcohol. Boiling  $HClAq$  converts it into di-oxy-styryl-pyrazole (*q. v.*).

**Amide**  $CHPh.CH.CN(NH.CO.NH_2).CO.NH_2$ . Formed from the nitrile and cold conc.  $H_2SO_4$  (Pinner & Spilker, *B.* 22, 692). Microcrystalline

powder, decomposing at 210°-220° with evolution of  $\text{NH}_3$ . Sol. alcohol, sl. sol. hot water.

**$\alpha$ -URAMIDO-PROPIONIC ACID**  $\text{C}_6\text{H}_4\text{N}_2\text{O}_5$ , i.e.  $\text{CH}_2\text{CH}(\text{NH.CO.NH}_2)\text{CO}_2\text{H}$ . *Lacturamic acid*. [155°]. Formed by evaporating a solution of alanine sulphate mixed with  $\text{KCyO}$  (Urech, A. 165, 99). Formed also by boiling lactyl-urea with baryta-water (Heintz, A. 169, 128). Prisms, sl. sol. cold water and alcohol, insol. ether.— $\text{BaA}'_2\text{aq}$  (dried at 100°).— $\text{PbA}'_2\text{aq}$ — $\text{AgA}'_2$  needles, m. sol. water.

**Nitrile**  $\text{CH}_2\text{CH}(\text{NH.CO.NH}_2)\text{CO}_2\text{H}$ . [106°] (Franchimont a. Klobbie, R. T. C. 7, 16).

**Amide**  $\text{CH}_2\text{CH}(\text{NH.CO.NH}_2)\text{CO}_2\text{H}$ . [196°]. Small needles (from alcohol), sol. water.

**URAMIDO-SUCCINIC ACID**. Amic acid  $\text{NH}_2\text{CO.CH}_2\text{CH}(\text{NH.CO.NH}_2)\text{CO}_2\text{H}$ . [138°] (G.). [157°] (P.). *Succinuramide*. *Amido-succinic acid*. S. 5.4 at 23°. Formed by

evaporating the mixed solutions of asparagine  $\text{KCyO}$  (Guareschi, G. 7, 404; R. 10, 1747). Dextro-asparagine gives a levo-compound, while levo-asparagine gives a dextro-compound (Piutti, B. 19, 1693). Prisms, nearly in. sol. alcohol and ether. According to Piutti, the dextro- and levo-compounds both melt at 157°.

**Reactions**.—1. Decomposed by fusion, with formation of malyl-uroide  $\text{C}_6\text{H}_4\text{N}_2\text{O}_5$  [230°-235°], which is also formed by heating urea with asparagine at 125° (Grimaux, A. Ch. [5] 11, 400) and crystallises from water in pointed rhombohedra.—2. Boiling  $\text{HClAq}$  (S.G. 1.12) forms malyl-ureidic acid  $\text{C}_6\text{H}_4\text{N}_2\text{O}_5$ , which is also got by heating aspartic acid with urea at 130°. Malyl-ureidic acid crystallises in prisms [215°-220°], S. 25 at 100°, which yields  $\text{BaA}'_2\text{aq}$  and is converted by heating with bromine-water into  $\text{C}_6\text{H}_4\text{Br}_2\text{N}_2\text{O}_5$ , S. 3 at 100°,  $\text{C}_6\text{H}_4\text{Br}_2\text{N}_2\text{O}_5$ , S. 25 at 100°,  $\text{C}_6\text{H}_4\text{Br}_2\text{N}_2\text{O}_5$ , which is v. sol. water,  $\text{C}_6\text{H}_4\text{Br}_2\text{N}_2\text{O}_5$ , S. c. 6 at 100°, and  $\text{C}_6\text{H}_4\text{Br}_2\text{N}_2\text{O}_5$ , S. 10 in the cold and c. 22 at 100°.

**URAMIDO-THIO-FORMIC ACID** v. THIO-ALLOPHANIC ACID.

**DI-URAMIDO-TOLUENE** v. URAMIDO-BENZYL-UREA.

**DI- $p$ -URAMIDO-DI- $o$ -TOLYL-SULPHIDE** [2:1:4]  $\text{S}(\text{C}_6\text{H}_4\text{Me.NH.CO.NH}_2)_2$ . *Thio- $p$ -tolyl-di-urea*. [151°] (when containing benzene of crystallisation). Formed by heating the hydrochloride of di- $p$ -amido-di-tolyl-sulphide with  $\text{KCNO}$  (Trehrar, B. 20, 669). Crystallises from benzene in white silky needles (containing  $\text{C}_6\text{H}_6$ ).

**URAMIL**  $\text{C}_6\text{H}_4\text{N}_2\text{O}_5$ , i.e.  $\text{CO} \begin{smallmatrix} \text{NH.CO} \\ \text{NH.CO} \end{smallmatrix} \text{CH.NH}_2$ . *Dialuramide*. *Amido-barbituric acid*. *Amido-malonyl-urea*. *Murexan*. Mol. w. 148. Formed by boiling alloxantin with  $\text{NH}_4\text{Cl}$  (Liebig a. Wohler, A. 26, 310; Grimaux, C. R. 87, 752) and by boiling ammonium thionurate with  $\text{HClAq}$ . Formed also by reducing nitro- or nitroso-barbituric acid with  $\text{HIAq}$  (Baeyer, A. 127, 223). It is also a product of the action of acids on murexide (Beilstein, A. 107, 188).

**Properties**.—Silky needles, sl. sol. hot water, insol. alcohol and ether. Sol. conc.  $\text{H}_2\text{SO}_4$  and re-ppd. on dilution. Its alkaline solution turns red in air, forming purpurates; thus it is converted in ammoniacal solution into murexide by boiling with air or  $\text{HgO}$ . Conc.  $\text{HNO}_3$  forms alloxan.

Bromine at 85° forms orange  $\text{C}_6\text{H}_4\text{Br}_2\text{N}_2\text{O}_5$  (Mulder, B. 14, 1060).

**URAMILIC ACID**  $\text{C}_6\text{H}_4\text{N}_2\text{O}_5$  (?). S. 14 in the cold; 33 at 100°. Formed by heating uramil with  $\text{H}_2\text{SO}_4$  and water, or by evaporating ammonium thionurate with some  $\text{H}_2\text{SO}_4$  (Liebig a. Wohler, A. 26, 314; Gregory, P. M. 24, 187). Transparent, four-sided prisms, sl. sol. cold water. Converted by boiling conc.  $\text{HNO}_3$  into nitro-barbituric acid.

**URANATES** v. URANIUM, OXYACIDS AND SALTS OF, p. 826.

**URANIUM**. U. At. w. 239 (not determined with very great accuracy). Mol. w. unknown. M.P. not determined accurately; between red heat and white heat. S.G. of fused U at 15° = 18.685 (Zimmermann, B. 15, 851). S.H. at 100° = 0.276 (Z., Lc.). S.V.S. 12.8.

**Historical**.—In 1789 Klaproth prepared some compounds of a new element from *pitchblende*; to the characteristic element of these compounds he gave the name uranium, from *uravós* = the heavens, in allusion to the planet *Uranus* which had been discovered a few years before (Croll's A. 1789 [2] 400). The compounds of U were examined by Richter (Gehlen's A. 4, 402), Buchholz (Gehlen's A. 4, 17, 134), Lecanu (J. Ph. 9, 141; 11, 279), Brande (S. 44, 1), Berzelius (P. 1, 359), and Arfvedson (P. 1, 245). In 1840, Péligot showed that the substance supposed till then to be U was really an oxide of U (A. Ch. [3] 5, 5); P. isolated the metal, and determined the at. w. to be 120. Mendeleeff in 1872 (Z. Suppl. 8, 133; cf. C. N. 41, 39 [1880]) proposed to double the at. w. of U, making it 240; this proposal was completely justified by the determination of S.H. of pure U by Zimmermann in 1882 (B. 15, 851), and by the determination of the V.D. of  $\text{UCl}_4$  and  $\text{UBr}_4$  (Z., A. 216, 2 [1883]).

**Occurrence**.—Never uncombined. A few minerals containing compounds of U are found sparsely distributed and not in large quantities; the chief of these is *pitchblende*, which consists of  $\text{U}_3\text{O}_8$  along with  $\text{SiO}_2$  and oxides of Sb, As, Ca, Cu, Fe, Mg, V, &c. Carbonate, sulphate, phosphate, niobate, tantalate, and various other compounds of U are also found in varying quantities in several rare minerals (v. Zimmermann, A. 232, 300; Eidden a. Mackintosh, Am. S. [3] 38, 474; Hillebrand, Am. S. [3] 38, 329; 40, 384). Lockyer (Pr. 27, 49) stated that some of the lines in the emission-spectrum of U coincide with dark lines in the solar spectrum. Hutchins a. Holden (P. M. [5] 24, 325) think there is no trustworthy evidence in favour of the existence of U in the solar atmosphere.

**Preparation**.—1. A mixture of  $\text{UCl}_4$ ,  $\text{NaCl}$ , and Na is strongly heated in a closed iron cylinder. Zimmermann (A. 116, 14) used a cylinder of soft iron with walls c. 3 centim. thick, bored from a larger cylinder (similar to that employed by Nilson a. Pettersson for preparing Be; B. 11, 383) fitted with a cap which could be screwed on tightly. He placed a layer of pure fused  $\text{NaCl}$  in the cylinder, then small pieces of Na (c. 3 to 4 pts. for 10 pts.  $\text{UCl}_4$ ), then  $\text{UCl}_4$  (which must be put into the cylinder as quickly as possible, as it is hygroscopic), and covered the whole with a layer of fused  $\text{NaCl}$ . Z. raised the cylinder to a white heat, kept it at

that temperature for some time, cooled, and washed the contents with dilute alkali solution, and then with water. According to Z., the metal as thus prepared is quite pure (*v. infra*).—2. Moissan (*C.R.* 116, 847) obtained U, containing from 5 to 18.5 p.c. C, by mixing the oxide prepared by strongly heating  $\text{UO}_2(\text{NO}_3)_2$  with excess of charcoal, compressing the mixture in a carbon crucible, imbedding this in  $\text{MgO}$ , and heating for 10–12 minutes in an electric furnace, using a current of 60 volts and 450 amperes.

$\text{UCl}_4$  is obtained by heating the nitrate  $\text{UO}_2(\text{NO}_3)_2$  in air, mixing the oxide thus obtained (chiefly  $\text{U}_3\text{O}_8$ ) with C, and heating in a stream of Cl (*v. URANIUM TETRACHLORIDE*, p. 823). The nitrate is obtained from *pitchblende* by powdering the mineral, washing with water, drying, and washing to remove S and As, dissolving in  $\text{HNO}_3\text{aq}$ , evaporating to dryness, dissolving in water, filtering from  $\text{Fe}_2\text{O}_3$ ,  $\text{PbSO}_4$ , &c., evaporating a little, and allowing to crystallise. The crystals of  $\text{UO}_2(\text{NO}_3)_2$  thus obtained are purified by draining in a funnel, washing with a little cold water, drying in the air, dissolving in ether in a wide-mouthed bottle, crystallising by spontaneous evaporation, and re-crystallising from hot water; the crystals of  $\text{UO}_2(\text{NO}_3)_2$  are then dissolved in water so as to form a conc. solution,  $\text{UO}_2\text{C}_2\text{O}_4$  is pptd. by adding  $\text{H}_2\text{C}_2\text{O}_4\text{aq}$  to this solution, the ppt. is washed with boiling water, and then decomposed by heat, and the  $\text{UO}_2$  thus produced is digested with conc.  $\text{HClaq}$ , washed, dissolved in  $\text{HNO}_3\text{aq}$ , and the solution is crystallised (Péligot, *A. Ch.* [3] 5, 5; 12, 258; cf. Ebelmen, *A.* 43, 286; Wertheim, *J. pr.* 29, 209).

The oxide  $\text{U}_3\text{O}_8$  used by Zimmermann (*v. supra*) for the preparation of  $\text{UCl}_4$ , from which pure U was obtained, was prepared by him as follows. A warm solution of commercial uranium hydroxide in  $\text{HClaq}$  was saturated with  $\text{H}_2\text{S}$ ; after standing for some time the liquid was filtered off,  $\text{NH}_3\text{aq}$  and  $(\text{NH}_4)_2\text{CO}_3\text{aq}$  were added in excess, the liquid was warmed and  $(\text{NH}_4)_2\text{SAq}$  was added; after standing the liquid was filtered, saturated with  $\text{HClaq}$ , and boiled till  $\text{CO}_2$  was removed, then mixed with  $\text{NH}_3\text{aq}$  and  $(\text{NH}_4)_2\text{SAq}$  and heated on the water-bath till most of the  $(\text{NH}_4)_2\text{S}$  was removed; the opp. of  $\text{UO}_2$  was collected, washed, and heated over the blowpipe; the  $\text{U}_3\text{O}_8$  thus formed was dissolved in  $\text{HNO}_3\text{aq}$  and the solution was crystallised; the crystals of  $\text{UO}_2(\text{NO}_3)_2$  were dissolved in ether, the solution was poured off from insoluble substances, evaporated to dryness, and the residue was strongly heated; the  $\text{U}_3\text{O}_8$  which remained was again dissolved in  $\text{HNO}_3\text{aq}$ , and the crystals that formed on evaporation were dissolved in ether, and the ethereal solution was evaporated to dryness and the residue decomposed by heating.

*Properties.*—A lustrous, hard, silver-white metal; S.G. 18.685 at  $15^\circ$  (Zimmermann, *B.* 15, 851); if  $\text{UCl}_4$  is reduced by Na at a red heat, U is obtained as a greyish-black powder. S.H. at  $100^\circ = .0276$  (Z., &c.). U is somewhat malleable, but cannot be hammered into thin plates. The emission-spectrum, obtained by the aid of electric sparks, shows only a few lines, the most marked being one in the yellow (Thalén, *A. Ch.*

[4] 18, 289). For the fluorescence, phosphorescence, and absorption-spectra of U compounds *v. Becquerel* (*A. Ch.* [4] 27, 539), also Morton & Bolton (*Am. Ch.* 3, 361, 401). U melts towards a white heat; according to Moissan (*C.R.* 116, 1429), the metal is volatilised by heating in an electric furnace using a current of 350 amperes and 75 volts. After long standing in the air the surface of U becomes covered with a steel-blue to black film of oxide; U that has been fused burns brilliantly when heated on Pt foil in the air; pulverulent U burns at  $150^\circ\text{--}170^\circ$  in the air. U combines directly with Cl or Br, also with S; the metal dissolves in dilute  $\text{H}_2\text{SO}_4\text{aq}$  or  $\text{HClaq}$ ; it is not acted on by acetic acid, nor by  $\text{KOHaq}$ ,  $\text{NaOHaq}$ , or  $\text{NH}_3\text{aq}$ .

The at. w. of U has been determined (1) by determining U and Cl in  $\text{UCl}_4$  (Péligot, *A. Ch.* [3] 5, 12 [1842]; Rammelsberg, *P.* 26, 318; 56, 125 [1842]); (2) by analyses of  $\text{UO}_2\text{C}_2\text{O}_4\cdot\text{H}_2\text{O}$  (Ebelmen, *A. Ch.* [3] 5, 181 [1842]; Péligot, *A. Ch.* [3] 20, 341 [1846]); (3) by analyses of  $\text{UO}_2(\text{C}_2\text{H}_3\text{O}_2)_2\cdot 2\text{H}_2\text{O}$  (Péligot, *l.c.*; Wertheim, *J. pr.* 29, 207); (4) by analyses of the double salt  $\text{UO}_2\cdot\text{Na}(\text{C}_2\text{H}_3\text{O}_2)_2$  (Wertheim, *l.c.*); (5) by transforming  $\text{UO}_2$  into  $\text{U}_2\text{O}_3$  and  $\text{UO}_2\cdot\text{Na}(\text{C}_2\text{H}_3\text{O}_2)_2$  into  $\text{Na}_2\text{UO}_4$  (Zimmermann, *A.* 232, 117, 273 [1886]); (6) by determining S.H. of U (Zimmermann, *B.* 15, 851 [1882]); (7) by determining V.D.s of  $\text{UBr}_4$  and  $\text{UCl}_4$  (Z., *A.* 216, 2 [1883]).

The at. w. of U was formerly taken as c. 120; in 1872 Mendeléeff adduced reasons for doubling this value, based on a comparative study of the properties of compounds of U to which he was led by considering the periodic arrangement of the elements (*A. Suppl.* 8, 178; *C. N.* 41, 39). When the at. w. of U was taken as 120, the formulae given to the chief oxides, chlorides, and salts of this element were  $\text{UO}$ ,  $\text{UCl}$ ,  $\text{USO}$ , &c.;  $\text{U}_2\text{O}_3$ ;  $\text{U}_2\text{O}$ ,  $\text{UOCl}$ ,  $\text{UO}_2(\text{NO}_3)_2$ , &c.; and U was classed with the iron metals. Mendeléeff pointed out that U was very much heavier than the iron metals, that the oxide  $\text{U}_2\text{O}_3$  did not form salts similar to those derived from  $\text{Fe}_2\text{O}_3$ , that the salts of  $\text{UO}$ , i.e.  $\text{USO}$ ,  $\text{U}(\text{NO}_3)_2$ , &c., were not isomorphous with the salts of  $\text{MgO}$ ,  $\text{FeO}$ ,  $\text{NiO}$ , &c. Mendeléeff also drew attention to the existence of a chloride which would have to be represented as  $\text{U}_2\text{Cl}_4$  if  $\text{U} = 120$ , and that this chloride was obtained by heating  $\text{UCl}_4$  in H. Mendeléeff proposed to double the value then accepted for the at. w. of U, and, following on this, to write the formulae of the chlorides, oxides, and salts as  $\text{UCl}_3$ ,  $\text{UO}_2$ ,  $\text{U}(\text{SO}_4)_2$ , &c.;  $\text{U}_2\text{O}_5$ ;  $\text{UO}_3$ ,  $\text{UO}_2\text{Cl}_2$ ,  $\text{UO}_2(\text{NO}_3)_2$ , &c.; and  $\text{UCl}_4$ . It was pointed out that many of these formulae are analogous to those of the corresponding compounds of Cr, Mo, and W; and it was shown that the properties of compounds of U more nearly resemble those of compounds of Cr, Mo, and W than of any other elements. Especial stress was laid by Mendeléeff on the acidic character of the highest oxide of U. Finally, Mendeléeff showed that an element with the properties of U, and an at. w. equal to c. 240, finds its proper place in Group V., series 12, of the periodic arrangement of the elements. Mendeléeff suggested that the S.H. of pure U should be determined; that the V.D. of the volatile chloride should be found; that the action of H

on the chloride then taken to be  $\text{UCl}_4$  should be studied; that salts of the lower oxide ( $\text{UO}$  if  $U=120$ ,  $\text{UO}_2$  if  $U=240$ ) should be examined, especially as regards their isomorphism with salts of  $\text{ThO}_2$ ,  $\text{SnO}_2$ ,  $\text{ZrO}_2$ , and  $\text{TeO}_2$ ; that the crystalline forms of corresponding compounds of  $\text{MoO}_3$ ,  $\text{WO}_3$ , and  $\text{UO}_2$  ( $U=240$ ) should be studied, and that an especially thorough crystallographic examination should be made of the compounds  $\text{R}_2\text{UO}_2\text{F}_6$ ; and that the physical properties of compounds of  $\text{Cr}$ ,  $\text{Mo}$ ,  $\text{W}$ , and  $\text{U}$  should be compared. Since the publication of Mendeléeff's memoir, the S.H. of  $\text{U}$ , and the V.D.s of  $\text{UBr}$  and  $\text{UCl}$ , have been determined, the action of  $\text{H}$  on  $\text{UCl}_4$  has been examined, and something has been done in the study of the crystalline forms of compounds of  $\text{U}$ , including those of the form  $\text{R}_2\text{UO}_2\text{F}_6$ ; the results of all these investigations fully confirm the justness of Mendeléeff's view that the at. w. of  $\text{U}$  is c. 240, and that this element must be classed with  $\text{Cr}$ ,  $\text{Mo}$ , and  $\text{W}$ . The exact value to be given to the at. w. of  $\text{U}$  has not been yet determined; Zimmermann's measurements gave 238.75 from the ratio  $\text{UO}_2:\text{U}_2\text{O}_5$ , and 238.67 from the ratio  $\text{UO}_2:\text{Na}(\text{C}_2\text{H}_3\text{O}_2)_2:\text{Na}_2\text{UO}_4$  ( $O=15.96$ ). The mol. w. of  $\text{U}$  is not known.

$\text{U}$  is the last member of the even-series family of Group VI.; this family also contains, besides  $\text{O}$ , the elements  $\text{Cr}$ ,  $\text{Mo}$ , —, and  $\text{W}$ . The chromium elements are both metallic and non-metallic in their chemical relations; they form oxides  $\text{MO}_2$  that are acidic, and some of the lower oxides are basic. The oxide  $\text{UO}_2$  forms some corresponding salts; a series of salts of the form  $\text{UO}_2\text{X}$  is also known, where  $\text{X}=\text{SO}_4$ , &c. Several series of uranates  $\text{M}_2\text{UO}_6$ ,  $\text{M}_2\text{U}_2\text{O}_8$ , &c., are known. The haloid compounds are  $\text{JX}_4$ ,  $\text{UX}_4$ , and  $\text{UX}_3$ . (For a comparison of the metals of the  $\text{Cr}$  family v. CHROMIUM GROUP OF ELEMENTS, vol. ii. p. 168; cf. CLASSIFICATION, vol. ii. p. 207.)

The atom of  $\text{U}$  is tetravalent in the gaseous molecules  $\text{UBr}_4$  and  $\text{UCl}_4$ .

**Reactions and Combinations.**—1. Heated in *air*  $\text{U}$  is burnt to a voluminous deposit of  $\text{U}_3\text{O}_8$  (perhaps containing also  $\text{UO}_2$ ), which stops the further oxidation of the metal. Pulverulent  $\text{U}$  burns when heated in *air* to  $150^\circ\text{--}170^\circ$ .—2.  $\text{U}$  burns brilliantly when heated in *chlorine*, forming  $\text{UCl}_4$ ; heated in *bromine* to c.  $240^\circ$  part of the metal is changed to  $\text{UBr}_4$ .—3. Heated in *sulphur* vapour  $\text{US}_2$  is produced.—4. It is generally said that  $\text{U}$  does not react with *water*; but, according to Moissan (*C. R.* 116, 347), the metal obtained by him by reducing the oxide by charcoal in an electric furnace decomposed water at the ordinary temperature; this specimen of  $\text{U}$  contained from 5 to 13.5 p.c.  $\text{C}$ .—5.  $\text{U}$  dissolves in *dilute sulphuric acid*, rapidly on warming, forming  $\text{USO}_4$ , and giving off  $\text{H}$ ; pulverulent  $\text{U}$  dissolves in hot conc.  $\text{H}_2\text{SO}_4$ , giving off  $\text{SO}_2$ ; the compact metal is scarcely acted on by conc.  $\text{H}_2\text{SO}_4$ .—6.  $\text{U}$  dissolves in *hydrochloric acid*, dilute or conc., rapidly on warming, forming a hyacinth-red solution of  $\text{UCl}_4$ , which goes green on shaking in *air*, and then contains  $\text{UCl}_5$ .—7. *Conc. nitric acid*, even when hot, scarcely acts on  $\text{U}$  that has been fused; the pulverulent metal is quickly oxidised by hot conc.  $\text{HNO}_3$  to  $\text{U}_3\text{O}_8$ .—8. Several *metallic salts* in solution

are reduced by  $\text{U}$ , with ppn. of the metals, e.g.  $\text{HgNO}_3$ ,  $\text{AgNO}_3$ ,  $\text{CuSO}_4$ ,  $\text{SnCl}_4$ ,  $\text{PtCl}_4$ ,  $\text{AuCl}_3$ .

**Detection and Estimation.**—Uranyl salts ( $\text{UO}_2\text{SO}_4$ , &c.) are formed by heating uranates with acids, also by the reactions of acids with  $\text{UO}_2$ , and also by oxidising uranous salts (salts of  $\text{UO}$ ).  $\text{K}_2\text{FeCy}_4\text{Aq}$  gives a brownish-red pp. with uranyl salts, soluble in  $\text{HClAq}$  or in  $(\text{NH}_4)_2\text{CO}_3\text{Aq}$ ; this reaction is said to be extremely delicate;  $\text{H}_2\text{O}_2\text{Aq}$  and alcohol give a brown pp. (Fairley, *C. N.* 62, 227); carbonates give yellow pps., soluble in excess, forming yellow liquids;  $\text{NaOHAq}$  or  $\text{KOHAc}$  forms yellow pps.,  $\text{NH}_4\text{ClAq}$  does not interfere with the ppn., but in presence of sugar or tartaric acid pps. are not produced. Uranous salts are produced by reducing uranyl salts in solution by  $\text{Zn}$  and  $\text{HClAq}$ . After reduction the solutions give green pps. with  $\text{KOHAc}$  or  $\text{NaOHAq}$ , the pps. becoming brown and then yellow in the air; with  $(\text{NH}_4)_2\text{SAq}$  green pps. are formed, quickly becoming dark green, and black on boiling;  $\text{K}_2\text{FeCy}_4\text{Aq}$  produces yellow-green pps. becoming red in the air (v. Zimmermann, *A.* 213, 235).

$\text{U}$  is generally estimated as  $\text{UO}_2$  or  $\text{U}_3\text{O}_8$  (v. Zimmermann, *A.* 232, 209). Solutions may be reduced by  $\text{Zn}$  and  $\text{H}_2\text{SO}_4\text{Aq}$ , and then titrated with  $\text{KMnO}_4\text{Aq}$ , the quantity of  $\text{O}$  used corresponding with the change of  $\text{UO}_2$  to  $\text{UO}_3$  (*Z.*, *l.c.*; v. also Bösloubeck, *J. pr.* 99, 231).

**Uranium, arsenates of.** A compound, probably  $\text{UO}_2\text{As}_2\text{O}_7$ , 4aq, is described by Rammelsberg (*P.* 59, 26). Werther (*J. pr.* 43, 321) describes  $\text{UO}_2\text{H}_2\text{AsO}_4$ , 3aq, and various *double salts* of this compound with arsenates of  $\text{Ca}$ ,  $\text{Cu}$ , and  $\text{Na}$ .

**Uranium, bromides of.**  $\text{UBr}_4$  is formed by heating  $\text{U}_3\text{O}_8$  mixed with  $\text{C}$  in  $\text{Br}$  vapour; and  $\text{UBr}_3$  by heating  $\text{UBr}_4$  in  $\text{H}$ . Zimmermann (*A.* 216, 5) failed to obtain a compound with more  $\text{Br}$  by heating  $\text{UBr}_4$  with  $\text{Br}$  to  $230^\circ$  in a sealed tube.

**URANIUM TETRABROMIDE  $\text{UBr}_4$ .** (*Uranous bromide*.) Mol. w. 558. Prepared by strongly heating a mixture of  $\text{U}_3\text{O}_8$  and sugar, mixing with sugar charcoal that has been heated to redness, placing the mixture in a tube, and heating it first in a stream of thoroughly dried  $\text{CO}_2$ , and then in  $\text{Br}$  vapour, and allowing to cool in  $\text{CO}_2$ ; the  $\text{Br}$  used must be perfectly freed from  $\text{Cl}$ ,  $\text{HBr}$ , and  $\text{H}_2\text{O}$  by distillation from  $\text{KBr}$ ,  $\text{MnO}_2$ , and  $\text{P}_2\text{O}_5$  (Zimmermann, *A.* 216, 2; Alibegoff, *A.* 232, 132; cf. Hermann, *J.* 1861, 260).  $\text{UBr}_4$  forms black, fusible leaflets; volatile at red heat, giving a vapour with V.D. 281 (*Z.*, *l.c.*); very hygroscopic; dissolves in water, with a hissing sound, forming a green liquid.

By evaporating a solution of  $\text{UO}_2\cdot 2\text{H}_2\text{O}$  in  $\text{HBrAq}$ , Rammelsberg (*P.* 59, 12) obtained green crystals of hydrated  $\text{UBr}_4$ , probably  $\text{UBr}_4\cdot 8\text{H}_2\text{O}$ .

**Uranoxybromides.** (*Bromoxy-uranates*.)  $\text{UO}_2\text{Br}_2\cdot 2\text{MBr}$  or  $\text{M}_2\text{UOBr}_4$ . By the reaction of  $\text{HBrAq}$  with  $\text{K}_2\text{UO}_4$  and  $(\text{NH}_4)_2\text{UO}_4$ , respectively, Sendtner (*A.* 195, 325) obtained yellowish, hygroscopic tablets of the composition  $\frac{1}{2}\text{UO}_2\text{Br}_2\cdot 2\text{H}_2\text{O}$ , where  $\text{M}=\text{NH}_4$  and  $\text{K}$ .

**URANIUM TRIBROMIDE  $\text{UBr}_3$ .** Mol. w. not determined. Obtained by Alibegoff (*A.* 233, 119; cf. Zimmermann, *A.* 216, 5) by passing dry  $\text{H}$  over molten  $\text{UBr}_4$ . Dark-brown needles; easily

volatilised; not changed by continued heating in H; very hygroscopic; warmed in H<sub>2</sub>S, in complete absence of air, forms U<sub>2</sub>S<sub>3</sub>.

**Uranium chlorides of.** By heating U in Cl both UCl<sub>4</sub> and UCl<sub>3</sub> are produced; and by heating UCl<sub>3</sub> in H, UCl<sub>4</sub> is formed.

**URANIUM PENTACHLORIDE UCl<sub>5</sub>.** Mol. w. not determined; formula probably molecular, from analogy of MoCl<sub>5</sub> and WCl<sub>5</sub>.

**Preparation.**—1. By heating U in excess of Cl. —2. A slow stream of dry Cl is passed over a mixture of charcoal and any oxide of U, or UO<sub>2</sub>Cl<sub>2</sub> heated to dull redness in a glass tube; dark-green octahedral crystals of UCl<sub>4</sub> are formed near the heated part of the tube, and in front of these needle-shaped crystals of UCl<sub>5</sub> are deposited, mixed with a loose brown powder, which is also UCl<sub>4</sub>. If the stream of Cl is rapid, most of the UCl<sub>5</sub> is produced as a light-brown, mobile powder (Roscoe, *C. J.* [2] 12, 933).

**Properties and Reactions.**—UCl<sub>5</sub> crystallises in long, dark, needle-shaped forms; the crystals are lustrous, and reflect greenish light, in transmitted light they are dark ruby red. Both the crystals and the brown powder are very hygroscopic. Dissolves in water, with a hissing sound, forming a yellow-green liquid and giving off HCl. Decomposed to UCl<sub>4</sub> and Cl when heated, either alone or in CO<sub>2</sub> or Cl; decomposition begins at 120° in CO<sub>2</sub>, and is complete at 235°. Heating in NH<sub>3</sub> probably produces a nitride (Roscoe, *l.c.*; no analyses given).

**Combination.**—A compound UCl<sub>4</sub>·PCl<sub>5</sub> is described by Cronander (*J.* 1873. 222) as an amorphous, yellow solid; formed by heating UO<sub>2</sub> with excess of PCl<sub>5</sub> in a sealed tube for a long time.

**URANIUM TETRACHLORIDE UCl<sub>4</sub>.** (*Uranous chloride*.) Mol. w. 380.48.

**Preparation.**—1. U is heated in Cl. —2. A mixture of charcoal and an oxide of U, or UO<sub>2</sub>Cl<sub>2</sub>, is heated in a slow stream of dry Cl (Péligot, *A.* 43, 258; cf. Roscoe, *C. J.* [2] 12, 933). The crystals that form nearest to the heated part of the tube are again heated in a stream of dry CO<sub>2</sub>, whereby traces of UCl<sub>5</sub> are volatilised and removed (Zimmermann, *A.* 216, 8). —3. A solution of ammonium uranate in HClAq is reduced by Zn, and the solution is evaporated and crystallised. Arendt a. Knop (*C. C.* 1857. 164) reduced, by boiling the solution for 15 min. with Cu and a little PtCl<sub>4</sub>Aq; they then filtered, saturated with H<sub>2</sub>S, filtered, boiled off H<sub>2</sub>S, and crystallised.

**Properties and Reactions.**—Dark green, lustrous, regular octahedral crystals; volatilises at red heat, in complete absence of moisture, giving a red vapour (Péligot, *l.c.*) with V.D. 192 (Zimmermann, *l.c.*). Very deliquescent; fumes much in air, giving off HCl; dissolves in water, with a hissing sound, forming a green solution that is unchanged in air; gives green, amorphous UCl<sub>3</sub> by evaporation *in vacuo*, but is decomposed by evaporation in the air. When UCl<sub>4</sub>Aq is dropped into boiling water all the U is pptd. as UO<sub>2</sub>·2H<sub>2</sub>O. Solution of UCl<sub>4</sub> reduces salts of Au and Ag to the metals, and FeCl<sub>3</sub> to FeCl<sub>2</sub>, &c. By heating in dry H one-fourth of the Cl is removed and UCl<sub>3</sub> remains (Péligot, *A.* 43, 266). According to Péligot (*l.c.*), UCl<sub>4</sub> com-

bines with several metallic chlorides to form double salts.

**Uranoychlorides. (Chloroxyuranates.)** UO<sub>2</sub>Cl<sub>2</sub>·2MCl<sub>2</sub>·2aq, or M<sub>2</sub>UO<sub>2</sub>Cl<sub>4</sub>·2aq. Salts of this composition, M = NH<sub>4</sub> and K, are produced by the reaction of large excess of HClAq with uranates of NH<sub>4</sub> and K (Péligot, *A.* 43, 279). The K compound is also formed by acting on UO<sub>2</sub>Cl<sub>2</sub> with excess of KClAq, and separating the KCl that crystallises with the K<sub>2</sub>UO<sub>2</sub>Cl<sub>4</sub> mechanically (Berzelius, *P.* 1, 366). The K compound forms thick plates (for crystalline measurements), de la Provostaye, *A. Ch.* [3] 6, 165; easily loses water; gives off HCl at a little above 100°; melts at red heat, giving off Cl, and leaving UO<sub>2</sub> and KCl. The ammonium compound forms very deliquescent rhombohedra.

**URANIUM TRICHLORIDE UCl<sub>3</sub>.** Mol. w. not determined. Obtained by Péligot (*l.c.*) by heating UCl<sub>4</sub> in dry H as long as HCl was given off. Also formed in solution by long-continued reduction of uranyl salts by Zn and HClAq (Zimmermann, *A.* 213, 300). A brownish-red solid; dissolves very readily in water, forming a red solution, which gives off H and becomes green (*v. P.*, *l.c.*; *Z.*, *l.c.*; also *A.* 216, 12).

**Uranium ferrocyanides of.** Various compounds are described by Wyrnhoff (*A. Ch.* [5] 8, 444) and Atterberg (*Bl.* [2] 24, 355) as obtained by pptg. K<sub>2</sub>FeCy<sub>4</sub>Aq by solutions of salts of U. The following formulae are given:

- (1) U<sub>2</sub>FeCy<sub>4</sub>·10aq; (2) U<sub>2</sub>K<sub>2</sub>FeCy<sub>4</sub>·6aq;
- (3) (UO<sub>2</sub>)<sub>2</sub>K<sub>2</sub>(FeCy<sub>4</sub>)<sub>2</sub>·6aq;
- (4) (UO<sub>2</sub>)<sub>2</sub>K<sub>2</sub>(FeCy<sub>4</sub>)<sub>2</sub>·12aq.

**Uranium fluorides of.** Only one compound, UF<sub>4</sub>, has been isolated with certainty.

**URANIUM TETRAFLUORIDE UF<sub>4</sub>.** (*Uranous fluoride*.) Mol. w. not determined; formula probably molecular, from analogy of UBr<sub>4</sub> and UCl<sub>4</sub>. Prepared by adding HFAq to U<sub>2</sub>O<sub>3</sub>, boiling, pouring off the yellow solution (which contains UO<sub>2</sub>F<sub>2</sub>), washing the green powder that remains, first on a filter and then by decantation, until free from HFAq, and drying at 100° (Smithells, *C. J.* 43, 125; cf. Bolton, *Z.* [2] 2, 353). The process of washing is very tedious, and occupies many days. UF<sub>4</sub> is a green powder; insol. in water and dilute acids; slowly dissolved by conc. acids; boiling NaOHaq produces UO<sub>2</sub>. Heated in a Pt crucible with the lid on, a small quantity of a white, bulky sublimate is obtained; this sublimate is UO<sub>2</sub>F<sub>2</sub> (Smithells, *l.c.*); the residue in the crucible is chiefly UO<sub>2</sub>. Heated on Pt foil, UF<sub>4</sub> leaves U<sub>2</sub>O<sub>3</sub> (*S.*, *l.c.*).

**Double salts.**—Bolton (*l.c.*) obtained the compounds UF<sub>4</sub>·KF and UF<sub>4</sub>·NaF—as green powders, insoluble in water and dilute acids, giving UO<sub>2</sub>, KF (or NaF), and HF when heated to redness, in closed vessels—by the action of formic or oxalic acid on UO<sub>2</sub>F<sub>2</sub>·3KF or UO<sub>2</sub>F<sub>2</sub>·NaF (*v. infra*) in sunlight. These compounds may be called *uranofluorides*, and written KUF<sub>4</sub> and NaUF<sub>4</sub>.

**Uranium hexafluoride UF<sub>6</sub>.** Was said by Ditte (*C. R.* 91, 116) to be formed by heating U<sub>2</sub>O<sub>3</sub> with HFAq, evaporating the yellow liquid, and heating the crystals of UF<sub>4</sub>·8HF thus obtained; but Smithells (*C. J.* 43, 125) has shown that the substance obtained by evaporating the

solution formed by heating  $\text{U}_3\text{O}_8$  with  $\text{HFAq}$  is  $\text{UO}_2\text{F}_2$  (v. URANIUM OXYFLUORIDE, p. 828).

**Uranoxyfluorides.** (*Fluoroxo-uranates.*) These compounds may be regarded either as double salts of  $\text{UO}_2\text{F}_2$  with alkali fluorides, or as salts derived from hypothetical acids  $\text{H}_x\text{UO}_x\text{F}_y$ . The compounds are formed by adding alkali fluorides to solutions of uranous nitrate, and crystallising under different conditions (v. Bolton, *Z.* [2] 2, 353; Baker, *C. J.* 85, 763). The compounds that have been isolated belong to several series: (1)  $\text{MF} \cdot \text{UO}_2\text{F}_2 \cdot x\text{aq} = \text{MUO}_2\text{F}_2 \cdot x\text{aq}$ , where  $\text{M} = \text{Na}$  and  $x = 2$  and 4 (Bolton); (2)  $3\text{MF} \cdot \text{UO}_2\text{F}_2 = \text{M}_3\text{UO}_2\text{F}_6$ , where  $\text{M} = \text{NH}_4$  and  $\text{K}$  (Bolton; Baker); (3)  $3\text{KF} \cdot 2\text{UO}_2\text{F}_2 \cdot 2\text{aq} = \text{K}_3\text{U}_2\text{O}_7\text{F}_8 \cdot 2\text{aq}$  (Baker); (4)  $5\text{KF} \cdot 2\text{UO}_2\text{F}_2 = \text{K}_5\text{U}_2\text{O}_7\text{F}_{12}$  (Baker); (5)  $82\text{BaF}_2 \cdot 5\text{UO}_2\text{F}_2 \cdot 2\text{aq}$  (Bolton). Two other series were described by Ditte (*C. R.* 91, 166),  $4\text{MF} \cdot \text{UO}_2\text{F}_2$  and  $4\text{MF} \cdot \text{UOF}_4 \cdot x\text{aq}$ ; but the experiments of Smithells (*C. J.* 48, 131) have shown that these compounds do not exist.

**Uranium, haloid compounds of.** U combines directly with Br and Cl, but not with I; no iodide, indeed, has been isolated. The haloid compounds of U belong to the form  $\text{UX}_n$ , where  $\text{X} = \text{Br}$  or  $\text{Cl}$ ;  $\text{UX}_n$ , where  $\text{X} = \text{Br}$ ,  $\text{Cl}$  or  $\text{F}$ ; and  $\text{UX}_n$ , where  $\text{X} = \text{Cl}$ . The compounds  $\text{UBr}_3$  and  $\text{UCl}_3$  have been gasified, and the formulae are molecular. From the analogy of  $\text{WCl}_4$  and  $\text{MoCl}_4$ , the formula  $\text{UCl}_3$  is probably molecular; this compound decomposes to  $\text{UCl}_4$  and  $\text{Cl}$  when heated, either alone or in  $\text{CO}_2$  or  $\text{Cl}$ . From the analogy of  $\text{CrCl}_3$ , it may be supposed that  $\text{UCl}_3$  and  $\text{UBr}_3$  are molecular formulae. No haloid compounds of U have been isolated corresponding with the chlorides of Cr, Mo, and W,  $\text{M}_2\text{Cl}_6$ . No haloid compounds of U are known containing each more than one halogen. Various oxyhaloid compounds, chiefly  $\text{UO}_2\text{X}_2$ , and compounds of these with alkali haloids, are known.

**Uranium, hydroxides of, v. URANIUM, OXIDES AND HYDRATED OXIDES OF (infra); also URANIUM OXYACIDS, AND SALTS OF (p. 826).**

**Uranium, iodides of.** No compound of U and I has been isolated. Hermann (*J.* 1861, 280) and Sendter (*Verbind. des Uraniums*, Erlangen, 1877) failed to obtain an iodide by heating a mixture of  $\text{UO}_2$  and C in I vapour or in HI.

**Uranium, nitride of,  $\text{U}_3\text{N}_4$ .** A greyish-black powder; obtained by heating  $\text{UCl}_3$  in  $\text{NH}_3$ , then mixing with  $\text{NH}_4\text{Cl}$  and heating for a long time in a stream of  $\text{NH}_3$  (Uhrlaub, *Verbind. einiger Metalle mit Stickstoff*, Göttingen, 1855). Roscoe (*C. J.* [2] 12, 933) states that a nitride is formed by heating  $\text{UCl}_3$  in  $\text{NH}_3$ , but no analyses are given.

**Uranium, oxides and hydrated oxides of.** When U is burnt in air the product is  $\text{U}_3\text{O}_8$ ; by heating this oxide with reducers, or for a long time in a stream of N or  $\text{CO}_2$ ,  $\text{UO}_2$  is formed;  $\text{UO}_2$  is produced by fusing  $\text{U}_3\text{O}_8$  with  $\text{KClO}_4$ , also by heating  $\text{UCl}_3(\text{NO}_2)_3$ ; by adding  $\text{H}_2\text{O}_2\text{Aq}$  to  $\text{UO}_2(\text{Q} \cdot \text{H}_2\text{O})_2\text{Aq}$  or  $\text{UO}_2(\text{NO}_3)_2\text{Aq}$  a hydrate of  $\text{UO}_2$  is obtained. Besides these four oxides, others, intermediate between  $\text{UO}_2$  and  $\text{UO}_3$ , perhaps exist. No definite hydrate of  $\text{UO}_2$  has been isolated; the pp. formed by adding  $\text{NH}_4\text{Aq}$  to  $\text{UCl}_3\text{Aq}$ , or to solution of a uranous salt ( $\text{U}(\text{SO}_4)_2$ , &c.), is either a hydrate, or a

mixture of hydrates, of  $\text{UO}_2$ . A hexahydrate of  $\text{U}_3\text{O}_8$  probably exists. Uranic acid is the monohydrate of  $\text{UO}_3$ .  $\text{UO}_2$  dissolves in some acids to form corresponding salts;  $\text{U}_3\text{O}_8$  is said to react with conc.  $\text{H}_2\text{SO}_4$  or  $\text{HClAq}$  to form both uranous salts  $\text{UX}_n$ , and uranyl salts  $\text{UO}_2\text{X}_n$ , where X = a divalent acidic radicle.  $\text{UO}_2$  interacts with several acids to form uranyl salts  $\text{UO}_2\text{X}_n$ ;  $\text{UO}_2$  also reacts as an acidic oxide with strong bases, forming uranates, di-uranates, &c.,  $\text{M}_2\text{UO}_4$ ,  $\text{M}_2\text{U}_2\text{O}_7$ , &c.

According to Guyard (*Bull.* [2] 1, 89), two oxides having the compositions  $\text{UO}$  and  $\text{U}_2\text{O}_3$  exist; but the more accurate investigations of Zimmermann (*A.* 213, 301) showed that the substances examined by Guyard were not definite compounds. Pélégot described a "black oxide  $\text{U}_2\text{O}_3$ "; Zimmermann (*A.* 232, 273) has shown that the substance is a mixture, in variable proportions, of  $\text{UO}$  and  $\text{U}_2\text{O}_3$ .

**URANIUM DIOXIDE  $\text{UO}_2$ .** (*Uranous oxide.*) Mol. w. not known. This oxide was supposed to be the element U until 1840, when Pélégot proved the presence of O in the substance (*A. Ch.* [3] 5, 5).

**Formation.**—1. By heating  $\text{U}_3\text{O}_8$  with such reducing agents as H (Arfvedson, *P.* 1, 245),  $\text{NH}_4\text{Cl}$  and S (Hermann, *J.* 1861, 258), a little C (Buchholz, *Gehlen's Ann.* 4, 17, 134), oxalic acid (Wertheim, *J. pr.* 20, 211), &c.—2. By heating  $\text{U}_3\text{O}_8$  for a long time in a stream of N or  $\text{CO}_2$  (Zimmermann, *A.* 232, 293).—3. By strongly heating  $\text{UO}_2\text{C}_2\text{O}_4$  in absence of air (Berzelius, *P.* 1, 359), or in a stream of H (Pélégot, *A. Ch.* [3] 5, 5; Ebelmeier, *A. Ch.* [3] 5, 189).

**Preparation.**—A mixture of  $\text{UO}_2\text{Cl}_2$  and excess of  $\text{NaCl}$  and  $\text{NH}_4\text{Cl}$  is strongly heated in absence of air; and the product is washed thoroughly with water, and dried (Wöhler, *Z.* 41, 345; cf. Hillebrand, *Zeit. f. anorg. Chemie*, 3, 243). If air is not excluded during heating, some  $\text{UO}_3$  is obtained (H., l.c.). This process gives  $\text{UO}_2$  as a black crystalline powder. In place of using  $\text{UO}_2\text{Cl}_2$ , a solution of ammonium uranate in  $\text{HClAq}$  may be mixed with excess of  $\text{NaCl}$  and  $\text{NH}_4\text{Cl}$ , and evaporated to dryness, and the residue heated. By fusing any oxide of U with borax for 24 hours, and washing with water and then with dilute acetic acid, or dilute  $\text{HClAq}$ , Hillebrand (l.c. p. 249) obtained jet-black octahedra of  $\text{UO}_2$  isomorphous with  $\text{ThO}_2$ .

**Properties.**—Prepared by heating  $\text{UO}_2\text{C}_2\text{O}_4$ ,  $\text{UO}_2$  is a dark-brown, pyrophoric powder; if the temperature has been kept high the oxide is lustrous, reddish-black, and not pyrophoric; prepared by heating  $\text{UO}_2\text{Cl}_2$  with  $\text{NaCl}$  and  $\text{NH}_4\text{Cl}$ ,  $\text{UO}_2$  forms black, non-pyrophoric, octahedral crystals. Pélégot gave S.G. 10.15; according to Hillebrand (l.c.), the S.G. is nearly 11.  $\text{UO}_2$  is insoluble in water,  $\text{HClAq}$ , and dilute  $\text{H}_2\text{SO}_4\text{Aq}$ ; it dissolves in  $\text{HNO}_3\text{Aq}$ , and in conc.  $\text{H}_2\text{SO}_4$  in presence of a little water.  $\text{UO}_2$  is oxidised to  $\text{U}_3\text{O}_8$  by heating in air.

**Reactions.**—1. Heated in air or oxygen  $\text{U}_3\text{O}_8$  is produced;  $\text{UO}_2$  burns brilliantly in the  $\text{O}_2\text{-H}$  flame (Clarke, *G.* 4, 62, 853).—2. Heating in chlorine produces  $\text{UO}_2\text{Cl}_2$ ; when mixed with carbon and heated in chlorine,  $\text{UCl}_4$  and  $\text{UCl}_3$  are formed.  $\text{UBr}_3$  is produced by heating  $\text{UO}_2$  mixed with carbon in bromine vapour.—3.  $\text{UO}_2$  is formed by heating  $\text{UO}_2$  in water vapour

(Regnault, *A. Ch.* [2] 62, 358).—4. Heating in vapour of carbon disulphide produces  $U_2O_3S_2$  (Hermann, *J.* 1861, 258; H. Rose, *G. A.* 73, 139).  $UO_2$  is said to be unchanged by heating in hydrosulphide (Arfvedson, *P.* 1, 245).—5. A solution of  $UO_2$  in conc. sulphuric acid gives green crystals of  $U(SO_4)_2$  on evaporation.

**HYDRATES OF URANIUM DIOXIDE.** No definite hydrate of  $UO_2$  has been isolated;  $NH_4Aq$  produces a reddish-brown pp. when added to  $UCl_4Aq$  or solution of a uranous salt, this pp. becomes black on boiling; when washed with air-free water and dried *in vacuo* it forms black, coherent lumps. A black pp. is also produced by dropping  $UCl_4Aq$  into boiling water. These black pps. contain  $UO_2$ ; they are probably hydrates of this oxide. The name *uranous hydroxide* is often given to the pp. obtained by either of the processes described; the pp. dissolves in dilute  $H_2SO_4Aq$ ,  $HNO_3Aq$ , and  $HClAq$ .

**URANOSO-URANIC OXIDE  $U_3O_8$ .** (*Olive-green oxide of uranium.* *Uranyl uranate*  $UO_2 \cdot 2UO_3$ .) Mol. w. not known.

**Occurrence.**—In combination with  $SiO_2$ , and oxides of Sb, As, Ca, Cu, Fe, Mg, &c., in *pitchblende*.

**Preparation.**— $U$ , or a decomposable  $U$  compound, e.g.  $UO_2(NO_3)_2$ , is heated in the air and then in a stream of  $O_2$ , and is allowed to cool in  $O$  (v. Zimmernmann, *A.* 232, 283). For a method of preparing  $U_3O_8$  from *pitchblende* v. URANIUM, *Preparation* of (p. 831).

**Properties.**—A dark olive-green powder, sometimes almost black, but always showing a green streak when rubbed on unglazed porcelain (Z., l.c.). S.G. 7.2 (Karsten, *S.* 65, 394); 7.31 (Ebelmen, *J.* pr. 27, 385). S.H. 0.7979 (Donath, *B.* 12, 742). Insoluble in water; slightly soluble in dilute  $HClAq$  or  $H_2SO_4Aq$ ; soluble in  $HNO_3Aq$ , also in  $H_2SO_4$  with a little water.

**Reactions.**—1. Gives off  $O$  when heated in air or in an indifferent gas; the final product of heating in  $N$  or  $CO_2$  is  $UO_2$  (Zimmernmann, *A.* 232, 283).—2. Reduced to  $UO_2$  by heating with hydrogen, carbon, sulphur, potassium, or sodium. 3. Heated in vapour of carbon disulphide  $U_2O_3S_2$  is formed.—4. Heated with conc. sulphuric acid, or with hydrochloric acid to  $180^\circ$ – $200^\circ$ , gives both uranous and uranyl sulphates, or chlorides; reacting as  $UO_2 \cdot 2UO_3$  (Z., *A.* 232, 287).—5. Silver nitrate solution is slowly reduced to Ag (Isambert, *C. R.* 80, 1089).

**HYDRATE OF URANOSO-URANIC OXIDE.** By adding  $NH_4Aq$  to  $UCl_4Aq$  and allowing the pp. to oxidise in the air, and drying *in vacuo* over  $H_2SO_4$ , Rammelsberg (*P.* 55, 319) obtained a greenish-black solid which may have been a hydrate of  $U_3O_8$ ; one determination of water only is given which agrees fairly with  $U_3O_8 \cdot 6H_2O$ .

**URANIUM TRIOXIDE  $UO_3$ .** (*Uranic oxide. Uranic anhydride. Uranyl oxide*  $(UO_3)_2$ .) Mol. w. not known. This oxide is obtained by carefully heating the hydrate  $UO_3 \cdot H_2O$  (v. *infra*) to  $800^\circ$  (Ebelmen, *A. Ch.* [2] 5, 199); to  $250^\circ$ , temperature being gradually raised (Jacquelin, *Ph. C.* 1845, 183). The oxide is also formed by heating  $UO_2 \cdot CO_2 \cdot 2(NH_4)_2CO_3$  to  $800^\circ$  (E., l.c.). The preparation of  $UO_3$  may be conducted by heating  $UO_2(NO_3)_2$  in a Pt basin until decomposition begins, then transferring to glass tubes

and heating these in an oil-bath to  $250^\circ$  so long as acid fumes are given off.

$UO_3$  is a chamois-yellow powder. S.G. 5.02 to 5.26 (Brauner & Watts, *P. M.* [5] 11, 60). Ebelmen (l.c.) described  $UO_3$  obtained by heating  $UO_2 \cdot CO_2 \cdot 2(NH_4)_2CO_3$  as a sealing-wax-red powder. When  $UO_3$  is heated to redness it gives off  $O$  and  $U_2O_3$  remains (E., l.c.; cf. Read, *C. J.* 65, 313 [1894]); the oxide seems to be somewhat volatile at the temperature of a porcelain oven (Elsner, *J.* 1866, 35).

$UO_3$  reacts with many acids as a basic oxide, but the salts formed are always basic salts of the forms  $UX_{n-2}UO_3$ , where  $X$  = the radicle of a monobasic acid, and  $UX_{n-1}UO_3$ , where  $X$  = the radicle of a dibasic acid. It is customary to write the formulae of these basic salts as  $UO_3 \cdot X_2$  and  $UO_3 \cdot XH$ , and to call them *uranyl salts*

( $UO_3$  = uranyl); thus  $U(NO_3)_2 \cdot 2UO_3 = UO_3(NO_3)_2$ , and  $U(SO_4)_2 \cdot 2UO_3 = UO_3(SO_4)_2$ .

$UO_3$  behaves towards strong bases as an acidic oxide, forming uranates  $M_2UO_6$ , and diuranates  $M_2U_2O_6$ , &c.; these salts are generally formed by fusing  $U$  compounds with bases and  $O$ , and by ppg. uranyl salt solutions by strong bases. When  $KOHAq$ ,  $NaOHAq$ ,  $NH_4Aq$ ,  $BaO_4Aq$ , or  $CaO_4Aq$  is added to a solution of uranyl salt, e.g. to  $UO_3(NO_3)_2Aq$ , the pp. consists of a uranate of the metal of the base. Alkali carbonates ppt. alkali uranates, but the pps. contain also  $CO_2$ ; the pps. dissolve in excess of the alkali carbonates forming double carbonates of uranyl and the alkali metal, e.g.  $UO_3 \cdot CO_3 \cdot 2(NH_4)_2CO_3$ . Addition of alkali or alkali carbonate to solutions of uranyl salts containing other metallic salts causes pptn. of a uranate of the metal of the salt present, generally mixed with alkali uranate (cf. URANIUM, OXYACIDS, AND SALTS THEREOF, p. 826).

By adding  $KOH$  to a cold solution of  $UCl_4$  or  $UO_3(NO_3)_2$ , and dialysing, Graham (*T.* 1861, 213) obtained a solution, free from acid and alkali, which he regarded as a loose compound of sugar and  $UO_3$ , and which he called *sucrate of peroxide of uranium*.

**HYDRATES OF URANIUM TRIOXIDE.** Pure hydrates of  $UO_3$  are not obtained by ppg. uranyl salt solutions by alkalis (v. *supra*); but according to Ebelmen (*A. Ch.* [3] 5, 199)  $UO_3 \cdot xH_2O$  is produced by boiling an aqueous solution of  $UO_2 \cdot CO_3 \cdot 2(NH_4)_2CO_3$  until a yellow pp. is formed, and allowing this pp. to stand for a long time. By the continued action of sunlight on  $UO_3(C_2O_4)_2$  in presence of water,  $UO_3 \cdot xH_2O$  is said to be formed; after washing and drying in the air, the solid has the composition  $UO_3 \cdot 2H_2O$ ; and after drying *in vacuo* the composition is  $UO_3 \cdot H_2O$  (E., l.c.). Berzelius (*B. J.* 24, 118) obtained  $UO_3 \cdot H_2O$  by heating  $UO_3(NH_4)_2$  on a sand-bath until acid fumes ceased to be given off, washing the residue with boiling water, and drying in air. The same hydrate is said to be formed by heating  $UO_3$  with  $KClO_4$  until fusion begins, boiling out with water, and drying in air (Druckmann, *J.* 1861, 256). The best method of preparing  $UO_3 \cdot H_2O$  seems to be that given by Malaguti (*A. Ch.* [8] 9, 463), viz. boiling a solution of  $UO_2(NO_3)_2$  in absolute alcohol as long as a

reaction proceeds, washing the yellow solid that separates with water, and drying in air or *in vacuo*;  $\text{EtNO}_3$ ,  $\text{N}_2\text{O}_5$ ,  $\text{C}_2\text{H}_5\text{O}$ , and  $\text{H}_2\text{CO}_3$  are formed in the reaction.

$\text{UO}_2\text{H}_2\text{O}$  is described as a yellow powder; S.G. 5.98 at  $15^\circ$  (Malaguti, *l.c.*); reddens litmus paper; when hot it absorbs  $\text{CO}_2$  from the air; heated to  $250^\circ$ – $300^\circ$  water is given off and  $\text{UO}_2$  remains (Ebelmen, *l.c.*; Jacquelin, *Ch. [3] 5*, 199); heated to redness gives off O and leaves  $\text{U}_3\text{O}_8$ .  $\text{UO}_2\text{H}_2\text{O}$  is generally called *uranic acid*; *v. URANIUM OXYACIDS, AND SALTS THEREOF (infra)*.

**URANIUM PEROXIDE.** By adding  $\text{UO}_2(\text{NO}_3)_2$  Aq to a mixture of  $\text{H}_2\text{O}_2$  Aq and a large excess of  $\text{H}_2\text{SO}_4$  Aq, and allowing to stand for a considerable time, Fairley (*C. J. 31*, 13, [1877]) obtained a small quantity of a heavy, crystalline, almost white ppt., which when dried (? in air, or at  $100^\circ$ ) had the composition  $\text{UO}_4$ . By adding dilute  $\text{H}_2\text{O}_2$  Aq to solution of  $\text{UO}_2(\text{NO}_3)_2$  or  $\text{UO}_2(\text{C}_2\text{H}_3\text{O}_2)_2$ , free from acids, Fairley (*l.c.* p. 127) obtained a yellowish-white ppt., which when dried by pressure between filter paper had the composition  $\text{UO}_4\text{H}_2\text{O}$ , and when dried at  $500^\circ$  the composition  $\text{UO}_4\text{H}_2\text{O}$ .

Zimmermann (*A. 232*, 273 [1886]) failed to obtain the tetrahydrate  $\text{UO}_4\text{H}_2\text{O}$ ; according to him the dihydrate  $\text{UO}_4\text{H}_2\text{O}$  is very hygroscopic, and begins to decompose at  $115^\circ$ . Alibegoff also obtained only  $\text{UO}_4\text{H}_2\text{O}$ ; he failed to prepare the anhydrous oxide  $\text{UO}_4$  (*A. 233*, 123 [1886]).

Hydrated uranium peroxide, dried at  $100^\circ$ , is a yellowish-white powder; decomposed by heat, giving off O and leaving much  $\text{U}_3\text{O}_8$ ; reacts with alkali solutions to give  $\text{UO}_4\text{H}_2\text{O}$ , and a solution from which alkali *peruranate*  $2\text{M}_2\text{O} \cdot \text{UO}_4$  8aq. crystallises (Fairley, *l.c.*; *v. Peruranates* under URANIUM OXYACIDS, AND SALTS THEREOF, p. 827).

**URANIUM OXYACIDS, AND SALTS THEREOF.**  $\text{UO}_2\text{H}_2\text{O} = \text{H}_2\text{UO}_4$  reacts with strong bases as an acid, forming uranates  $\text{M}_2\text{UO}_4$ ; di-uranates  $\text{M}_2'\text{U}_2\text{O}_8$  are also known, and a few tri- and hexa-uranates. A few peruranates are derived from hydrated uranium peroxide  $\text{UO}_4\text{H}_2\text{O}$ . The compounds of  $\text{UO}_2\text{X}_2$  with MX (X = Br, Cl, or F) may be regarded as bromoxy-, chloroxy-, and fluoxy-uranates. The substance known as *uranium red* is perhaps  $\text{UO}_2\text{ONH}_4\text{SNH}_4$ , i.e. the ammonium salt of an oxythio-uronic acid (*v. URANIUM OXSULPHIDES*, p. 828).

**URANIC ACID  $\text{H}_2\text{UO}_4$ .** This compound is obtained as a yellow powder, which reddens litmus paper, and is decomposed to  $\text{UO}_2$  and  $\text{H}_2\text{O}$  at  $250^\circ$ – $300^\circ$ , and to  $\text{U}_3\text{O}_8$  and O at a higher temperature, by boiling a solution of  $\text{UO}_2(\text{NO}_3)_2$  in absolute alcohol, washing the solid that separates with water, and drying in air or *in vacuo*. (For other methods of preparation, and more details *v. HYDRATES OF URANIUM TRIOXIDE*, p. 825.) The salts of  $\text{H}_2\text{UO}_4$  are prepared indirectly.

**URANATES, DI-URANATES, &c.** Salts derived from  $\text{H}_2\text{UO}_4$ ; salts derived from the hypothetical acids  $\text{H}_2\text{U}_2\text{O}_8$ ,  $\text{H}_2\text{U}_3\text{O}_{12}$ ,  $\text{H}_2\text{U}_4\text{O}_{16}$ , are also known.

**URANATES.** Salts of the composition  $\text{M}'_2\text{UO}_4$  and  $\text{M}''_2\text{UO}_4$ . These salts are prepared by ppg. solutions of uranyl salts by bases in solution, or by adding alkali solution to a mix-

ture of a uranyl salt and a metallic oxide in solution; also, in many cases, by oxidising  $\text{U}_3\text{O}_8$  or  $\text{UO}_2$  in presence of a base or a salt of a base. The uranates are insoluble in water, and are not readily decomposed by heat except the ammonium salt. Carson and Norton (*Am. J. 10*, 219) have pointed out that analyses of uranates always show considerable differences between the percentages of U found and calculated; they have found the same anomaly in analyses of uranates of ammonium and several ammonium derivatives, such as  $\text{NEtH}_4$ ,  $\text{NEt}_2\text{H}_2$ , &c.

**Ammonium uranates.** The pure salt does not seem to have been isolated. An impure uranate containing c. 90 p.c.  $\text{UO}_2$  ( $(\text{NH}_4)_2\text{UO}_4$  requires 84.66 p.c.  $\text{UO}_2$ ) is obtained by adding  $\text{NH}_3$  Aq to a solution of a uranyl salt (Féligot); it is a yellow powder, which loses  $\text{H}_2\text{O}$  and  $\text{NH}_3$  above  $100^\circ$ , very slightly soluble in water, and insol.  $\text{NH}_3$  Aq (Arfvedson, *P. 1*, 245). An impure salt is also obtained by adding  $\text{NH}_4\text{Cl}$  Aq or  $(\text{NH}_4)_2\text{SO}_4$  Aq to boiling  $\text{Na}_2\text{UO}_4$  Aq, as long as  $\text{NH}_3$  and  $\text{CO}_2$  are given off, washing the ppt., and drying at a low temperature (Anthon, *D. P. J. 156*, 211). Heated to redness gives  $\text{U}_3\text{O}_8$ ; many of the compounds of U are prepared from ammonium uranate.

**Potassium uranate  $\text{K}_2\text{UO}_4$ .** Prepared by heating 6g.  $\text{U}_3\text{O}_8$  with  $\text{HCl}$  Aq and  $\text{HNO}_3$  Aq, adding 4g. KCl and 16g.  $\text{NH}_4\text{Cl}$ , evaporating to dryness, heating very strongly until the fused mass is orange-yellow, and washing with water (Zimmermann, *A. 213*, 290). The salt is said to be formed also by strongly heating  $\text{UO}_4\text{H}_2\text{O}$  (obtained by ppg. a uranyl salt by a phosphate) with  $\text{K}_2\text{SO}_4$  (Grandean, *A. Ch. [6] 8*, 223). Orange-yellow, rhombic tablets; insol. water, cold or hot; easily sol. acids (Zimmermann, *l.c.*).

**Sodium uranate  $\text{Na}_2\text{UO}_4$ .** Prepared by fusing  $\text{U}_3\text{O}_8$  with NaCl and  $\text{Na}_2\text{CO}_3$ , or with NaCl with gradual addition of  $\text{NaClO}_4$ , and washing with water; resembles  $\text{K}_2\text{UO}_4$  (Zimmermann, *l.c.*).

**Lithium uranate  $\text{Li}_2\text{UO}_4$ .** has been prepared similarly to  $\text{K}_2\text{UO}_4$ ; it is said to be decomposed by hot water (Z., *l.c.*). Uranates of Ba, Ca, and Sr— $\text{MUO}_4$ —are said by Ditte (*C. R. 95*, 988) to be formed by heating the chlorides of these metals with  $\text{U}_3\text{O}_8$ .

**DI-URANATES.** Salts of the composition  $\text{M}'_2\text{U}_2\text{O}_8$  and  $\text{M}''_2\text{U}_2\text{O}_8$ . The formulae may also be written  $\text{M}'_2\text{UO}_4 \cdot \text{UO}_4$  and  $\text{M}''_2\text{UO}_4 \cdot \text{UO}_4$ .

**Barium di-uranate  $\text{BaU}_2\text{O}_8$ .** Formed by ppg.  $\text{UO}_2(\text{C}_2\text{H}_3\text{O}_2)_2$  Aq by  $\text{BaO}$  Aq (Berzelius, *P. 1*, 359); also by heating to redness  $\text{UO}_2 \cdot \text{Ba}(\text{C}_2\text{H}_3\text{O}_2)_2$  (Wertheim, *J. pr. 29*, 207). A yellowish-red powder.

**Calcium di-uranate  $\text{CaU}_2\text{O}_8$ .** Formed, according to Ditte (*C. R. 95*, 988), by strongly heating  $\text{U}_3\text{O}_8$  with  $\text{Ca}(\text{ClO}_4)_2$ ; a yellowish-green solid.

**Copper di-uranate  $\text{CuU}_2\text{O}_8$ .** This salt is said to be formed as a green crystalline powder, by fusing  $\text{Cu}(\text{UO}_2\text{PO}_4)_2$  8aq. with  $\text{Na}_2\text{CO}_3$ , and washing with water (Debray, *A. Ch. [8] 61*, 461).

**Lead di-uranate  $\text{PbU}_2\text{O}_8$ .** Formed by digesting  $\text{UO}_2(\text{C}_2\text{H}_3\text{O}_2)_2$  Aq with freshly pptd.  $\text{PbCO}_3$  (Wertheim, *J. pr. 29*, 207); also by adding  $\text{NH}_3$  Aq to a mixture of  $\text{UO}_2(\text{NO}_3)_2$  Aq and  $\text{Pb}(\text{NO}_3)_2$  Aq (Arfvedson, *P. 1*, 258). A yellowish-

red powder, becoming green when heated; strongly heated in H, gives a pyrophoric mixture of Pb and  $UO_2$ .

**Potassium di-uranate**  $K_2U_2O_7$ . Formed by melting together  $UO_2$  and  $K_2CO_3$  and washing with water; also by strongly heating  $UO_2 \cdot K_2(CO_3)_2$  or  $UO_2 \cdot K_2(C_2H_3O_2)_2$  (Berzelius, *P.* 1, 359). A yellowish-red powder.

**Silver di-uranate**  $Ag_2U_2O_7$ . Obtained by adding amorphous  $K_2UO_4$  to molten  $AgNO_3$  and washing with ice-cold water (Alibegoff, *A.* 232, 129; 233, 117, 143). Also by strongly heating  $UO_2 \cdot Ag_2(C_2H_3O_2)_2$  (Wertheim, *J. pr.* 29, 221; cf. Rammelsberg, *P.* 59, 10). An amorphous, yellow-red solid; easily sol. acids; decomposed by hot water (Alibegoff, *loc.*).

**Sodium di-uranate**  $Na_2U_2O_7$ . Gaq. Obtained by ppg. uranyl salts by  $NaOH$ aq (Patera, *J. pr.* 51, 125; cf. Stolba, *Fr.* 3, 74). Loses water of crystallisation over  $H_2SO_4$ . A light-yellow to darkish-yellow powder. Known commercially as *uranium yellow* (v. DICTIONARY OR APPLIED CHEMISTRY, vol. iii. p. 893).

*Di-uranate of strontium*  $SrU_2O_7$  is said also to exist (Ditte, *C. R.* 95, 988).

**TRI-URANATES.** The only salt that has been isolated is *sodium tri-uranate*  $Na_3U_3O_{10}$ ; it is prepared by fusing  $UO_2(SO_4)$  with  $NaCl$  and boiling out with water. This salt forms yellow leaflets resembling mosaic gold; S.G. 6.912; hygroscopic; insol. water, sol. acids (Drenkmann, *J.* 1861. 255).

**HEXA-URANATES.** The *potassium salt*,  $K_6U_6O_{18}$ , Gaq, is described as a yellow microscopically crystalline powder, which loses all water at  $300^\circ\text{--}400^\circ$ ; prepared by melting  $UO_2(SO_4)$  with  $KCl$  (Drenkmann, *J.* 1861. 255).

**PERI-URANATES.** By adding excess of alkali and  $H_2O_2$ aq to solutions of uranyl salts, Fairley (*C. J.* 31, 134) obtained salts which may be formulated as  $M_2UO_4 \cdot xaq$  and  $M_2U_2O_8 \cdot xaq$  where  $M = NH_4, K$ , or  $Na$ , and  $R = UO_2$ .

**Ammonium-uranyl peruranate**  $(NH_4)_4(UO_2)_3UO_4$ . Saq. The formula may also be written  $(NH_4)_4O_4U_4O_{12}$ . Saq, or  $(NH_4)_2O_4U_4O_{12}$ . Saq, or, regarding the compound as a double peroxide of U and  $NH_4$ , as  $2UO_2(NH_4)_2O_4$ . Saq. The salt is prepared by adding excess of  $NH_4$ aq and  $H_2O_2$ aq to a solution of a uranyl salt and ppg. by alcohol; it is an orange-yellow solid, readily soluble in water. The quantity of  $KMnO_4$  in solution decolourised shows that the ratio of U to 'peroxide oxygen' in the salt is U:3O.

**Potassium per-uranate**  $K_4U_4O_{16}$ . This salt may also be looked on as a double peroxide of U and  $K(UO_2 \cdot K_2O_4 \cdot 10aq)$ , or as  $2K_2O_4U_4O_{16}$ . 10aq. It is prepared by adding alcohol to a solution obtained by treating  $UO_2(NO_3)_2$ aq with  $KOH$ aq and excess of  $H_2O_2$ aq, and rapidly drying the orange-yellow pp. by pressure in filter paper. The salt rapidly absorbs  $CO_2$  from the air and loses O; it is easily decomposed by heat, giving off  $H_2O$  and O. Experiments showed that the ratio of U to 'peroxide oxygen' is U:3O.

**Sodium peruranate**  $Na_4U_4O_{16}$ . Saq. This formula may also be written  $UO_2 \cdot Na_2O_4$ . Saq or  $2Na_2O_4U_4O_{16}$ . Saq. The salt is prepared by dissolving 'ordinary uramic hydrate,' or  $UO_2 \cdot xaq$ , in excess of  $NaOH$ aq along with excess of  $H_2O_2$ aq, allowing to crystallise if conc. solutions

are used, or ppg. by a little alcohol if dilute solutions are used, and drying by pressure in filter paper. Poleck (*B.* 27, 1051 [1894]) obtained this salt by adding sodium superoxide to solution of a salt of U. The salt is golden-yellow and lustrous; it slowly absorbs  $CO_2$  from the air, and gives off O. When heated, alone or in  $CO_2$ , it gives off  $3O$ ; it also loses  $3O$  in contact with acidified  $KMnO_4$  or other unstable O compounds. The ratio of U to 'peroxide oxygen' is U:3O as measured by the quantity of  $KMnO_4$  decolourised by a solution of the salt.

#### Sodium-uranyl per-uranate

$Na_4(UO_2)_3UO_4$ . Gaq. The formula may also be written  $Na_4O_4U_4O_{12}$ , Gaq or  $Na_2O_4U_4O_{12}$ , Gaq; or, regarding the compound as a double peroxide of U and Na, as  $2UO_2 \cdot Na_2O_4$ . Gaq. The salt is prepared similarly to  $Na_4U_4O_{16}$ , but using only the minimum quantity of  $NaOH$ aq required for solution, and adding alcohol, when it separates as a red oil which slowly crystallises to a red solid. The quantity of  $KMnO_4$  in solution decolourised by a solution of the salt showed that the ratio of U to 'peroxide oxygen' is U:3O.

**Uranium oxybromide of**  $UO_2Br_2$ . (*Uranyl bromide*.) In preparing  $UBr_4$  by heating a mixture of  $UO_2$  and C in Br vapour, Hermann (*J.* 1861. 260) obtained a yellow, easily volatile sublimate, which was probably an oxybromide. By heating  $UO_2$  with Br and water, also by dissolving  $UO_2$  in  $HBr$ aq, a colourless liquid is obtained, which on evaporation gives yellow needles of the *hydrated oxybromide*  $UO_2Br_2 \cdot 7aq$  (Sendtner, *A.* 195, 325). This compound combines with  $NH_3$  and  $KBr$  to form  $UO_2Br_2 \cdot 2MBr$  (v. URANOXYBROMIDES, p. 822).

**Uranium oxychloride of**  $UO_2Cl_2$ . (*Uranyl chloride*.) Formed by strongly heating  $UO_2$  in  $Cl_2$ ; a yellow, crystalline solid, easily fused, but volatilised only at a high temperature; heated with K forms  $UO_2$  and  $KCl$  (Peligot, *A. Ch.* [3] 5, 5). By dissolving  $UO_2 \cdot H_2O$  in  $HCl$ aq, also by oxidising  $UCl_4$  by  $HNO_3$ aq and evaporating, yellowish-green crystals of  $UO_2Cl_2 \cdot xH_2O$  are obtained (Klaproth, *Crell's A.* 1789 [2]. 387).

By dissolving  $UO_2Cl_2$  in ether and evaporating, Regelsberger (*A.* 227, 119) obtained yellow needles of the compound  $UO_2Cl_2 \cdot 2Et_2O$ .

$UO_2Cl_2$  forms compounds with  $NH_3$  and  $KCl$  of the form  $2MCl \cdot UO_2Cl_2$  (v. URANOXYCHLORIDES, p. 823).

$UO_2Cl_2$  combines with  $NH_3$  to form  $UO_2Cl_2 \cdot xNH_3$ , where  $x = 2, 3$ , and 4. The first of these compounds,  $UO_2Cl_2 \cdot 2NH_3$ , is formed by passing dry  $NH_3$  into  $UO_2Cl_2$  dissolved in ether, drying the voluminous yellow pp. that forms, and then placing it *in vacuo* over  $H_2SO_4$  until all ether is removed; the second compound,  $UO_2Cl_2 \cdot 3NH_3$ , is formed by the action of  $NH_3$  on  $UO_2Cl_2 \cdot 2NH_3$ ; and a mixture of  $UO_2Cl_2 \cdot 3NH_3$  and  $UO_2Cl_2 \cdot 4NH_3$  is produced by passing  $NH_3$  over solid  $UO_2Cl_2$ . When strongly heated in air these compounds give off all  $NH_3$  and  $Cl$  and leave  $U_2O_5$ ; heated out of contact with air they give  $UO_2$  (Regelsberger, *A.* 227, 119). The three compounds are called by B. *uranyl ammonium chlorides*, and their formulae are written  $UO_2(NH_4Cl)_2$ ,  $UO_2(NH_4Cl)(NH_3 \cdot NH_4Cl)$ , and  $UO_2(NH_3 \cdot NH_4Cl)_2$ . Water reacts thus:—

(2)  $\text{UO}_2(\text{NH}_4\text{Cl})_2 + 2\text{H}_2\text{O} = \text{UO}_2(\text{OH})_2 + 2\text{NH}_4\text{Cl}$ ; the second reaction takes place quickly with warm water.

**Uranium oxyfluoride of  $\text{UO}_2\text{F}_2$ . (Uranyl fluoride.)** This compound is produced by boiling  $\text{U}_3\text{O}_8$  with  $\text{HFAq}$ , filtering off  $\text{UF}_3$  (v. URANIUM TETRAFLUORIDE, p. 823), and evaporating the filtrate; it is also formed, in small quantities, by heating  $\text{UF}_4$  in a closed Pt crucible. The compound differs according to the method of preparation (Smithells, *C. J.* 43, 125).

**$\alpha$ -Oxyfluoride.** About 1 gram  $\text{UF}_4$  is heated in a Pt crucible with the lid on, temperature being raised as quickly as possible; after five minutes the crucible is allowed to cool, the light, bulky sublimate is removed, and the crucible is again heated for five minutes, and these processes are repeated several times (S., *l.c.* p. 129). This form of  $\text{UO}_2\text{F}_2$  is a very bulky, light, white, crystalline solid; it is very soluble in water, forming a yellow liquid; heated in air it is gradually changed to  $\text{U}_3\text{O}_8$ .

**$\beta$ -Oxyfluoride.**  $\text{U}_3\text{O}_8$  is treated with boiling  $\text{HFAq}$  in a leaden vessel, the yellow solution is poured off from green  $\text{UF}_3$ , heated until the excess of  $\text{HF}$  is driven off, and allowed to evaporate; evaporation may be completed over  $\text{H}_2\text{SO}_4$  and  $\text{CaO}$  in *vacuo*; the residue is dried at  $100^\circ$  (S., *l.c.* p. 130). This form of  $\text{UO}_2\text{F}_2$  is a yellow spongy mass; in one instance the preparation had a semi-crystalline appearance, forming yellow, lustrous scales; it is very soluble in water or alcohol; heated on Pt foil  $\text{U}_3\text{O}_8$  is formed; heated in a closed crucible it is slowly decomposed, giving  $\text{UO}_2$ .  $\beta$ - $\text{UO}_2\text{F}_2$  probably forms a compound with  $\text{HF}$ , by evaporating a solution of  $\text{U}_3\text{O}_8$  in  $\text{HFAq}$  over  $\text{H}_2\text{SO}_4$  and  $\text{CaO}$  until the weight was constant, Smithells (*l.c.* p. 131) obtained a substance which gave results on analyses agreeing fairly with the formula  $\text{UO}_2\text{F}_2 \cdot \text{HF} \cdot \text{H}_2\text{O}$ .

A solution in water of either form of  $\text{UO}_2\text{F}_2$  mixed with  $\text{KFAq}$  and  $\text{KHF}_2\text{Aq}$ , and evaporated, gives the quadric acid fluoxy-urate  $\text{K}_4\text{UO}_2\text{F}_6$  (S., *l.c.* p. 130-1). For the compounds of  $\text{UO}_2\text{F}_2$  with  $\text{MF}$  v. URANIOXYFLUORIDES (p. 824).

Ditte (*C. R.* 91, 115) gave the formula  $\text{UOF}_2$  to the sublimate obtained by heating, in a closed Pt crucible, the solid that remained when  $\text{U}_3\text{O}_8$  was treated with boiling  $\text{HFAq}$ . Ditte said that this solid was  $\text{UO}_2\text{F}_2$ ; Smithells (*l.c.*) has, however, shown that the solid obtained by the method used by Ditte is  $\text{UF}_4$ , and that the sublimate formed by heating this is  $\alpha$ - $\text{UO}_2\text{F}_2$ .

**Uranium oxysulphides of.** Two compounds probably exist.

**URANIUM OXYSULPHIDE  $\text{U}_3\text{O}_2\text{S}_2$ .** This composition was given by Hermann (*J.* 1861, 258) to a dark, greyish-black solid, obtained by heating  $\text{UO}_2$ ,  $\text{U}_3\text{O}_8$ , or  $\text{NH}_4$  uranate to redness in vapour of  $\text{CS}_2$ . Dissolves in conc.  $\text{HClAq}$ ; burns when heated in air (*cf.* H. Rose, *G. A.* 73, 139).

**URANYL SULPHIDE  $(\text{UO}_2)_2\text{S}$ .** A brown solid, obtained by prep. an ammoniacal solution of a uranyl salt by cold  $(\text{NH}_4)_2\text{SAq}$ , and quickly washing with conc. alcohol. Probably not obtained pure, as it quickly decomposes; water produces  $\text{UO}_2 \cdot \text{H}_2\text{O}$ ; at  $40^\circ$ – $50^\circ$  it is changed to  $\text{UO}_2$  and S (Remelé, *P.* 124, 114; Zimmermann, *A.* 204, 204).  $(\text{UO}_2)_2\text{S}$  is somewhat sol. water or dilute alcohol; dissolved by conc.  $\text{HClAq}$ , giving  $\text{UCl}_4$

and S; dissolved by  $(\text{NH}_4)_2\text{SAq}$ , only in presence of  $(\text{NH}_4)_2\text{CO}_3\text{Aq}$  (Zimmermann, *l.c.*), forming a brown liquid.

**Uranium black.** By allowing  $(\text{UO}_2)_2\text{S}$  to stand in contact with freshly prepared  $(\text{NH}_4)_2\text{SAq}$ , in absence of air, a dull black amorphous powder is obtained. This solid dissolves in mineral acids, giving off traces of  $\text{H}_2\text{S}$ ; it dissolves partly in warm  $(\text{NH}_4)_2\text{CO}_3\text{Aq}$ , but not in warm  $(\text{NH}_4)_2\text{SAq}$ , nor in caustic alkali solutions; heated in a tube to c.  $270^\circ$  it gives off a very little  $\text{NH}_3$  and  $\text{H}_2\text{O}$ . Zimmermann (*A.* 204, 204) gives the formula  $\text{U}_3\text{O}_8$  to uranium black, neglecting (as impurities) the traces of  $\text{NH}_3$  and S which the substance contains.

**Uranium red.** By allowing  $(\text{UO}_2)_2\text{S}$  to stand for 24–48 hours in contact with cold  $(\text{NH}_4)_2\text{SAq}$ , exposed to air, a deep-red solid is obtained; soluble in dilute mineral acids, with separation of S and evolution of  $\text{H}_2\text{S}$ ; gives off  $\text{NH}_3$ , S, and  $\text{H}_2\text{O}$  when heated to  $150^\circ$  and, at above  $200^\circ$ , leaves  $\text{U}_3\text{O}_8$  (Zimmermann, *l.c.*). According to Z., the formation of this red substance takes place only when  $(\text{NH}_4)_2\text{S}_2\text{O}_8$  is present in the  $(\text{NH}_4)_2\text{SAq}$  used;  $(\text{NH}_4)_2\text{S}_2\text{O}_8$  is formed by the action of the air. Z. gives to uranium red the composition  $\text{U}_2\text{S}(\text{NH}_4)_2\text{O}_2 = \text{UO}_2 \cdot \text{ONH}_4 \cdot \text{SNH}_4 \cdot 2\text{U}_3\text{O}_8$  (*cf.* Patern, *J. pr.* 51, 122; Remelé, *P.* 124, 155; Hermann, *J.* 1861, 14).

**Uranium, salts of.** Two classes of salts are formed by treating oxides of U with acids;  $\text{UO}_2$  forms corresponding salts,  $\text{UX}$ , when X = the radicle of a dibasic acid, and  $\text{UX}$ , when X = the radicle of a monobasic acid;  $\text{UO}_3$  forms salts  $(\text{UO}_3)_X$  when X = the radicle of a dibasic acid, and  $(\text{UO}_3)_X$ , when X = the radicle of a monobasic acid. The salts  $\text{UX}^I$  and  $\text{UX}^{II}$  are called *uranous salts*; and  $(\text{UO}_3)_X^I$  and  $(\text{UO}_3)_X^{II}$  are called *uranyl salts*. (For reactions of the two classes of salts v. URANIUM, *Detection and estimation of*, p. 822.) Besides the normal salts, a large number of basic salts of both classes is known, and also many double salts.

The chief *uranous salts* are *arsenates*, *phosphates*, and *sulphites*. The chief *uranyl salts* are *arsenates*, *bromate*, *double carbonates*, *chromates*, *hypophosphite*, *iodate*, *nitrate*, *oxalate*, *phosphates*, *phosphite*, *selenates*, *selenites*, *sulphates*, and *sulphites* (v. NITRATES, SULPHATES, &c.).

**Uranium, sulphides of.** When U is burnt in vapour of S, the disulphide  $\text{US}_2$  is formed; by passing  $\text{H}_2\text{S}$  over heated  $\text{UBr}_3$  the sesquisulphide  $\text{U}_2\text{S}_3$  is produced; and by heating  $\text{U}_3\text{S}_4$  in H the monosulphide  $\text{US}$  is obtained. The mol. w. of none of these is known.

**URANIUM DISULPHIDE  $\text{US}_2$ .** Prepared by heating U in vapour of S (Péligot, *P.* 54, 422; *cf.* Zimmermann, *A.* 216, 18); also by heating  $\text{UCl}_4$  to redness in  $\text{H}_2\text{S}$  (Hermann, *J.* 1861, 258). A dark greyish-black powder; becomes crystalline when fused with borax; oxidises slowly in air, rapidly on heating. Easily soluble in conc.  $\text{HClAq}$  (Hermann, *l.c.*).

**URANIUM SESQUISULPHIDE  $\text{U}_2\text{S}_3$ .** A stream of dry  $\text{H}_2\text{S}$ , perfectly free from air, is passed over heated  $\text{UBr}_3$ , as long as  $\text{HBr}$  is given off. Grey-black solid, forming pseudomorphs of  $\text{UBr}_3$ ; decomposes in air, giving off  $\text{H}_2\text{S}$ ; burns when heated in air; scarcely acted on by  $\text{HClAq}$  or

diffuse  $\text{HNO}_3$ ; decomposed violently by conc.  $\text{HNO}_3$  (Alibegoff, *A.* 233, 117).

**URANIUM MONOSULPHIDE** *US*. A black, amorphous powder; obtained by passing dry  $\text{H}$  over  $\text{U}_2\text{S}_3$  kept at a red heat, for c. 40 hours, until  $\text{H}_2\text{S}$  is no longer given off. Similar in properties to  $\text{U}_2\text{S}_3$  (Alibegoff, *A.* 233, 135).

**URANIUM THIO-ACIDS**, salts of. No thio-acid, nor salt of a thio-acid, of  $\text{U}$  has been definitely isolated. *Uranium red* (*v. supra*, p. 828) may perhaps be an ammonium oxythionate of  $\text{U}$ .

M. M. P. M.

**URANOXYBROMIDES** *v.* p. 822, under

**URANIUM TETRABROMIDE.**

**URANOXYCHLORIDES** *v.* p. 823, under

**URANIUM TETRACHLORIDE.**

**URANOXYFLUORIDES** *v.* p. 824, under

**URANIUM TETRAFLUORIDE.**

**URANYL COMPOUNDS**, compounds of the radicle  $\text{UO}_2$ ; *v.* **URANYL AMMONIUM CHLORIDES** (p. 827), **URANYL BROMIDE** (p. 827), **URANYL CHLORIDE** (p. 827), **URANYL FLUORIDE** (p. 828), **URANYL SALTS** (p. 828), **URANYL SULPHIDE** (p. 828).

**URAZOLE.** A name given by Pinner (*B.* 20, 2358) to di-oxy-triazole, which may be represented as  $\text{NH}_2\text{C}(\text{OH})\text{N}=\text{N}$  or  $\text{NH}_2\text{CO}\text{N}=\text{NH}$ .

**UREA**  $\text{CH}_4\text{N}_2\text{O}$ , *i.e.*  $\text{CO}(\text{NH}_2)_2$ . *Carbamide*. Mol. w. 60. [1927] (Lubavitz *B.* 3, 205). S.G. 1.323 (Schröder, *B.* 127 562). S. (alcohol) 20 in the cold; 100 at  $78^\circ$ . H.C.v. 152,500. H.C.p. 152,200 (Stohmann & Langbein, *J. pr.* [2] 44, 387); 160,900 (Berthelot & Petit, *C. R.* 109, 759; 110, 887). H.F. 80,800.

**Occurrence.**—In the urine of mammalia, especially in that of flesh-eaters (Fourcroy & Vauquelin, *A. D.* 1799). Occurs in small quantity in blood, muscle, chyle, and lymph of mammalia (Wurtz, *C. R.* 49, 52; Poisseuille & Gobley, *J.* 1859, 612; Verdoel & Dollfus, *A.* 74, 214; Munk, *Pf.* 11, 100; Pickard, *C. R.* 83, 1179; 87, 533; Gréhan & Quinquand, *C. R.* 108, 1092; Garrod, *Pr.* 53, 478). Constitutes about 30 p.c. of the solid substance of the vitreous humour of the eye (Millon, *C. R.* 26, 119; *A.* 66, 128). Occurs also in saliva (Rabuteau, *J.* 1873, 877), in cow's milk (Lefort, *Z.* 1866, 190; Vogel, *J.* 1867, 932), and in other animal secretions.

**Formation.**—1. By evaporating a solution of ammonium cyanate (Liebig & Wöhler [1828], *B. J.* 12, 266; *P.* 12, 253; 15, 619; *A.* 38, 108). 2. By adding a little  $\text{HNO}_3$  to an ethereal solution of cyanamide (Cannizzaro & Cloëz, *A.* 78, 230) or by the action of dilute (50 p.c.)  $\text{H}_2\text{SO}_4$  on cyanamide (Baumann, *B.* 6, 1373).—3. From  $\text{COCl}_2$  and dry  $\text{NH}_3$  (Begnault, *A. Ch.* [2] 69, 180; Natanson, *A.* 98, 287), guanidine and  $\text{NH}_4\text{Cl}$  being formed at the same time (Fenton, *C.* 735, 793).—4. By heating carbonic ether, with  $\text{NH}_3$  at  $180^\circ$ .—5. By heating ammonium carbamate at  $140^\circ$  (Bassoroff, *J. pr.* [2] 1, 283).—6. By passing an alternating electric current through a solution of ammonium carbamate (Drechsel, *J. pr.* [2] 22, 481).—7. By electrolysis of ammonia solution, using carbon electrodes (Milot, *Bl.* [2] 46, 243).—8. By passing a mixture of  $\text{NH}_3$  and  $\text{CO}_2$  through a red-hot tube (Dexter, *Am.* 4, 85).—9. Formed by passing air charged with  $\text{NH}_3$  and vapour of benzene over a red-hot helix of platinum wire (Herroun, *C. J.*

89, 471). Acetylene, but not ethylene, may be substituted for benzene.—10. By heating ammonium thiocarbamate  $\text{NH}_4\text{CO}_2\text{SNH}_2$ , or by shaking it with water and  $\text{PbCO}_3$ .—11. By the action of aqueous  $\text{KMnO}_4$  on thio-urea (Maly, *M.* 11, 277).—12. By the action of  $\text{KMnO}_4$  on  $\text{KCy}$  in acid solution (Baudrimont, *J.* 1880, 393).—13. By the action of  $\text{NH}_4\text{Aq}$  and  $\text{H}_2\text{S}$  on copper fulminate (Gladstone, *A.* 66, 2).—14. By heating oxamide with  $\text{HgO}$  (Williamson, *Mémoires du Congrès scientif. de l'uisse*, *A.D.* 1847).—15. By oxidation of uric acid.—16. By the action of  $\text{KClO}_4$  and  $\text{HCl}$  on guanine (Strecker, *A.* 118, 159).—17. By boiling guanidine with baryta (Baumann, *B.* 6, 1376).—18. By boiling biguanide sulphate or phenyl-biguanide sulphate with baryta (Emich, *M.* 12, 11).—19. By the action of baryta on arginin (Schulze & Likiernik, *B.* 24, 2701).—20. By boiling creatin with baryta.—21. A product of oxidation of proteins by  $\text{KMnO}_4$  (Béchamp, *A. Ch.* [3] 48, 348; *C. R.* 70, 866; Ritter, *Bl.* [2] 16, 327). Stædeler (*J. pr.* 72, 251) and Loew (*J. pr.* [2] 2, 289) failed to obtain urea in this manner. Dreschel (*B.* 23, 3097) obtained urea from albumen by electrolysis, but not by oxidation.

**Preparation.**—1. Urine, concentrated by evaporation, is treated with nitric or oxalic acid, and the ppl. nitrate or oxalate of urea is decomposed by  $\text{CaCO}_3$ .—2. A solution of potassium cyanate mixed with ammonium sulphate is evaporated on a water-bath to dryness, and the residue extracted with alcohol.—3. A mixture of dry  $\text{K}_2\text{FeCy}_4$  (28 pts.) and  $\text{MnO}_2$  (14 pts.) is heated till sticky on an iron plate. A cold aqueous extract of the mass is mixed with  $(\text{NH}_4)_2\text{SO}_4$  (20.5 pts.), evaporated to dryness, and extracted with alcohol (Liebig).—4. Dry  $\text{K}_2\text{FeCy}_4$  (8 pts.) is fused with  $\text{K}_2\text{CO}_3$  (3 pts.) and  $\text{PbO}$  (15 pts.) added to the melted mass. The cooled mixture is dissolved in water, mixed with  $(\text{NH}_4)_2\text{SO}_4$  (8 pts.) evaporated, and extracted with alcohol (Clemm, *A.* 66, 382). Any  $\text{K}_2\text{FeCy}_4$  left can be removed by  $\text{FeSO}_4$ .—5. Lead cyanate is digested with  $(\text{NH}_4)_2\text{SO}_4$  (J. Williams, *C. J.* 21, 64).—6. From  $\text{NH}_4\text{Aq}$ ,  $\text{CO}_2$ , and lead carbonate (Schmidt, *B.* 10, 193).—7. By the action of  $(\text{NH}_4)_2\text{SO}_4$  on  $\text{KCyO}$  obtained by heating dry  $\text{K}_2\text{FeCy}_4$  with  $\text{K}_2\text{Cr}_2\text{O}_7$ ; the yield being 25 p.c. of the weight of ferrocyanide (O. A. Bell, *C. N.* 32, 99).—8. A stream of dry  $\text{NH}_3$  gas is passed through phenyl-carbonate (from phenol-sodium and  $\text{COCl}_2$ ), melted in a water-bath, and the melt is then poured into hot water; the aqueous solution after separation from the phenol is evaporated to crystallisation (Hentschel, *B.* 17, 2286).

**Properties.**—Dimetric crystals, *v. s.* sol. water, *sp.* sol. cold alcohol, insol.  $\text{CHCl}_3$ , nearly insol. ether. Sublimes at  $130^\circ$ . *In vacuo* it distils at  $135^\circ$  (Bourgeois, *Bl.* [3] 7, 48). Urea is not attacked by pure  $\text{HNO}_3$  (Franchimont, *R. T. C.* 6, 217).

**Reactions.**—1. When heated alone at  $150^\circ$ – $170^\circ$  it yields  $\text{NH}_3$ , cyanuric acid and biuret; at  $140^\circ$  it yields ammelide.—2. Decomposed into  $\text{CO}_2$  and  $\text{NH}_3$  by heating with water in sealed tubes above  $100^\circ$ , by boiling with potash, lime, or magnesia, by warming with conc.  $\text{H}_2\text{SO}_4$ , by evaporating with lead acetate, and by the action of ozone (Görup-Besanez, *A.* 125, 207).

in presence of free alkali. CaO produces cyanamide (Emich, *M.* 10, 330). A 8 p.c. HCl solution decomposes 4 p.c. of the urea in 24 hours. NaOH aq. of the same strength has less effect. Cold water does not decompose urea (Berthelot a. André, *Bl.* [2] 47, 840).—3. *Alcoholic potash* forms, on heating in sealed tubes, cyanic acid,  $\text{NH}_3$ , and water (Haller, *Bl.* [2] 45, 705).—4. Urea hydrochloride at  $145^\circ$  yields  $\text{NH}_4\text{Cl}$  and cyanuric acid (De Vry, *A.* 61, 249).—5. *Chlorine* passed over melted urea forms HCl, nitrogen,  $\text{NH}_4\text{Cl}$ , and cyanuric acid (Wurtz, *A.* 64, 307).—6. *Hypochlorous acid, hypochlorites, chlorine-water, and hypochlorites*, set free nitrogen, e.g.  $\text{CON}_2\text{H}_4 + 3\text{HOCl} = \text{CO}_2 + 3\text{HCl} + 2\text{H}_2\text{O} + \text{N}_2$ .—7. *Nitrous acid* added to a hot solution forms  $\text{CO}_2$  and nitrogen:  $\text{CON}_2\text{H}_4 + \text{N}_2\text{O} = \text{CO}_2 + 2\text{H}_2\text{O} + 2\text{N}_2$ . Nitrous acid (2 mols.) when added to a cold solution of urea (1 mol.) reacts as follows:  $2\text{CON}_2\text{H}_4 + \text{N}_2\text{O}_2 = (\text{NH})_2\text{CO}_2 + 2\text{N}_2 + \text{CO}_2$  (Claus, *B.* 4, 140).—8. Neutral  $\text{KMnO}_4$  has no action in the cold, and acts but slowly at  $100^\circ$ . In acid solutions  $\text{KMnO}_4$  gives off nitrogen (1 vol.) and  $\text{CO}_2$  (2 vols.) (Béchamp, *J.* 1856, 696; cf. Wanklyn a. Gamgee, *C. J.* 21, 25).—9. *Bromine* added gradually to an alcoholic solution of urea forms  $\text{NH}_4\text{Br}$ , cyanuric acid, and nitrogen. In sealed tubes Br gives  $\text{NH}_4\text{Br}$  and cyanamide (Smolka, *M.* 8, 64).—10. Heating with  $\text{P}_2\text{O}_5$  forms cyanic and cyanuric acids, ammeline, cyanamide, and  $\text{NH}_3$  (Weltzien, *A.* 107, 219).—11. Yields cyanamide on warming with Na (Fenton, *C. J.* 41, 262).—12. Conc.  $\text{HNO}_3$  reacts thus:  $\text{CON}_2\text{H}_4 + 2\text{HNO}_3 = \text{CO}_2 + \text{N}_2\text{O} + \text{NH}_4\text{NO}_3 + \text{H}_2\text{O}$  (Franchimont, *R. T. C.* 2, 96; 3, 219).—13.  $\text{P}_2\text{S}_5$  forms crystalline  $\text{C}_2\text{H}_4\text{N}_4\text{P}_2\text{S}_5\text{O}_2$ , which yields  $\text{C}_2\text{H}_4\text{AgN}_4\text{P}_2\text{S}_5\text{O}_2$  and  $\text{C}_2\text{H}_4\text{Ag}_2\text{N}_4\text{P}_2\text{S}_5\text{O}_2$ , and gives off  $\text{PH}_3$  on warming (Kutschig, *M.* 9, 406).—14. *Zinc dust* at a red heat forms  $\text{ZnCy}_2$ , ammonia, and hydrogen (Aufschlager, *M.* 13, 272).—15.  $\text{CS}_2$  at  $100^\circ$  forms COS and ammonium sulphocyanide. With alcohol and  $\text{CS}_2$  the products are mercaptan,  $\text{CO}_2$ , and ammonium sulphocyanide (Ladenburg, *Z.* [2] 5, 253; *B.* 1, 273; 2, 271; Fleury, *A.* 123, 144).—16. *Alcohols* in sealed tubes form carbamic ethers and alkyl allophanates (Cahours, *C. R.* 76, 1387).—17. Boiling  $\text{Ac}_2\text{O}$  forms acetamide and diacetamide (Hofmann, *B.* 14, 2733).—18.  $\text{ZnEt}_2$  forms  $\text{CON}_2\text{H}_4\text{Zn}$ , which is reconverted into urea by water (Gal, *Bl.* [2] 39, 648).—19. *Oxalic ether* at  $135^\circ$ – $170^\circ$  forms oxamide, allophanic ether, and alcohol (Grabowski, *A.* 134, 115). *Oxamic ether* forms, on fusion, oxalamide (Carstanjen, *J. pr.* [9] 9, 143).—20. *Methylamido-acetic acid* (sarcosine) forms methyl-hydantoin on fusion (Ruppert, *B.* 6, 1278).—21. *Aniline* at  $150^\circ$ – $170^\circ$  gives  $\text{NH}_3$  and di-phenyl-urea (Baeyer, *A.* 131, 251).—22. *Aniline sulphuric acid* at  $120^\circ$  gives  $\text{NH}_3$ ,  $\text{CO}_2$ ,  $\text{NH}_4\text{C}_6\text{H}_4\text{SO}_3\text{H}$  (Villo, *Bl.* [5] 6, 6).—23. *Biguanide sulphate* forms, on heating, ammeline,  $\text{NH}_3$ , and  $(\text{NH}_4)_2\text{SO}_4$  (Smolka a. Friedreich, *M.* 10, 95).—24. Heated with acetone and  $\text{ZnCl}_2$  or  $\text{P}_2\text{O}_5$  at  $110^\circ$ – $140^\circ$  it gives *s*-tri-methylpyridine and base  $\text{C}_4\text{H}_8\text{N}$  [ $119^\circ$ ]; ( $320^\circ$ ) (Riehm, *A.* 238, 22). This base forms hard monoclinic crystals, with metallic ring; its solutions fluoresce. It gives  $\text{B}_2\text{H}_6\text{PtCl}_6$ : [ $225^\circ$ ].—25. Heated with acetyl-urea (1 mol.), urea (2 mols.) forms  $\text{CH}_2(\text{CMe:N.CO.NH}_2)_2$ , which crystallises from alcohol [ $200^\circ$ ] (Combes, *Bl.* [3]

7, 790). The same body is formed, together with  $\text{CH}_2(\text{CMe:N})_2\text{CO}$  [ $198^\circ$ ], by adding  $\text{HClAq}$  or  $\text{H}_2\text{SO}_4$  to an alcoholic solution of urea and acetyl-acetone (Evans, *J. pr.* [2] 46, 352; 48, 499).—26. *Benzoyl-acetone* forms, in like manner,  $\text{Bz.CH}_2\text{CMe:N.CO.NH}_2$  [ $191^\circ$ ] and  $\text{CH}_2(\text{CMe:N})_2\text{CO}$  [ $227^\circ$ ] (Evans, *J. pr.* [2] 46, 352; 48, 509).—27. *Acetoacetic ether* (2 mols.) and  $\text{NaOEt}$  (2 mols.) form in the cold  $\text{C}_{12}\text{H}_{22}\text{N}_4\text{O}_2\text{Na}_2$  [c.  $165^\circ$ ] (Ernert, *A.* 258, 361). Acetoacetic ether in alcoholic solution forms uramido-crotonic acid (*q. v.*).—28. *Urea* reacts with aldehydes in the cold. In aqueous solution a diureide  $\text{R.CH(NH.CO.NH}_2)_2$  is usually formed, while solid urea forms triureides. On warming with excess of aldehyde, *N*- and tri-ureides yield tetra- and hexa-ureides (H. Schiff, *A.* 151, 186). These ureides are sparingly soluble neutral solids, and are split up by warming with acids into the parent substances. Benzoic aldehyde forms benzylidene-di-urea (*q. v.*), while *o*-oxy-benzoic aldehyde forms  $\text{C}_6\text{H}_4(\text{OH}).\text{CH}(\text{NH.CO.NH}_2)_2$  aq., which is converted by acetoacetic ether in alcohol into  $\text{C}_6\text{H}_4(\text{OH}).\text{CH.N.CO.N:CMe.CH}_2\text{CO}_2\text{Et}$  [ $200^\circ$ ],  $\text{C}_6\text{H}_4(\text{OH}).\text{CH.N.CO.NH.CO.NH.CO}_2\text{Et}$  [ $204^\circ$ ], and  $\text{C}_6\text{H}_4(\text{OH}).\text{CH.N.CO}_2\text{NH}$ , which decomposes between  $260^\circ$  and  $270^\circ$  (Bignelli, *B.* 24, 2963). Acrolein forms  $(\text{CON}_2\text{H}_5)_2\text{C}_2\text{H}_4\text{O}$ , which chars at  $250^\circ$  (Lüdy, *M.* 10, 295). *o*-Nitrobenzoic aldehyde forms nitro-benzylidene-di-urea  $\text{C}_6\text{H}_4(\text{NO}_2).\text{CH}(\text{NH.CO.NH}_2)_2$  aq. [ $190^\circ$ ]. In like manner cinnamic aldehyde in alcohol forms the di-ureide  $\text{C}_6\text{H}_5\text{C}_2\text{H}_4\text{CH}(\text{NH.CO.NH}_2)_2$  [ $176^\circ$ ] (Bignelli, *B.* 24, 2964), and cinnamic aldehyde forms  $\text{Ph.CH:CH.CH}(\text{NH.CO.NH}_2)_2$  [ $172^\circ$ ], and compounds melting at  $116^\circ$  and  $212^\circ$ .—29. *Chloral* added to conc. aqueous solutions of urea forms  $(\text{C}_2\text{HCl}_3\text{O})\text{CON}_2\text{H}_4$  [ $150^\circ$ ], *v. c.* sol. hot water, and  $(\text{C}_2\text{HCl}_3\text{O})_2\text{CON}_2\text{H}_4$  [ $190^\circ$ ] nearly insol. hot water, both compounds being crystalline (Jacobsen, *A.* 157, 246). Chloral cyanhydrin at  $105^\circ$  forms the very stable crystalline  $\text{C}_2\text{H}_4\text{Cl}_2\text{N}_4\text{O}$  (Pinner a. Fuchs, *B.* 10, 1069).—30. *Benzene sulphonic chloride* at  $100^\circ$  forms colourless crystals of  $\text{C}_6\text{H}_5\text{SONH}_2\text{C}_2\text{O}$  aq. (Elander, *Bl.* [2] 34, 207). Naphthalene (*a*)-sulphonic chloride acts similarly.—31. *Cinnamoyl chloride* forms  $\text{C}_6\text{H}_5(\text{NH.CO.NH})_2\text{C}_2\text{H}_4\text{NH.CO.NH}_2$  [ $184^\circ$ ] (Bignelli, *B.* 24, 2965).—32.  $\text{ClCH}_2\text{OH}$  forms methyl-urea, which is split up by hot dilute  $\text{H}_2\text{SO}_4$  into formic aldehyde and urea (Von Hemmelmayr, *M.* 12, 89).—33. *Trichlorolactic acid* and a little water form, on heating, acetylene-urea  $\text{C}_2\text{H}_2\text{N}_4\text{O}_2$  (Pinner, *B.* 17, 1997).—34. *Hexachloro-acetone* (2 mols.) heated with urea (1 mol.) at  $150^\circ$  forms  $\text{CO}_2\text{N}_2\text{H}_4(\text{C}_2\text{Cl}_6\text{O})_2$ , crystallising from alcohol in hexagonal plates (Clöze, *A. Ch.* [6] 9, 145).

*Detection*.—Urea gives, in conc. solution, crystalline pps. with nitric and oxalic acids. Urea dissolved in amyl alcohol is completely pptd. by an ethereal solution of oxalic acid (Brücke, *M.* 3, 195). Murex-lus (*C. R.* 78, 132) filters quid urine, dries the filter at  $35^\circ$ , and employs it as a test for urea, which it converts into ammonium carbonate. A conc. aqueous solution of furfuraldehyde followed by a drop of  $\text{HClAq}$  (S.G. 1.10) colours a crystal of urea

violet (Schiff, *B.* 10, 774). *o*-Nitro-benzoic aldehyde added to an alcoholic solution of urea forms, on warming, a white pp. of *o*-nitro-benzylidene-di-urea [200°]. When present in small quantities this compound may be detected by resolving into the parent substances by boiling with very dilute  $H_2SO_4$ , and then adding a little phenylhydrazine solution, which produces a red colour (Lüdy, *M.* 10, 295). Mercuric nitrate gives a white pp. with solutions of urea. The various methods of estimating urea may also be employed for its detection.

**Estimation.** — Hypobromite method. Urea is mixed with NaOH (100 g. in 250 c.c. water) to which bromine (25 g.) has been added, and the nitrogen collected and measured (Knop, *Fr.* 9, 226; Hüfner, *J. pr.* [2] 3, 1; Dupré, *C. J.* 31, 534; Simpson a. Keefe, *C. J.* 31, 838; Russell a. West, *C. J.* 27, 749; Eykman, *R. T. C.* 3, 125; Schleich, *J. pr.* [2] 10, 263; Colquhoun, *C. N.* 67, 123; Camerer, *Zeit. Biol.* 29, 239). When this method is applied to urine it must be remembered that uric acid gives off 48 p.c. and creatinin 37 p.c. of its nitrogen in this way (Falk, *Fr.* 21, 300). Nevertheless, the quantity of nitrogen evolved is 8 p.c. less than the calculated amount (R. a. W.). Using Knop's solution, ammonia, urea, and oxamide give off 93, 92.3, and 75 p.c. of their nitrogen as gas (Foster, *C. J.* 33, 470; 35, 129). In the case of urea and oxamide the 'suppressed' nitrogen is present as cyanate and as nitrate (Fauconier; Luther, *H.* 13, 500). The amount of 'suppressed' nitrogen is less in dilute than in concentrated solutions (Hüfner, *H.* 1, 350; cf. Pflüger a. Bohlend, *Pf.* 38, 325; 39, 1, 143), and is greatly diminished by the addition of 1 to 5 p.c. acetoacetic ether (Jacoby, *Fr.* 24, 318). According to Duggan (*Am.* 4, 47), if bromine is added to a solution of urea in NaOH aq the yield of nitrogen is 99.4 p.c. of the theoretical amount. In estimating urea in urine Pflüger (*Fr.* 26, 117) adds  $HCl$  aq (1 c.c.) to urine (10 c.c.), ppt. various nitrogenous bodies by phosphotungstic acid, neutralises the filtrate with lime and then adds an equal volume of conc. NaOH aq and, after allowing to stand for some time, decomposes with Knop's hypobromite. Frothing of albuminous urine can be avoided by first shaking with a pilule of fat (Méhu, *J. Ph.* [5] 15, 607). Hamburger (*R. T. C.* 2, 181) introduced a volumetric method of employing hypobromite, but Pflüger a. Schenck (*Pf.* 37, 399) consider the method to be untrustworthy. E. Salkowski adds two drops of  $HCl$  to urine (2.5 c.c.) diluted with 5 or 10 volumes of water until the air is expelled from the flask, then adds the hypobromite, continues boiling, and collects the nitrogen. Fenton (*C. J.* 33, 300) recommends the use of sodium hypochlorite, which was first proposed by E. W. Davy (A.D. 1854). In this case free  $NaOH$  must not be present, though excess of  $Na_2CO_3$  may be present.

**Mercuric nitrate method.** Urea is completely pptd. by a solution of  $Hg(NO_3)_2$ . The white pp. is not decomposed, and therefore not turned yellow by  $Na_2CO_3$ . Urine (2 vols.) is mixed with a solution (1 vol.) prepared from saturated solutions of baryta (2 vols.) and  $Ba(NO_3)_2$  (1 vol.); filtered through a dry filter

from the ppt. sulphate and phosphate and 15 c.c. (equivalent to 10 c.c. urine) of the filtrate are titrated with standard mercuric nitrate till a drop taken out gives a yellow pp. with  $Na_2CO_3$  (Liebig, *A.* 85, 370). Assuming the compound  $CON_2H_2HgO$  to be formed, 1 pt. urea should ppt. 7.2 pts.  $HgO$ , but in practice 7.72 pts. of the latter are required. A solution of 71.48 g. mercury in  $HNO_3$  diluted to 1 litre is equivalent to .01 g. urea per c.c. If the urine contains more than 2 p.c. urea the titration gives too low results; in this case the urine must be diluted. When mercuric nitrate is added to a solution of urea nitric acid is set free. Liebig recommended the addition of  $Na_2CO_3$  from time to time to keep the liquid neutral. Pflüger (*Fr.* 19, 375) proceeds as follows: During the titration, after each addition of  $Hg(NO_3)_2$  a drop is placed in contact with a little pasty  $NaHCO_3$ . Long before the titration is ended, a yellow colour is seen between the two drops, but disappears on mixing them together. When the yellow colour is permanent, the titration is near its end; at this point the solution is neutralised by  $Na_2CO_3$ , and the titration continued till a permanent yellow colour is got on mixing the drops. Should the entire liquid become yellow on adding  $Na_2CO_3$ , a fresh quantity of urea solution must be taken and the operation repeated with greater speed. The presence of over 1 p.c.  $NaCl$  in urine interferes with the titration when  $Na_2CO_3$  is used as indicator, the final reaction not being sharp. Since  $NaHCO_3$  does not ppt.  $HgCl_2$ , when the bicarbonate is used as indicator the titration may proceed as if  $NaCl$  were absent, subtracting the amount of  $Hg(NO_3)_2$  that is converted into  $HgCl_2$  by the chloride (Rautenburff, *A.* 133, 55; Pfeiffer, *Fr.* 24, 475; Pflüger, *Fr.* 27, 120). It is, however, better to ppt. the chlorides by  $AgNO_3$  and titrate in the usual way.

**Barium carbonate method.** The solution is heated with  $BaCl_2$  and  $NH_4AgN$  sealed tubes at 220°-240° and the ppt.  $BaCO_3$  weighed (Bunsen, *A.* 65, 575). Before applying this method to urine other substances which might form  $BaCO_3$  must be pptd. by phosphotungstic acid (Pflüger a. Bleibtreu, *Fr.* 28, 377).

**Kjeldahl's method.** Nitrogen in urea may be estimated by Kjeldahl's method. 5 c.c. urine pre heated with  $H_2SO_4$  (10 c.c.) and Nordhausen  $H_2SO_4$  (10 c.c.) until no more water or gas comes off, and the liquid is clear yellow. After cooling, water (200 c.c.) and  $NH_4OH$  are added and  $NH_3$  distilled off. In the case of urine it must be remembered that about 13 p.p. of the nitrogen is, on an average, combined in substances other than urea (Pflüger, *Pf.* 35, 464; 40, 533; Camerer, *Z. B.* 24, 306).

**Other methods.** Urea may also be estimated by fermentation and determination of ammonia set free (Miguel, *C. R.* 111, 501).

Canpani (*G.* 17, 137) proposes to decompose urea by nitrous acid, and pass the  $CO_2$  into a solution of lime-water of known strength, and titrate with oxalic acid.

Cazenave and Hugouneng (*Bl.* [2] 43, 82) heat urea with a large excess of water and titrate the resulting ammonium carbonate.

Riegler (*F.* 83, 49) decomposes urea with Millon's reagent and measures the mixture of  $N$  and  $CO_2$  evolved.

Mölnar & Sjöqvist (*Er.* 80, 888) add 5 c.c. of a saturated solution of BaCl<sub>2</sub> containing 5 p.c. baryta to 5 c.c. urine and then add 100 c.c. of a mixture of 97 p.c. alcohol (2 pts.) and ether (1 pt.). After 24 hours the liquid is filtered, the pp. washed with 50 c.c. alcohol-ether, and the filtrate and washings evaporated at 50° to 25 c.c., MgO and some water added, and the evaporation continued as long as NH<sub>3</sub> comes off. The urea is then determined by Bunsen or Kjeldahl's method (Böttker, *H.* 17, 140f).

**Salts.**—B'HCl. Very deliquescent crystalline mass, formed from urea and dry HCl. Decomposed by water into urea and HCl. At 140° it yields NH<sub>4</sub>Cl and cyanuric acid.—B'HNO<sub>3</sub>. Small plates, sl. sol. water and alcohol, v. sl. sol. HNO<sub>3</sub>.—B'<sub>2</sub>ILC<sub>2</sub>O<sub>4</sub>. S. 4.4 at 15°. S. (alcohol of S.G. 833) 1.65. Monoclinic tables; *a:b:c* = 1: .964: .491;  $\alpha$  = 82° 10' (Loschmidt, *Sitz.* W. 51, ii. 7, 384). V. sol. hot water. Ppd. from its aqueous solution by oxalic acid.—B'<sub>2</sub>H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>.aq (Lubavin, *A. Suppl.* 8, 83).—B'HAuCl<sub>4</sub>.aq: orange-red prisms or needles, v. sol. water, alcohol, and ether.—B'<sub>2</sub>H<sub>2</sub>AsCl<sub>4</sub>: yellow needles, v. sol. hot water (Heintz, *A.* 202, 264).—B'<sub>2</sub>H<sub>2</sub>PtCl<sub>6</sub>.2aq. Yellow, deliquescent tables, v. sol. water and alcohol, insol. ether (Heintz, *A.* 198, 91).—B'<sub>2</sub>H<sub>2</sub>PO<sub>4</sub>. Large crystals, v. sol. water and alcohol, sl. sol. ether (Lehmann, *Buchn. Rep.* 15, 224; Schneltzer & Birnbaum, *Z.* [2] 5, 206). Its solution does not ppt. MgSO<sub>4</sub>.—B'<sub>2</sub>2H<sub>2</sub>PO<sub>4</sub>. Its aqueous solution gives a crystalline pp. of cyanuric acid on heating.

**Tri-chloro-acetate** B'<sub>2</sub>C<sub>2</sub>HCl<sub>3</sub>O<sub>2</sub>. Plates (from alcohol) (De Clermont, *J.* 1873, 536).—**The fumarate** B'<sub>2</sub>C<sub>2</sub>H<sub>2</sub>O<sub>4</sub>, maleates B'<sub>2</sub>C<sub>2</sub>H<sub>2</sub>O<sub>4</sub>, and B'<sub>2</sub>C<sub>2</sub>H<sub>2</sub>O<sub>4</sub>, malate B'<sub>2</sub>C<sub>2</sub>H<sub>2</sub>O<sub>4</sub>, gallate B'<sub>2</sub>C<sub>2</sub>H<sub>2</sub>O<sub>4</sub>, and succinate B'<sub>2</sub>C<sub>2</sub>H<sub>2</sub>O<sub>4</sub> [145°], all crystallise in monoclinic forms (Loschmidt, *Sitz.* W. 52, ii. 238). The parabanate B'<sub>2</sub>C<sub>2</sub>H<sub>2</sub>N<sub>2</sub>O<sub>4</sub> and tartrate B'<sub>2</sub>C<sub>2</sub>H<sub>2</sub>O<sub>4</sub> are trimetric.—The citrate B'<sub>2</sub>C<sub>2</sub>H<sub>2</sub>O<sub>4</sub> is triclinic (L.). An acid tartrate B'<sub>2</sub>C<sub>2</sub>H<sub>2</sub>O<sub>4</sub> and an acid citrate B'<sub>2</sub>C<sub>2</sub>H<sub>2</sub>O<sub>4</sub> have been prepared (Hasiwetz, *J.* 1856, 698).—**Cyanurate** B'<sub>2</sub>C<sub>2</sub>N<sub>2</sub>H<sub>2</sub>O<sub>4</sub>. Monoclinic crystals.—**Picrate** B'<sub>2</sub>C<sub>2</sub>H<sub>2</sub>N<sub>2</sub>O<sub>4</sub> [142°] (Smolka, *M.* 6, 920). S. 1.9 at 18.5°. S. (95 p.c. alcohol) 3 at 18°. Slender yellow needles (from alcohol). **Tri-chloro-methano sulphinate** B'CCl<sub>3</sub>.SO<sub>2</sub>H. [96°–100°]. Thin prisms (McGowan, *J. pr.* [2] 34, 220).

**Compounds with metallic oxides.**—B'<sub>2</sub>Ag<sub>2</sub>O (Liebig). Formed by adding moist Ag<sub>2</sub>O to a solution of urea. Grey powder composed of slender needles. According to Müllder (B. 6, 1019), the yellow pp. got by adding NaOH to a solution of urea mixed with AgNO<sub>3</sub> is CON<sub>2</sub>H<sub>2</sub>Ag. It combines with iodine, forming CON<sub>2</sub>H<sub>2</sub>AgI, a greenish mass, darkened by light (Tafel & Enoch, B. 23, 1554).—B'<sub>2</sub>HgO. Got by adding Hg(NO<sub>3</sub>)<sub>2</sub> to a solution of urea, mixed with KOH. White pp.—B'<sub>2</sub>3HgO. White pp. formed by adding HgCl<sub>2</sub> to a solution of urea, and HgCl<sub>2</sub> changes to a yellow granular powder on boiling with water.—B'<sub>2</sub>HgO. Formed by adding Hg(NO<sub>3</sub>)<sub>2</sub> to a warm solution of urea (Desmaignes, *A.* 82, 282; Liebig, *A.* 65, 289).

**Compounds with metallic salts.**—B'AgNO<sub>3</sub>. Prisms. Yields silver cyanate on

boiling with water.—B'PdCl. Ppd. by adding a solution of PdCl<sub>2</sub> to one of urea (Drechsel, *J. pr.* [2] 20, 469).—B'NaCl<sub>aq</sub>. [60°–70°]. Formed by evaporation of a solution of urea and NaCl. Deliquescent prisms. Alcohol extracts urea from the compound.—B'NaNO<sub>3</sub>. aq. Prisms (from water).—B'NH<sub>4</sub>Cl. Deliquescent crystals.—B'<sub>2</sub>(NH<sub>4</sub>)<sub>2</sub>HCl. Formed by dissolving urea in bleaching-powder solution (Beckmann, *A.* 91, 367). Large plates, sol. alcohol mixed with ether.—B'<sub>2</sub>Mg(NO<sub>3</sub>)<sub>2</sub> (Werther, *J. pr.* 35, 5).—B'<sub>2</sub>Ca(NO<sub>3</sub>)<sub>2</sub>.—B'<sub>2</sub>ZnCl<sub>2</sub>. Very deliquescent crystals (Neubauer & Kerner, *A.* 101, 337).—B'<sub>2</sub>CdCl<sub>2</sub>. Needles.—B'<sub>2</sub>Hg(NO<sub>3</sub>)<sub>2</sub>3HgO. Granular powder formed by mixing warm dilute solutions of urea and mercuric nitrate. At the moment of formation the pp. is flocculent.—B'<sub>2</sub>Hg(NO<sub>3</sub>)<sub>2</sub>2HgO. \*Formed by pouring mercuric nitrate into a solution of urea as long as a pp. is produced, and keeping the whole at 40° to 50° for some time (Liebig). Six-sided laminae.—B'<sub>2</sub>Hg(NO<sub>3</sub>)<sub>2</sub>HgO. Formed by adding an acid solution of mercuric nitrate to a solution of urea nitrate. Crusts of small tabular crystals (Liebig, *A.* 85, 296).—B'<sub>2</sub>HgCl<sub>2</sub>. Flat crystals, v. sl. sol. cold water (W.).—B'<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>3aq. Formed by the action of water on the product of the action of CrO<sub>2</sub>Cl<sub>2</sub> on urea (W. J. Bell, *Pr.* 83, 267; 45, 321). Olive-green needles (from hot water). PtCl<sub>4</sub> added to its solution in hot water ppts. silky green needles of B'<sub>2</sub>Cr<sub>2</sub>Cl<sub>6</sub>(PtCl<sub>4</sub>)<sub>2</sub>.2aq. The chromate treated with PbCl<sub>2</sub> forms lead chromate and a liquid from which gaseous HCl ppts. green prisms of B'<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>6aq, the aqueous solution of which heated with Ag<sub>2</sub>SO<sub>4</sub> gives dark-green prisms of B'<sub>2</sub>Cr<sub>2</sub>(SO<sub>4</sub>)<sub>2</sub>10aq. In a similar way green prisms of B'<sub>2</sub>Cr<sub>2</sub>(NO<sub>3</sub>)<sub>2</sub> may be got.—B'<sub>2</sub>Cr<sub>2</sub>Cl<sub>6</sub>O<sub>12</sub>2aq. Green monoclinic crystals, got from the product of the action of CrO<sub>2</sub>Cl<sub>2</sub> on urea by crystallising from conc. HCl<sub>aq</sub> (1 vol.) diluted with water (9 vols.). By treatment with water it is split up into B'<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and B'<sub>2</sub>Cr<sub>2</sub>Cl<sub>6</sub>. By treatment with conc. HCl<sub>aq</sub> (1 vol.) and water (6 vols.) it is converted into the salts B'<sub>2</sub>Cr<sub>2</sub>Cl<sub>6</sub>O<sub>12</sub>3aq.—B'<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>4aq.—B'<sub>2</sub>Cr<sub>2</sub>Br<sub>2</sub>6aq.—B'<sub>2</sub>Cr<sub>2</sub>Cl<sub>6</sub>6HgCl<sub>2</sub>.—B'<sub>2</sub>Cr<sub>2</sub>(C<sub>2</sub>O<sub>4</sub>)<sub>2</sub>4aq.—B'<sub>2</sub>Cr<sub>2</sub>I<sub>2</sub>.—B'<sub>2</sub>Cr<sub>2</sub>(SO<sub>4</sub>)<sub>2</sub>I<sub>2</sub>.—B'<sub>2</sub>Cr<sub>2</sub>(CO<sub>3</sub>)<sub>2</sub>I<sub>2</sub>.—B'<sub>2</sub>Cr<sub>2</sub>(CO<sub>3</sub>)<sub>2</sub>I<sub>2</sub>.—B'<sub>2</sub>Cr<sub>2</sub>Br<sub>2</sub>. Bronze-yellow tables, giving off bromine in air.—B'<sub>2</sub>CuCl<sub>2</sub>. Small blue crystals.

**Formyl derivative** NH<sub>2</sub>.CO.NH.OH. [159°]. H.F. 13,400 (Matignon, *C. R.* 112, 1367). Formed by boiling urea with conc. formic acid (Geuther, *Z.* [2] 4, 300). Crystals, v. sol. water, being decomposed into urea and formic acid.

**Acetyl derivative** C<sub>2</sub>H<sub>3</sub>N<sub>2</sub>O<sub>2</sub> &c. NH<sub>2</sub>.CO.NHAc. **Acetureide**. Mol. w. 102. [214°]. H.F. –200 (M.). S. (alcohol) 1 in the cold; 10 at 78°. Formed by boiling urea with AcCl or Ac<sub>2</sub>O (Zinin, *A.* 92, 405; G.; Zrde, *R. T. C.* 8, 235). Got also by the action of KMnO<sub>4</sub> on methyl-uracil (Behrend, *A.* 229, 29). Four-sided needles (from alcohol). Slowly but completely decomposed by pure HNO<sub>3</sub> with evolution of CO<sub>2</sub> (1 vol.) and N<sub>2</sub>O (2 vols.) (Françoisimont, *R. T. C.* 6, 215). It is not ppe. by Hg(NO<sub>3</sub>)<sub>2</sub>.

**Di-acetyl derivative** CO(NHAc)<sub>2</sub>. [153°]. A product of the action of COCl<sub>2</sub> on acetamide at 50° (Schmidt, *J. pr.* [2] 5, 63).

Formed also from mercuric fulminate and  $\text{AcCl}$  (Scholl, *B.* 23, 8515). Needles (from alcohol), sl. sol. cold water.

*Chloro-acetyl derivative*

$\text{NH}_2\text{CO.NH.CO.CH}_2\text{Cl}$ . Formed from chloro-acetyl chloride and urea (Jazukovitch, *Z.* 1868, 234; Tommasi, *C. R.* 76, 640). Thin needles (from alcohol). Begins to melt at  $160^\circ$ .

*Tri-chloro-acetyl derivative*

$\text{NH}_2\text{CO.NH.CO.CCl}_3$ . [150°]. Crystals (from alcohol) (De Clermont, *J.* 1874, 798; Meldola & Tommasi, *C. J.* 1874, 404; Cloez, *A. Ch.* [6] 9, 219). Nearly insol. hot water.

*Bromo-acetyl derivative*

$\text{NH}_2\text{CO.NH.CO.CH}_2\text{Br}$ . Needles (from dilute alcohol) (Baeyer, *A.* 130, 156). Pure  $\text{HNO}_3$  gives off  $\text{CO}_2$  (1 vol.) and  $\text{N}_2\text{O}$  (2 vols.) (Franchimont, *R. T. C.* 6, 218).

*Tri-bromo-acetyl derivative*

$\text{NH}_2\text{CO.NH.CO.CBr}_3$ . [148°]. Formed by the action of  $\text{Br}$  on an aqueous solution of di-bromobarbituric acid (Baeyer). Crystals, v. sol. hot alcohol. Yields crystalline  $\text{B}_2\text{Ba}(\text{OH})_2\text{aq}$ , v. e. sol. water.

*Cyano-acetyl derivative*

$\text{NH}_2\text{CO.NH.CO.CH}_2\text{Cy}$ . [200°–210°] (Mulder, *B.* 12, 466). Crystalline.

*Butyryl derivative*  $\text{NH}_2\text{CO.NH.C}_4\text{H}_9\text{O}$

[176°]. Formed from urea and butyryl chloride (Moldenhauer, *A* 94, 101). Plates.

*Isovaleryl derivative*  $\text{C}_4\text{H}_9\text{O}$

[191°]. Minute prisms, v. sl. sol. water.

*Carbonyl derivative*  $\text{CO}(\text{NH.CO.NH})_2$

Formed by heating urea with  $\text{COCl}_2$  at  $100^\circ$  (E. Schmidt, *J. pr.* [2] 5, 39; Emich, *M.* 10, 347). Powder composed of minute crystals, v. sl. sol. cold water and alcohol. Decomposed by heat into  $\text{NH}_3$  and cyanuric acid. Boiling  $\text{KOH}$  also produces cyanuric acid.— $\text{B}^*\text{HgO}$ : crystalline powder, insol. water.

*Succinyl derivative*

$\text{C}_4\text{H}_5\text{O}_2(\text{NH.CO.NH})_2$ . Formed by heating urea (2 mols.) with succinyl chloride (1 mol.) at  $65^\circ$  (Conrad, *J. pr.* [2] 9, 301). Colourless powder, v. sl. sol. hot water.

*Methyl-malonyl derivative*

$\text{CHMe.C}_2\text{O}_2\text{N}_2\text{H}_4\text{CO}$ . [192°]. Formed by heating methyl-malonic acid with urea and  $\text{POCl}_3$  (Franchimont & Klobbie, *R. T. C.* 7, 22). Pointed plates, v. sol. water and alcohol.

*Benzoyl derivative*  $\text{NH}_2\text{CO.NH.Bz}$

[c. 200°]. S. (alcohol) 1 in the cold; 4 at  $78^\circ$ . Formed by heating urea with  $\text{BzCl}$  or  $\text{Bz}_2\text{O}$  at  $150^\circ$  (Zinin, *A.* 92, 404; Geuther, *Z.* [2] 4, 299). Four-sided plates (from alcohol), insol. ether.

*Di-benzoyl derivative*  $\text{CO}(\text{NEBz})_2$

[210°] (S.); [197°] (H.). A product of the action of  $\text{COCl}_2$  on benzamide at  $165^\circ$  (E. Schmidt, *J. pr.* [2] 5, 58). Formed also by heating guanidine carbonate with  $\text{Bz}_2\text{O}$  at  $100^\circ$  (Creath, *B.* 7, 1739) and by treating mercuric fulminate with  $\text{BzCl}$  (Holleman, *R. T. C.* 10, 72; *B.* 23, 2998, 3742). Needles (from alcohol), sl. sol. water. Aniline at  $180^\circ$  gives  $\text{NBz}$ , benzamide, benzanilide, and *p*-di-benzoyl-urea.

*Di-benzoyl derivative*  $\text{NH}_2\text{CO.NBz}$

[c. 197°]. Formed by heating sodium benzoyle cyanamide  $\text{NaBzN.CN}$  with  $\text{BzCl}$ , followed by boiling alcohol (Buddéus, *J. pr.* [2] 42, 97). White needles.

VOL. IV.

*m-Nitro-benzoyl derivative*

$\text{NH}_2\text{CO.NH.CO.C}_6\text{H}_4\text{NO}$ ; [1:8]. Plates (Griess, *B.* 8, 222).

*m-Amido-benzoyl derivative*  $\text{C}_6\text{H}_4\text{N}_2\text{O}$

Formed by boiling the preceding body with aqueous ammonium sulphide (G.). Needles (from water), decomposing at  $200^\circ$ .— $\text{B}^*\text{HCl aq}$ : needles.— $\text{B}^*\text{H.PtCl}_4$ .

*(\beta)-Naphthoyl derivative*

$\text{NH}_2\text{CO.NH.CO.C}_{10}\text{H}_7$ . [215°]. Formed from naphthoyl chloride and urea (Vieth, *A.* 180, 319). Minute needles, m. sol. alcohol, v. sl. sol. benzene.

*Di-(\beta)-naphthoyl urea* [286°] (Ekstrand, *B.* 20, 1853). Needles.

*Lactyl derivative* v. LACTYL-UREA.

*Glycolyl derivative* v. HYDANTOIN.

Reference.—OXY-UREA.

UREA CARBOXYLIC ACID v. ALLOPHANIC ACID.

UREA CHLORIDES. A name sometimes used to denote alkyl-carbamic chlorides  $\text{X.NH.CO.Cl}$ .

*URECHITIN*  $\text{C}_{22}\text{H}_{32}\text{O}_8$

Occurs, together with urechitoxin, in the leaves of *Urechites suberecta*, growing in Jamaica (Bowrey, *C. J.* 33, 252). Crystallises from alcohol in needles (containing aq), tastes bitter. It is very poisonous (*Pr.* 27, 309). Nearly insol. water, m. sol. ether. Appears to be a glucoside. Conc.  $\text{H}_2\text{SO}_4$  forms a yellow liquid, turning red, and finally purple, especially in presence of an oxidising agent.

*Urechitoxin*  $\text{C}_{12}\text{H}_{16}\text{O}_5$ . Bitter poison, split up by acids into sugar and urechitoxetin.

UREIDES. Compounds obtained by elimination of water between urea and an acid or an aldehyde. \* Many of them may be represented as amides in which  $\text{NH}_2$  is replaced by  $\text{NH.CO.NH}_2$ .

BIURET v. vol. i. p. 517.

URETHANE v. CARBAMIC ETHER.

ISURETINE v. FORMAMIDOXIM.

URIC ACID  $\text{C}_5\text{H}_4\text{N}_2\text{O}_6$  i.e.

$\text{CO} \begin{array}{c} \text{NH.CO.C.NH} \\ \text{NH} \text{---} \text{C.NH} \end{array} \text{CO}$  (Medicus, *A.* 175, 243; Fischer, *B.* 17, 329, 1776). Mol. w. 168. S.G. 1.87. H.C.p. 461,400 (Berthelot, *C. R.* 110, 887; Matignon, *C. R.* 110, 1267); 462,500 (Stohmann, *J. pr.* [2] 44, 590). H.C.v. 462,700 (M.). H.F. 148,100 (M.). S. -002 at  $0^\circ$ ; -006 at  $20^\circ$ ; -0625 at  $100^\circ$  (Blarez & Denigès, *C. R.* 104, 1847; cf. Gayrod, *Pr.* 35, 63).

Occurrence.—In urine and in urinary calculi (Schöde, *A.D.* 1776; Liebig & Wöhler, *A.* 26, 241; Horbaczowski, *M.* 12, 221). \* About .5 g. is daily excreted in human urine. Uric acid occurs in urine of carnivora, herbivora (Mittelbach, *H.* 12, 463), and of birds. Serpent's urine is chiefly composed of acid ammonium urate. A considerable quantity occurs in the blood of gouty subjects, and sodium urate is deposited as 'chalk stones.' Very small quantities are normally present in the liver, lungs, brain, and blood. It occurs in the green gland of the fresh-water crayfish (Griffiths, *Pr.* 36, 187). Urea, glycocoll, leucine, and aspartic acid give, to bowls appear in the urine as uric acid (Jaffé & Meyer, *B.* 10, 1930; Knierim, *B.* 10, 1930).

Synthesis.—1. By rapidly heating glycocoll (1 pt.) with urea (10 pts.) to  $230^\circ$  (Horbaczowski, *B.* 15, 2678; *M.* 3, 796; 6, 856).—2. By heating

8 H

urea with tri-chloro-lactic acid or its amide (Horbaczewski, *M.* 8, 201, 584).—8. By preparing methyl-uracil from acetoacetic ether acid urea; converting methyl-uracil into nitro-uracil carb-oxylic acid by treatment with fuming  $\text{HNO}_3$ ; boiling the carboxylic acid with water, and reducing the resulting nitro-uracil to amido-uracil, and finally to isobarbituric acid by means of tin and  $\text{HClAq}$ ; oxidising the isobarbituric acid to isodialuric acid; and heating the isodialuric acid (1 pt.) with urea (1 pt.) and  $\text{H}_2\text{SO}_4$  (6 pts.) (Behrend & Roosen, *A.* 251, 235).—4. By fusing urea (4 g.) with cyano-acetic acid (1 g.) (Formánek, *B.* 24, 3419).

**Preparation.**—1. Serpent's urine is dissolved in boiling  $\text{KOH}$ aq, filtered, and the uric acid ppd. by  $\text{HCl}$  or dilute  $\text{H}_2\text{SO}_4$ . If the uric acid is much coloured a little  $\text{KMnO}_4$  or  $\text{K}_2\text{Cr}_2\text{O}_7$  (Gibbs, *Am. S.* [2] 48, 215) should be added to the boiling alkaline solution before ppn.—2. Guano is boiled with borax (1 pt.) and water (120 pts.), and the solution of sodium urate thus obtained ppd. by  $\text{HCl}$ .—3. Guano is extracted with dilute  $\text{HCl}$ aq, and the residue dissolved in conc.  $\text{H}_2\text{SO}_4$ , and ppd. by water.

**Properties.**—White anhydrous scales (by ppn.). When slowly deposited from dilute solutions (e.g. urine) it separates as large crystals (containing 2aq). Nearly insol. water, insol. alcohol and ether. Sol. conc.  $\text{H}_2\text{SO}_4$ , and reppd. by water. Its solution in hot  $\text{H}_2\text{SO}_4$  deposits on cooling a deliquescent compound of uric acid with  $\text{H}_2\text{SO}_4$ . Uric acid is m. sol. glycerin, hot  $\text{NaOAc}$ , and sodium phosphate. Lithium carbonate (1 pt.) dissolved in water (90 pts.) can dissolve uric acid (4 pts.). Aqueous  $\text{K}_2\text{CO}_3$  also dissolves uric acid.

**Reactions.**—1. Decomposed by heat, without fusion, yielding  $\text{HCN}$  and a sublimate of cyanuric acid, ammonium cyanate, urea, and ammonium carbonate, and leaving a carbonaceous residue. 2. Water at  $180^\circ$  forms mycomelic acid (Hlasiwetz, *A.* 103, 211).—3. Potash-fusion yields  $\text{NH}_3$  and potassium oxalate, carbonate, and cyanate.—4. Chlorine and bromine in presence of water yield alloxan, urea, and parabanic acid (Hardy, *A. Ch.* [4] 2, 372). Alloxan is also produced by iodine, by  $\text{HNO}_3$ , and by  $\text{MnO}_2$  and  $\text{H}_2\text{SO}_4$ .—5. Boiling with water and  $\text{PbO}$  yields allantoin. Allantoin is also produced by ozone (Gorup-Besanez, *A.* 110, 94), alkaline  $\text{K}_2\text{FeCy}_6$ ,  $\text{KMnO}_4$  (Claus, *B.* 7, 226), and  $\text{MnO}_2$  and water. 6. Pure  $\text{HNO}_3$  decomposes uric acid in the cold, with evolution of  $\text{CO}_2$  (14 vols.),  $\text{N}_2\text{O}$  (24 vols.), and nitrogen (4 vols.) (Franchimont, *R. T. O.* 6, 222). 7.  $\text{KNO}_3$  and  $\text{HOAc}$  yield urilinic acid (Sokoloff, *Z.* [2] 5, 78) and stryphnic acid (Gibbs, *Am. J.* [2] 48, 215).—8.  $\text{HIAq}$  at  $165^\circ$  forms glycoecoll,  $\text{NH}_3$ , and  $\text{CO}_2$  (Strecker, *Z.* [2] 4, 215).—9. Exposed to the air in alkaline solution it yields oxonic and urazanic acids.—10. A dilute solution of sodic urate absorbs oxygen from the air at  $35^\circ$  according to the equation  $\text{C}_5\text{H}_4\text{N}_4\text{O}_6 + \text{O} + 2\text{H}_2\text{O} = \text{C}_5\text{H}_4\text{N}_4\text{O}_7$  (uroxanic acid). Uric acid in dilute  $\text{NaOH}$  solution is completely decomposed by 35 days' digestion at  $85^\circ$  (Nencki & Sieber, *J. pr.* [2] 56, 18). 5 g. uric acid dissolved in 200 c.c. water and 20 g. potash disappeared in 5 days. However, if no oxygen be present the uric acid is not affected.—11. In fermenting urine uric

acid is completely split up into  $\text{CO}_2$  and  $\text{NH}_3$  (Sestini, *G. Z.* 20, 138).

**Detection.**—Uric acid may be recognised by its insolubility in water and  $\text{HClAq}$ , by its crystalline character under the microscope, and especially by the murexide reaction. When evaporated with  $\text{HNO}_3$  on a water-bath it leaves an orange residue, which is coloured violet-red by ammonia and violet-blue by potash. A solution of uric acid in aqueous  $\text{Na}_2\text{CO}_3$  produces a dark-brown spot of reduced silver when added to paper moistened with  $\text{AgNO}_3$  (Schiff, *A.* 109, 65). Uric acid (1 mol.) reduces boiling Fehling's solution, forming a pp. of  $\text{Cu}_2\text{O}$  (1 mol.) (W. Müller, *J. Th.* 1881, 73). In presence of  $\text{KOH}$  uric acid dissolves  $\text{CuO}$ , forming a blue solution, which slowly deposits white cuprous urate. The compound  $\text{C}_5\text{H}_4\text{N}_4\text{O}_6\text{Cu}_2\text{O}$  is ppd. when an alkaline solution of uric acid is treated with Fehling's solution and hydroxylamine hydrochloride (Balke, *J. pr.* [2] 47, 546). Uric acid evaporated with a little dilute  $\text{HNO}_3$  gives a blue colour on shaking with  $\text{H}_2\text{SO}_4$  and benzene containing thiophene (Denigès, *J. Ph.* [5] 18, 161).

**Estimation in urine.**—1. Urine (500 c.c.) is concentrated,  $\text{HCl}$  is added, and after twenty-four hours the pp. is collected and weighed. Uric acid may be separated from xanthine by ppn. with conc.  $\text{H}_2\text{SO}_4$  (Horbaczewski, *H.* 18, 341; cf. Wulff, *H.* 17, 334).—2. Urine (200 c.c.) is mixed with conc.  $\text{Na}_2\text{CO}_3$ aq (10 c.c.), and after an hour conc.  $\text{NH}_4\text{Cl}$ aq (20 c.c.) added. After forty-eight hours the pp. is collected, washed with  $\text{HCl}$  (1 pt. of S.G. 1.125), diluted with water (10 pts.), the washings allowed six hours to deposit any dissolved uric acid, the combined pps. washed with alcohol and dried at  $110^\circ$  (Salkowski, *Fr.* 16, 373). Uric acid may also be ppd. as ammonium urate by saturating urine with solid  $\text{NH}_4\text{Cl}$  (30 g. to 100 c.c.) (Hopkins, *Fr.* 52, 93).—3. Fresh urine is mixed with very dilute (15 p.c.)  $\text{NaOHAq}$ , filtered from phosphates, and diluted to S.G. 1.010. To 300 c.c. of this solution is added 50 c.c. of magnesia mixture ( $\text{MgSO}_4$ , 7aq (1 pt.),  $\text{NH}_4\text{Cl}$  (2 pts.),  $\text{NH}_4\text{Aq}$  (4 pts. of S.G. 924), and water (8 pts.)). The pp. is filtered off, and 175 c.c. of the filtrate mixed with 5 g.  $\text{CaCO}_3$  and 5 c.c. of a 8 p.c. solution of  $\text{AgNO}_3$ . The pp. is washed and dried, and a nitrogen estimation made by Kjeldahl's method (Camerer, *Z. B.* 26, 84; cf. Salkowski, *Pf.* 5, 819).—4. Urine (25 c.c.) is mixed with  $\text{NaHCO}_3$  (1 g.), and  $\text{NH}_4\text{Aq}$  (2 to 3 c.c.), and ammoniacal  $\text{AgNO}_3$  (1 to 2 c.c. of a solution of 5 g.  $\text{AgNO}_3$  in 100 c.c. water, to which  $\text{NH}_4\text{Aq}$  is added till the ppd.  $\text{Ag}_2\text{O}$  is just re-dissolved). The pp. is collected, washed, dissolved in  $\text{HNO}_3$ , and the silver determined volumetrically by the sulphocyanide method (Hayercraft, *Fr.* 25, 167; 30, 648). This method is liable, according to Salkowski (*H.* 14, 31) and Gossage (*Pr.* 44, 384), to an error which may amount to 60 p.c. The error is partly due to variations in composition of the silver urate, and partly to presence of bodies of the xanthine group (Derode, *Bl.* [3] 7, 863).—5. Also Herrmann, *H.* 12, 196; Ozapek, *H.* 12, 502).—5. In a solution containing not more than 0.25 p.c. of uric acid 1 c.c. of decinormal permanganate is reduced by 0.074 g. uric acid (Blarez & Denigès, *C. R.* 104, 789).—6. By treat

ment with a standard iodine solution in presence of alkali (Kresidl, *M.* 14, 109).

**Salts.**— $(\text{NH}_4)\text{HA}''$ . S. °06 at 15°. Slender needles.— $(\text{NH}_4)_2\text{HA}''$ .— $(\text{NH}_4)_3\text{HA}''$ . (Maly, *J.* 1868, 621).— $\text{K}_2\text{A}''$ . S. 8 at 16°. Small needles.— $\text{KHA}''$ . S. 18 at 20°. Amorphous.— $\text{Na}_2\text{A}''$  aq. S. 1.5. Nodules.— $\text{NaHA}''$  4aq (dried at 100°). Crystalline powder. S. °09 at 15°; °8 at 100°. Occurs as an amorphous urinary deposit.— $\text{LiHA}''$ . S. 27 at 20°; °9 at 40°; 2.5 at 100° (Schilling, *A.* 122, 241).— $\text{BaA}''$  aq (dried at 100°). Granular pp. S. °13 in the cold.— $\text{BaH}_2\text{A}''$ , 2aq (dried at 100°). Amorphous, insoluble powder (Behrend a. Roosen, *A.* 251, 250).— $\text{CaA}''$ . S. °066 in the cold; °07 at 100°.— $\text{CaH}_2\text{A}''$ , 2aq. S. °15 in the cold; °37 at 100°. More sol.  $\text{KClAq}$ .— $\text{SrA}''$  2aq. Minute stellate groups of needles. S. °023 in the cold; °055 at 100°.— $\text{SrH}_2\text{A}''$ , 2aq.— $\text{MgH}_2\text{A}''$ , 6aq. S. °03 in the cold; °6 at 100°.— $\text{PbH}_2\text{A}''$ , (dried at 100°). Insol. water.— $\text{PbA}''$  (dried at 100°).— $\text{Cu}_2\text{A}''$  aq.— $\text{Cu}_3\text{A}_2(\text{OH})$ , 4aq; green pp.

**Reference.**—METHYL-URIC ACID.

**Iso-uric acid**  $\text{C}_5\text{H}_4\text{N}_2\text{O}_6$ . Formed by boiling cyanamide (1 pt.) with an aqueous solution of alloxantin (2 pts.) (Mulder, *B.* 6, 1236; 7, 1633). Powder, almost insol. water. Oxidised by boiling with I and water. Its solution in  $\text{K}_2\text{CO}_3$  reduces  $\text{AgNO}_3$ .

**Pseudo-uric acid**  $\text{C}_5\text{H}_4\text{N}_2\text{O}_6$ , i.e.

$\text{CO} < \text{NH.CO} > \text{CH.NH.CO.NH}_2$ . Formed by the action of  $\text{KCyO}$  on uramil (Baeyer, *A.* 127, 3), and by heating uramil with urea at °180° (Grimaux, *Bl.* [2] 31, 535). White crystalline powder composed of small prisms, v. sl. sol. water.  $\text{HNO}_3$  yields alloxan. Boiled with water and  $\text{PbO}_2$  it yields oxalic acid, but no allantoin.  $\text{H}_2\text{SO}_4$  at 150° forms xanthinino.— $(\text{NH}_4)_2\text{HA}''$  aq.— $\text{KHA}''$  aq; scales.— $\text{NaHA}''$  2aq; groups of prisms, v. sol. hot water.— $\text{BaA}''$  5aq; groups of slender needles.

**URINILIC ACID**  $\text{C}_5\text{H}_4\text{N}_2\text{O}_6$ . Formed by the action of  $\text{KNO}_3$  and  $\text{HOAc}$  on uric acid (Sokoloff, *Z.* 1869, 78). Prisms (from water).— $\text{K}_2\text{HA}''$ . Prisms, v. e. sol. water.  $\text{CaA}''$ . Crystalline pp. insol. water and  $\text{HOAc}$ .— $\text{SrA}''$ .— $\text{Ba}_2\text{A}''$ .— $\text{CdHA}''$  8aq.— $\text{CuHA}''$  4aq. Slender red needles.— $\text{Ag}_2\text{HA}''$ . Pp.— $\text{Ag}_3\text{A}''$ . Gelatinous pp. quickly blackening in light.

**UROBILIN.**

**Occurrence.**—Often in urine (Jaffé; Disqué, *H.* 2, 271; *C.* C. 1878, 711; Eikholz, *J. Physiol.* 14, 326). In bile, especially of the moose.

**Preparation.**—Urine containing urobilin is ppd. by lead acetate and sub-acetate until the absorption band at F is removed. The pp. is extracted with alcohol, acidified with  $\text{HCl}$  or  $\text{H}_2\text{SO}_4$ , filtered, diluted with water, and extracted with chloroform.

**Properties.**—A red amorphous, shiny substance. Prepared as above it contains  $\text{HCl}$ , or  $\text{H}_2\text{SO}_4$ , as the case may be. Its spectrum exhibits a dark band at F, destroyed by  $\text{NH}_3$ , but on adding  $\text{NaOH}$  another band near the red is formed (MacMunn, *Pr.* 80, 250; 81, 26, 206; v. also HYDROBILANIN, this vol. p. 273).

**Detection and estimation in urine:** Jolles, *H.* 18, 545; Studensky, *C.* C. 1893, ii. 668.

**UROCANINIC ACID**  $\text{C}_{10}\text{H}_8\text{N}_2\text{O}_6$ . [213°]. Occurs in dog's urine (Jaffé, *B.* 7, 1669; 8, 811).

Prisms (containing 4aq), v. sol. hot water, insol. alcohol and ether. Decomposed by fusion into  $\text{CO}_2$  and urocanine  $\text{C}_{10}\text{H}_8\text{N}_2\text{O}_4$ , an amorphous base yielding  $\text{B}''\text{H}''\text{PtCl}_4$ .— $\text{HA}''2\text{HCl}$ ; needles, v. e. sol. water.— $\text{HA}''2\text{HNO}_3$ ; crystalline pp. insol. dilute  $\text{HNO}_3$ , v. sol. water.— $\text{HA}''\text{H}_2\text{SO}_4$ . Minute needles and plates.

**UROCHLORALIC ACID**  $\text{C}_8\text{H}_8\text{Cl}_2\text{O}_6$  (?) [142°]. S. (ether) 4. Found in the urine after administration of chloral (Von Mering a. Musculus, *B.* 8, 662; *H.* 6, 483; Kütz, *C.* C. 1881, 486). Silky needles, v. e. sol. water and alcohol. Decomposed by boiling dilute  $\text{H}_2\text{SO}_4$  into tri-chloroethyl alcohol and glycuronic acid  $\text{C}_6\text{H}_8\text{O}_6$ .— $\text{NaA}''$ .— $\text{KA}''$ .— $\text{BaA}''$ ; satiny plates (from ether-alcohol).

**UROFUSCOHEMATIN** v. this vol. p. 274.

**UROLEUCIC ACID**  $\text{C}_{10}\text{H}_{10}\text{O}_6$ . [133-5°]. An acid occurring in human urine which darkens on addition of alkalis (Kirk, *Brit. Med. Journ.* [1888] 2, 232). Crystals. Its solution is ppd. by  $\text{Pb}(\text{OAc})_2$  and gives a transient green colour with very dilute  $\text{FeCl}_3$ .  $\text{FeCl}_3$  colours the crystals red.

**UROMELANIN**  $\text{C}_{10}\text{H}_8\text{N}_2\text{O}_6$ . A black substance which separates on treating urine with  $\text{H}_2\text{SO}_4$  or  $\text{HClAq}$  in presence in air (Thudichum, *J. pr.* 104, 257; *C.* R. 106, 1803; Ploetz, *H.* 8, 89; Udranski, *H.* 11, 537; 12, 32; this vol. p. 274). It yields  $\text{C}_{10}\text{H}_8\text{AgN}_2\text{O}_6$  (Thudichum).

**URONITROTOLUOLIC ACID**  $\text{C}_{10}\text{H}_8\text{N}_2\text{O}_6$ . Occurs in urine of dogs after a dose of o-nitrotoluene (Jaffé, *H.* 2, 47). Very deliquescent. Asbestos-like mass, v. e. sol. water and alcohol. Decomposed by dilute  $\text{H}_2\text{SO}_4$  into o-nitro-benzyl alcohol and a syrupy acid. Salts.— $\text{BaA}''$ ; crystalline powder, v. e. sol. water, insol. alcohol.— $\text{CO}(\text{NH}_2)_2\text{HA}''$  2aq. [149°]. Needles, v. e. sol. water, sl. sol. cold alcohol.

**UROROSEIN** v. this vol. p. 274.

**UROSULPHINIC ACID**  $\text{C}_5\text{H}_4\text{N}_2\text{SO}_6$ . Formed by heating thio-uramido-barbituric acid (1 pt.) with  $\text{H}_2\text{SO}_4$  (2 pts.) at 160° (Nencki, *B.* 4, 724; 5, 45). Nodules (from hot  $\text{HClAq}$ ). Its K salt crystallises in needles, m. sol. cold water.

**UROXANIC ACID**  $\text{C}_5\text{H}_4\text{N}_2\text{O}_6$ . Formed by leaving a solution of uric acid (5 g.) in water (200 c.c.) containing  $\text{KOH}$  (20 g.) to stand for 5 days at 35°, neutralising by  $\text{HOAc}$ , filtering, and evaporating (Nencki a. Sieber, *J. pr.* [2] 24, 604; cf. Städeler, *A.* 78, 286; 80, 119; Strecker, *A.* 155, 177; Mulder, *B.* 8, 1291). Tetrahedra, sl. sol. cold water, insol. alcohol. Decomposed by boiling water into  $\text{CO}_2$ , urea, and allanturic acid.— $\text{K}_2\text{A}''$  3aq. Four-sided pearly plates, v. sl. hot water.— $\text{CaA}''$  4aq.— $\text{BaA}''$  5aq.— $\text{PbA}''$  4aq. Insol. water.— $\text{Ag}_3\text{A}''$ ; flocculent pp., turned red by light.

**URSONE**  $\text{C}_{10}\text{H}_8\text{O}_6$  2aq. [265°] (Gintl, *M.* 14, 255). Occurs in the leaves of the bear-berry (*Arctostaphylos Uva-ursi*) (Trommsdorff, *Ar. Ph.* [2] 80, 273; Hlasiwetz, *J. pr.* 68, 123). Needles, insol. water, acids, and alkalis, sl. sol. alcohol and ether. Conc.  $\text{H}_2\text{SO}_4$  added to its solution in  $\text{Ac}_2\text{O}$  gives a red colour, changing through blue to green. Does not react with hydroxylamine or phenyl-hydrazine. Reduced by  $\text{HI}$  and  $\text{F}$  at 860° to  $\text{C}_{10}\text{H}_8$ , (256°-267°).

**Acetyl derivative** [264°].

**Benzoyl derivative** [214°].

**URUSHIC ACID**  $C_{11}H_{10}O_8$ . S.G. 25-985. Occurs in urushi or Japanese lacquer (Yoshida, *C. J.* 43, 473). Dark, pasty mass, v. sol. benzene and ether, insol. water. Br in  $CS_2$  forms  $C_{11}H_{12}Br_2O_8$ .  $HNO_3$  forms  $C_{11}H_{10}(NO_3)_2O_8$ , which forms  $FeA_3$ . Chromic acid mixture forms oxyurushic acid  $C_{11}H_{10}O_8 \cdot PbA'$ , dried at  $100^\circ$ . [ $110^\circ$ - $115^\circ$ ]. Flocculent pp.— $FeH_2A'_{12}2aq$ .— $FeH_2A'$ . Deep-black pp.

**USNETIC ACID**  $C_8H_8O_8$ . [ $178^\circ$ ]. Occurs in small quantity, together with usnic acid, in the lichen *Usnea barbata* (Hesse, *B.* 10, 1326). Flat prisms (from alcohol), v. sol. ether.  $FeCl_3$  colours its alcoholic solution: bluish-violet. Bleaching-powder does not colour its alkaline solution. Is perhaps identical with decarbusnic.

**USNIC ACID**  $C_{11}H_{10}O_8$  (Salkowski; Paterno) or  $C_{11}H_{10}O_8$  (Hesse), or  $C_{11}H_{10}O_8$  (Stenhouse a. Groves, *C. J.* 39, 234). *Carbusnic acid*. [ $195.4^\circ$  cor.]. S. (ether) 3 at  $20^\circ$ . Occurs in the lichens *Usnea barbata*, *Usnea florida*, *Leora sordida* (Knop, *A.* 49, 103; Rochleder a. Heldt, *A.* 48, 12; Thomson, *A.* 53, 252; Stenhouse, *Pr.* 18, 222; *A.* 68, 97, 114; 155, 51; Hesse, *A.* 117, 843; Paterno, *G.* 8, 225; Salkowski, *B.* 8, 1459). Sulphur-yellow monoclinic crystals, sl. sol. alcohol, v. sol. hot ether and benzene. Does not yield betorcin when heated. Conc.  $H_2SO_4$  forms usnic acid  $C_{11}H_{10}O_{10}$  [ $213^\circ$ ] crystallising in small yellowish prisms (Stenhouse a. Groves, *C. J.* 39, 236). When it is heated with an alcoholic solution of aniline it yields the anilide  $C_{11}H_{10}O_8(NHPh)$ , crystallising from alcohol in pale-yellow plates [ $171^\circ$ ], and forming in  $KOH$  aq a yellow solution from which  $HCl$  ppts.  $C_{11}H_{12}NO_8$  [ $171^\circ$ ].

**Salts.**— $NaC_{11}H_9O_8$  2aq (Spica, *A.* 12, 432). Pale-yellow, silky needles.— $KC_{11}H_9O_8$  3aq or  $KC_{11}H_9O_8$  3aq. Pale-yellow plates (from 50 p.c. alcohol) (Hesse, *B.* 10, 1325).— $KC_{11}H_9O_8$  aq or  $KC_{11}H_9O_8$  aq. Yellow prisms (from 93 p.c. alcohol).— $CaA_2$ : green pp.

**Decarbusnic**  $C_{11}H_{10}O_8$ . [ $175^\circ$ ]. Formed by heating usnic acid (1 pt.) with alcohol ( $3\frac{1}{2}$  pts.) at  $150^\circ$  (Paterno, *G.* 12, 234). Yellow, silky needles, sol. hot alcohol, sl. sol. water and ether. Not coloured by  $FeCl_3$ . Not attacked by  $AcCl$ . Reduces warm ammoniacal  $AgNO_3$ . Boiling  $KOH$  aq in absence of air splits it up into  $HOAc$  and decarbusnic acid  $C_{11}H_{10}O_8$ , which crystallises from alcohol in lemon-yellow prisms [ $199^\circ$ ] and yields, when boiled with  $Ac_2O$ , two acetyl derivatives  $C_{11}H_{10}AcO_8$  [ $148^\circ$ ] (isomeric with decarbusnic) and  $C_{11}H_{10}Ac_2O_8$  [ $131^\circ$ ].

**Pyrousnic acid**  $C_{11}H_{10}O_8$  (P.);  $C_{11}H_{10}O_8$  (Salkowski, *B.* 8, 1461). [ $197^\circ$ ]. Formed, together with pyrousnic acid, by boiling usnic acid (2 pts.) with  $KOH$  (5 pts.) and water (5 pts.) in an atmosphere of hydrogen (Paterno, *G.* 8, 213; 125

242). Shining scales (from ether), v. sol. alcohol, sl. sol. ether. Its alkaline solution absorbs oxygen from the air, turning green and ultimately brown. Reduces ammoniacal  $AgNO_3$  readily.  $Ac_2O$  yields an acetyl derivative [ $205^\circ$ ]. Alcohol and  $HCl$  form an ether [ $147^\circ$ ]. Pyrousnic acid is split up on dry distillation in a current of  $H$  into  $CO_2$  and usneole  $C_{11}H_{12}O_8$ , which crystallises from alcohol in yellow prismatic tablets [ $176^\circ$ ] and is converted by  $AcCl$  into a di-acetyl derivative [ $142^\circ$ ].

**Pyrousnic acid**  $C_{11}H_{10}O_8$ , i.e.  $C_{11}H_{12}O_8(CO_2H)$ . [ $186^\circ$ ]. Formed by boiling usnic acid, (10 pts.) with  $KOH$  (25 pts.) and water (25 pts.) for 15 minutes (Paterno, *G.* 12, 238). Colourless plates or needles (from alcohol).  $Ac_2O$  yields  $C_{11}H_{10}AcO_8$  [ $168^\circ$ ]. When heated in a current of  $H$ , pyrousnic acid is split up into  $CO_2$  and usnetole  $C_{11}H_{10}O_8$ , which crystallises from dilute alcohol in yellowish needles [ $179^\circ$ ].

(*B.*) Usnic acid v. CLADONIC ACID.

**UVIC ACID** v. PYROTETRARIC ACID.

**UVINONE**  $C_{11}H_{12}O_8$ , i.e.

$O \langle CMe:C.CO.C:CMe \rangle O$  (?) [ $247^\circ$ ]. Formed, to the extent of 2 p.c., by distilling pyrotettricaric acid (Dietrich a. Paal, *B.* 20, 1086). Yellow needles (by sublimation), sol.  $HOAc$ , v. sl. sol. alcohol. Conc.  $H_2SO_4$  forms a solution with green fluorescence. Br at  $100^\circ$  forms crystalline  $C_{11}H_{12}Br_2O_8$ .

**UVITIC ACID**  $C_8H_8O_8$ , i.e.

$C_8H_8Me(CO_2H)_2$  [ $13:5$ ]. *Mesidic acid*. Mol. w. 180. [ $288^\circ$ ]. H.C.v. and p. 928,900. H.F. 193,100 (Stohmann, *J. pr.* [2] 40, 128). Formed, together with uvitonic acid, by boiling pyruvic acid with baryta-water (Finck, *A.* 122, 184). Formed also by oxidation of mesitylene or mesitylenic acid (Fittig a. Von Furtenbach, *Z.* [2] 4, 1; *A.* 147, 295), by oxidation of dimethyl-ethyl-benzene (Wroblewski, *A.* 192, 217), and by heating  $C_8H_8Me(SO_2NH_2)(CO_2H)$  with conc.  $HCl$  aq at  $230^\circ$  (Hall a. Remsen, *Am.* 2, 136). Slender needles (from water), v. sl. sol. hot water, m. sol. alcohol and ether. Yields toluene on heating with soda-lime (Baeyer, *Z.* [2] 4, 119). The Ca salt heated with lime yields m-toluic acid (Böttlinger a. Ramsay, *A.* 168, 255). Chromic acid mixture oxidises it to trimesic acid.

**Salts.**— $K_2A''$ : plates (from alcohol), v. sol. water.— $BaA''$  aq.— $CaA''$  aq.— $Ag_2A''$ . Nearly insol. cold water.

*Ethyl ether EtA''*. [ $35^\circ$ ]. Crystalline.

**References.**—AMIDO-, BROMO-, NITRO-, and OXY-UVITIC ACID.

**Isouvitic acid** v. CARBOXY-PHENYL-ACETIC ACID.

**Uvitonic acid** v. METHYL-PYRIDINE-DICARBOXYLIC ACID.

**VALERAL** v. VALERIC ALDEHYDE.

**VALERAL-DI-ACETONAMINE** v. *Pentyl-diacetonamine*.

**VALERALDINE**  $C_{11}H_{20}NS_2$ . *Thiovaleraldine*.

[ $41^\circ$ ]. Formed by the action of  $H_2S$  on isovaleric aldehyde ammonia suspended in water (Beiswährtz, *A.* 90, 109; Parkinson, *A.* 90, 119). Formed also from thioisovaleric aldehyde and dry  $NH_3$  (Schröder, *B.* 4, 468). Plates (from

ether), with powerful smell, sol. alcohol, insol. water.—B'HCl. Needles, sol. water.

**VALECREATININ** v. METHYL-GUANIDO-VALERIC ACID.

**VALERIAN OIL.** An essential oil obtained from the root of *Valeriana officinalis*. It contains a terpene  $C_{10}H_{16}$  (156°) [ $\alpha$ ]<sub>D</sub> = -21°, a camphene, borneol  $C_{10}H_{16}O$ , di-bornyl oxide ( $C_{10}H_{16}O$ ) (285°-290°), formyl-, acetyl-, and valeryl-borneol, and a little valeric acid (Gerhardt, *A. Ch.* [3] 7, 275; Pierlot, *A. Ch.* [3] 56, 291; Bruylants, *J. Ph.* [4] 27, 349; B. 11, 452; Haller, *C. R.* 103, 161; Oliviero, *G. R.* 117, 1096).

**n-VALERIC ACID**  $C_5H_{10}O_2$  i.e.  $CH_3(CH_2)_3CO_2H$ . Mol. w. 102. (180° cor.). S.G.  $\frac{2}{3}$  9562 (Zander, *A.* 224, 65);  $\frac{1}{4}$  9446;  $\frac{3}{8}$  9375 (Perkin);  $\frac{2}{3}$  9298 (Brühl). C.E. (0°-10°) 00098 (Z.). S. 3-5 at 16°. S.V. 130-0 (Z.). M.M. 5-513 at 13-6°.  $\mu_D$  = 1.4093.  $R_D$  = 43-16 (Brühl). H.F. 137,800 (Stohmann, *J. pr.* [2] 49, 99). Occurs in crude wood vinegar (Grodzki a. Krämer *B.* 11, 1358).

**Formation.**—1. By saponifying its nitrile (n-butyl cyanide) (Lieben a. Rossi, *A.* 159, 58; *G.* 1, 239).—2. By oxidation of n-amyl alcohol (L. a. R.).—3. By the action of metallic silver on a mixture of EtI and  $\beta$ -iodopropionic acid (W. von Schneider, *Z.* [2] 5, 344).—4. By oxidising  $\alpha$ -oxy-n-caproic acid (Erlenmeyer, *B.* 9, 1840).—5. By heating  $\beta$ -acetyl-propionic acid with HI and P at 200° (Kehrer a. Tollens, *A.* 206, 233).—6. By reducing  $\beta$ -acetyl-propionic acid with sodium-amalgam (Wolff, *A.* 208, 110).—7. By heating n-propyl-malonic acid at 180° (Juslin, *B.* 17, 2504; Furth, *M.* 9, 308).—8. By fermentation of calcium lactate (Fitz, *B.* 13, 1309; 14, 1044). 9. By heating the lactone of  $\gamma$ -oxy-n-valeric acid with HIAq and P at 240° (Fittig, *A.* 226, 346).—10. A product of oxidation of castor oil by dilute  $HNO_3$  (Wahlforss, *B.* 22 *Ref.*, 438).

**Properties.**—Liquid, smelling like butyric acid.

**Salts.**—KA'. Plates (from alcohol).—CaA'. aq. S. 10-267 at 0°; 8-144 at 60°. Least soluble at 60°-70° (F.).—CaA'. 1½ aq (Schurlemmer, *A.* 161, 270).—BaA'. S. 21-693 at 0°; 23-076 at 80°.—MnA'. aq.—GuA'. minute green needles. More sol. cold than hot water.—ZnA'. S. 2-6 at 25°.—AgA'. S. 2-29 at 3°; 6-41 at 70-5°.

**Methyl ether** MeA'. (127-3°). S.G.  $\frac{2}{3}$  9097 (G.);  $\frac{2}{3}$  8795. C.E. (0°-10°) 00106. S.V. 149-1 (Gartenmeister, *A.* 233, 273).  $\mu_D$  = 1.3997.  $R_D$  = 50-7.

**Ethyl ether** EtA'. Mol. w. 130. (144-7° cor.). S.G.  $\frac{2}{3}$  8939 (G.);  $\frac{2}{3}$  8705 (Lieben a. Rossi, *A.* 165, 117);  $\frac{2}{3}$  8661 (Brühl). S.V. 174-3. C.E. (0°-10°) 00111.  $\mu_D$  = 1.402.  $R_D$  58-03 (B.).

**n-Propyl ether** PrA'. (167-5°). S.G.  $\frac{2}{3}$  8888. C.E. (0°-10°) 00106 (G.). S.V. 197-8.

**n-Butyl ether** C<sub>4</sub>H<sub>9</sub>A'. (185-8°). S.G.  $\frac{2}{3}$  8847. C.E. (0°-10°) 00101. S.V. 222-1.

**n-Amyl ether** C<sub>5</sub>H<sub>11</sub>A'. Mol. w. 172. (203-7°). S.G.  $\frac{2}{3}$  8812 (G.);  $\frac{2}{3}$  8568 (Brühl). C.E. (0°-10°) 00097. S.V. 245-8.  $\mu_D$  1.417.  $R_D$  80-48.

**n-Heptyl ether** C<sub>7</sub>H<sub>15</sub>A'. (223-8°). S.G.  $\frac{2}{3}$  8797. C.E. (0°-10°) 00096. S.V. 272-0.

**n-Heptyl ether** C<sub>7</sub>H<sub>15</sub>A'. (243-6°). S.G.  $\frac{2}{3}$  8786. C.E. (0°-10°) 00090. S.V. 297-4.

**n-Octyl ether** C<sub>8</sub>H<sub>17</sub>A'. (260-2°). S.G.  $\frac{2}{3}$  8784. C.E. (0°-10°) 00088. S.V. 322-6.

**Amide** C<sub>5</sub>H<sub>9</sub>CO.NH<sub>2</sub>. Mol. w. 101. (116°). Pearly plates (Weidel a. Ciamician, *B.* 13, 69). V. sol. water, alcohol, and ether.

**Nitrile** C<sub>5</sub>H<sub>7</sub>CN. **n-Butyl cyanide.** (140°). S.G.  $\frac{2}{3}$  816 (Lieben a. Rossi, *A.* 158, 171). Formed, together with amylamine, by allowing a mixture of hexoic amide (1 mol.) and bromine (2 mols.) to run into a 10 p.c. solution of NaOH (Hofmann, *B.* 17, 1410).

**Isovaleric acid** (CH<sub>3</sub>)<sub>2</sub>CH.CH<sub>2</sub>CO<sub>2</sub>H. **Isopropyl-acetic acid.** (176° cor.). S.G.  $\frac{1}{2}$  9336;  $\frac{3}{8}$  9261 (Perkin);  $\frac{3}{8}$  931 (E. a. H.). M.M. 5-635 at 16°. S. 4-24 at 20°.

**Vapour tension:** Richardson, *C. J.* 49, 767.

**Heat of neutralisation:** Gal a. Werner, *B.* [2] 46, 801.

Occurs in the fat of *Daphninum Phocæna* (Chevreul [1817], *Corps gras*, pp. 99, 209), in valerian root (Grote *B.* J. 11, 225; Trommsdorff a. Etting, *A.* 4, 229; 6, 176), in the root of *Angelica Archangelica* (Meyer a. Zenner, *A.* 55, 828), in the root of *Athamanta Oroselinum*, in the bark of the alder tree, in the berries and bark of the Guelder rose (*Viburnum Opulus*) (Moro, *A.* 55, 330), in the root of *Viburnum prunifolium* (Allen, *Ph.* [3] 11, 418), and in oil of geranium (O. Jacobsen, *A.* 157, 232). A valeric acid occurs in rosin oil (Lwoff, *B.* 20, 1017) and in yolk of wool (suint) (Buisine, *B.* [2] 48, 639).

**Formation.**—1. By oxidation of inactive fermentation amyl alcohol (Dumas a. Stas, *A.* 38, 156; 35, 143; Erlenmeyer a. Hef, *A.* 160, 257; Pedler, *C.* J. 21, 74).—2. By boiling its nitrile with alcoholic potash (E. a. H.; Schmidt a. Sachtleben, *A.* 193, 87).—3. Together with the active acid by oxidation of leucine (amido-hexolic acid) (E. a. H., cf. Neubauer, *A.* 106, 50).—4. By heating isopropyl-malonic acid at 180° (*B.* 11, 596).—5. By oxidising di-methyl-allyl-carbinol, treating the resulting CMe<sub>2</sub>(OH).CH<sub>2</sub>CO<sub>2</sub>H with HI, and reducing the  $\beta$ -iodo-valeric acid so formed by means of 3 p.c. sodium-amalgam applied in an acid solution (Schirokoff, *J. pr.* [2] 23, 286).—6. By the action of KOH or HClAq on *Athamantin* (Schnedermann a. Winckler, *A.* 51, 324).—7. By putrefactive fermentation of proteids (Iljenko, *A.* 63, 269).—8. By the action of CrO<sub>3</sub> on gelatin and albumen (Schlieper, *A.* 59, 7; Guckelberger, *A.* 64, 71).—9. From isopropyl-aceto-acetic ether (Frankland a. Duppa, *A.* 145, 84).—10. By distilling isopropyl-malonic acid (Conrad a. Bischoff, *A.* 204, 151).—11. A product of distillation of colophony (Renard, *A. Ch.* [6] 1, 253).

**Preparation.**—1. Isoamyl alcohol is oxidised by less than the calculated quantity of KMnO<sub>4</sub> in the cold. Some acetic acid is formed, but this can be got rid of by distilling a dilute solution of the acids, for valeric acid passes over in the first quarter of the distillate, the acetic acid remaining behind (Duclaux, *C. R.* 105, 171).—2. By oxidising isoamyl alcohol (1,000 c.c.) with K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> (1,000 g.) dissolved in water (3,500 c.c.) by adding in the cold H<sub>2</sub>SO<sub>4</sub> (1,400 g.) mixed with water (800 g.). The resulting isoamyl isovalerate is saponified by potash (Pierre a. Puchot, *A. Ch.* [4] 29, 229).—3. By

distilling valerian root with dilute phosphoric acid, neutralising the distillate with  $\text{Na}_2\text{CO}_3$ , and decomposing the resulting  $\text{Na}^+$  salt by  $\text{H}_2\text{SO}_4$ . In purifying valeric acid use may be made of the fact that the acid forms crystalline acid salts with K and Na (Lescaudr, *Bk.* [2] 27, 104).

**Properties.**—Liquid, inactive to light. Its smell is powerful and unpleasant. Sol. water. Separated from aqueous solution by  $\text{CaCl}_2$ . Volatile with steam. Mixes with alcohol and ether. It is set free from its salts by mineral acids, by  $\text{HOAc}$ , by oxalic, tartaric, citric, and malic acids, but not by butyric acid. When conc. valeric acid is added to a solution of cupric acetate, anhydrous cupric valerate separates in oily drops, which soon change to a greenish-blue crystalline powder of the hydrated salt; butyric acid would at once give a crystalline pp. (Larocque & Huraut, *J. Ph.* [3] 9, 430).

**Reactions.**—1. Oxidised by chromic acid mixture at  $20^\circ$  to acetic acid and  $\text{CO}_2$ .—2. Boiling dilute  $\text{HNO}_3$  forms nitro-valeric acid, methyl-malic acid, and a little di-nitro-propane (when prepared from valerian) or di-nitro-butane (when prepared from isoamyl alcohol) (Bredt, *B.* 14, 1782; 15, 2319; cf. Dessaignes, *A.* 79, 874).—3. Dilute alkaline  $\text{KMnO}_4$  forms  $\text{CMe}_2(\text{OH})\text{CH}_2\text{CO}_2\text{H}$ .—4. Electrolysis of the K salt in 50% solution yields octane  $\text{C}_8\text{H}_{18}$  (Kolbe, *A.* 69, 259).—5. Passed through a red-hot tube it yields ethylene, propylene, butylene, and other hydrocarbons (Hofmann, *C. J.* 3, 121).—6. The Ca salt yields di-isobutyl ketone on distillation by itself, valeric aldehyde on distillation with calcium formate, and methyl isobutyl ketone on distillation with calcium acetate.

**Salts.**— $\text{NH}_4\text{A}$ . V. sol. water and alcohol.  $(\text{NH}_4)_2\text{H}_2\text{A}$ .— $\text{KA}$ . Deliquescent crystalline mass. S. (alcohol) 26 at  $20^\circ$ . [140].— $\text{LiA}$ . 3 aq. Nodules.— $\text{TlA}$ . V. sol. water.— $\text{CaA}$ . 8 aq. needles (Barone, *A.* 165, 120; Schmidt & Sachtleben, *A.* 193, 87; Schirokoff, *J. pr.* [2] 23, 286). S. 18.4 at  $0^\circ$  (Sedlitzky, *M.* 8, 563).— $\text{CaA}$ . 4 aq.— $\text{CaA}$ . 5 aq.— $\text{BaA}$ . Triclinic plates. S. 94 at  $18^\circ$ . S. (alcohol) 3.3 at  $20^\circ$ .— $\text{BaA}$ . 2 aq.— $\text{BaA}$ . 2 aq.— $\text{SrA}$ .— $\text{MnA}$ . 2 aq.— $\text{ZnA}$ . 2 aq. Crystalline.— $\text{ZnA}$ . S. 1 in the cold. S. (80 p.c. alcohol) 1.7 in the cold; S. (ether) .2 in the cold; .5 at  $35^\circ$  (Witstein, *J.* 1847, 557).— $\text{ZnA}$ . 12 aq.— $\text{ZnA}$ . 3 aq.— $\text{ZnA}$ . 2  $\text{NH}_3$  (Iutschak, *B.* 5, 30).— $\text{CuA}$ . Green crystalline pp.— $\text{CuA}$ . aq.— $\text{BiA}$ .  $(\text{OH})_2\text{O}_2$  (Schuchtt, *Ar. Ph.* [3] 2, 97).— $\text{FeA}$ .— $\text{FeA}$ .  $(\text{OH})_2$ .— $\text{FeA}$ .  $(\text{OH})_2$ .— $\text{PbA}$ . easily fusible laminae.— $\text{PbA}$ .  $\text{O}_2$ . Groups of needles, sl. sol. water.— $\text{AgA}$ . S. .177 at  $0^\circ$  (Sedlitzky); .185 at  $20^\circ$  (Erlenmeyer).

**Methyl ether**  $\text{MeA}$ . (116°). S.G. 2. 9007. C.E. ( $0^\circ$ – $10^\circ$ ) .001174. S.V. 149.6 (Elsässer, *A.* 218, 815); 148.3 (R. Schiff, *A.* 220, 884). S.H. ( $21^\circ$ – $45^\circ$ ) .491 (Kopp). Smells like bananas.

**Ethyl ether**  $\text{EtA}$ . (134°). (E.). [135° cor.] (Perkin). S.G. 2. 8851 (E.); 8714; 8332 (P.). C.E. ( $0^\circ$ – $10^\circ$ ) .001034. S.V. 173.4 (E.); 173.0 (S.). M.M. 7.615 at  $18^\circ$ . Oil, sol. alcohol. Smells like rennet apples and water-mint (Pierre & Puchot, *A. Ch.* [4] 20, 284). Converted by sodium into oxy-decanoic acid, ethyl ethoxy-decanoate (Hantzsch, *A.* 249,

84), an acid  $\text{C}_{10}\text{H}_{18}\text{O}_2$  [c.  $127^\circ$ ] ( $295^\circ$ ), and other bodies (Greiner, *Z.* [2] 2, 460; Wanklyn, *C. J.* 17, 871; Geuther & Greiner, *J.* 1865, 319).

**n-Propyl ether**  $\text{PrA}$ . (156°). S.G. 2. 8809. C.E. ( $0^\circ$ – $10^\circ$ ) .000997. S.V. 197.5 (Elsässer); 196.8 (Schiff).

**Isopropyl ether**  $\text{PrA}$ . (142°). S.G. 2. 870; 864 (Silva, *A.* 153, 136).

**Di-chloro-propyl ether**  $\text{C}_3\text{H}_5\text{Cl}_2\text{A}$ . ( $245^\circ$ ) at 737 mm. S.G. 2. 1.149. Formed from epichlorhydrin and isovaleryl chloride (Truchot, *A.* 188, 298).

**Isobutyl ether**  $\text{C}_4\text{H}_9\text{A}$ . (169°) (Elsässer, *A.* 218, 328); (173°) (P. a. P.). S.G. 2. 8736 (E.). 2. 8884 (P. a. P.). C.E. ( $0^\circ$ – $10^\circ$ ) .001027. S.V. 223.4 (E.).

**Isoamyl ether**  $\text{C}_5\text{H}_{11}\text{A}$ . (188°) (Kopp; R. Schiff, *A.* 234, 344); (196°) (Balard); (190°) (Balbiano, *J.* 1876, 348); (194°) (Kahlbaum). S.G. 2. 870 (Balbiano). S.V. 244.5. V.D. 6.1. Smells, when dissolved in alcohol (7 pts.), like apples.

**Octyl ether**  $\text{C}_8\text{H}_{17}\text{A}$ . (250°). S.G. 2. 862 (Zincke, *A.* 152, 6).

**Cetyl ether**  $\text{C}_{18}\text{H}_{37}\text{A}$ . [25°]. (280°–290°) at 202 mm. S.G. 2. 852 (Dollfus, *A.* 131, 283).

**Allyl ether**  $\text{C}_3\text{H}_5\text{A}$ . (154°). Oil (Cahours & Hofmann, *A.* 108, 296).

**Glyceride derivative v. GLYCERIN.**  
**Chloride**  $\text{Pr.CH}_2\text{COCl}$ . (114°) at 726 mm. S.G. 2. 9887.  $\mu_D$  1.4213. It 49.14.

Liquid, easily decomposed by water (Béchamp, *C. R.* 42, 224; Brühl, *A.* 203, 24).

**Bromide**  $\text{C}_3\text{H}_5\text{OBr}$ . (143°). Liquid.  
**Iodide**  $\text{C}_3\text{H}_5\text{OI}$ . (168°) (Cahours, *C. R.* 44, 1252).

**Anhydride**  $(\text{C}_5\text{H}_9\text{O})_2\text{O}$ . Mol. w. 186. (215°) (Chiozza, *A.* 84, 106). Converted by hydrated  $\text{BaO}$  into the oily peroxide  $(\text{C}_5\text{H}_9\text{O})_2\text{O}_2$  (Brodie, *Pr.* 12, 655).

**Aceto-valeric anhydride**  $(\text{C}_5\text{H}_9\text{O})\text{OAc}$ . (147°–160°) (Autenrieth, *B.* 20, 8187).

**Amide**  $\text{C}_5\text{H}_9\text{CONH}_2$ . [128°] (Letts, *B.* 5, 669; Hofmann, *B.* 15, 982); [135°] (Schmidt & Sachtleben, *A.* 193, 102). (231°). Silky plates, v. sol. water and alcohol.

**Anilide**  $\text{C}_5\text{H}_9\text{CONHPh}$ . [115°] (Chiozza, *A. Gb.* [3] 39, 201; Kelbe, *B.* 16, 1200; cf. Dumas, *C. R.* 25, 475, 658; Dessaignes, *A.* 68, 333). Sl. sol. hot water, v. sol. alcohol and ether.

**Nitrile**  $\text{Pr.CH}_2\text{CN}$ . **Isobutyl cyanide**. Mol. w. 83. (129°) (R. Schiff, *B.* 12, 587). S.G. 2. 823. V.D. 2.89. Formed by heating ammonium valerate or valeramide with  $\text{P}_2\text{O}_5$  (Dumas, Malgutti & Leblanc, *C. R.* 25, 558). Occurs among the products of oxidation of gelatin and casein by chromic acid mixture (Schlieper, *A.* 59, 15; Guckelberger, *A.* 64, 72), of the action of chlorine on leucine (Schwanert, *A.* 102, 228), and of the action of conc.  $\text{HNO}_3$  on castor oil (Hell & Kitrosky, *B.* 24, 980). Formed also, together with valeramide, by heating valeric acid with potassium sulphocyanide (Letts, *B.* 5, 669). It is also got by the action of cold  $\text{Ac}_2\text{O}$  on the oxim of valeric aldehyde (Dollfus, *B.* 26, 1915). Prepared by digesting isobutyl iodide with  $\text{KC}_y$  and alcohol, (Erlenmeyer & Hall, *A.* 160, 266). Liquid, smelling like almonds, dissolving in about four times its volume of water

Sodium converts it, on heating, into cyanbutine  $C_4H_7N$ , crystallising in stellate groups of needles, which yield  $BHCl$  and  $B_2H_4PtCl_6$ , and is converted by nitrous acid into  $C_4H_7(OH)N$ , [39°] (E. von Meyer, *J. pr.* [2] 37, 407).

Active valeric acid  $CHMeEt.CO_2H$ . Methyl-ethyl-acetic acid. Hydrotiglic acid. (177° i.v.). S.G.  $\frac{1}{173}$  .938 (Saur). S.V. 129.1 (Lossen, A. 254, 60). Occurs in the essential oil from the fruit of *Angelica Archangelica* (R. Müller, *B.* 14, 2476).

**Formation.**—1. By oxidation of isoamyl alcohol.—2. By reducing tiglic acid with HI and P (Schmidt a. Berendes, A. 191, 117).—3. By heating methyl-ethyl-malonic acid (Bischoff a. Conrad, A. 204, 151).—4. From methyl-ethyl-acetoacetic ether (Saur, A. 188, 257).—5. By reducing angelic acid (Schmidt, A. 208, 261).—6. By reducing bromo-hydro-tiglic acid (Pagensteher, A. 195, 121).—7. By the action of NaOEt and EtI on propionyl-propionic acid (Israel, A. 231, 219).—8. By oxidation of the corresponding aldehyde (Lieben a. Zeisel, *M.* 7, 56).

**Properties.**—The acid obtained by synthetic methods is inactive, but when obtained by oxidation of active amyl alcohol it is dextro-rotatory, but is mixed with inactive isovaleric acid. By oxidation of an amyl alcohol  $[a]_D = -4.4^\circ$  Guye and Chavanne (*C. R.* 116, 1454) obtained a valeric acid (174°),  $[a]_D = +13.6^\circ$ , S.G.  $\frac{2}{22}$  .938. By oxidation of an amyl alcohol  $[a]_D = -5.2^\circ$  at 22° Rogers (*C. J.* 63, 1130) got a valeric acid (175°), S.G.  $\frac{2}{22}$  .936,  $[a]_D = +13.9^\circ$  at 22°. Methyl-ethyl-acetic acid can be separated from isopropyl-acetic acid through the greater solubility of its silver salt. Dilute  $KMnO_4$  oxidises methyl-ethyl-acetic acid to  $CMeEt(OH).CO_2H$ .

**Salts.**— $CaA_2$ , 5aq; needles. S. (of  $CaA_2$ ) 1. — $BaA_2$ ; gummy mass. — $ZnA_2$ . Needles, ore sol. cold than hot water. — $CuA_2$ ; bluish-green, crystalline pp. — $AgA_2$ ; groups of needles. 1:13 at 20° (O. a. B.); 1:11 at 1° (Sedlitzky, *M.* 8, 668).

Ethyl ether EtA'. (133.5° i.v.). S.G.  $\frac{1}{5}$  .8695.

Nitrile  $C_4H_7N$ . (125°). S.G. 2 .8061. Formed by adding Na and EtI to a solution of acetonitrile in benzene (Hanriot a. Bouveault, *M.* [2] 51, 173). Liquid.

Valeric acid  $CM_2.CO_2H$ . Tri-methyl-acetic acid. [35°]. (163.5° i.v.). S.G.  $\frac{2}{22}$  .905.  $\beta$ . 2:2; 20°. Heat of neutralisation: Gal a. Werner, *M.* [2] 46, 801. Formed by heating its nitrile with alcoholic potash or conc.  $H_2SO_4$  at 90° (Butleroff, A. 165, 322; 170, 151; 173, 355; 1, 5, 478). Formed also by action of  $CrO_3$  on inosolin (Friedel a. Silva, B. 6, 146, 820) and on tri-methyl-pyruvic acid (Glücksman, *M.* 20, 77). Monometric crystals. Does not yield a homo-derivative on heating with Br, either alone or in presence of P (Reformatzky, B. 23, 596).

**Salts.**— $NaA$ , 2aq. Prisms, v. sol. water. — $HA$ . Needles, m. sol. water. — $CaA$ , 5aq. — $BaA$ , 4aq. S.  $\frac{1}{4}$  at 1°. — $SrA$ , 5aq. — $BaA$ , 5aq. — $34$  at 2° (Landau, *M.* 14, 707). — $MgA$ , 8aq. — $ZnA$ , 8aq. S. (of  $ZnA$ ) 1:7 at 20°. The cold saturated solution becomes filled on warming

with a solid salt, which dissolves up again on cooling. — $PbA$ . — $PbHA$ . needles. — $CuA$  aq; greenish pp. — $AgA$ . S. 1:1 at 1°; 1:27 at 27° (Stiasny, *M.* 13, 599).

Methylether MeA'. (101°) (Butleroff). Ethyl ether EtA'. (118.5° i.v.). S.G. 2 .875.

Tert-butylether  $C_4H_9A$ . (135° i.v.). Amyl ether  $CM_2.CH_2A$ . (165°) (Tissier, *Bl.* [2] 24, 558).

Chloride  $CM_2.COCl$ . (106°).

Anhydride  $(CM_2.CO)_2O$ . (190°).

Amide  $CM_2.CO.NH_2$ . [154°]. (212°).

Formed by heating the ammonium salt in sealed tubes at 230° (Fanchimont a. Klobbie, R. T. C. 6, 238). Long needles. Decomposed by pure  $HNO_3$  (S.G. 1.53; with evolution of  $N_2O$ ).

Methylamide  $CM_2.CO.NHMe$ . [91°]. (204°).

Dimethylamide  $CM_2.CO.NMe_2$ . (186°).

Ethylamide  $CM_2.CO.NHEt$ . [49°]. (204°).

Diethylamide  $CM_2.CO.NEt_2$ . (203°).

S.G. 13 .891.

Nitrile  $CM_2.CN$ . Tert-butyl cyanide. [16°]. (106°). Formed, together with a polymeride (160°), by the action of tert-butyl iodide on dry potassio-mercuric cyanide below 5° (Butleroff, A. 170, 151; Freund a. Lenze, B. 23, 2866; 24, 2161). Crystalline mass with pungent smell. On heating with aniline hydrochloride it yields phenyl-valeramide, which forms an oxalate [192°]. Hydroxylamine forms the amidoxim  $CM_2.C(NH_2).NOH$  [116°].

**References.**—AMIDRO, BROMO, CHLORO, IODO, NITRO, NITROSO, and OXY-VALERIC ACIDS.

#### n-VALERIC ALDEHYDE

$CH_3.CH_2.CH_2.CH_2.CHO$ . (103°) S.G. 11 .819. Formed by distilling calcium n-valerate with calcium formate (Lieben a. Rossi, A. 159, 70; Zander, A. 224, 81).

Isovaleric aldehyde  $(CH_3)_2CH.CH_2.CHO$ .

Valeral. Mol. w. 86. (92.5°). S.G.  $\frac{1}{15}$  .8041; 2° .7951 (Perkin, C. J. 45, 477).  $\mu$ . 1.8934.  $R_D^{20}$  40.66 (Brühl). V.D. 43.06 (calc. .43) (Schröder, B. 4, 400, 468). S.V. 118.5. Formed by oxidation of isoamyl alcohol (Dumas a. Stas, A. Ch. [2] 73, 145; Parkinson, A. 90, 114; Kolbe a. Guthrie, A. 109, 296). Formed also by distilling calcium iso-valerate with calcium formate (Lamprecht, A. 97, 370), by the distillation of isovalerates (Chancel, A. 60, 318; Ebersbach, A. 106, 262; Schmidt, B. 5, 600), by oxidation of gluten (Keller, A. 72, 84) and castor oil (Arzbücher, A. 73, 202), and by the action of  $SO_2$  on leucine (Schwanert, A. 102, 228).

**Properties.**—Neutral oil, with pungent fruity odour. Polymerises on keeping. Mixes with alcohol and ether. On heating with ammonium sulphocyanide it yields a dark-red liquid, sol. alcohol, ether, and HOAc (Broday, M. 8, 87). Alkaline sodium nitroprusside gives a violet-red colour, destroyed by HOAc (Von Ertlo, A. 267, 876). Combines with sodium bisulphite, forming  $(O_2H_2O)NaHSO_3$ .

**Reactions.**—1. Readily oxidised to valeric acid.—2. Chlorine forms mono- and di-chloro-valeric aldehydes, and, at 140°, oily  $C_5H_9Cl_2O$  (204°), which is converted by alcoholic soda into  $C_5H_9Cl_2O$  (209°).—3.  $PCl_5$  forms  $C_5H_9Cl_2O$ .—4. Potash-fusion gives valeric acid.—5. Heating with lime forms isoamyl alcohol, calcium

valerate and other bodies (Fittig, A. 117, 68).—6. Sodium-amalgam and water slowly form isoamyl alcohol (Wurtz, Z. 134, 201).—7. Sodium forms isoamyl alcohol, sodium valerate, decyl alcohol  $C_{10}H_{20}O$  (203°), an oil ( $C_8H_{16}O$ )<sub>2</sub> (260°–290°), the compound  $C_{10}H_{18}O_2$ , and the acid  $C_{10}H_{18}O_2$  (Borodin, Z. 1864, 353; E. 5, 480).—8. KOH at 0° produces an oily polymeride, lighter than water, not capable of combining with  $NaHSO_4$ , and yielding isovaleric aldehyde and the compounds  $C_{10}H_{18}O$  and  $C_{10}H_{18}O_2$  on distillation (Borodin, B. 6, 982). This polymeride, left in contact with  $Na_2CO_3$  aq., often forms needles of  $C_{10}H_{18}O_2$  [70°].—9. Heating with KOH forms the aldehyde  $C_{10}H_{18}O$  and a compound  $C_{10}H_{18}O_2$  (260°–290°). S.G. .90.—10. Heating with zinc at 180° forms decenoic aldehyde  $C_{10}H_{18}O$  (190°), S.G. .2 .862 (Riban, C. R. 75, 96; Kekulé, A. 162, 77) and other products.—11. ZnEt<sub>2</sub> produces the oil ( $C_{10}H_{18}O$ )<sub>2</sub> in large quantity (Beilstein a. Rieth, A. 126, 242). ZnMe<sub>2</sub> followed by water, forms mekyl-isobutylcarbinol (Kuvsinoff, J. R. 1887, 204).—12. Dry  $K_2CO_3$  at 50° forms an oily polymeride, which is reconverted at 180° into the aldehyde. Boiling with  $K_2CO_3$  yields  $C_{10}H_{18}O$  (v. supra),  $C_{10}H_{18}O_2$  (265°–270°), and  $C_{10}H_{18}O_3$  (235°–240°) (Gäss a. Hell, B. 8, 369).—13. Dry  $K_2CO_3$  added to moist isovaleric aldehyde forms, after some days, crystals of a polymeride [84°], which is reconverted at 108° into the original aldehyde (Bruylants, B. 8, 414).—14.  $PH_3I$  forms a compound ( $C_8H_{16}O$ )<sub>2</sub> $PH_3I$ , crystallising from ether in plates [119°], converted by cold potash into ( $C_8H_{16}O$ )<sub>2</sub> $PH_3OH$ , crystallising in prisms [125°], insol. water (De Girard, A. Ch. [6] 2, 33; C. R. 94, 215).—15. On heating with hypophosphorous acid in an atmosphere of hydrogen the compound ( $C_8H_{16}O$ )<sub>2</sub> $H_3PO_3$  [160°] is formed. It yields  $BaA_2$  aq (Ville, C. R. 109, 71).—16.  $AcCl$  at 100° combines, forming chloro-amyl acetate  $C_8H_{17}CHClOAc$  (Maxwell Simpson, Pr. 27, 120).—17. *m*-Amido-benzoic acid forms  $C_{10}H_{17}NO_2$  [c. 430°].—18. Dry  $HCl$  forms ( $C_8H_{17}CHCl$ )<sub>2</sub> $O$  (180°) (Bruylants, B. 8, 414).—19. Conc.  $NH_3$  aq forms isovaleric aldehyde-ammonia  $C_8H_{17}CH(NH_2)OH$  7aq [58°] (Erdmann, A. 130, 211; Petersen, A. 132, 158; Ljubavin, B. 6, 1460), which yields, on allowing its alcoholic solution to stand, or on boiling with potash, the oily 'trioxymylamine'  $C_8H_{17}NO_3$ , forming  $BHCl$  [113°] and  $B'H_2PtCl_6$ .  $AgNO_3$  reacts with isovaleric aldehyde-ammonia, forming ( $C_8H_{17}N$ )<sub>2</sub> $AgNO_3$  and ( $C_8H_{17}N$ )<sub>2</sub> $AgNO_3$  (Goldschmidt, B. 11, 1200; Mixter, J. 1878, 438).—20. Alcoholic  $NH_3$  at 150° forms valeritrine, hydrovaleritrine, and other bodies. Valeritrine  $C_{10}H_{18}N$  is a very unstable liquid (250°–260°), yielding  $B'HgCl_2$  [88°],  $B'H_2PtCl_6$ , and  $B'C_8H_{17}NO_3$  [130°]. Hydrovaleritrine  $C_{10}H_{18}N$  or  $C_{10}H_{17}N$  is a liquid, yielding crystalline  $B'HCl$ , S. 2-87 at 22°, not melted at 180° (Ljubavin, B. 8, 565).—21.  $H_2S$  passed into an aqueous solution forms thiovaleric aldehyde  $C_8H_{17}S$  (89°). An isomeride (115°) is got, together with a polymeride [94-5°], by heating isovaleric aldehyde with sulphur at 250° (Barbaglia, B. 13, 1674; 17, 2654; G. 11, 95; 16, 426).—22.  $CS_2$  and  $NH_3$  aq form carbovaleraldine  $C_{10}H_{18}N_2S_2$  (Schröder, B. 4, 469; Mulder, A. 168, 237), which melts at 109°

(Guareschi, A. 222, 811).—23.  $NH_3CS.OEt$  and  $HCl$  form  $C_8H_{17}(NH_3CS.OEt)$  [108°] (Bischoff, B. 7, 1078).—24.  $H_2Se$  passed into an aqueous solution of valeric aldehyde forms  $C_8H_{17}Se$  [56-5°].—25. Acetone and dilute  $NaOH$  yield  $Pr.CH_2CH.CO.CH_3$  (180°) (Barbier a. Bouveault, C. R. 118, 198).

Oxim  $C_8H_{17}CH:NOH$ . Mol. w. 101. (163°). S.G. .92 .8934 (in vacuo);  $\mu_n$  1.487 (Petraczek, B. 16, 829; Trapezonzanz, B. 26, 1428). It is a *syn*-oxim, because it yields valeritritrile when mixed with  $Ac_2O$  and ether (Dollfus, B. 25, 1915).

Isovaleric orthoaldehyde. Amylidene glycol. Acetyl derivative  $C_8H_{17}CH(OAc)_2$  (195°). Formed by heating isovaleric aldehyde with  $Ac_2O$  at 200°.

Benzoyl derivative  $C_8H_{17}CH(OBz)_2$  [111°]. (264°). Formed by heating the aldehyde with  $Bz_2O$  at 260° (Guthrie a. Kolbe, A. 109, 298).

Di-methyl ether  $C_8H_{17}CH(OMe)_2$  (124°). S.G. .12 .852. Formed from isovaleric aldehyde (2 vols.),  $MeOH$  (5 vols.), and  $HOAc$  (1 vol.) (Alsborg, J. 1864, 486).

Di-ethyl ether  $C_8H_{17}CH(OEt)_2$  (168°). S.G. .12 .835. Formed in like manner.

Di-isomyl ether  $C_8H_{17}CH(OC_4H_9)_2$  (c. 248°). S.G. .1 .849.

Ethyl isomyl ether  $C_8H_{17}CH(OEt)(OC_4H_9)$  (c. 205°). S.G. .12 .875. Formed by the action of  $Na$  on an ethereal solution of isovaleric ether (Greiner, Z. 1866, 465).

Valeric aldehyde  $CHMeEt.CHO$ . (91°). Formed by reducing tiglic aldehyde with iron and  $HOAc$  (Herzig, M. 8, 123; Lieben a. Zeisel, M. 7, 56), and by warming  $CH_2CH.CHEt.OH$  with dilute (1 p.c.)  $H_2SO_4$  (Kondakoff, J. R. 20, 154).

Valeric aldehyde  $CMe_2.CHO$ . [8°]. (75°). S.G. .12 .7927 (Tissier, Bl. [2] 24, 558).

Di-isovaleric aldehyde v. DECENOIC ALDEHYDE.

Reference.—DI-BROMO-, CHLORO-, IODO-, and OXY-VALERIC ALDEHYDE.

VALEROGUANAMINE  $C_8H_{17}N$ , i.e.

$PrCH_2CH.N.C(NH) > NH$ . Butylguanamine.

[173°]. Formed by heating guanidine isovalerate (Bandrowski, B. 9, 240; Haaf, J. pr. [2] 43, 76). Flat plates (from water). Weak base.— $BHCl$ : needles, v. sol. water.— $B'H_2SO_4$ .— $B'AgNO_3$ .

VALEROLACTIDE v. OXY-VALERIC ACID.

VALEROLACTONE v. OXY-VALERIC ACID.

VALERONE v. DI-ISOBUTYL KETONE.

VALERONITRILE v. Nitrile of VALERIC ACID.

VALEROVALERIC ACID v. VALERYL-VALERIC ACID.

DIVALERYL  $C_{10}H_{18}O_2$ , i.e.  $C_8H_{17}CO.CO.C_8H_{17}$  (270°–280°). Formed by the action of  $N_2$  on valeryl chloride (Brühl, B. 12, 815). Oil.

VALERYL-ACETOPHENONE v. PHENYL-BUTYL METHYLENE KETONE.

VALERYL CHLORIDE v. Chloride of VALERIC ACID.

VALERYL-CYANAMIDE v. CYANIC ACIDS.

VALERYLENE v. PENTYNE and also BROMO- and DI-CHLORO-VALERYLENE.

VALERYLENE TETRABROMIDE v. TETRABROMO-PENTANE.

**VALERYLENE HYDRATE** v. PENTENYL ALCOHOL.

**VALERYLENE HYDROCHLORIDE** g. CHLORO-AMYLENE.

**VALERYL-VALERIC ACID.** *Ethyl ether*  $C_{12}H_{20}O_4$ , *g.*  $CH_3Pr.CO.CHPr.CO_2Et$ . (206°) at 722 mm. Formed by the action of sodium on isovaleric ether (Greiner, *Z.* 1866, 461; Wohlbruck, *B.* 20, 2335). Oil, sol. alcohol and ether.

**VALYLENE**  $C_8H_8$ . Mol. w. 66. (50°). A product of the action of alcoholic potash on valerylène dibromide (Reboul, *A.* 135, 372). Liquid, with odour of garlic and prussic acid. Ammoniacal  $CuCl_2$  ppt. yellow  $C_8H_8Cu$ , which yields the pure hydrocarbon on treatment with dilute  $HClAq$ . Bromine at 0° forms crystalline  $C_8H_8Br_2$ . Ammoniacal  $AgNO_3$  yields a white pp. of  $C_8H_8Ag$ .

**VANADATES** v. VANADIUM OXYACIDS, AND SALTS AND DERIVATIVES THEREOF, p. 851.

**VANADIC ACIDS** v. VANADIUM OXYACIDS, p. 851.

**VANADIUM.**  $\bar{V}$ . At. w. 51.2. Mol. w. not known. Melts at a very high temperature; probably higher than m.p. of Mo, which does not melt at 1700°–1800° (Moissan, *C. R.* 116, 1225). S.G. 5.5 at 15° (Roscoe, *T.* 1869, 679). For emission-spectrum, obtained by using electric sparks, v. Thalén (*A. Ch.* [4] 18, 243).

*Historical.*—In 1801 Del Rio announced the discovery of a new metal in a lead ore from Zimapan in Mexico (*C. A.* 71, 7); to this metal he gave the name *erythronium*, but at a later time he thought the metal was only impure chromium. In 1830 Sefström found a new element in the bar-iron and refinery slags where iron-ore from Taberg in Sweden was smelted (*P.* 21, 43); this element he called *vanadium* (from a Scandinavian deity *Vanadis*). In the same year (*P.* 21, 49) Wöhler found that the lead ore examined in 1801 by Del Rio contained lead vanadate; and he showed that the metal which Del Rio had called erythronium, and had then supposed to be impure chromium, was really vanadium. In 1831 Berzelius supposed he had prepared vanadium by heating an oxychloride of  $NH_4$ , and also by heating the highest oxide with  $K$  (*P.* 22, 1); but in 1867 Roscoe (*T.* 1869, 1; 1869, 679; v. also 1870, 317) showed that one of the substances which until then had been taken to be the element V was a nitride, and that another substance, taken to be V, was an oxide of this element. Roscoe obtained pure V by heating  $VCl_3$  to redness for many hours in dry H. Roscoe was led to doubt the accuracy of the statement of the properties and at. w. of V that had been accepted on the authority of Berzelius, because he found that several compounds of V and Pb were isomorphous, but that it was impossible to assign comparable formulae to these compounds if the at. w. given by Berzelius for V were accepted (*v. T.* 1868, 1 *et seq.*). Berzelius gave the value 68.5 to the at. w. of V; he assigned the formulae  $VO$ ,  $VO_2$ , and  $VO_3$  ( $O_2=8$ ) to the three oxides, and classed V with Cr, Mo, and W. Roscoe's researches showed that the at. w. of the metal is 51.2, that the oxides are best represented as  $V_2O_3$ ,  $V_2O_5$ , and  $V_2O_6$ , that the substance thought to be V, was

really chiefly  $V_2O_5$ , that the compound supposed by Berzelius to be  $VCl_3$  was  $VOCl_3$ , and that V must be classed with Pand As.

*Occurrences.*—Small quantities of compounds of V are found fairly widely distributed; the element does not occur uncombined. The chief minerals that contain V compounds are *mottramite* (Cu-Pb vanadate), *descloisite* (Pb-Zn vanadate), *dechenite* (Pb-Zn-Cu vanadate), *roscoelite* (Al vanadate with K silicate), *vanadinite* (vanadate of lead with lead chloride), and some other minerals, which generally contain vanadates of Cu, Pb, Zn, or Ca. Small quantities of compounds of V are found in all *pisolitic limonites* (Böttger, *C. C.* 1873, 514), in some *pitchblendes*, *clays*, and *basalts*, and in a few other rocks. Compounds of V have also been found, in small quantities, in the slag from copper extraction works (Karsten, *P.* 52, 629; Witz n. Osmond, *Bl.* [2] 38, 49); in many specimens of pig-iron (*v.* Riley, *C. J.* 17, 21; cf. Hodges, *C. N.* 26, 238; Walz, *Am. Ch.* 6, 453); in some meteorites (*v.* Apjohn, *C. J.* 27, 104); in caustic soda and sodium phosphate (Schöne a. Rahmelsberg, *B. B.* 1864, 681; Donath, *D. P. J.* 240, 318); and, according to Lookyer (*Pr.* 27, 279), probably in the sun.

*Preparation.*—1. From the refinery slag of the Taberg iron-ore. The finely-powdered slag is heated with  $KNO_3$  and  $Na_2CO_3$ , the fused substance is digested with boiling water, and solution of a salt of Ba or Pb is added to the filtered liquid; the ppd. Ba or Pb vanadate is decomposed by boiling with a slight excess of  $H_2SO_4$ , and the solution is filtered from  $BaSO_4$  or  $PbSO_4$ ; the filtrate is neutralised by  $NH_4Aq$  and concentrated, and pieces of  $NH_4Cl$  are placed in the liquid until some  $NH_4Cl$  remains undissolved; the  $NH_4VO_3$ , which is thus ppd. as a white crystalline powder is washed with conc.  $NH_4ClAq$ , and then with alcohol, and is then decomposed by heating strongly in an open vessel, whereby  $V_2O_5$  is produced (Berzelius, *P.* 22, 1). Wöhler (*A.* 78, 125) employed a very similar process for preparing  $V_2O_5$  from *limonite*.—2. From vanadinite. L'Hôte (*C. R.* 101, 1151) recommends to mix finely-powdered *vanadinite* (approximately  $3Pb_3V_2O_7 \cdot PbCl_2$ ) with four times its weight of lampblack and a little oil, to heat strongly in a closed vessel, and then to heat to 300° in a stream of dry Cl, whereby  $VOCl_3$  is formed, and distilled over into a cooled U-tube; other compounds of V are readily prepared from  $VOCl_3$ .—3. From the cobalt-ore of Mottram in Cheshire. This source of V compounds was discovered by Roscoe (*v. C. J.* [2] 6, 326). The Cheshire Keuper sandstone contains carbonates of Cu, carbonate of Pb and *galena*, *black cobalt-ochre*, iron oxides, and salts of As, Ag, Mn, and Ba. The compound of V was probably *vanadinite*. The sandstone was crushed, and the metallic compounds were dissolved by  $HClAq$ ; bleaching-powder and milk of lime were added till the reaction was alkaline; and it was from the pp. thus obtained that Roscoe prepared V and its compounds. The lime pp. contained chiefly As, Cu, Fe, Pb, V, and Ca in combination with  $SO_4$  and  $PO_4$ ; it was heated in a furnace with ground coal to remove As, then roasted with a quarter its weight of  $Na_2CO_3$ ,

and lixiviated with water; the solution was saturated with  $H_2S$  and filtered, and  $H_2S$  was boiled off; crude oxide of V was then pptd. by  $NH_4Aq$ ; the oxide was dried and heated with conc.  $HNO_3Aq$  to oxidise it to vanadic acid, which was then boiled with saturated  $(NH_4)_2CO_3Aq$ , and the somewhat soluble  $NH_4$  vanadate was crystallised from water, and then strongly heated in an open vessel; the  $V_2O_5$  thus obtained was suspended in water into which  $NH_3$  was passed; the solution of  $NH_4$  vanadate was filtered from silica, phosphates, &c., evaporated to dryness, and heated in an open vessel until  $V_2O_5$  remained.

The metal vanadium is prepared by reducing  $VCl_3$  in H (for preparation of  $VCl_3$ , *v. VANADIUM DICHLORIDE*, p. 844). The process is conducted in perfectly pure and dry H; every trace of moisture and air must be excluded. The pure and dry H is passed for 12 hours through a porcelain tube, connected (by specially arranged paraffin-joints) by a glass tube, to the H apparatus; the  $VCl_3$  is then placed in the porcelain tube (a special arrangement for doing this is described by Roscoe), and H is passed through the apparatus for 6 hours. The porcelain tube is then gradually heated to full redness, and the passage of H is continued so long as HCl is given off, after which the tube is allowed to cool for several hours in the stream of H. The process occupies from 40 to 80 hours according as from 1 to 4 g. of  $VCl_3$  are used. The V thus obtained contains traces of H and O. Reduction proceeds more quickly at a white heat, but the product is not so pure; it generally contains c. 95 to 96 p.c. V. (For details, and figures of the apparatus, *v. Roscoe*, *T.* 1869. 679; 1870. 317; or *C. J.* [2] 8, 344; 9, 23.)

Moissan (*C. R.* 116, 1225) obtained V containing from 17.5 to 25.7 p.c. C, by heating a mixture of C and one of the oxides of V in an electric furnace, using a current of 70 volts and 1,000 amperes; with a current of 70 volts and 850 amperes reduction proceeded very slowly.

Vanadium, mixed with  $V_2O_5$ , was obtained by Roscoe (*l.c.*) by strongly heating a mixture of one of the chlorides of V with Na in an atmosphere of H, and lixiviating with water; the admixed black, powdery  $V_2O_5$  can be removed from the heavier, grey, lustrous, metallic powder, by repeated washings with water, and a substance containing c. 91 p.c. V can be obtained.

The substance supposed by Berzelius (*P.* 22, 1) to be V, and obtained by heating  $V_2O_5$  with K, was shown by Roscoe to consist chiefly of  $V_2O_5$ . The black powder which Uhrlaub (*F.* 103, 134) prepared by heating V oxychloride in  $NH_3$ , or which he supposed to be V, was found by Scharfrik (*W. A. B.* 38, 5) to be  $VN_3$  (*cf. Roscoe, l.c.*).

**Properties.**—A light-grey, lustrous powder; under the microscope it is seen to be composed of crystalline, silver-white particles. Does not become coherent and dense when strongly compressed. S.G. 5.5 at  $15^\circ$ . Not magnetic. Is not oxidised in air at the ordinary temperature, nor by moistening and then drying *in vacuo*. Has not been melted, except perhaps when reduced from the oxides by C in an electric furnace (*v. Moissan, C. R.* 116, 1225). When powdered V is thrown into a Bunsen flame it burns brilliantly; when strongly heated in O it forms

$V_2O_5$ ; and when slowly heated in air it perhaps forms  $V_2O_4$ , then  $V_2O_3$ ,  $V_2O_2$ , and finally  $V_2O$ . Burns in Cl, forming  $VCl_3$ ; combines with N to form VN; also combines with S. V is insoluble in  $HClAq$ ; it dissolves in hot conc.  $H_2SO_4$  and in  $HNO_3Aq$ . V dissolves in molten NaOH, giving off H, and forming  $\delta$  vanadate. V acts on glass vessels in which it is heated, forming a compound with Si; it also alloys with Pt (*B., l.c.*).

The at. w. of V has been determined (1) by reducing  $V_2O_5$  to  $V_2O_4$  by heating in H (Berzelius, *P.* 22, 15 [1831]; Roscoe, *T.* 1868. 8); (2) by oxidising  $V_2O_4$  to  $V_2O_5$  by  $HNO_3$  (*B., l.c.* [1831]); (3) by analysing  $(V_2O_5)(SO_4)_2 \cdot 4H_2O$  (*B., l.c.*, p. 18 [1831]); (4) by ppg.  $VOCl_3$  by  $AgNO_3Aq$ , removing excess of Ag from the filtrate, evaporating to dryness, heating, and weighing the  $V_2O_5$  produced (*B., l.c.* [1831]); (5) by determining the weight of Ag required to ppt. the Cl from  $VOCl_3$ ; also by weighing the  $AgCl$  ppt.; also by filtering from  $AgCl$ , evaporating, and weighing the  $V_2O_5$  obtained (Roscoe, *T.* 1868. 23); (6) by determining V.D.s of, and analysing,  $VCl_3$  and  $VOCl_3$  (*g. v.*). The results obtained by Berzelius (with the necessary corrections on account of the wrong formulae used by him; *v. Roscoe, l.c.*) gave values for at. w. of V varying from 49.3 to 52.5; Roscoe's values from the reduction of  $V_2O_5$  to  $V_2O_4$  varied from 51.13 to 51.55, and from the analyses of  $VOCl_3$  from 50.32 to 51.877. The S.I. of V has not been determined.

Vanadium is both metallic and non-metallic in its reactions.  $V_2O_5$  interacts with strong acids to form divanadyl salts,  $V_2O_5(SO_4)_2$ , &c.; hypovanadates  $V_2O_5(OM)_2$  are also derived from a hydrate of  $V_2O_5$ ;  $V_2O_5$  interacts with conc.  $H_2SO_4$  to form  $V_2O_5 \cdot 3SO_3$  and  $V_2O_5 \cdot 2SO_3 \cdot xH_2O$ ;  $V_2O_5$  also forms  $V_2O_5 \cdot H_2O$  (=HVO), and  $V_2O_5 \cdot 2H_2O$  (=H<sub>2</sub>V<sub>2</sub>O<sub>7</sub>), which react as acids, and salts of the acid  $H_2VO_4$  are also known;  $V_2O_5$  also combines with various acidic oxides ( $P_2O_5$ ,  $MoO_3$ , &c.) and basic oxides, to form complex, salt-like compounds. The sulphides of V dissolve in alkali sulphide solutions; several thiovanadates have been isolated, *e.g.*  $(NH_4)_2VS_4$ ; and also thio-oxyvanadates, *e.g.*  $Na_2VS_2O_6$ . The haloid compounds of V are generally decomposed by water to oxyhaloid compounds.

Vanadium is placed in Group V., with N, P, As, Nb, Sb, Bi, Er, Ta and Bi. V is the second member of the even series family of this group, the family consisting of N, V, Nb, Ta and an unknown element with an at. w. between those of Th (=232) and U (=239). Group V does not show a marked division into families; the gradation of properties from N to Bi is fairly regular, nevertheless the families (1) N and P, (2) V, Nb and Ta, (3) As, Sb and Bi are distinctly indicated. No hydrides of members of the vanadium family have been isolated with certainty. The highest oxides,  $M_2O_5$ , are salt-forming; all of them interact with alkalis to form salts containing the elements M in the acidic radicles;  $V_2O_5$  also forms basic salts  $(VO)_2R_2$ , with strong acids; normal salts have not been obtained by the reactions of  $M_2O_5$  with acids. Oxyacids of V, viz.  $H_2VO_4$  and  $H_4V_2O_7$ , have been isolated, but definite oxyacids of Nb and Ta are unknown. Both Nb and Ta form chlorides, corresponding with their highest

oxides  $M_2O_3$ ; but the highest haloid compound of V is  $VX_5$ , corresponding with  $V_2O_5$ ; oxyhaloid compounds of V of the form of  $VX_3$  exist ( $VOCl_3$ ,  $VOBr_3$ ) (v. NITROGEN GROUP OF ELEMENTS, vol. iii. p. 671).

In considering the relations between vanadium and the elements of Group V, the position of V in series 4 must be taken into account: as compared with the elements that form series 3, in which series P is placed, the elements of the vanadium series are metallic (V is preceded by Ti, Sc, Ca and K, and is followed by Cr, Mn, and the iron elements); the elements of the vanadium series are nearly as metallic, and also as non-metallic, as Rb, Sr, Y, Nb, Mo, —, and the Ru metals, which elements form series 6, i.e. the niobium series. Hence V would be expected to be distinctly more like a metal, in its chemical relations, than P, and about equal to Nb in its metallic and non-metallic tendencies. As V is the second member of the even series family of Group V., it might be expected to resemble N, which is the first of the even series elements of this group; but it is to be remembered that the differences between the first and second even series members of the groups (i.e. the differences between Li and K, Be and Ca, B and Sc, C and Ti, N and V, O and Cr, F and Mn), become more marked in passing from Group I. to Group VII., and it is also to be remembered that the resemblances between the first even series members and the succeeding odd series members, become more marked as the atomic weights increase; F is more like Cl and Br than O is like S, Se, and Te; but O resembles S, Se, and Te more than N resembles P, As, Sb, &c.; and C is more like Si, Ge, Sn, &c., than B is like Al, Ga, In, &c.; and C less resembles Si, &c., than N resembles P, &c.

**Reactions and Combinations.**—(Roscoe, *T.* 1869. 679; 1870. 317.) 1. Heated in air, V burns to  $V_2O_5$ ; lower oxides are first formed if the temperature is low.—2. Does not decompose water at  $100^\circ$ .—3. Heated to redness in chlorine burns to  $VCl_3$ ; heated in bromine produces  $VBr_3$ ; does not combine with iodine.—4. Heated with excess of sulphur, V forms  $V_2S_3$  (v. Kay, *C. J.* 87, 728).—5. Heating in a stream of pure nitrogen produces VN.—6. V combines directly with silicon and also with platinum.—7. Mollen potash or soda dissolves V, forming an alkali vanadate and giving off H.—8. V dissolves in conc. sulphuric acid (? forming a vanadyl salt); also in nitric acid, probably forming a basic nitrate; also, slowly, in hydrofluoric acid (? forming VF<sub>3</sub>).

**Detection and Estimation.**—Small quantities of compounds of V give a colorless borax or microcosmic salt bead in the outer flame, becoming green in the reducing flame; if much V compound is present the bead is yellow in the outer flame. Solutions of  $V_2O_5$  in acids are not pptd. by  $H_2S$ , but are reduced to solutions of  $V_2O_3$ , which are lavender-blue; if reduction is effected by Zn, Cd, or Na-amalgam the liquid becomes green, then blue, and finally lavender-blue; after reduction the solution bleaches indigo very rapidly, and soon absorbs O. Solutions of vanadates, either neutral or acidified by acetic acid, give finely-divided black pps. with tincture of galls, and the liquids appear like ink.

When an acidified solution of a vanadate is shaken with an ethereal solution of  $H_2O_2$ , the latter solution becomes dark red (Werther, *J. pr.* 88, 195).

Vanadium is generally estimated by converting it into an ammonium salt, strongly heating this in air, and either weighing the  $V_2O_5$  thus produced or heating in H and weighing the  $V_2O_3$  that remains. For a volumetric method of estimating V, v. Gerlach (*B.* 10, 1216).

**Vanadium, acids of, v. VANADIUM OXYACIDS, AND SALTS, AND DERIVATIVES THEREOF, p. 851.**

**Vanadium, bromides of.** Only one bromide of V has been obtained.

**VANADIUM TRIBROMIDE  $VBr_3$ .** Mol. w. not known; from analogy of  $PBr_3$ ,  $AsBr_3$ , &c., the formula  $VBr_3$  is probably molecular. Formed by heating V or VN to redness in vapour of Br. Also by passing Br vapour over a mixture of  $V_2O_5$  and C kept at a red heat;  $VOBr_3$  is formed, then  $VOBr_2$ , and then  $VBr_3$  sublimes (Roscoe, *T.* 1870. 317). Roscoe (*l.c.*) recommends to prepare  $VBr_3$  by placing pure VN in a porcelain boat in a tube of hard glass, driving out all air by dry  $CO_2$ , then passing vapour of Br through the tube while that part where the boat is placed is heated to redness, when brown vapours are given off and condense on the cooler parts of the tube, and finally driving out all traces of Br by a stream of dry  $CO_2$ .  $VBr_3$  is a greyish black, opaque, amorphous, very deliquescent solid; loses Br even in a sealed tube; heated gently in air gives  $V_2O_5$ , and at a higher temperature  $V_2O_3$ . Dissolves in water, without giving off any Br, forming a brown liquid which goes green on addition of a few drops of  $HClAq$ ; this reaction is said by R. to be characteristic of a salt of  $V_2O_5$ .

**Vanadium, chlorides of.** Three chlorides have been isolated:  $VCl_3$ ,  $VCl_2$ , and  $VCl$ . V burns when heated in  $Cl_2$  forming  $VCl_3$ , and the other chlorides are formed by reducing  $VCl_3$  by H. The V.D. of  $VCl_3$  has been determined, and the formula  $VCl_3$  is molecular; the formula  $VCl_2$  is probably molecular, from the analogy of  $AsCl_3$ ,  $PbCl_2$ ,  $BiCl_3$ , &c.;  $VCl_3$ ,  $AsCl_3$ ,  $PbCl_2$  and  $BiCl_3$  are the only haloid compounds of the form  $MX_3$  that have been isolated in Group V.; the mol. w.s. of these compounds have not been determined.

**VANADIUM TETRACHLORIDE  $VCl_4$ .** Mol. w. 192.68. Prepared by Roscoe (*T.* 1869. 691).

**Formation.**—1. V or VN is heated in  $Cl_2$ .—2. The vapour of  $VOCl_3$ , mixed with excess of  $Cl_2$ , is passed slowly over a long layer of sugar-charcoal heated to redness.

**Preparation.**—VN is heated to redness in a tube of hard glass, in a current of pure, dry  $Cl_2$ , which must be free from air. The first few drops of distillate are rejected, as they contain traces of  $VOCl_3$  formed from traces of oxide in the nitride used. The dark-red liquid that is formed is saturated with dry  $Cl_2$ , then heated for some hours in a current of dry  $CO_2$  in a vessel connected with an upright condenser, and then fractionated.

**Properties and Reactions.**—A thick, dark, brownish-red liquid; boils at  $154^\circ$  under 760 mm. pressure. S.G. 1.8584 at  $0^\circ$ , 1.8363 at  $8^\circ$ , 1.8159 at  $30^\circ$ . V.D. 98.1 at c.  $200^\circ$ . Does not solidify at any temperature above  $-18^\circ$ . Slowly decomposes to  $VCl_3$  and  $Cl_2$  at ordinary tempera-

tures, more quickly when exposed to light, and rapidly when heated. Gives off white fumes in the air. Dissolves in water, forming a blue solution, which does not bleach; this solution is oxidised by  $\text{KMnO}_4$  aq to  $\text{HClAq}$  and  $\text{V}_2\text{O}_5$  aq,  $2\text{VCl}_3$  taking up O. Reacts violently with alcohol and ether, forming deep-coloured liquids. When heated with Br in a sealed tube,  $\text{VCl}_3$  is formed.  $\text{VCl}_3$  does not combine with Cl to form a higher chloride.  $\text{H}_2\text{S}$  reacts with  $\text{VCl}_3$  to form  $\text{VCl}_2$ ,  $\text{HCl}$ , and S (Kay, *C. J.* 38, 736).

**VANADIUM TRICHLORIDE  $\text{VCl}_3$ .** Mol. w. not determined, but formula is probably molecular from analogy of  $\text{PCl}_3$ ,  $\text{AsCl}_3$ , &c. Prepared by heating  $\text{VCl}_3$  in a retort as long as Cl is given off, and heating the residual solid to  $160^\circ$  in a stream of dry  $\text{CO}_2$  (Roscoe, *T.* 1869, 691). Also by heating pure  $\text{V}_2\text{S}_5$  in a stream of dry, air-free Cl, separating  $\text{S}_2\text{Cl}_2$  by repeatedly distilling the liquid product, and heating the residue at  $140^\circ$  in dry  $\text{CO}_2$  to remove the last traces of  $\text{S}_2\text{Cl}_2$  (Halberstadt, *B. f.* 1619). Lustrous, peach-blossom coloured tablets, resembling  $\text{CrCl}_3$ ; S.G. 8.0 at  $18^\circ$ . Deliquesces very rapidly in air to a brown liquid, which goes green on addition of a drop or two of  $\text{HClAq}$ ; this solution is oxidised by  $\text{KMnO}_4$  aq,  $2\text{VCl}_3$  taking up 2O, to  $\text{HClAq}$  and  $\text{V}_2\text{O}_5$  aq. Soluble in alcohol and in ether. Heated in air forms  $\text{V}_2\text{O}_5$ . Heated in H is reduced to  $\text{VCl}_2$ , and then, gradually, to V.

**VANADIUM DICHLORIDE  $\text{VCl}_2$ .** Mol. w. not known. Formula possibly  $\text{VCl}_2$ . Prepared by passing vapour of  $\text{VCl}_3$ , mixed with a large excess of pure, dry H, through a glass tube heated to dull redness. The distillation of  $\text{VCl}_3$  should be slow, and the mixture of vapour of  $\text{VCl}_3$  and H should be brought at once into the heated part of the tube. Forms apple-green, micaceous, hexagonal plates; S.G. 8.23 at  $18^\circ$ ; very hygroscopic. Dissolves in water, forming a violet solution, which bleaches indigo and litmus, and reacts as a solution of a salt of  $\text{V}_2\text{O}_5$ . Dissolves in alcohol and in ether. The solution in water is oxidised by  $\text{KMnO}_4$  aq to  $\text{HClAq}$  and  $\text{V}_2\text{O}_5$  aq,  $2\text{VCl}_2$  taking up 3O. Heated in H, is slowly reduced to V; heating to whiteness in  $\text{NH}_3$  produces VN (Roscoe, *l.c.*).

**Vanadium, ferrocyanide of, v. vol. ii. p. 337.**

**Vanadium, fluorides of.** Only one fluoride,  $\text{VF}_3$ , has been isolated; there are indications of the existence of a higher fluoride in solutions in conc.  $\text{HFAq}$ .

**VANADIUM TRIFLUORIDE  $\text{VF}_3 \cdot 3\text{H}_2\text{O}$ .** Mol. w. not known; formula probably molecular, from analogy of trihalides of other elements of Group V. Prepared by evaporating a solution of  $\text{V}_2\text{O}_5$  in  $\text{HFAq}$  at  $100^\circ$ , and crystallising from water containing a little  $\text{HFAq}$ . A white crystalline crust, consisting of rhombohedra. Easily soluble in water; solution reacts acid. Insoluble in conc. alcohol. Effloresces in air; loses some water at  $106^\circ$ , and all at  $130^\circ$ , with absorption of O;  $\text{V}_2\text{O}_5$  is formed on heating to redness in air. An aqueous solution reduces Ag salts to Ag, Hg and Cu salts to mercurous and cuprous salts; all acids or alkali carbonates ppt.  $\text{V}_2\text{O}_5 \cdot x\text{H}_2\text{O}$  from  $\text{VF}_3$  aq (E. Petersen, *J. pr.* [3] 40, 44).

**Vanadoxyfluorides. (Fluovandates.)** A number of compounds of the forms  $\text{VF}_x \cdot x\text{MF}$  and  $\text{VF}_x \cdot x\text{M}^n\text{F}$ , were obtained by Petersen (*l.c.*) by adding various fluorides to solutions of  $\text{V}_2\text{O}_5$ .

in  $\text{HFAq}$ , and crystallising. These salts are generally greenish coloured, and crystalline; most of them are soluble in water, but not in  $\text{KFAq}$ ; they lose water of crystallisation from  $100^\circ$  to  $200^\circ$ . The vanadoxyfluorides may be regarded as salts of hypothetical acids  $\text{HVF}_x$ ,  $\text{H}_2\text{VF}_x$ , and  $\text{H}_3\text{VF}_x$ ; they may also be formulated as double salts (*q. supra*). The following salts are described by Petersen (*l.c.*):

**Ammonium vanadoxyfluorides**  $\text{NH}_4\text{VF}_x \cdot 2\text{aq}$ ,  $(\text{NH}_4)_2\text{VF}_x \cdot \text{aq}$ , and  $(\text{NH}_4)_3\text{VF}_x$ .

**Cadmium vanadoxyfluoride**  $\text{CdVF}_x \cdot 7\text{aq}$  (Piccini a. Giorgis, *G.* 22 [1] 55).

**Cobalt vanadoxyfluoride**  $\text{CoVF}_x \cdot 7\text{aq}$ .

**Nickel vanadoxyfluoride**  $\text{NiVF}_x \cdot 7\text{aq}$ .

**Potassium vanadoxyfluoride**  $\text{K}_2\text{VF}_x \cdot \text{aq}$ .

**Sodium vanadoxyfluoride**  $\text{Na}_2\text{VF}_x \cdot \text{aq}$ .

$= 2\text{VF}_x \cdot 5\text{NaF} \cdot \text{aq}$  (?  $\text{Na}_2\text{VF}_x \cdot \text{aq}$ ).

**Zinc vanadoxyfluoride**  $\text{ZnVF}_x \cdot 7\text{aq}$  (P. a. G., *l.c.*).

**Vanadoxyfluorides. (Fluovandates.)**

These salts are generally produced by dissolving  $\text{V}_2\text{O}_5$  in  $\text{HFAq}$ , adding metallic fluorides, and crystallising; also by dissolving  $\text{V}_2\text{O}_5$  in solutions of metallic fluorides, and crystallising; some of them are obtained by treating solutions of  $\text{V}_2\text{O}_5$  in metallic fluoride solutions with reducing agents, and then crystallising. The vanadoxyfluorides have been examined by Baker (*C. J.* 33, 388 [1878]), Ditté (*C. R.* 105, 1067; 106, 270 [1888]), Piccini a. Giorgis (*G.* 18, 186 [1889]; *G.* 22 [1] 55 [1892]), and Petersen (*B.* 21, 3257 [1888]; more fully in *J. pr.* [2] 40, 193, 271 [1890]). There are still considerable discrepancies between the results obtained by the different observers. For a criticism of Baker's results v. Petersen (*J. pr.* [2] 40, 289-92). The vanadoxyfluorides belong to two main classes: (1) those obtained by dissolving  $\text{V}_2\text{O}_5$  in  $\text{HFAq}$ , adding a fluoride (or carbonate), and crystallising; many of these salts are also formed by dissolving  $\text{V}_2\text{O}_5$  in solutions of fluorides, and crystallising; (2) those obtained by partially reducing solutions of  $\text{V}_2\text{O}_5$  in  $\text{HFAq}$ , then adding fluorides, and crystallising. The first class of salts may be divided into (i.) those wherein one atom of O in  $\text{V}_2\text{O}_5$  is substituted by 2F, and which, therefore, are represented as  $x\text{MF}_y \cdot y\text{VO}_2\text{F}$  ( $\text{V}_2\text{O}_5$  gives  $\text{V}_2\text{O}_4\text{F}_2 = 2\text{VO}_2\text{F}$ ); and (ii.) those wherein 3O in  $\text{V}_2\text{O}_5$  is substituted by 6F, and which, therefore, are represented as  $x\text{MF}_y \cdot y\text{VOF}_3$  ( $\text{V}_2\text{O}_5$  gives  $\text{V}_2\text{O}_3\text{F}_6 = 2\text{VOF}_3$ ). Salts of the second class are regarded as compounds of  $\text{MF}^+$  with  $\text{VOF}_2^-$ , and  $\text{VOF}_2^-$  is looked on as obtained by substituting 2O in  $\text{V}_2\text{O}_5$  by 4F ( $\text{V}_2\text{O}_5$  gives  $\text{V}_2\text{O}_3\text{F}_4 = 2\text{VOF}_2$ ). The salts derived from  $\text{V}_2\text{O}_5$ , i.e.  $x\text{MF}_y \cdot y\text{VO}_2\text{F}$  and  $x\text{MF}_y \cdot y\text{VOF}_3$ , are often called *fluovandates*, and those derived from  $\text{V}_2\text{O}_3$ , i.e.  $x\text{MF}_y \cdot y\text{VOF}_2$ , are often called *fluorhyponandates*; the former class of salts will here be called *vanadoxyfluorides*, and the latter *hyprvanadoxyfluorides*.

**Ammonium vanadoxyfluorides.** Three salts are described by Baker (*C. J.* 33, 388 [1878]), and also by Piccini a. Giorgis (*G.* 22 [1] 55, [1892]); the formulae given by the different experimenters do not agree.

**Lamellar ammonium vanadoxyfluoride.** This salt was obtained by Baker by dissolving  $\text{V}_2\text{O}_5$  in  $\text{NH}_4\text{HFAq}$ , and then adding more  $\text{NH}_4\text{HF}_2$ ; it separates in small yellow, pearly,

hexagonal plates. P. a. G. obtained the salt by dissolving  $V_2O_5$  in a slight excess of  $HFAq$ , adding  $NH_4F$  in the ratio  $3NH_4F:2V_2O_5$ , and evaporating. B. gives the formula  $6NH_4F.V_2O_5.2VOF_2.2aq$ ; P. a. G. give the formula  $3NH_4F.2VOF_2$ . If both formulae are expressed as  $3NH_4F.2VOF_2$ , then  $x = 1\frac{1}{2}$  in Baker's formula and  $-2$  in the formula of P. a. G. A salt obtained by Petersen (*J. pr.* [2] 40, 193, 271 [1890]), by a similar process to those used by B. and by P. a. G., was formulated by him as  $7NH_4F.4VOF_2.HF$ .

**Pyramidal ammonium vanadoxyfluoride.** Obtained by Baker by adding  $NH_4HF$  to a solution of the lamellar salt; P. a. G. prepared the salt by dissolving  $V_2O_5$  in excess of  $HFAq$ , and exactly neutralising the hot solution by  $NH_4Aq$ . This salt crystallises in yellow, simple pyramids (Baker). The formula assigned by B. is  $12NH_4F.V_2O_5.2VOF_2$ , while that given by P. a. G. is  $3NH_4F.VO_2F_2$ ; Petersen gives the same formula as P. a. G. If Baker's formula is expressed as  $3NH_4F.VO_2F_2$ ,  $x$  must be put  $= 1\frac{1}{2}$ , and  $y = 1\frac{1}{2}$ .

**Acicular ammonium vanadoxyfluoride.** Baker obtained this salt by dissolving the pyramidal salt in warm  $HFAq$  and allowing to cool; P. a. G. prepared it by a similar reaction. This salt crystallises in pale-yellow acicular prisms; when dry it has the odour of  $HF$ ; it acts on glass. The formula given by P. a. G. is  $3NH_4F.2VOF_2$ ; Baker assigned to this salt the formula  $3NH_4HF.2VOF_2$ , but his analyses were, admittedly, not very trustworthy.

Adopting the formulae given by P. a. G. for the three ammonium vanadoxyfluorides, these salts are represented as

- (1)  $3NH_4F.2VOF_2 = (NH_4)_3V_2O_5F_8$ ,
- (2)  $3NH_4F.VO_2F_2 = (NH_4)_3VO_2F_5$ ,
- (3)  $3NH_4F.2VOF_2 = (NH_4)_3V_2O_5F_8$ .

A few of the other vanadoxyfluorides seem to belong to one or other of these types; P. a. G. and also Petersen, describe a *potassium vanadoxyfluoride*  $8KF.2VOF_2 = K_3V_2O_5F_8$ , belonging to the same form as the lamellar ammonium salt. But most of the vanadoxyfluorides described belong to forms which are not represented by the ammonium salts. The following are the principal salts:—

**Ammonium salts.**  $9NH_4F.5VOF_2.3HF$ ;  $7NH_4F.4VOF_2.HF$  (Petersen).

**Potassium salts**  $2KF.VO_2F_2$ ;  $2KF.VOF_2$ ;  $8KF.2VOF_2.HF$ ;  $4KF.VF_3.VOF_2$  (P.).

**Sodium salt**  $3NaF.VOF_2.VO_2F_2.aq$  (P. a. G.).

**Zinc salts.**  $ZnF_2.VO_2F_2.7aq$  (P. a. G.);  $ZnF_2.ZnO.2VOF_2.14aq$  (B.).

In none of these compounds does the atomic ratio of V to O exceed 1:2. According to Ditte (*C. R.* 105, 1067; 106, 270 [1889]), many compounds of alkali fluorides with  $V_2O_5$  are formed by heating the constituents together, digesting with water, and crystallising; the atomic ratio of V to O in these compounds, as given by Ditte, is 2:5. The formula assigned to the compounds may be generalised as  $xV_2O_5.yMF$ ;  $M = K$  or  $Na$ ,  $x = 1, 3$ , and 4, and  $y = 1, 2, 4$ , and 8. Ditte (*l.c.*) says that crystals of  $V_2O_5.4NH_4F.4aq$  are obtained by dissolving  $V_2O_5$  in hot conc.  $NH_4Aq$ , and that this compound is formed, along with  $V_2O_5.3NH_4F.4aq$ , when  $V_2O_5$  is dissolved in cold

conc.  $NH_4Aq$ ; but the experiments of Baker, Piccini a. Giorgis, and Petersen, all agree in assigning to the compounds formed in these reactions, formulae wherein the atomic ratio of V to O does not exceed 1:2.

**Hypovanadoxyfluorides. (Fluorohypovanadates.)** These compounds are formed by partially reducing mixtures of  $V_2O_5$  and fluorides, or carbonates, dissolved in  $HFAq$ . If sufficient F is assigned to the metal present to form the normal fluoride, then the atomic ratio of V to the remaining F in these compounds is 1:2, and that of V to O is 1:1; the formulae are written  $xMF.yVOF_2$ . All the salts described by Baker and Piccini a. Giorgis, except one, belong to the form  $2MF.VOF_2$  or  $M_2F.VOF_2$ ; these formulae may evidently be written  $M_2$  (or  $M'$ )  $VOF_2$ .

**Ammonium hypovanadoxyfluoride**  $2NH_4F.VOF_2.aq$  ( $=(NH_4)_2VOF_2.aq$ ) was prepared by Baker (*C. J.* 83, 395) by passing  $H_2S$  into a solution of  $V_2O_5$  in  $HFAq$ , concentrating, filtering, and adding  $NH_4F$ . The same salt was prepared by Piccini a. Giorgis (*G. Z.* [1] 55) by electrolytically reducing a solution of  $NH_4VO_3$  in  $HFAq$ , after adding  $NH_4F$ ; also by reducing  $NH_4VO_3$  in  $HFAq$  by  $SO_2Aq$ , neutralising by  $NH_4Aq$ , and adding  $NH_4F$ ; and in each case dissolving the crystals that were formed (said by P. a. G. to be  $3NH_4F.VOF_2$ ) in hot  $HFAq$ , and crystallising. Petersen (*J. pr.* [2] 40, 195) also obtained this salt. The salt crystallises in clear blue monoclinic forms;  $a:b = 0.653:1$  (Baker, *l.c.*).

Petersen (*J. pr.* [2] 40, 197) described two other ammonium hypovanadoxyfluorides,  $7NH_4F.4VOF_2.5aq$  and  $3NH_4F.VOF_2$ .

The other hypovanadoxyfluorides described by P. a. G. (*l.c.*) are  $2KF.VOF_2$  and  $MF_2.VOF_2.2aq$  where  $M = Cd, Co, Ni$  and  $Zn$ . The K salt was prepared by reducing  $V_2O_5$  in  $HFAq$  by  $SO_2Aq$  and adding  $KF$ ; the other salts by dissolving  $MO$ , or  $MCO_3$ , along with  $V_2O_5$  in  $HFAq$ , and reducing electrolytically. According to Petersen (*l.c.* pp. 199, 200), the salts  $7KF.8VOF_2$  and  $8NaF.3VOF_2.2aq$  also exist.

P. a. G. (*l.c.*) remark that the tendency to form highly fluorinated compounds increases in the family V, Nb, Ta as the atomic weight increases; thus,  $VOF_2$  is not affected by a little  $HFAq$ , while  $NbOF_2$  forms  $NbOF_3$ , and  $TaOF_2$  is converted into  $TaF_5$ . They also point out that the three compounds,  $ZnF_2.VO_2F_2.7aq$ ,  $ZnF_2.VOF_2.7aq$ , and  $ZnF_2.VF_3.7aq$ , all crystallise with the same number of molecules of water, all contain the same number of atoms, have the same crystalline form, and are geometrically isomorphous.

**VANADIUM PENTAFLUORIDE  $VF_5$ .** According to Petersen (*J. pr.* [2] 40, 271), this compound exists in a solution of  $V_2O_5$  in conc.  $HFAq$ . No compound was isolated, nor is any trustworthy evidence given of the existence of  $VF_5$  in solution.

**Vanadium, haloid compounds of.** When V is heated in excess of Cl the tetrachloride  $VOCl_4$  is produced; heating in Br produces the tribromide  $VBr_3$ . V does not combine with I. The haloid compounds of V belong to the forms  $VX_3$ ,  $VX_4$ , and  $VX_5$ ;  $X = Cl$  in each case,  $X = Br$  or  $F$  in the case of  $VX_3$ . The formula  $VX_3$  is molecular; the other formulae are probably molecular.  $VOCl_2$ ,  $BiCl_3$ ,  $AsI_3$ , and  $PI_3$  are the

only dihalides known of members of Group V. Attempts to prepare halides higher than  $VX_3$  have failed. Solutions in water of the haloid compounds of V behave like solutions of the corresponding oxides in haloid acids;  $VCl_3$  Aq like a solution of  $V_2O_5$  in  $HCl$  Aq,  $VX_3$  Aq like a solution of  $V_2O_5$  in  $HXA$  Aq, and  $VCl_3$  Aq like a solution of  $V_2O_5$  in  $HCl$  Aq.  $VOCl_3$  is decomposed by heat to  $VCl_3$  and  $Cl_2$ , and heating  $VOCl_3$  with H produces  $VCl_3$ .  $VF_3$  combines with metallic fluorides to form *vanadofluorides*, many of which belong to the form  $M^xVF_3$ , or  $M^xVF_5$ , (v. p. 844). Several oxychlorides and oxybromides of V have been isolated:  $VOX_2$  and  $VOX_3$ , where  $X = Cl$  or  $Br$ ; also  $VOCl$ ,  $V_2O_3Cl$ , and  $VO_2Cl$ ; the existence of other oxybromides also is probable. No oxyfluoride has been isolated with certainty. But many compounds exist which may be regarded as containing the oxyfluorides  $VO_2F$ ,  $VOF_3$ , and  $VOF_5$ , respectively; the compounds  $VO_2F \cdot xMF$  and  $VOF_3 \cdot xMF$  are obtained by dissolving  $V_2O_5$  and fluorides in  $HFA$  Aq and crystallising; they are described as *vanadoxyfluorides* (p. 844); the compounds  $VOF_3 \cdot xMF$  are obtained by partially reducing solutions of  $V_2O_5$  and fluorides in  $HFA$  Aq, they are described as *hypovanadoxyfluorides* (p. 845).

**Vanadium, iodides of.** No iodide of V has been isolated. No reaction occurs when vapour of I is passed over VN heated to redness, nor do I and  $V_2O_5$  react at any temperature (Roscoe, *C. J.* [2] 9, 28). I does not react with  $V_2O_5$  when digested therewith for a long time in presence of water or alcohol (Guyard, *Bt.* [2] 25, 351).

**Vanadium, nitrides of.** V and N combine directly. Two nitrides are known.

**VANADIUM MONONITRIDE VN.** Mol. wt. not known. Obtained by heating V in a stream of pure N; also by saturating  $VOCl_3$  with dry  $NH_3$ , and heating to full whiteness in a stream of  $NH_3$ . Better prepared by heating  $NH_4VO_3$  in the air, and then heating the residue to a full white heat in a stream of dry  $NH_3$  (Roscoe, *C. J.* [2] 8, 844). VN may also be prepared by heating  $V_2O_5$  to whiteness in  $NH_3$  (R., l.c.). VN is a greyish-brown, metal-like powder; heated in air it is oxidised to  $V_2O_5$ , and then to  $V_2O_6$ ; heated with soda-lime it gives off  $NH_3$ .

**VANADIUM DINITRIDE  $VN_2$ .** A black powder; exposed to air gives off  $NH_3$ , and is oxidised. Prepared by saturating  $VOCl_3$  with dry  $NH_3$ , heating the solid so obtained in a glass tube as long as  $NH_3$  sublimes, washing the residue with water containing a little  $NH_3$ , and drying *in vacuo* over  $H_2SO_4$  (Roscoe, *C. J.* [2] 6, 349); examined by Uhrlaub, who did not succeed in determining its composition (P. 103, 184; cf. Schafarik, *W. A. B.* 33, 5).

**Vanadium, oxides and hydrated oxides of.** By gently heating V in air the oxide  $V_2O_3$  is possibly formed, and, on continued heating, oxidation proceeds to  $V_2O_4$ ,  $V_2O_5$ ,  $V_2O_6$ , and finally  $V_2O_7$ . The oxides  $V_2O_4$ ,  $V_2O_5$ , and  $V_2O_6$  are also formed by reducing  $V_2O_5$  by heating with H or K. Several oxides intermediate between  $V_2O_4$  and  $V_2O_5$  seem also to exist. The oxides  $V_2O_4$ ,  $V_2O_5$ ,  $V_2O_6$ , and  $V_2O_7$  are feebly basic;  $V_2O_4$  and  $V_2O_5$  are also acidic. The oxides of V correspond in composition with the oxides of N; corresponding oxides of Bi

are known. The names generally given to the oxides of V do not, unfortunately, tally with the names given to the corresponding oxides of N; thus,  $V_2O_3$  is generally called hypovanadous oxide, while NO is called nitric oxide;  $V_2O_5$  is called vanadic oxide, while the name nitrogen peroxide is often quite wrongly applied to  $NO_2$ . The mol. w. of none of the oxides of V is known.

**? VANADIUM MONOXIDE (?  $V_2O$ ).** When the powdered metal is slowly heated in a current of air it glows brightly, with absorption of oxygen, forming in the first place a brown oxide ( $V_2O$  or  $V_2O_2$ ); and on further heating this oxide again glows, and passes through the black trioxide and blue tetroxide to pentoxide (Roscoe, *C. J.* [2] 8, 357). This statement seems to contain all that is known of an oxide lower than  $V_2O_3$ .

**VANADIUM DIOXIDE  $V_2O_4$ .** (*Hypovanadous oxide*.) This substance was supposed by Berzelius (P. 22, 1) to be V; Roscoe (T. 1868, 1) proved it to be an oxide with the atomic ratio  $V:O = 1:1$ . The mol. w. is not known; the formula is generally written  $V_2O_4$  rather than  $VO$ , as the double formula is, on the whole, more in keeping with the reactions of the compound.

**Formation.**—1. By heating one of the higher oxides with K (Berzelius, l.c.).—2. By passing vapour of  $VOCl_3$ , mixed with much dry H, over red-hot charcoal (Schafarik, A. 109, 85).—3. By strongly heating  $V_2O_5$  and  $V_2O_6$ , mixed in the ratio  $V_2O_5:V_2O_6$ , out of contact with air (Petersen, *J. pr.* [2] 40, 193).

**Preparation.**—A mixture of much dry H and vapour of  $VOCl_3$  (q. v. p. 854) is passed through a hard glass tube containing powdered charcoal and kept red hot. Some solid oxychlorides are deposited on the cooler parts of the tube, while the  $V_2O_4$  remains mixed with the C. The contents of the tube are then strongly heated in a current of dry H to remove traces of Cl compounds; and the grey metal-like  $V_2O_4$  is separated from the C (Roscoe, *C. J.* [2] 6, 354). When Zn, Cd, or Na-amalgam is added to a solution of  $V_2O_4$  in  $H_2SO_4$  Aq (prepared by dissolving the oxide in hot conc. acid and diluting with 50 pts. water), the liquid becomes blue, green, and finally lavender. The lavender solution absorbs O very rapidly; exposure to the air for a few seconds causes the colour to change to deep chocolate-brown. By determining the quantity of standardised  $KMnO_4$  Aq decolourised by the lavender solution, Roscoe (*C. J.* [2] 6, 354) proved that this solution contained  $V_2O_4$ , probably combined with  $SO_2$ . After passing air into the lavender solution until it becomes permanently blue, the solution contains  $V_2O_5$ ; if the free acid in the lavender solution is neutralised by zinc, and the liquid is then exposed to the air until permanently brown, and a little acid is then added, a green solution is formed which contains  $V_2O_6$  (R., l.c.).

**Properties and Reactions.**—A light-grey, lustrous powder; or a lustrous, metal-like, crystalline crust, S.G. 8.64; very brittle; fuses at a very high temperature. Heated to redness in air,  $V_2O_4$  burns to  $V_2O_5$ ; heated in O, burns to  $V_2O_6$ . Insoluble in water; dissolves in dilute acids, giving a lavender solution, which bleaches strongly; from these solutions  $KOH$  Aq or

# VANADIUM OXIDES

447

$\text{NH}_4\text{Aq}$  ppm. a brown hydrated oxide, which rapidly oxidises (Brierley, *C. J.* 49, 824). According to Petersen (*J. pr.* [2] 40, 194),  $\text{V}_2\text{O}_5$  dissolves in  $\text{HFAq}$ , and on evaporation, solution of the residue in water, and evaporation over  $\text{H}_2\text{SO}_4$ , blue, microscopic crystals are obtained, which are, perhaps,  $\text{VOF}_3 \cdot 2\text{aq}$ ; no analyses were made. Addition of alkali fluorides to  $\text{V}_2\text{O}_5$  in  $\text{HFAq}$  produces various compounds of the form  $x\text{VOF}_3 \cdot y\text{MF}$  (v. HYPOVANADIC FLUORIDES, p. 846).

**HYDRATE OF VANADIUM DIOXIDE.** By adding  $\text{NH}_4\text{Aq}$  to a lavender-coloured solution of  $\text{V}_2\text{O}_5$  in  $\text{H}_2\text{SO}_4\text{Aq}$ , Brierley (*C. J.* 49, 824) obtained a deep-purple gelatinous pp. which he said was hydrated  $\text{V}_2\text{O}_5$ ; the pp. rapidly oxidised in the air.

**VANADIUM TRIOXIDE  $\text{V}_2\text{O}_5$ .** (*Vanadous oxide Vanadium sesquioxide*.) Mol. w. not known. This compound was represented by Berzelius as  $\text{VO}$  ( $\text{V} = 68.5$ ,  $\text{O} = 8$ ).

**Formation.**—1. By heating  $\text{V}_2\text{O}_5$  to redness in  $\text{H}$  (Schafarik, *A.* 109, 85). The presence of traces of  $\text{P}_2\text{O}_5$  prevents reduction (Roscoe, *C. J.* [2] 6, 331).—2. By heating  $\text{V}_2\text{O}_5$  in a carbon crucible (Berzelius, *P.* 22, 1).

**Preparation.**—Pure  $\text{V}_2\text{O}_5$  is heated in perfectly pure and dry  $\text{H}$  until the substance ceases to lose weight; the tube is allowed to cool completely in  $\text{H}$ , and then a stream of dry air is passed through it (Roscoe, *C. J.* [2] 6, 331). When a solution of  $\text{V}_2\text{O}_5$  in conc.  $\text{H}_2\text{SO}_4$  is much diluted, and then treated with  $\text{Mg}$  until the liquid is green, this solution contains  $\text{V}_2\text{O}_5$ , combined with  $\text{SO}_2$  (v. VANADOUS SALTS, *infra*). A similar solution is obtained from the lavender solution of  $\text{V}_2\text{O}_5$  in  $\text{H}_2\text{SO}_4\text{Aq}$  (prepared from  $\text{V}_2\text{O}_5$  in  $\text{H}_2\text{SO}_4$ , v. *supra*) by neutralising free acid by zinc, exposing to the air, and adding a little acid (Roscoe, *C. J.* [2] 6, 337).

**Properties and Reactions.**— $\text{V}_2\text{O}_5$  is a black powder, resembling graphite; or, formed by reducing  $\text{VOCl}_3$  by  $\text{H}$ , it is a black, lustrous, crystalline crust. S.G. 4.72 at  $16^\circ$ . Does not fuse in the blowpipe flame. When warm  $\text{V}_2\text{O}_5$  is exposed to the air it glows and oxidises to  $\text{V}_2\text{O}_5$ ; and even at the ordinary temperature it takes up  $\text{O}$ , being changed after some months to  $\text{V}_2\text{O}_5$  (R., c.). Heated in  $\text{Cl}$  gives  $\text{V}_2\text{O}_5$  and  $\text{VOCl}_3$  (R., l.c.). Heated in  $\text{NO}_2$  to  $300^\circ\text{--}400^\circ$   $\text{V}_2\text{O}_5$  is oxidised to  $\text{V}_2\text{O}_5$  (Sabatier & Senderens, *C. R.* 115, 236). Heating to redness in  $\text{H}_2\text{S}$  produces  $\text{V}_2\text{S}_5$  (Kay, *J.* 87, 728).  $\text{V}_2\text{O}_5$  dissolves in hot conc.  $\text{LSO}_4$ , forming  $\text{V}_2\text{O}_5 \cdot x\text{SO}_3$  (v. VANADOUS SALTS, *infra*).  $\text{V}_2\text{O}_5$  dissolves in  $\text{HFAq}$ , and  $\text{VF}_3 \cdot \text{H}_2\text{O}$  has been isolated from this solution (v. VANADIC FLUORIDES, p. 844).

**HYDRATE OF VANADIUM TRIOXIDE.** By adding  $\text{COH}_4\text{Aq}$  or  $\text{NH}_4\text{Aq}$  to an aqueous solution of  $\text{V}_2\text{O}_5 \cdot 4\text{SO}_3 \cdot 9\text{H}_2\text{O}$  (v. *infra*) Brierley (*C. J.* 49, 824) obtained a dirty green, gelatinous pp., which oxidised rapidly in air. According to B., this pp. was hydrated  $\text{V}_2\text{O}_5$ .

**VANADOUS SALTS  $\text{V}_2\text{O}_5 \cdot x\text{X}$**  ( $\text{X} = \text{acidic oxide}$  or  $\text{V}_2\text{R}_n$  ( $\text{R} = \text{acidic radicle}$ )). Only one salt derived from an oxyacid has been certainly isolated; it has the composition  $\text{V}_2\text{O}_5 \cdot 4\text{SO}_3 \cdot x\text{H}_2\text{O}$ , the formula may be written  $\text{V}_2\text{H}_4(\text{SO}_3)_x \cdot y\text{H}_2\text{O}$ . Vanadous tetrasulphate, or acid vanadous sulphate,  $\text{V}_2\text{O}_5 \cdot 4\text{SO}_3 \cdot x\text{H}_2\text{O}$  or  $\text{V}_2\text{H}_4(\text{SO}_3)_4 \cdot y\text{H}_2\text{O}$ .

A hydrate with  $x=3$  or  $y=2$  was obtained

by Gerland (*B.* 10, 2111 [1877]) by heating a solution of  $\text{V}_2\text{O}_5$  in a large excess of conc.  $\text{H}_2\text{SO}_4$  for a long time at  $120^\circ$ , and treating the blue crystalline crusts thus formed (consisting chiefly of  $\text{V}_2\text{O}_5 \cdot 3\text{SO}_3 \cdot 2\text{aq}$ , v. HYPOVANADIC SALTS, p. 848) with boiling water, when  $\text{V}_2\text{O}_5 \cdot 4\text{SO}_3 \cdot 8\text{H}_2\text{O}$  remained. G. supposed that reduction of  $\text{V}_2\text{O}_5$  was effected by dust in the air.

Brierley (*C. J.* 49, 822 [1886]) prepared  $\text{V}_2\text{O}_5 \cdot 4\text{SO}_3 \cdot 9\text{H}_2\text{O}$  ( $= \text{V}_2\text{H}_4(\text{SO}_3)_4 \cdot 9\text{H}_2\text{O}$ ) by electrolysis a solution of  $\text{V}_2\text{O}_5$  in  $\text{H}_2\text{SO}_4$ . The solution was prepared by reducing  $\text{V}_2\text{O}_5$  in conc.  $\text{H}_2\text{SO}_4$ , after dilution, by  $\text{SO}_2$ . The deep-blue solution was placed in a Pt dish which formed the negative electrode, and a porous pot containing dilute  $\text{H}_2\text{SO}_4$  was arranged so that it just touched the surface of the liquid in the Pt dish; a plate of Pt immersed in the  $\text{H}_2\text{SO}_4\text{Aq}$  formed the positive electrode. The Pt dish was warmed during the process, so that electrolysis and evaporation proceeded together. Electrolysis was continued until the liquid was deep green, and a drop placed in a little water showed no trace of blue colour. Conc.  $\text{H}_2\text{SO}_4$ , equal to twice the bulk of the green liquid, was added; after 24 hours the green, sandy pp. was collected, washed with conc. alcohol, and dried over  $\text{H}_2\text{SO}_4$  in coal-gas. The salt dissolved in water, and alkali ppd. from this solution a dirty-green gelatinous substance, said by B. to be  $\text{V}_2\text{O}_5 \cdot x\text{H}_2\text{O}$ . This pp. dissolved in an aqueous solution of  $\text{V}_2\text{O}_5 \cdot 4\text{SO}_3 \cdot 9\text{H}_2\text{O}$ , forming a chocolate-brown solution, giving a lustrous green solid on evaporation, which dissolved in water to form a brown solution. B. concluded that the brown solution contained a compound of  $\text{V}_2\text{O}_5$  and  $\text{SO}_3$ , more basic than  $\text{V}_2\text{O}_5 \cdot 4\text{SO}_3$ .

Gerland (*B.* 11, 106 [1878]) mentions the normal vanadous sulphate  $\text{V}_2(\text{SO}_4)_3$  ( $= \text{V}_2\text{O}_5 \cdot 3\text{SO}_3$ ) as if he had prepared it; no details are given.

**VANADIUM TRIOXIDE  $\text{V}_2\text{O}_5$ .** (*Hyovanadite oxide*.) Mol. w. not known. Represented by Berzelius as  $\text{VO}_2$  ( $\text{V} = 68.5$ ,  $\text{O} = 8$ ).

**Formation.**—1. By allowing  $\text{V}_2\text{O}_5$  to absorb  $\text{O}$  from the air (cf. HYPOVANADIC VANADIC OXIDES, p. 851).—2. By strongly heating a mixture of 5 pts.  $\text{V}_2\text{O}_5$  and 6 pts.  $\text{V}_2\text{O}_5$ , in absence of air.—3. By the electrolysis of molten  $\text{V}_2\text{O}_5$  (Buff & Wöhler, *A.* 110, 277).—4. By heating  $\text{V}_2\text{O}_5 \cdot \text{Cl}_3$  in a stream of  $\text{CO}_2$  (Crow, *C. J.* [2] 15, 453).

**Preparation.**—A solution of  $\text{V}_2\text{O}_5$  in  $\text{H}_2\text{SO}_4$ , obtained by reducing  $\text{V}_2\text{O}_5$  in conc.  $\text{H}_2\text{SO}_4$  by  $\text{SO}_2$ , is ppd. by  $\text{Na}_2\text{CO}_3\text{Aq}$ , and the pp. is washed and dried by heating *in vacuo* (Berzelius, *P.* 22, 1).—2.  $\text{V}_2\text{O}_5$  is exposed to the air for some months, until the colour has changed to blue (Roscoe, *J.* [2] 6, 338).—3.  $\text{V}_2\text{O}_5$  is dissolved in hot conc.  $\text{HClAq}$ ; when  $\text{Cl}$  ceases to be given off the liquid is saturated with  $\text{H}_2\text{S}$ , filtered from  $\text{S}$ , evaporated to dryness at  $100^\circ$  and the  $\text{V}_2\text{O}_5 \cdot \text{Cl}_3$  thus formed is heated to redness in a stream of dry  $\text{CO}_2$  (Crow, *l.c.* pp. 457, 458).

**Properties and Reactions.**—A blue, lustrous, crystalline powder; prepared by heating  $\text{V}_2\text{O}_5 \cdot \text{Cl}_3$  in  $\text{CO}$ , it forms a dark-green, amorphous powder (Crow, *l.c.*). Infusible at a high temperature. Insoluble in water. When kept in a loosely-stoppered bottle  $\text{V}_2\text{O}_5$  gradually absorbs  $\text{O}$ , forming  $\text{V}_2\text{O}_5$  (Crow, *l.c.*). Dissolves easily in acids, forming bright-blue liquids; the same solutions are obtained by the action of moderate

reducers, such as  $\text{SO}_2\text{Aq}$ ,  $\text{H}_2\text{SAq}$ , or  $\text{H}_2\text{C}_2\text{O}_4\text{Aq}$ , on solutions of  $\text{V}_2\text{O}_5$  in acids, also by passing air into  $\text{V}_2\text{O}_5$  in  $\text{H}_2\text{SO}_4\text{Aq}$  until the liquid becomes permanently blue (Roscoe, *l.c.*; *v. infra*, HYPOVANADIC SALTS). Petersen (*J. pr.* [2] 40, 194) supposed that the blue microscopic crystals he obtained, by dissolving  $\text{V}_2\text{O}_5$  in process of  $\text{HFAq}$  and evaporating were  $\text{VOF}_2\cdot x\text{aq}$ , but he did not obtain enough to make an analysis.  $\text{V}_2\text{O}_5$  dissolves readily in alkali solutions, forming hypovanadates,  $\text{M}_2\text{V}_2\text{O}_8$  (*q. v.* under VANADIUM OXIDES, AND SALTS AND DERIVATIVES THEREOF, p. 853).

**HYDRATES OF HYPOVANADIC OXIDE.** By adding  $\text{Na}_2\text{CO}_3\text{Aq}$ , drop by drop, to a solution of  $\text{V}_2\text{O}_5$  in  $\text{HClAq}$  or  $\text{H}_2\text{SO}_4\text{Aq}$ , till the supernatant liquid was colourless, filtering rapidly in  $\text{CO}_2$ , and drying on a porous tile over  $\text{H}_2\text{SO}_4$  *in vacuo*, Crow (*l.c.*) obtained the black, amorphous *heptahydrate*  $\text{V}_2\text{O}_5\cdot 7\text{aq}$ ; and on heating this in  $\text{CO}_2$  for some hours at  $100^\circ$  he obtained the *trihydrate*  $\text{V}_2\text{O}_5\cdot 3\text{aq}$ .

**HYPOVANADIC (or vanadyl) SALTS**  $\text{V}_2\text{O}_5\cdot x\text{X}$  (X=acidic oxide). Only a few compounds of  $\text{V}_2\text{O}_5$  with acidic oxides have been isolated. The sulphates have been studied more than any other salts; they are most simply represented as  $\text{V}_2\text{O}_5\cdot x\text{SO}_3\cdot y\text{H}_2\text{O}$ . The compound  $\text{V}_2\text{O}_5\cdot 2\text{SO}_3$  may be called the normal sulphate; the formula may be expressed as  $\text{V}_2\text{O}_5(\text{SO}_3)_2$  or  $\text{VO}\cdot\text{SO}_3$ . The compound  $\text{V}_2\text{O}_5\cdot 3\text{SO}_3\cdot 6\text{H}_2\text{O}$  may be called acid sulphate; the formula may be expressed as  $\text{V}_2\text{O}_5\cdot \text{SO}_3(\text{SO}_3\text{H})_2\cdot 5\text{H}_2\text{O}$  or  $(\text{V}_2\text{O}_5)_2\text{H}_2(\text{SO}_3)_2\cdot 5\text{H}_2\text{O}$ , or  $(\text{VO}\cdot\text{SO}_3)_2\cdot \text{H}_2\text{SO}_4\cdot 5\text{H}_2\text{O}$ ; or it may be written  $\text{V}_2\text{O}_5\cdot 2\text{SO}_3\cdot \text{H}_2\text{SO}_4\cdot 5\text{H}_2\text{O}$ . When the formulae of the compounds of  $\text{V}_2\text{O}_5$  with acidic oxides are written  $\text{V}_2\text{O}_5\cdot \text{X}$  the compounds are generally called *hypovanadic salts*; when the formulae are written  $\text{V}_2\text{O}_5\cdot x\text{R}$  (R=acidic radicle) the name *divanadyl salts* is usually given to the compounds; and when these compounds are regarded as  $\text{VO}\cdot x\text{R}$ , it is customary to call them *vanadyl salts*. Hypovanadic sulphates are obtained (1) by dissolv-

$\text{H}_2\text{SO}_4$  and heating to the boiling-point of the liquid for a long time. The salt separated as a green-blue powder; insoluble in water, gold or hot; insoluble  $\text{HClAq}$  and  $\text{H}_2\text{SO}_4$ . (G. does not say how the salt was obtained pure for analysis; no analyses are given of the salt prepared exactly as described above.) Various *hydrates* are described by G. obtained by different processes. Crow (*C. J.* [2] 15, 456 [1876]), obtained the *heptahydrate* by repeatedly treating hexahydrated trisulphate (*v. infra*) with absolute alcohol.

**Hypovanadic trisulphate, or acid divanadyl sulphate**,  $\text{V}_2\text{O}_5\cdot 3\text{SO}_3\cdot x\text{H}_2\text{O}$  or  $(\text{V}_2\text{O}_5)_2\text{H}_2(\text{SO}_3)_3\cdot y\text{H}_2\text{O}$  [ $y=x-1$ ]. (*Acid vanadyl sulphate*  $(\text{VO}\cdot\text{SO}_3)_2\cdot \text{H}_2\text{SO}_3\cdot y\text{H}_2\text{O}$ .) Hydrates with  $x=4$  and 3 (or  $y=3$  and 2) were prepared by Gerland (*B. 10*, 2, 109); and a hydrate with  $x=6$  (or  $y=5$ ) by Crow (*C. J.* [2] 15, 455).

By dissolving  $\text{V}_2\text{O}_5$  in a large excess of conc.  $\text{H}_2\text{SO}_4$ , heating for a long time at c.  $120^\circ$ , and drying the small, blue, transparent crystals that formed on a porous tile over  $\text{H}_2\text{SO}_4$ , Gerland obtained a substance which gave analytical results approaching those required by the formula  $\text{V}_2\text{O}_5\cdot 3\text{SO}_3\cdot 4\text{H}_2\text{O}$ . The salt was not obtained quite free from admixed  $\text{V}_2\text{O}_5\cdot 4\text{SO}_3\cdot x\text{H}_2\text{O}$ . This *tetrahylate* was partially decomposed by cold water, giving lustrous scales which, after washing with alcohol and ether and drying over  $\text{H}_2\text{SO}_4$ , had the composition of a *trihydrate*,  $\text{V}_2\text{O}_5\cdot 3\text{SO}_3\cdot 3\text{H}_2\text{O}$ .

Crow obtained a *hexahydrate*  $\text{V}_2\text{O}_5\cdot 3\text{SO}_3\cdot 6\text{H}_2\text{O}$ , by reducing by  $\text{SO}_2$  a solution of  $\text{V}_2\text{O}_5$  in conc.  $\text{H}_2\text{SO}_4$ , heating at  $100^\circ$  for some time, drying the light-blue crystals that separated on a tile, removing acid by washing with ether, and drying by pressure between paper. The crystals deliquesced in air to a blue syrup; they were insoluble in ether, and scarcely soluble in absolute alcohol.

The formulae of the various hydrated hypovanadic sulphates are as follows:—

<i>Hypovanadic sulphates</i> ;	or	<i>Divanadyl sulphates</i> ;	or	<i>Vanadyl sulphates</i> .
$\text{V}_2\text{O}_5\cdot 2\text{SO}_3$		$\text{V}_2\text{O}_5(\text{SO}_3)_2$		$\text{VO}\cdot\text{SO}_3$ (Gerland).
$\text{V}_2\text{O}_5\cdot 2\text{SO}_3\cdot 3\text{H}_2\text{O}$		$\text{V}_2\text{O}_5(\text{SO}_3)_2\cdot 3\text{H}_2\text{O}$		$2(\text{VO}\cdot\text{SO}_3)\cdot 3\text{H}_2\text{O}$ (G.)
$\text{V}_2\text{O}_5\cdot 2\text{SO}_3\cdot 4\text{H}_2\text{O}$		$\text{V}_2\text{O}_5(\text{SO}_3)_2\cdot 4\text{H}_2\text{O}$		$\text{VO}\cdot\text{SO}_3\cdot 2\text{H}_2\text{O}$ (Crow, confirming Berzelius).
$\text{V}_2\text{O}_5\cdot 2\text{SO}_3\cdot 7\text{H}_2\text{O}$		$\text{V}_2\text{O}_5(\text{SO}_3)_2\cdot 7\text{H}_2\text{O}$		$2(\text{VO}\cdot\text{SO}_3)\cdot 7\text{H}_2\text{O}$ (G., also C.)
$\text{V}_2\text{O}_5\cdot 2\text{SO}_3\cdot 10\text{H}_2\text{O}$		$\text{V}_2\text{O}_5(\text{SO}_3)_2\cdot 10\text{H}_2\text{O}$		$\text{VO}\cdot\text{SO}_3\cdot 5\text{H}_2\text{O}$ (G.)
$\text{V}_2\text{O}_5\cdot 2\text{SO}_3\cdot 13\text{H}_2\text{O}$		$\text{V}_2\text{O}_5(\text{SO}_3)_2\cdot 13\text{H}_2\text{O}$		$2(\text{VO}\cdot\text{SO}_3)\cdot 13\text{H}_2\text{O}$ (G.)
$\text{V}_2\text{O}_5\cdot 3\text{SO}_3\cdot 3\text{H}_2\text{O}$		$(\text{V}_2\text{O}_5)_2\text{H}_2(\text{SO}_3)_3\cdot 2\text{H}_2\text{O}$		$2(\text{VO}\cdot\text{SO}_3)\cdot \text{H}_2\text{SO}_3\cdot 2\text{H}_2\text{O}$ (G.)
$\text{V}_2\text{O}_5\cdot 3\text{SO}_3\cdot 4\text{H}_2\text{O}$		$(\text{V}_2\text{O}_5)_2\text{H}_2(\text{SO}_3)_3\cdot 3\text{H}_2\text{O}$		$2(\text{VO}\cdot\text{SO}_3)\cdot \text{H}_2\text{SO}_3\cdot 3\text{H}_2\text{O}$ (G.)
$\text{V}_2\text{O}_5\cdot 3\text{SO}_3\cdot 5\text{H}_2\text{O}$		$(\text{V}_2\text{O}_5)_2\text{H}_2(\text{SO}_3)_3\cdot 5\text{H}_2\text{O}$		$2(\text{VO}\cdot\text{SO}_3)\cdot \text{H}_2\text{SO}_3\cdot 5\text{H}_2\text{O}$ (C.)

ing  $\text{V}_2\text{O}_5$  in hot conc.  $\text{H}_2\text{SO}_4$  and boiling; (2) by dissolving  $\text{V}_2\text{O}_5$  in conc.  $\text{H}_2\text{SO}_4$ , reducing by  $\text{SO}_2$ , or  $\text{H}_2\text{C}_2\text{O}_4$ , and evaporating; (3) by dissolving  $\text{V}_2\text{O}_5$  in conc.  $\text{H}_2\text{SO}_4$  and boiling in the air for some time. In reaction (5)  $\text{V}_2\text{O}_5\cdot x\text{SO}_3$  seems to be formed and then partially reduced, by dust or products of combustion of coal-gas, to  $\text{V}_2\text{O}_5\cdot x\text{SO}_3$ ; the products are mixtures of  $\text{V}_2\text{O}_5\cdot x\text{SO}_3$  and  $\text{V}_2\text{O}_5\cdot x\text{SO}_3$  (Gerland, *B. 11*, 98).

**Hypovanadic disulphate, or normal divanadyl sulphate**,  $\text{V}_2\text{O}_5\cdot 2\text{SO}_3$ , or  $\text{V}_2\text{O}_5(\text{SO}_3)_2$ . (*Vanadyl sulphate*  $\text{VO}\cdot\text{SO}_3$ .) Prepared by Gerland (*B. 10*, 2109 [1877]; supplementing *B. 9*, 869) by dissolving  $\text{V}_2\text{O}_5$  in a large excess of conc.

Bevan (*C. N.* 38, 294) obtained *divanadyl dithionate* by adding  $\text{BaS}_2\text{O}_8\text{Aq}$  to  $\text{V}_2\text{O}_5(\text{SO}_3)_2\text{Aq}$ , filtering, and evaporating *in vacuo*; the salt was not obtained pure. By dissolving  $\text{V}_2\text{O}_5$  in  $\text{KNO}_3\text{Aq}$  Berzelius (*P. 22*, 1) obtained a blue liquid which probably contained *hypovanadic nitrate*; but no solid could be isolated, as on evaporation to dryness decomposition occurred, with formation of  $\text{V}_2\text{O}_5$ .  $\text{V}_2\text{O}_5$  also dissolves in  $\text{H}_3\text{PO}_4\text{Aq}$ ; on evaporation at  $50^\circ$  blue crystals are obtained, which deliquesce to a blue syrup; these crystals are probably *hypovanadic phosphate*, but no analyses are given (*B. l.c.*). Berzelius obtained what were probably com-

pounds of  $V_2O_5$  with  $As_2O_3$ ,  $B_2O_3$ ,  $CrO_3$ ,  $MoO_3$ , and a few other acidic oxides (*Lehrbuch* [5th ed.] 3, 1053).

**VANADIUM PENTOXIDE  $V_2O_5$ .** (*Vanadic oxide. Vanadic anhydride.*) Mol. w. not known. Represented by Berzelius as  $VO_2$  ( $V = 68.5$ ,  $O = 8$ ).

**Formation.**—1. By strongly heating any of the lower oxides in air or  $O_2$ .—2. By heating  $NH_4VO_3$  in air to dull redness.—3. By decomposing  $VOCl_3$  by water.—4. By heating  $V_2O_4 \cdot 4SO_3$  9aq to bright redness (Brierley, *C. J.* 49, 824).

**Preparation.**—Pure  $VOCl_3$  is decomposed by water, and the ppt.  $V_2O_5$  is washed till the washings are free from acid ( $HClAq$  is produced) and heated until dry (Schafarik, *J. pr.* 76, 142). For the preparation of  $V_2O_5$  from vanadinite and other sources of V compounds, *see VANADIUM, Preparation of* (p. 841).

**Properties.**—A pale-yellow powder, with a reddish tinge. When heated to full redness out of contact with any reducing agents,  $V_2O_5$  melts, and solidifies on cooling to a mass of yellow-red, crystalline needles, appearing ruby-red by transmitted light; should the  $V_2O_5$  used contain  $V_2O_4$ , which is often the case when the  $V_2O_5$  is prepared by heating  $NH_4VO_3$ , the solid obtained by fusion and cooling appears violet to nearly black, and does not seem to be crystalline (Berzelius, *P.* 22, 1). As molten  $V_2O_5$  cools nearly to its solidifying-point much heat is given out, and the mass glows until solidification is complete (*ib.*, *loc.*).  $V_2O_5$  is said not to be changed at a white heat, provided no trace of a reducing agent is present (*ib.*, *loc.*); but according to Read (*C. J.* 65, 313 [1894]) molten  $V_2O_5$  gives off  $O$ , producing  $V_2O_4$ , which on cooling in air takes up  $O$ , forming steel-blue crystals of  $V_2O_4$ . The crystals of  $V_2O_5$  are rhombic (*v.* Nordenskjöld, *P.* 112, 160). S.G. (crystalline) 3.5 at  $20^\circ$  (Schafarik, *J. pr.* 76, 142).  $V_2O_5$  is odourless and tasteless; it reddens moist litmus paper; 1,000 pts. boiling water dissolve scarcely 1 pt.  $V_2O_5$  (*ib.*, *loc.*). With molten alkalis or alkali carbonates  $V_2O_5$  produces *vanadates* (*q.v.* p. 851).  $V_2O_5$  dissolves in conc.  $H_2SO_4$ ,  $HClAq$ ,  $HNO_3Aq$ , or  $HFAq$  (*cf.* VANADIC SALTS, p. 850).

According to Ditté (*C. R.* 101, 698),  $V_2O_5$  exists in three forms: (1) *red*, obtained by heating  $NH_4VO_3$  in a closed crucible, treating with  $HNO_3$ , and repeatedly heating to redness; (2) *yellow*, obtained by heating  $NH_4VO_3$  to  $440^\circ$  in a stream of air; and (3) *crystalline*, obtained by treating the yellow form with  $HNO_3$ , and then fusing. D. says that the red form is somewhat soluble in water, 1,000 c.c. dissolving 8 g. at  $20^\circ$ ; that the yellow form is very slightly soluble, and the crystalline form is insoluble, in water. He also says that the red form absorbs water from the air, producing hydrates with  $2H_2O$  and  $5H_2O$ ; and that addition of  $NHCl$ ,  $KCl$  (and other salts) to an aqueous solution of the red variety causes ppn. of a hydrate of the yellow form of  $V_2O_5$ , which hydrate, when dry, is a dark-red powder having the composition  $V_2O_5 \cdot 2H_2O$  ( $=H_2V_2O_7$ ) and is almost insoluble in water. (No analyses are given by D.)

**Reactions.**—1. When heated and kept molten,  $V_2O_5$  is formed, and this absorbs  $O$  as it cools in air and forms  $V_2O_4$  (Read, *C. J.* 65, 313 [1894]). 2. Heated to redness in hydrogen till it ceases to lose weight,  $V_2O_5$  is reduced to  $V_2O_4$  (Schafarik,

*A.* 109, 85); traces of  $P_2O_5$  prevent the reduction (Roscoe, *C. J.* [2] 6, 331).—3. Heating with potassium produces  $V_2O_3$  (Berzelius, *P.* 22, 1).—4.  $V_2O_5$  is produced by heating  $V_2O_4$  in a carbon crucible (*ib.*, *loc.*). For action of  $Mg$ ,  $Zn$ , &c. on solutions of  $V_2O_5$ , *see* VANADIC SALTS, (p. 850).—5. When mixed with carbon and heated in chlorine,  $V_2O_5$  yields  $VOCl_3$  (Roscoe, *C. J.* [2] 6, 342).—6. Electrolysis of molten  $V_2O_5$  produces  $V_2O_3$  (Buff a. Wöhler, *A.* 110, 277).—7. According to Ditté (*C. R.* 103, 55), fusion with potassium cyanide produces  $V_2O_3$  ( $N$ ,  $K_2O$ , and  $CO$ , being also formed). Carnot (*S. R.* 184, 1803, 1850; 105, 119) says that a boiling solution of potassium cyanide produces  $KVO_3$  ( $CO_2$  and  $N$  being given off); and that by dropping  $V_2O_5$  into excess of boiling  $KCNAq$  there is formed  $K_2V_2O_6$  (with evolution of  $N$  and  $CO_2$ ). No analyses are given either by D. or C.—8. Ditté (*C. R.* 103, 55) asserts that the products of the interaction of  $V_2O_5$  and potassium iodide or bromide are  $K_2V_2O_6$ ,  $KVO_3$ , and  $I$  or  $Br$ . The reactions are said to occur between  $V_2O_5$  and molten  $KI$  or  $KBr$ ; and  $KIAq$  is said to react in the same way as the molten salt.—9. When  $V_2O_5$  is heated with molten boron trioxide, a pale-yellow glass is formed, which is said by Guyard (*Bl.* [2] 40, 351) to be a vanadic borate; no analyses, composition, or methods of purification are given.—10.  $V_2O_5$  dissolves in hot conc. sulphuric acid, forming  $V_2O_5 \cdot xSO_3$ , generally along with more or less  $V_2O_4 \cdot xSO_3$  (*v.* VANADIC SALTS, p. 850).—11.  $V_2O_5$  dissolves in conc. hydrochloric acid;  $Cl$  is given off on heating; after the passage of  $H_2S$  followed by evaporation at  $100^\circ$  the oxychloride  $VO_2Cl_2$  2aq is obtained (Crown, *C. J.* 30, 457; *cf.* VANADIUM DIOXYMONOCHLORIDE, p. 854).—12. By dissolving  $V_2O_5$  in conc. hydrochloric acid in presence of platinum chloride, Brauner (*M.* 3, 58) obtained large tablets having the composition  $2VO_2Cl \cdot PtCl_4$ . 21aq.—13. An oxyiodide  $2VO_2I_2$  2aq is obtained, according to Ditté (*C. R.* 102, 1310), by adding excess of hydriodic acid to a warm aqueous solution of red  $V_2O_5$ , removing free  $I$  by shaking with silver powder, filtering, and evaporating *in vacuo*. (No analyses are given).—14.  $V_2O_5$  dissolves in hydrofluoric acid, forming a pale-yellow solution, the colour of which becomes deeper on dilution (Piccini a. Giorgis, *G.* 22 [1] 55). Petersen (*J. pr.* [2] 40, 271) supposed that a solution in conc.  $HFAq$  contained  $VF_3$ ; but he did not separate this compound, nor does he give any direct evidence in favour of its existence beyond the preparation from the solution of  $V_2O_5$  in  $HFAq$  of a compound which may be represented as  $xKF \cdot VF_3 \cdot VOF_3$ , and other compounds of the forms  $xMF_3 \cdot VOF_3$ , and  $xMF_3 \cdot VO_2F$ . By adding metallic fluorides to solutions of  $V_2O_5$  in  $HFAq$ , and crystallising, vanadoxyfluorides are formed; these compounds are of the forms  $xMF_3 \cdot VOF_3$ , and  $xMF_3 \cdot VO_2F$  (*v.* VANADOXYFLUORIDES, p. 844).—15. Vanadoxyfluorides are also formed by dissolving  $V_2O_5$  in alkali fluoride solutions, and crystallising (*cf. infra*, Combinations, No. 5).—16. If a solution of  $V_2O_5$  in hydrofluoric acid is partially reduced, and then evaporated with metallic fluorides, hypovanadoxyfluorides (*q.v.* p. 845) are formed; these salts are of the form  $xMF_3 \cdot VOF_2$ .—17. By boiling  $V_2O_5$  with hydrogen peroxide solution, a

black liquid was obtained that deposited a black-brown crust of indefinite composition (Cammerer, *Chem. Zeit.* 19, 957).—18. By fusion with alkali or alkali carbonates vanadates are formed (v. VANADATES, p. 851).

**Combinations.**—1. With *wolff*, but not directly, to form  $V_2O_5 \cdot H_2O$  and  $V_2O_5 \cdot 2H_2O$  (v. *Metavanadic acid* and *Pyrovanadic acid*, under VANADIUM OXYACIDS, AND SALTS AND DERIVATIVES THEREOF, p. 851).—2. With various *acidic oxides*: (1) With  $SO_2$  to form  $V_2O_5 \cdot xSO_2$ , formed by dissolving  $V_2O_5$  in hot conc.  $H_2SO_4$ ; (2) with  $As_2O_3$  to form  $V_2O_5 \cdot xAs_2O_3$ ; (3) with  $P_2O_5$  to form  $V_2O_5 \cdot xP_2O_5$ ; (4) with  $IO_2$  to form  $V_2O_5 \cdot xIO_2$ ; (5) with  $MoO_3$  to form  $V_2O_5 \cdot xMoO_3$ ; (6) with  $WO_3$  to form  $V_2O_5 \cdot xWO_3$ ; (7) with  $P_2O_5$  and  $SiO_2$  to form  $V_2O_5 \cdot xP_2O_5 \cdot ySiO_2$ . Most of these compounds combine with the stronger bases  $M_2O$  and  $MO$  to form salt-like compounds. The compounds of  $V_2O_5$  with  $SO_2$  are described as *vanadic sulphates* under VANADIUM SALTS (*infra*); the compounds with other acidic oxides are described respectively as *arseno-vanadic acids* and *salts*, *iodo-vanadic acids*, *holobydo-vanadic acids* and *salts*, *phospho-vanadic acids* and *salts*, *phospho-silico-vanadic acid*, and *tungsto-vanadic acids* and *salts*, under VANADIUM OXYACIDS, AND SALTS AND DERIVATIVES THEREOF (v. pp. 853-4).—3. With *vanadium tetroxide* to form oxides intermediate between  $V_2O_5$  and  $V_2O_4$  (v. HYPOVANADO-VANADIC OXIDES, p. 851).—4. With *vanadium trioxide* to form  $V_2O_4$ ; produced by heating equivalent weights of the two oxides out of contact with air (Berzelius, *P.* 22, 1; Petersen, *J. pr.* [2] 40, 193).—5. With *alkali fluorides*. According to Ditté (*C. R.* 105, 1067; 106, 270), several compounds of the form  $xV_2O_5 \cdot yMF$  are formed by fusing  $V_2O_5$  with alkali fluorides, extracting with water, and crystallising; D. gives formulae where  $x=1, 3$  and  $4$ ,  $y=1, 2, 4$  and  $8$ , and  $M=K$  and  $Na$ ; but he does not give analyses of the salts (v. VANADOXYFLUORIDES, p. 844).

**HYDRATES OF VANADIC OXIDE.** The hydrates  $V_2O_5 \cdot H_2O = HVO_4$  and  $V_2O_5 \cdot 2H_2O = H_2V_2O_7$  have been isolated; these compounds are acids (v. VANADIC ACIDS, p. 851). Ditté (*C. R.* 101, 698) asserts, without giving analyses, that a pentahydrate  $V_2O_5 \cdot 5H_2O$  is formed by absorption of water from the air by the red form of  $V_2O_5$  (v. VANADIUM PENTOXIDE, *Properties*, p. 849).

**VANADIC SALTS**  $V_2O_5 \cdot xX$  ( $X$ =acidic oxide). A few compounds of this form have been isolated. The sulphates have been better studied than the other salts. Two sulphates,  $V_2O_5 \cdot 2SO_3 \cdot xH_2O$  and  $V_2O_5 \cdot 8SO_3 \cdot xH_2O$ , have been isolated. If  $x$  is taken to be 2 in the first salt and 8 in the second, then the formulae may be written as  $(VO_2)_2SO_4 \cdot H_2SO_4 \cdot H_2O$  and  $(VO_2)_2SO_4 \cdot 2H_2SO_4 \cdot H_2O$  respectively:  $[(VO_2)_2SO_4 \cdot H_2SO_4 \cdot H_2O = V_2O_5 \cdot 2SO_3 \cdot 2H_2O]$ ;  $[(VO_2)_2SO_4 \cdot 2H_2SO_4 \cdot H_2O = V_2O_5 \cdot 8SO_3 \cdot 3H_2O]$ . If the salts are anhydrous, as seems most probable from the analyses, then the formulae may be written  $(VO_2)_2SO_4 \cdot SO_3$  and  $(VO_2)_2SO_4 \cdot 2SO_3$ , respectively. Neither of the salts can be regarded as the normal salt. The sulphates are obtained by dissolving  $V_2O_5$  in hot conc.  $H_2SO_4$ .

**Vanadic disulphate**  $V_2O_5 \cdot 2SO_3$  (?  $xH_2O$ ). Prepared by Berzelius (*P.* 22, 39); examined also by Fritzsche (*J. pr.* 53, 93), Gerland (*B.* 11,

98), and Münzig (*C. C.* 1899 (ii.) 908). The salt seems to be without water of crystallisation;  $P_2$  (*l.c.*) says it crystallises with  $H_2O$ .  $V_2O_5$  is dissolved in hot conc.  $H_2SO_4$ , and the solution is boiled for a considerable time, when small crystals separate, some of which are brown and some ruby-red, lustrous, and transparent. The crystals are heated in a bath of molten lead until  $SO_2$  ceases to be given off (*G.*, *l.c.*). According to Münzig (*l.c.*), the orange-coloured crystalline powder that separates when  $V_2O_5$  is added to boiling conc.  $H_2SO_4$  until the acid is saturated is  $V_2O_5 \cdot 2SO_3$ . By keeping a solution of  $V_2O_5$  in a large excess of conc.  $H_2SO_4$  at  $130^\circ$ – $150^\circ$  for a long time, Gerland (*l.c.*) obtained a hard, opaque, sealing-wax red, crystalline crust composed of  $V_2O_5$  and  $SO_3$  in approximately the ratio  $V_2O_5 : 2SO_3$ .

$V_2O_5 \cdot 2SO_3$  [ $= (VO_2)_2SO_4 \cdot SO_3$ ] is described by *G.* (*l.c.*) as a clear red, crystalline, deliquescent solid; addition of a drop or two of water ppts.  $V_2O_5 \cdot xH_2O$ .

**Vanadic trisulphate**  $V_2O_5 \cdot 3SO_3$  (?  $xH_2O$ ). This salt seems to have been obtained by Berzelius (*l.c.*). Ditté (*C. R.* 102, 757) gave  $x$  the value 3; Gerland's analyses (*l.c.*) were inconclusive, the percentage of water found varying from 8 to 7.3. *G.* (*l.c.*) prepared this salt by long-continued boiling of a solution of  $V_2O_5$  in a large excess of conc.  $H_2SO_4$ ; small crystals separated, some of them brown and some ruby-red and transparent (probably regular octahedra). When the boiling was not continued for so long a time, *G.* noticed that fine, golden-yellow, lustrous needles separated. The composition of the crystals in each case was very nearly that required by the formula  $V_2O_5 \cdot 3SO_3$ . More or less  $V_2O_5 \cdot 2SO_3$  was always formed; *G.* found that addition of a little  $HClO_4$  prevented the formation of much  $V_2O_5 \cdot 2SO_3$ .

$V_2O_5 \cdot 3SO_3$  is very deliquescent; soluble in cold water or alcohol; a slight rise of temperature suffices to ppt.  $V_2O_5 \cdot xH_2O$ . By adding to a solution of this salt in cold water the proper quantity of  $K_2SO_4$ , *G.* (*l.c.*) obtained small, amber-yellow crystals, which, after a few washings with cold water, pressure between paper, and drying over  $H_2SO_4$ , had the composition of the double salt  $V_2O_5 \cdot 2SO_3 \cdot K_2O \cdot 6Ag$ . The same crystals were obtained by using the disulphate  $V_2O_5 \cdot 2SO_3$ . Replacement of  $K_2SO_4$  by  $(NH_4)_2SO_4$  produced the double salt  $V_2O_5 \cdot 2SO_3 \cdot (NH_4)_2O \cdot 4Ag$ . No double salts were obtained by using  $Na_2SO_4$  or  $MgSO_4$ , but the trisulphate ( $V_2O_5 \cdot 3SO_3$ ) crystallised unchanged.

Gerland (*B.* 11, 102) found that when a solution of  $V_2O_5$  in hot conc.  $H_2SO_4$  was largely diluted and dialysed,  $H_2SO_4$  passed rapidly through the dialyser, along with small quantities of  $V$  compounds, until the liquid in the dialyser contained  $V_2O_5$  and  $SO_3$  in the ratio  $V_2O_5 : 3SO_3$ , after which  $SO_3$  passed very slowly through, and the composition of the substance in the dialyser gradually approached  $V_2O_5 \cdot 2SO_3$ . By dialysing a diluted solution of  $V_2O_5$  in cold conc.  $H_2SO_4$ , the conditions being the same as in the experiment with the hot acid, *G.* found that  $SO_3$  passed through the dialyser regularly, and that, after a time, the ratio of  $V_2O_5$  to  $SO_3$  in the dialyser was 1:1.82. *G.* supposed these results to mean that a solution of  $V_2O_5$  in cold

$\text{H}_2\text{SO}_4$  contains loose, easily decomposed compounds of  $\text{V}_2\text{O}_5$  and  $\text{H}_2\text{SO}_4$ , but that a solution of  $\text{V}_2\text{O}_5$  in hot  $\text{H}_2\text{SO}_4$  contains  $\text{V}_2\text{O}_5 \cdot 3\text{SO}_3$ , which gradually loses  $\text{SO}_3$  until  $\text{V}_2\text{O}_5 \cdot 2\text{SO}_3$  is formed.

Solutions of  $\text{V}_2\text{O}_5$  in conc.  $\text{H}_2\text{SO}_4$  may be reduced to sulphates of lower oxides (Roscoe, C. J. [2] 6, 334; Rammelsberg, B. B. 1880, 787):—Zn, Cd, or Na-amalgam causes reduction to lavender solutions of  $\text{V}_2\text{O}_5 \cdot x\text{SO}_3$ ; Mg effects reduction to green solutions of  $\text{V}_2\text{O}_5 \cdot x\text{SO}_3$ ; and  $\text{H}_2\text{S}$ ,  $\text{SO}_2$ , or oxalic acid reduces only to blue solutions of  $\text{V}_2\text{O}_5 \cdot x\text{SO}_3$ .

By fusing  $\text{V}_2\text{O}_5$  with  $\text{B}_2\text{O}_3$  (Guyard, Bl. [2] 25, 354) obtained a green glass, which he took to be a *vanadic borate*; no analyses or descriptions are given.

The compounds of  $\text{V}_2\text{O}_5$  with  $\text{As}_2\text{O}_3$ ,  $\text{I}_2\text{O}_5$ ,  $\text{P}_2\text{O}_5$ ,  $\text{MoO}_3$ , and  $\text{WO}_3$ , respectively—or some of these compounds—may perhaps be regarded as vanadic arsenates, iodates, &c.; v. ARSENO-VANADIC ACIDS AND SALTS, IODO-VANADIC ACIDS, &c., p. 853.

**HYPOVANADO-VANADIC OXIDES.** Several oxides seem to exist intermediate between  $\text{V}_2\text{O}_5$  and  $\text{V}_2\text{O}_4$ . Roscoe noticed that  $\text{V}_2\text{O}_5$  gradually absorbed O and  $\text{H}_2\text{O}$  from the air, forming a greenish solid; Brierley (C. J. 49, 30) found that a pale grass-green substance was formed after some months, having the composition  $\text{V}_2\text{O}_5 \cdot 2\text{V}_2\text{O}_4 \cdot 8\text{aq} = \text{V}_2\text{O}_5 \cdot 4\text{aq}$ . By dissolving this solid in dilute  $\text{H}_2\text{SO}_4\text{aq}$  and neutralising by  $\text{KHOaq}$ , B. obtained  $2\text{V}_2\text{O}_5 \cdot 4\text{V}_2\text{O}_4 \cdot 6\text{K}_2\text{O} \cdot \text{aq}$ . By gently heating the compound

$2\text{V}_2\text{O}_5 \cdot 3\text{V}_2\text{O}_4 \cdot 3(\text{NH}_4)_2\text{O} \cdot 6\text{aq}$  (v. HYPOVANADO-VANADATES, p. 853), B. (l.c.) obtained a dark-green solid that absorbed water from the air, and then had the composition  $3(\text{V}_2\text{O}_5 \cdot \text{V}_2\text{O}_4) \cdot 8\text{aq} = 3\text{V}_2\text{O}_5 \cdot 8\text{aq}$  (cf. Ditte, C. R. 101, 151; also Manasse, A. 240, 23).

Compounds of  $\text{SO}_3$  with oxides intermediate between  $\text{V}_2\text{O}_5$  and  $\text{V}_2\text{O}_4$  are formed by the reducing action of zinc on solutions of  $\text{V}_2\text{O}_5$  in  $\text{H}_2\text{SO}_4$  (v. Rammelsberg, B. B. 1880, 787).

**Vanadium oxyacids, and salts and derivatives thereof.** Two oxyacids have been isolated,  $\text{HVO}_3$  and  $\text{H}_2\text{V}_2\text{O}_7$ , corresponding with  $\text{HPO}_3$  and  $\text{H}_2\text{P}_2\text{O}_7$ ; salts of these, also salts of the tribasic acid  $\text{H}_3\text{VO}_4$ , and several more complex salts, are known. Salts derived from the hypothetical hypovanadic acid  $\text{V}_2\text{O}_5(\text{OH})_2$  ( $= 2\text{V}_2\text{O}_5 \cdot \text{H}_2\text{O}$ ) have also been prepared; and several compounds are known which are most simply regarded as  $x\text{V}_2\text{O}_5 \cdot y\text{V}_2\text{O}_4 \cdot z\text{MO}$ , and which may be called hypovanado-vanadates.  $\text{V}_2\text{O}_5$  also combines with several acidic and basic oxides simultaneously to form compounds of the general form,  $x\text{V}_2\text{O}_5 \cdot y\text{X} \cdot z\text{MO}$ ; these compounds are generally described as arseno-vanadates, phospho-vanadates &c.

**VANADIC ACIDS.** Two vanadic acids,  $\text{HVO}_3$  and  $\text{H}_2\text{V}_2\text{O}_7$ , have been isolated; salts of the triacid acid,  $\text{H}_3\text{VO}_4$ , are known, but the acid itself has not certainly been prepared.

**Metavanadic acid  $\text{HVO}_3$ .** (Monobasic vanadic acid. *Monohydrate of vanadic oxide*  $\text{V}_2\text{O}_5 \cdot \text{H}_2\text{O}$ .) Gerland (B. 9, 872 [867]) prepared this acid by adding an excess of  $\text{NH}_4\text{Claq}$  to cold  $\text{CuSO}_4\text{aq}$ , then adding  $\text{NH}_4\text{VO}_3\text{aq}$  till a permanent pp. formed, heating to  $75^\circ$ , washing the lustrous yellow scales that slowly separated with dilute  $\text{H}_2\text{SO}_4\text{aq}$  and  $\text{SO}_2\text{aq}$  (to remove  $\text{V}_2\text{O}_5$ ), then washing with water, and drying at

$100^\circ$  until the smell of  $\text{NH}_3$  ceased. Manasse (A. 240, 52) obtained  $\text{HVO}_3$  by decomposing conc. solutions of the Ca, Mg, or Sr salt by a little  $\text{HNO}_3\text{aq}$ , and washing the pp. with dilute  $\text{HNO}_3\text{aq}$ , and then with hot water. Metavanadic acid forms golden-yellow crystalline scales; it is unchanged in air; dissolves very slightly in water; insoluble in absolute alcohol; soluble in  $\text{NH}_4\text{aq}$ ,  $\text{KOHaq}$ , or  $\text{NaOHaq}$ . By adding  $\text{NH}_4\text{VO}_3\text{aq}$  to  $\text{CuSO}_4\text{aq}$ , filtering from the pp. that formed, and dialysing for several days, Gerland (l.c. p. 874) obtained a solution in the dialyser of vanadic acid, which remained clear when heated, and on continued evaporation gave a pp. of red amorphous  $\text{V}_2\text{O}_5$ . Metavanadic acid forms a series of salts (v. METAVANADATES, *infra*).

This compound is used as a colour in place of gold bronze, under the name of *vanadium bronze*. According to Guyard (Bl. [2] 25, 356), the substance commonly known as *vanadium bronze* is really an ammonium vanadate.

**Pyrovanadic acid  $\text{H}_2\text{V}_2\text{O}_7$ .** (Tetrabasic vanadic acid. *Dihydrate of vanadic oxide*  $\text{V}_2\text{O}_5 \cdot 2\text{H}_2\text{O}$ .) This acid is obtained by decomposing a fairly conc. solution of an alkali vanadate of the form  $\text{M}_2\text{V}_2\text{O}_7$  or  $\text{M}_2\text{V}_2\text{O}_8$  (v. TETRAVANADATES and HEXAVANADATES, p. 852) by  $\text{HNO}_3\text{aq}$ , washing with cold water, and drying in the air (von Hauer, J. pr. 80, 321). According to Ditte (C. R. 101, 638), the red form of  $\text{V}_2\text{O}_5$  (v. p. 849) absorbs  $\text{H}_2\text{O}$  from the air, forming  $\text{V}_2\text{O}_5 \cdot 2\text{H}_2\text{O}$ , and also  $\text{V}_2\text{O}_5 \cdot 5\text{H}_2\text{O}$ . Pyrovanadic acid is described as a brown, amorphous powder, resembling  $\text{FeO} \cdot \text{H}_2\text{O}$ ; dried over  $\text{H}_2\text{SO}_4$ , it is said to lose half its water. Very slightly soluble in water; the solution is clear yellow; it reddens litmus.  $\text{H}_2\text{V}_2\text{O}_7$  is insol. in absolute alcohol; it dissolves readily in  $\text{NH}_4\text{aq}$ . For salts of this acid v. PYROVANADATES (p. 852).

**VANADATES.** The greater number of the vanadates belong to the series (1)  $\text{MVO}_3$ , (2)  $\text{M}_2\text{V}_2\text{O}_7$ , (3)  $\text{M}_2\text{VO}_6$ , (4)  $\text{M}_2\text{V}_2\text{O}_8$ , or (5)  $\text{M}_2\text{V}_2\text{O}_{10}$ . Series (1), (2), and (3) may be called normal salts; the formulae may be written as (1)  $\text{M}_2\text{O} \cdot \text{V}_2\text{O}_5$ , (2)  $2\text{M}_2\text{O} \cdot \text{V}_2\text{O}_7$ , and (3)  $3\text{M}_2\text{O} \cdot \text{V}_2\text{O}_6$ . Series (4) and (5) may be called acid salts; the formulae may be written as (4)  $\text{M}_2\text{O} \cdot 2\text{V}_2\text{O}_8$ , and (5)  $\text{M}_2\text{O} \cdot 3\text{V}_2\text{O}_{10}$ . Acid salts are also known intermediate between series (1) and (4); the chief of these are (6)  $3\text{M}_2\text{O} \cdot 4\text{V}_2\text{O}_8 = \text{M}_6\text{V}_4\text{O}_{20}$  ( $\text{M}_2\text{O} \cdot \text{V}_2\text{O}_8 = 1:1\frac{1}{2}$ ), (7)  $5\text{M}_2\text{O} \cdot 5\text{V}_2\text{O}_8 = \text{M}_{10}\text{V}_5\text{O}_{25}$  ( $\text{M}_2\text{O} \cdot \text{V}_2\text{O}_8 = 1:1\frac{1}{2}$ ), and (8)  $2\text{M}_2\text{O} \cdot 3\text{V}_2\text{O}_8 = \text{M}_4\text{V}_3\text{O}_{18}$  ( $\text{M}_2\text{O} \cdot \text{V}_2\text{O}_8 = 1:1\frac{1}{2}$ ). A few salts of the form  $3\text{M}_2\text{O} \cdot \text{V}_2\text{O}_8 = \text{M}_6\text{V}_2\text{O}_{16}$  ( $\text{M}_2\text{O} \cdot \text{V}_2\text{O}_8 = 1:1$ ) may be called basic salts. Some salts, especially those of Si and Ti, belong to more complex forms.

Roscoe (C. J. [2] 9, 28) has shown that the alkali orthovanadates,  $\text{M}_2\text{VO}_6$ , or  $3\text{M}_2\text{O} \cdot \text{V}_2\text{O}_6$ , are easily decomposed in aqueous solution at the ordinary temperature to pyrovanadates,  $\text{M}_2\text{V}_2\text{O}_7$ , and  $\text{MOHAq}$ ; but that orthovanadates are formed, rather than meta- or pyro-vanadates, by fusing  $\text{V}_2\text{O}_5$  with alkali carbonates; further, that aqueous solutions of alkali pyrovanadates are readily decomposed by  $\text{CO}_2$  to alkali carbonates and metavanadates.

**METAVANADATES  $\text{M}'\text{VO}_3$  or  $\text{M}_2\text{O} \cdot \text{V}_2\text{O}_7$ .** Ammonium metavanadate  $\text{NH}_4\text{VO}_3$ . Obtained by dissolving  $\text{V}_2\text{O}_5 \cdot x\text{H}_2\text{O}$  in excess of  $\text{NH}_4\text{aq}$ , warming, and allowing to evaporate.

**Forms a white, crystalline crust.** Dissolves slowly in cold water, quickly in boiling water. Decomposed by heat, giving  $V_2O_5$  when air is present. According to Berzelius (*P.* 22, 1), when a solution of  $V_2O_5 \cdot xH_2O$  in excess of  $NH_4Aq$  is allowed to evaporate without having been heated,  $NH_4VO_3$  separates in lemon-yellow crystals (v. B., *l.c.*; Roscoe, *C. J.* [2] 6, 322; Ditte, *C. R.* 102, 918; Norblad, *B.* 8, 126; Wagner, *D. P. J.* 223, 633; Böttger, *C. C.* 1873 514).

**Barium metavanadate**  $Ba(VO_3)_2 \cdot aq$ . A yellowish-white pp.; obtained, along with red crystals, by ppg.  $NH_4VO_3Aq$  by  $BaCl_2Aq$  (Manasse, *A.* 240, 23). Sl. sol. in water. Loses  $H_2O$  when heated to c.  $200^\circ$  (Berzelius; Norblad, *l.c.*).

**Potassium metavanadate**  $KVO_3 \cdot zaq$ . Formed by dissolving  $V_2O_5$  in  $KOHAq$  in the ratio  $V_2O_5 : KOH$ . Various hydrates have been obtained as white crystalline solids, melting to a clear yellow liquid, which solidifies to white, lustrous  $KVO_3$  (v. Berzelius, *l.c.*; Ditte, *C. R.* 104, 902, 1061, 1168).

**Sodium metavanadate**  $NaVO_3$ . Obtained by Roscoe (*C. J.* [2] 9, 31) by fusing  $V_2O_5$  and  $Na_2CO_3$  in the ratio  $V_2O_5 : 2Na_2CO_3$ , dissolving in water, crystallising  $Na_2V_2O_7 \cdot 18aq$ , and passing  $CO_2$  into an aqueous solution of this salt, when  $NaVO_3$  crystallised out and  $Na_2CO_3$  remained in solution. Small yellowish-white crystals, probably monoclinic prisms, melting readily and solidifying to a yellow crystalline mass (*cf.* Norblad, *l.c.*). Hydrates with 2, 4, and 5  $H_2O$  have been obtained (*cf.* Ditte, *l.c.*).

The other metavanadates that have been prepared are  $Cd(VO_3)_2$  (Ditte, *C. R.* 104, 1705);  $Ca(VO_3)_2 \cdot 4aq$  (von Hauer, *J. pr.* 69, 385; 80, 324; Manasse, *A.* 240, 23; *cf.* Roscoe, *C. J.* [2] 9, 32);  $Co(VO_3)_2 \cdot 3aq$  (D., *l.c.*; Radau, *A.* 251, 114), forms double salts with  $KVO_3$  (R., *l.c.*);  $Pb(VO_3)_2$  (R., *l.c.*; D., *l.c.*);  $LiVO_3 \cdot 2aq$  (Ditte, *C. R.* 104, 1168);  $Mg(VO_3)_2 \cdot 6aq$  (D., *l.c.*; Manasse, *l.c.*);  $Mn(VO_3)_2 \cdot 4aq$  (Radau, *l.c.*);  $AgVO_3 \cdot 4NH_3 \cdot 2aq$  (D., *l.c.*);  $Sr(VO_3)_2 \cdot 4aq$  (Norblad, *l.c.*; Manasse, *l.c.*);  $Zn(VO_3)_2 \cdot 2aq$  (D., *l.c.*).

**ORTHOVANADATES**  $M_2V_2O_7$  or  $3M_2O \cdot V_2O_5$ .

**Potassium orthovanadate**  $K_2VO_7$ . Obtained by fusing  $V_2O_5$  with  $K_2CO_3$ ; decomposed by water, giving  $KOHAq$  and  $K_2V_2O_7$  (Rammelsberg, *B. B.* 1883, 8).

**Sodium orthovanadate**  $Na_2VO_7 \cdot xH_2O$ . Roscoe (*C. J.* [2] 9, 39) obtained the salt with  $16H_2O$  by fusing  $V_2O_5$  and  $Na_2CO_3$  in the ratio  $V_2O_5 : 3Na_2CO_3$ , allowing to cool, dissolving in as little cold water as possible, quickly adding excess of conc. alcohol, allowing to stand for some hours, washing the crystals that formed with small quantities of alcohol, and drying on a porous plate over  $H_2SO_4$  *in vacuo* (*cf.* Czuczajewicz, *A.* 120, 84; Rammelsberg, *B. B.* 1883, 8). Baker (*C. J.* 47, 353) obtained  $Na_2VO_7 \cdot xH_2O$  with  $x = 8(?)$ , 10, and 12; he also obtained the double salt  $Na_2VO_7 \cdot NaF \cdot 19H_2O$ . The crystalline forms are given by B., and the various hydrates, of  $Na_2VO_7$  are shown to be isomorphous with corresponding arsenates and phosphates.  $Na_2VO_7Aq$  changes to  $Na_4V_2O_7Aq$  and  $NaOHAq$ ; the change occurs slowly at ordinary temperatures, and rapidly at higher temperatures (R., *l.c.*).

The other orthovanadates that have been pre-

pared are  $Ca_2(VO_3)_2 \cdot CaCl_2$  (Hautefeuille, *U. R.* 103, 800; 104, 501);  $Pb_2(VO_3)_2$  and  $8Pb_2(VO_3)_2 \cdot PbCl_2$  (R., *l.c.*);  $Ag_2VO_3$  (R., *l.c.*);  $Tl_2VO_3$  (Carnelley, *C. J.* 26, 323).

**PYROVANADATES**  $M_2V_2O_7$  or  $3M_2O \cdot V_2O_5$ .

**Barium pyrovanadate**  $Ba_2V_2O_7$ . Obtained, as a white amorphous powder, by adding  $BaCl_2Aq$  to freshly-prepared  $Na_2VO_7Aq$ , washing, and drying at  $100^\circ$ . The salt is slightly soluble in water (Roscoe, *C. J.* [2] 9, 33).

**Potassium pyrovanadate**  $K_2V_2O_7$ . Hard, deliquescent monoclinic prisms, formed by adding  $KOHAq$  to  $KVO_3Aq$ , rapidly evaporating to a syrup, and placing over  $H_2SO_4$  (Norblad, *B.* 8, 126).

**Sodium pyrovanadate**  $Na_2V_2O_7 \cdot 16H_2O$ . Formed by fusing  $V_2O_5$  and  $Na_2CO_3$  in the ratio  $V_2O_5 : 2Na_2CO_3$ , dissolving, and crystallising; also by exposing  $Na_2VO_7Aq$  to air free from  $CO_2$  until addition of alcohol ppts. silky scales ( $Na_2V_2O_7$ ) (Roscoe, *l.c.*, p. 31). White six-sided tables; e. sol. water, insol. alcohol.  $Na_2V_2O_7Aq$  is decomposed by  $CO_2$  to  $Na_2CO_3Aq$  and  $NaVO_3Aq$  (R., *l.c.*).

The other pyrovanadates that have been prepared are  $2Ca_2V_2O_7 \cdot 5aq$  (Roscoe, *l.c.*; *cf.* Ditte, *C. R.* 104, 1705);  $Cu_2V_2O_7 \cdot 3aq$  (von Hauer, *l.c.*);  $Pb_2V_2O_7$  (Ditte, *l.c.*);  $2Pb_2V_2O_7 \cdot PbO$  (Roscoe, *l.c.*);  $Li_2V_2O_7 \cdot 6aq$  (von H., *l.c.*);  $Mn_2V_2O_7$  (Ditte, *l.c.*);  $Ag_2V_2O_7$  (Roscoe, *l.c.*; Ditte, *l.c.*);  $Tl_2V_2O_7$  (Carnelley, *C. J.* 26, 323);  $Zn_2V_2O_7$  (D., *l.c.*).

**TETRAVANADATES**  $M_4V_4O_{11}$  or  $M_2O \cdot 2V_2O_5$  (also called *divanadates*).

**Ammonium tetra vanadate**  $(NH_4)_4V_4O_{11} \cdot zaq$ ;  $z = 3$  or 4. Formed by adding a little acetic acid to boiling  $NH_4VO_3Aq$  and evaporating *in vacuo*; also by saturating  $NH_4Aq$  with  $V_2O_5$  in a closed, warmed flask, and allowing to evaporate; red prismatic crystals with a golden-yellow sheen (Berzelius, *P.* 22, 1; Rammelsberg, *B. B.* 1883, 8; von Hauer, *l.c.*; Ditte, *C. R.* 102, 918).

**Potassium tetra vanadate**  $K_4V_4O_{11} \cdot zaq$ ;  $z = 3, 4, 7$ , and 10. Obtained by saturating  $K_2CO_3Aq$  at  $80^\circ$  with excess of  $V_2O_5$ , and allowing to cool; also by adding acetic acid to  $V_2O_5$  in  $KOHAq$ , concentrating at  $80^\circ$ , and letting cool (Ditte, *C. R.* 104, 902, 1061, 1168; *cf.* Norblad, *B.* 8, 126). Orange-coloured tablets (v. also Gibbons, *C. N.* 80, 267).

The other tetra vanadates are  $CaV_4O_{11} \cdot 9aq$  (Manasse, *A.* 240, 23);  $PbV_4O_{11}$  (Ditte, *l.c.*);  $Li_2V_4O_{11} \cdot 9aq$  (Norblad, *l.c.*);  $MgV_4O_{11} \cdot 9aq$  (B., *l.c.*; von Hauer, *l.c.*);  $NiV_4O_{11} \cdot 3aq$  (Radau, *A.* 251, 114);  $Na_2V_4O_{11} \cdot 9aq$  (Berzelius, *P.* 22, 1; von Hauer, *l.c.*; Norblad, *l.c.*);  $SrV_4O_{11} \cdot 9aq$  (B., *l.c.*; von H., *l.c.*).

**HEXAVANADATES**  $M_6V_6O_{19} \cdot xH_2O$  or

$M_2O \cdot 3V_2O_5 \cdot xH_2O$  (also called *trivanadates*). These salts have been described by Norblad (*B. B.* 126) and Ditte (*C. R.* 104, 902, 1061, 1168). The chief are those where  $M_2 = (NH_4)_2$ ,  $Ca$ ,  $K$ , and  $Na$ .

The principal vanadates belonging to other series than those already mentioned are the following:—(1)  $3M_2O \cdot 4V_2O_5$  ( $= M_4H_4V_4O_{20}$ ),  $M = Ca$  and  $Sr$  (v. Manasse, *l.c.*); (2)  $3MO \cdot 5V_2O_5$  ( $= M_3H_3V_3O_{25}$ ),  $M = Ba$ ,  $Mg$ ,  $K$ , (v. Manasse, *l.c.*; Radau, *A.* 251, 114); (3)  $2MO \cdot 3V_2O_5$  ( $= M_2H_2V_2O_{17}$ ),  $M = (NH_4)$ ,  $Ba$ ,  $Li$ ,  $Mg$ ,  $K$ ,  $Na$  (v. Ditte, *l.c.*; also *C. R.* 96,

1048; Manasse, *l.c.*; Norblad, *l.c.*); (4)  $4M_2O \cdot V_2O_5$  ( $= M_2V_2O_5$ ),  $M = Li$  and  $Na$  (*v. Ditte, l.c.*).

Several other vanadates not belonging to any of these series have also been described; for  $Ca$  and  $Sr$  salts (and double salts), *v. Manasse (l.c.)*; and for  $Tl$  salts *v. Carnelley (C. J. 26, 323)*.

**HYPOVANADATES.** Salts of hypothetical hypovanadic acid  $V_2O_4(OH)_2$  ( $= 2V_2O_5 \cdot H_2O$ ). These salts belong to the form  $M_2^xV_2O_4 \cdot xH_2O$  ( $= M_2O \cdot 2V_2O_4 \cdot xH_2O$ ). The formation of the  $NH_4$  and  $K$  salts was described by Berzelius; a series of salts was prepared and examined by Crow (*C. J. [2] 15, 458*). The alkali salts are obtained by treating fairly conc.  $VO_2Cl$  aq. with excess of caustic alkalis, allowing the pps. to settle in closed vessels, washing with alkali solution, then with dilute alcohol containing a little acetic acid, and finally with alcohol alone, and drying between paper. The salts of  $Pb$  and  $Ag$  are obtained by ppn. from a solution of the  $K$  salt. The salts form brown to black crystalline powders; the alkali salts dissolve in water. Crow prepared salts with  $M_2 = (NH_4)_2, Ba, Pb, K, Ag,$  and  $Na$ .

**HYPOVANADO-VANADATES.** Salts of the form  $nV_2O_5 \cdot mV_2O_4 \cdot pM_2O \cdot xH_2O$ . Alkali salts of this series were obtained by Brierley (*C. J. 49, 32*) by reducing  $V_2O_5 \cdot Ag$  by  $SO_2$ , adding  $V_2O_5$  in alkali, then a slight excess of alkali, and then acetic acid; pouring into alkali acetate solution, washing the pps. with alcohol, and drying over  $CaCl_2$ . The salts crystallise in greenish-black, or black, prisms. The following were prepared: (1)  $2V_2O_5 \cdot V_2O_4 \cdot 2Na_2O \cdot 13H_2O$ ; (2)  $2V_2O_5 \cdot V_2O_4 \cdot 2K_2O \cdot 6H_2O$ ; (3)  $2V_2O_5 \cdot 2V_2O_4 \cdot (NH_4)_2O \cdot 14H_2O$ ; these salts are soluble in water: (4)  $2V_2O_5 \cdot 4V_2O_4 \cdot 5K_2O \cdot H_2O$ ; (5)  $2V_2O_5 \cdot 4V_2O_4 \cdot 3(NH_4)_2O \cdot 6H_2O$ ; these are insoluble in water.

**COMPLEX VANADIC ACIDS AND SALTS.** Vanadic oxide  $V_2O_5$  combines with several anhydrides, such as  $As_2O_3, I_2O_5, P_2O_5$ , &c., and many of the compounds thus produced combine with basic oxides. The compounds of  $V_2O_5$  with certain anhydrides are generally regarded as acidic; and the compounds formed of  $V_2O_5$ , anhydrides, and bases are usually classed as salt-like substances. It is quite likely that many of the compounds of  $V_2O_5$  with anhydrides, such as  $As_2O_3, P_2O_5$ , &c., would be better classed as salts, just as the compounds of  $V_2O_5$  with  $SO_3$  are classed as salts.

**ARSENO-VANADIC ACIDS AND SALTS.** By boiling  $V_2O_5$  with excess of  $H_3AsO_4$  aq. and concentrating the solution, Fernandez (*B. 17, 1632*) obtained lustrous, golden-yellow crystals of  $V_2O_5 \cdot As_2O_3 \cdot 11aq$  (*cf. Friedheim & Schmitz-Dumont, B. 23, 2600*). Gibbs (*P. Am. A. 21, 50*) obtained  $xV_2O_5 \cdot yAs_2O_3$  aq. ( $x$  and  $y$  probably either 5 and 8, or 7 and 6), by decomposing a mixture of  $Na$  vanadate and arsenate by  $HNO_3$  aq. For various compounds of the form  $mV_2O_5 \cdot nAs_2O_3 \cdot pMO$ , where  $m$  and  $n$  are 1 and 1, 2 and 5, 1 and 2, 2 and 1, &c., and  $p$  varies from 7 to 5, *v. F. & S. D. (l.c.)*.

**IODO-VANADIC ACIDS.** Ditte (*C. R. 102, 367*) says that compounds of  $V_2O_5$  and  $I_2O_5$  are formed by heating  $V_2O_5$  with conc.  $HIO_4$  aq; he gives formulæ, but no analyses.

**MOLYBDO-VANADIC ACIDS AND SALTS.** For descriptions of numerous compounds of the forms  $xV_2O_5 \cdot yMoO_3$  aq.,  $xV_2O_5 \cdot yMoO_3 \cdot pMO$  aq., and also  $xV_2O_5 \cdot yMoO_3 \cdot mP_2O_5 \cdot pMO$  aq., *v. Gibbs (P. Am. A. 18, 232)*.

**PHOSPHO-VANADIC ACIDS AND SALTS.** Various compounds of  $V_2O_5, P_2O_5$ , and  $H_2O$  are described by Gibbs (*P. Am. A. 21, 50*); Ditte (*C. R. 102, 757*) also assigned formulæ to substances obtained by heating  $V_2O_5$  with conc.  $H_3PO_4$ . Friedheim (*B. 23, 1580*) obtained  $V_2O_5 \cdot P_2O_5 \cdot 2H_2O$  by dissolving  $V_2O_5$  in syrupy  $H_3PO_4$ .

For descriptions of a great many compounds of the form  $xV_2O_5 \cdot yP_2O_5 \cdot zMO$  aq., *v. Gibbs (l.c.)*; and *cf. Friedheim (l.c.)*.

F. divides the compounds formed by reacting with  $V_2O_5$  on alkali phosphates into two classes, which he calls *luteo-* and *purpureo-* compounds.

Luteo- compounds are formed by (1) the interactions of phosphoric and vanadic acids in solution; (2) the interactions of solutions of phosphates and vanadates in presence of small quantities of acids; (3) the interactions of solutions of phosphates and vanadic acid; (4) the interactions of vanadates and phosphoric acid, by heating solutions nearly to boiling and evaporating. These compounds are yellow, granular, and indistinctly crystalline; the alkali compounds are very slightly soluble in water, solution being accompanied by decomposition. The following luteo- compounds are described by F.:  $V_2O_5 \cdot P_2O_5 \cdot 2H_2O$  9aq.,  $V_2O_5 \cdot P_2O_5 \cdot (NH_4)_2O \cdot H_2O$  2aq.,  $2V_2O_5 \cdot P_2O_5 \cdot (NH_4)_2O$  7aq.,  $V_2O_5 \cdot P_2O_5 \cdot K_2O \cdot H_2O$  2aq. and  $2V_2O_5 \cdot P_2O_5 \cdot K_2O$  7aq.

Purpureo- compounds are formed by dissolving vanadic acid in conc. solutions of alkali phosphates, and by adding phosphoric acid to conc. solutions of alkali vanadates; in each case the solutions should be strongly heated. The purpureo- compounds described by F. belong to the form  $12V_2O_5 \cdot P_2O_5 \cdot 7M_2O \cdot 26aq$ ; they are dark-red crystalline substances, sol. in water.

F. regards the luteo- compound of the form  $V_2O_5 \cdot P_2O_5 \cdot 2H_2O$  9aq as acid phosphate of the radicle  $VO_2$ , thus  $(VO_2)_2H_2PO_4$  9aq; he compares this with the acid orthophosphates  $MH_2PO_4$ . The compounds of the form  $V_2O_5 \cdot P_2O_5 \cdot M_2O \cdot H_2O$  aq are looked on as double acid phosphates of alkali metal and  $VO_2$ , thus  $NH_4(VO_2)HPO_4$ . The luteo- compounds  $2V_2O_5 \cdot P_2O_5 \cdot M_2O$  aq are formulated by F. as double compounds of alkali metavanadates and  $(VO_2)_2H_2PO_4$ ; thus  $2V_2O_5 \cdot P_2O_5 \cdot K_2O \cdot 2H_2O$  5aq  $= 2(KVO_2 \cdot (VO_2)_2H_2PO_4 \cdot 2\frac{1}{2}aq)$ . The purpureo- compounds which belong to the form  $12V_2O_5 \cdot P_2O_5 \cdot 7M_2O$  aq are looked on by F. as double compounds of acid vanadates and acid phosphates; this view of their constitution is expressed by the statement

$12V_2O_5 \cdot P_2O_5 \cdot 7M_2O \cdot xH_2O = P_2O_5 \cdot 2M_2O \cdot H_2O + 72V_2O_5 \cdot 5M_2O + (x-1)H_2O$ . These views of F. are considerably modified in a later paper (*Zeit. f. anorg. Chemie, 5, 437*), where the purpureo- compounds are looked on as divanadates with some  $V_2O_5$  isomorphously replaced by  $P_2O_5$ . According to F., many of the substances described by Gibbs and by Ditte do not exist.

Berzelius (*P. 22, 1*) described a compound

of  $V_2O_5$ ,  $P_2O_5$ , and  $SiO_2$  with  $H_2O$ , which may be named *phospho-silico-vanadic acid*.

**TUNGSTO-VANADIC ACIDS AND SALTS.** The compounds of  $V_2O_5$  with  $WO_3$  and bases that have been described are very numerous, and the formulae given are generally extremely complex (v. Gibbs, *P. Am. A.* 18, 232; Rosenheim, *A.* 251, 197, 234; and especially Friedheim, *B.* 17, 1505; 23, 1505; 24, 1173).

**Vanadium oxybromides of.** Two compounds of V with O and Br have been isolated;  $VOBr_2$  and  $VOBr_3$ , corresponding with two of the five oxychlorides. According to Schafarik (*N. A. B.* 33, 14; 47 [11] 851), other oxybromides also exist.

**VANADIUM OXYDIBROMIDE  $VOBr_2$ .** (*Vanadyl dibromide*.) A brown, deliquescent powder. Prepared by heating  $VOBr_3$  (v. *infra*); decomposition to  $VOBr_2$  and Br occurs slowly at temperatures below  $180^\circ$ , and suddenly at  $180^\circ$ . Heated in air forms  $V_2O_5$ ; dissolves in water, forming a blue solution (Roscoe, *C. J.* [2] 9, 26). Ditte (*C. R.* 102, 1310) says that a compound  $VOBr_2 \cdot 4H_2O$  is formed, as dark-green, deliquescent crystals, by treating red  $V_2O_5$  with HBr. D. writes the formula  $V_2O_5 \cdot Br_2 \cdot 2HBr \cdot 7H_2O$ .

**VANADIUM OXYTRIBROMIDE  $VOBr_3$ .** (*Vanadyl tribromide*.) Prepared by passing vapour of pure Br over  $V_2O_5$ , heated to redness, condensing the yellowish-white vapours that are formed, removing excess of Br from the red liquid by heating to  $40^\circ$ – $50^\circ$  at c. 100 mm. pressure in a current of perfectly dry air, and then distilling *in vacuo* (Roscoe, *C. J.* [2] 9, 24).  $VOBr_3$  is a red, very hygroscopic liquid that boils at  $130^\circ$ – $136^\circ$  at 100 mm. pressure; S.G. 2.9673 at  $0^\circ$ ; 2.9325 at  $15.5^\circ$ ; decomposes slowly at the ordinary temperature, and suddenly at  $180^\circ$ , to  $VOBr_2$  and Br (l. c.).

**Vanadium oxychlorides of.** Five compounds of V with O and Cl have been isolated:  $VOCl$ ,  $VOCl_2$ ,  $VOCl_3$ ,  $V_2O_5 \cdot Cl$ , and  $V_2O_5 \cdot Cl_2$ .

**VANADIUM OXYMONOCHLORIDE  $VOCl$ .** (*Vanadyl monochloride*.) Obtained by the regulated reduction of  $VOCl_3$  by H. The mixed vapours are passed through a red-hot tube;  $VOCl$  is deposited near the end whereat the vapours enter the tube. A brown, light, flocculent powder; insol. in water; easily dissolved by  $HNO_3$  (Roscoe, *C. J.* [2] 6, 347).

**VANADIUM OXYDICHLORIDE  $VOCl_2$ .** (*Vanadyl dichloride*.) Prepared by heating a slight excess of  $VOCl_3$  with zinc for some days in a sealed tube, at  $400^\circ$ , cutting off the part of the tube on which the sublimates of  $VOCl_3$  has formed ( $V_2O_5$  and  $ZnCl_2$  are the other products), quickly placing it in a wider tube, and removing  $VOCl_3$  by heating in a stream of dry  $CO_2$  at  $130^\circ$ . Also obtained by passing vapour of  $VOCl_3$  and H through a red-hot tube;  $VOCl_2$  is deposited near the end of the tube whereat the gases enter, and  $V_2O_5 \cdot Cl$  at the further end of the tube (Roscoe, l. c., p. 348). Lustreous, grass-green, deliquescent tablets; S.G. 2.88 at  $13^\circ$ ; slowly decomposed by water; soluble in dilute  $HNO_3$ . A compound with  $PtCl_4$ , having the composition  $2(VOCl_2 \cdot PtCl_4) \cdot 21aq$ , is said by Brauner (*M.* 3, 58) to be formed by dissolving  $V_2O_5$  in conc.  $HCl$  in presence of  $PtCl_4$ .

**VANADIUM OXYTRICHLORIDE  $VOCl_3$ .** (*Vanadyl trichloride*.) Mol. w. 173.27.

**Formation.**—1. By heating  $V_2O_5$  gently in a stream of Cl (Berzelius, *P.* 22, 1).—2. By heating a mixture of  $V_2O_5$  and C in Cl.

**Preparation.**—A mixture of  $V_2O_5$  and sugar-charcoal is heated to redness in a stream of dry H, and allowed to cool in that gas; a stream of dry Cl is then passed over the mixture, which is heated to redness, and the product is condensed; the liquid thus obtained is heated for some hours in a flask with an inverted condenser, in a current of dry  $CO_2$ , and then rectified over Na (Roscoe, *C. J.* [2] 6, 342).

**Properties and Reactions.**—A clear, mobile, lemon-yellow liquid (Berzelius, l. c.; Roscoe, l. c.; Schafarik, *A.* 109, 85). S.G. 1.836 at  $17.5^\circ$ , 1.828 at  $24^\circ$  (R., l. c.); 1.86534 at  $0^\circ$ , 1.63073 at b.p. (Thorpe, *C. J.* 37, 348). B.P.  $127.19^\circ$  (T., l. c.). S.V. 106.25. Does not solidify above  $-15^\circ$  (R., l. c.). V.D. 88.38 at  $186^\circ$  (R., l. c.; cf. T., *C. N.* 24, 827; Schafarik, l. c.). Gives off thick, yellowish-red fumes in the air. Dissolves in a little water, forming a thick, red liquid; dissolves in much water, forming a clear yellow liquid; dissolves in absolute alcohol with a red colour, but the solution soon becomes blue, owing to reduction. Heated to  $60^\circ$ – $70^\circ$  in a closed tube with ether forms needles of the composition  $VOCl_2 \cdot Et_2O$  (Bedson, *C. J.* 29, 309).

**DIVANADIUM DIOXYMONOCHLORIDE  $V_2O_5 \cdot Cl$ .** (*Divanadyl monochloride*.) Yellow-bronze, microscopic crystals, resembling mosaic gold; formed by passing  $VOCl_3$  and H through a red-hot tube. The crystals are deposited on the part of the tube farthest from the end whereat the gases enter (Roscoe, *C. J.* [2] 6, 348). Insoluble in water; soluble in  $HNO_3$ . This compound was thought by Schafarik (*A.* 109, 85) to be V.

**HYDRATED VANADIUM DIOXYMONOCHLORIDE  $VO_2 \cdot Cl \cdot 5aq$ .** (*Hypovanadic chloride*  $V_2O_5 \cdot Cl \cdot 5aq$ .) Formed, as a brown, deliquescent solid, by passing  $H_2S$  into a solution of  $V_2O_5$  in hot  $HCl$ , filtering from S, and evaporating (Crow, *C. J.* 30, 457). Heated in a stream of dry  $CO_2$  gives off HCl and  $H_2O$ , and leaves  $V_2O_5 \cdot Cl$  (l. c.) gives the hydration as  $V_2O_5 \cdot Cl \cdot 5aq$ .

**Vanadium oxyfluorides of.** No compound of V with O and F has been isolated with certainty.  $V_2O_5$  dissolves in excess of  $HFAq$ ; on evaporation, solution in water, and evaporation over  $H_2SO_4$ , Petersen (*J. pr.* [2] 40, 194) obtained blue, microscopic crystals which he supposed might be  $VOF_2 \cdot 5aq$ , inasmuch as a solution of these crystals in  $HFAq$  treated with fluorides yielded salts of the form  $xMF_2 \cdot yVOF_2$  (v. *HYPOVANADOXYFLUORIDES*, p. 845). F. did not obtain enough of the blue crystals for analysis.

**Vanadium oxyiodides of.** According to Ditte (*C. R.* 102, 1310), an oxyiodide  $2VOI_2 \cdot 9H_2O$  is formed, as a black, deliquescent mass, by adding excess of  $HIAq$  to a warm solution of red  $V_2O_5$ , removing free I by shaking with finely-divided Ag, filtering, and evaporating *in vacuo*. The compound is said to react with  $NH_3$ , giving  $(NH_4)_2VOI_2$ . D. writes the formula as  $V_2O_5 \cdot I_2 \cdot 2H_2O$ ; but no analyses are given.

No reaction occurs when I is heated with  $V_2O_5$  (Roscoe, *C. J.* [2] 9, 28); nor when  $V_2O_5$  is digested with water, or alcohol, and I (Guyard,

Bl. [2] 25, 351).  $V_2O_5$  and  $I_2O_5$  probably combine (v. Ditte, C. R. 102, 757, 1019).

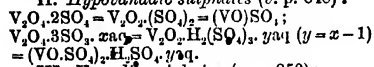

**Vanadium, oxy-sulphides of.** None of these compounds has been certainly isolated. Oxy-sulphides may perhaps be formed by decomposing alkali thiovanadates in solution by dilute acids (v. Kay, C. J. 87, 728).

**Vanadium, salts of.** Compounds of the oxides  $V_2O_5$ ,  $V_2O_4$ , and  $V_2O_3$  with acidic oxides have been isolated; the formulae of one or two of the compounds may be written as derived from oxyacids by replacing H by V, but it is simpler, and more in keeping with the facts that are known, to represent all the compounds by the general formula  $V_2O_5 \cdot yX$ , where X is an acidic oxide. The best-studied compounds of  $V_2O_5$  with acidic oxides may be represented as salts of the radicle  $V_2O_5$  (divanadyl), or of the radicle VO (vanadyl); and the compounds of  $V_2O_4$  with acidic oxides as acid salts of the radicle  $VO_2$ . The sulphates have been better studied than the other salts; the following table presents the compositions of the sulphates.

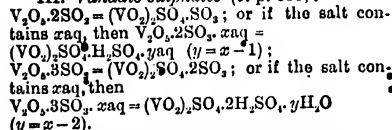

I. *Vanadous sulphates* (v. p. 847):

II. *Hypovanadous sulphates* (v. p. 848):

III. *Vanadic sulphates* (v. p. 850):

Alkalis probably ppt.  $V_2O_5 \cdot zaq$  from solutions of vanadous sulphates (v. p. 847); from solutions of hypovanadous sulphates alkalis ppt.  $V_2O_4 \cdot zaq$  (v. p. 848).

$V_2O_5$  dissolves in oxyacids, forming lavender solutions which probably contain  $V_2O_5 \cdot xX$ , where X is an acidic oxide (v. p. 846).

Various salts of  $V_2O_5$ ,  $V_2O_4$ , and  $V_2O_3$ , besides the sulphates probably exist, but they have not been thoroughly examined (v. HYPOVANADIC SALTS, p. 848; VANADIC SALTS, p. 850; ARSENO-VANADIC ACIDS AND SALTS, p. 853; IODO-VANADIC ACIDS, p. 853; MOLYBDO-VANADIC ACIDS AND SALTS, p. 853; PHOSPHO-VANADIC ACIDS AND SALTS, p. 853; and TUNGSTO-VANADIC ACIDS AND SALTS, p. 854).

**Vanadium, silicide of.** Roscoe (C. J. [2] 8, 358) says that V acts on glass or porcelain vessels when strongly heated therein, forming a compound with Si; tubes in which V chlorides are reduced by heating in H get coated with a grey lustrous mirror of this compound? No details or analyses are given.

**Vanadium, silicofluoride of.** By boiling  $V_2O_5$  with  $H_2SiF_6$  Aq and alcohol, Guyard (Bl. [2] 40, 352) obtained a greyish, uncrystallisable mass which he took to be a silicofluoride of V; no analyses or details of preparation are given.

**Vanadium, sulphides of.** Berzelius (P. 22, 1) described two compounds of V and S, one obtained by pptg. a solution of an alkali thiovanadate by dilute acid, and the other by heating  $V_2O_5$  in  $H_2S$ . B. gave the formulae  $VS_2$  and

$VS_3$  to the compounds he described. The sulphides of V were re-examined by Kay in 1880 (C. J. 87, 728), who found that the pp. obtained by adding dilute  $HClAq$  or  $H_2SO_4$  to a solution of sodium vanadate saturated with  $H_2S$ , or to solution of  $V_2O_5$  in an alkali hydrosulphide, contained O, but probably had not a definite composition; and that the product of heating  $V_2O_5$  in  $H_2S$  is the trisulphide  $V_2S_3$ ; Kay prepared three sulphides,  $V_2S_3$ ,  $V_2S_2$ , and  $V_2S_4$ , corresponding to three of the four oxides; the sulphides dissolve in solutions of alkalisulphides, probably forming thiovanadates (q. v. infra).

**VANADIUM DISULPHIDE  $V_2S_2$ .** (*Hypovanadous sulphide*.) Prepared by heating  $V_2S_3$  to full redness, for a long time, in H quite free from O. Forms black lustrous plates, or a brownish-black powder; S.G. 4.2 to 4.4. Absorbs O very quickly when heated in air, giving  $V_2O_5$ ,  $V_2O_4$ , and then  $V_2O_3$ , with evolution of  $SO_2$ . Not acted on by boiling  $HClAq$ , dilute or conc., nor by boiling dilute  $H_2SO_4$  or cold conc.  $H_2SO_4$ . Dissolves in hot conc.  $H_2SO_4$ ; dissolves in  $HNO_3$  Aq. Slowly acted on by  $NaOHAq$  or  $KOHAq$ , hot or cold; dissolves in  $(NH_4)_2SAq$  or  $KHSaAq$ , forming purple to reddish-brown solutions (Kay, l.c. p. 735).

**VANADIUM TRISULPHIDE  $V_2S_3$ .** (*Vanadous sulphide*.) Formed by strongly heating  $V_2O_5$  in a stream of  $H_2S$  (Berzelius, l.c.; Kay, l.c. p. 736); also by heating any chloride of V, or  $VOCl_3$ , to redness in  $H_2S$  (K., l.c.); and by strongly heating  $V_2O_5$  in a stream of vapour of  $CS_2$  so long as any reaction occurs (K., l.c.). Forms dark, lustrous plates, or a black amorphous powder; S.G. 3.7 to 4.0. Oxidised by heating in air, finally to  $V_2O_5$ , giving off  $SO_2$ . Scarcely acted on by dilute  $HClAq$  or  $H_2SO_4$  Aq, hot or cold, nor by conc.  $HClAq$ ; readily oxidised by  $HNO_3$  Aq. Soluble in  $(NH_4)_2SAq$  or  $KHSaAq$ , forming purple-red to golden-red solutions; also somewhat soluble in  $KOHAq$ ,  $NaOHAq$  or  $NH_4OHAq$  (Kay, l.c.).

**VANADIUM PENTASULPHIDE  $V_2S_5$ .** (*Vanadic sulphide*.) Prepared by mixing  $V_2S_3$  with  $\frac{2}{3}$  its weight of pure powdered S, heating to fusion (c. 400°) in a narrow tube quite filled with  $CO_2$  and sealed, cooling, and dissolving out excess of S with  $CS_2$ . A black powder; S.G. 3.0. Heated in a gas that does not react with it,  $V_2S_5$  gives off S and leaves  $V_2S_3$ ; heated in air gives off  $SO_2$ , forming  $V_2O_5$  and finally  $V_2O_3$ . Behaves towards acids similarly to  $V_2S_3$ . Dissolves in hot  $NaOHAq$ ; also in  $(NH_4)_2SAq$  or  $KHSaAq$ , forming yellow to red solutions (Kay, l.c. p. 738).

**Vanadium thio-acids, and salts thereof.** No compound of V with H and S has been isolated, but some thiovanadates, and also some oxythiovanadates, have been prepared by Krüss & Ohnwald (B. 23, 2547).

**Ammonium thio-orthovanadate  $(NH_4)_2VS_4$ .** Obtained, in purple crystals, resembling  $KMnO_4$ , S.G. 1.62, by passing  $H_2S$  into a solution of  $NH_4VO_3$  in  $NH_4Aq$  S.G. 898; the solution is saturated in the cold, and is kept cold while  $H_2S$  is passed in. A brown pp. is formed, and this dissolves after passing in more  $H_2S$  to a dark-violet liquid, from which the salt crystallises after some time.

**Sodium monoxo-thio-orthovanadate  $Na_2VOB_2 \cdot 5aq$ .** Obtained by saturating 80 c.c.

$\text{NaOHAq}$  S.G. 1.122, with  $\text{H}_2\text{S}$ , adding a solution of 8 g.  $\text{Na}_2\text{V}_2\text{O}_7$  in 6 c.c. water, cooling the liquid by ice, and passing in  $\text{H}_2\text{S}$  for 4 hours. The salt was also obtained without water of crystallisation by Krüss (*Zeit. f. anorg. Chemie*, 8, 264) by fusing a mixture of  $\text{V}_2\text{O}_5$ ,  $\text{Na}_2\text{CO}_3$ , and S, until excess of S was removed. Small crystals, that melt at the ordinary temperature to a red, oily liquid (K. a. O., l.c.).

**Sodium trioxo-thio-orthovanadate**  
 $\text{Na}_2\text{VO}_3\text{S}$ . 10aq. Obtained by heating  $\text{Na}_2\text{V}_2\text{O}_7\text{Aq}$  to boiling, adding freshly prepared  $\text{NaSHAq}$ , cooling by ice, and adding alcohol. A red oil, that solidifies to a crystalline mass which melts at  $18^\circ$  (K. a. O., l.c.).

**Ammonium monoxo-thio-pyrovandate**  
 $(\text{NH}_4)_2\text{VO}_2\text{S}$ . Formed by passing  $\text{H}_2\text{S}$  into a cooled solution of  $\text{NH}_4\text{VO}_3$  in  $\text{NH}_4\text{Aq}$  S.G. greater than .898, and allowing the liquid to stand for some months, when crystals separate having S.G. 1.715 (K. a. O., l.c.).

**Potassium monoxo-thio-pyrovandate**  
 $\text{KVOS}$ . 8aq. Obtained by passing  $\text{H}_2\text{S}$  into  $\text{KVO}$ , in  $\text{KOH Aq}$  S.G. 1.472, air being excluded and the liquid cooled by ice. Crystals resemble  $\text{KMnO}_4$ ; S.G. 2.144; loses all water slowly at  $150^\circ$ . By evaporating the mother-liquor from this salt *in vacuo*, large crystals of the salt  $2\text{KVOS}$ . 8aq are obtained (K. a. O., l.c.).

**VANADOXYFLUORIDES and Hypovanadoxyfluorides**; v. pp. 844-5.

**VANADYL COMPOUNDS**; compounds of the radicle VO: v. VANADIUM OXYBROMIDES (p. 854), VANADIUM OXYCHLORIDES (p. 854), and HYPOVANADIC SALTS (p. 848).

**VANILLIC ACID** v. Methyl derivative of PROTOCATECHUIC ACID.

**VANILLIN** v. Methyl derivative of PROTOCATECHUIC ALDEHYDE.

**VANILLO-DIACETONAMINE** v. ACETONAMINE.

**VAPOUR DENSITIES**. The term 'vapour density' is now generally employed to signify the specific gravity of a gas referred to hydrogen as unity. For descriptions of the principles of the methods used in determining vapour densities, v. DENSITIES, RELATIVE, vol. ii. p. 374; and for an account of the application of vapour densities to finding molecular weights, v. ATOMIC AND MOLECULAR WEIGHTS, vol. i. p. 340.

**VEGETABLE PROTEIDS** v. PROTEIDS.

**VERATRABINE** v. JERVINE.

**VERATRIC ACID** v. Di-methyl derivative of PROTOCATECHUIC ACID.

**Homo-veratric acid** v. DI-OXY-PHENYL-ACETIC ACID.

**VERATROLE** v. Di-methyl ether of PYROCATECHIN.

**VERATRUM ALKALOIDS**.

**Veratrine**  $\text{C}_{22}\text{H}_{33}\text{NO}_7$ , v. *Cevadine*. [205°]. S. 12 at  $15^\circ$ . Occurs in the seeds of *Veratrum Sabadilla* (Meissner, N. J. T. 5, 3; Pelletier & Caventou, A. Ch. [2] 14, 69; Cœurbe, A. Ch. [2] 52, 862; Merck, A. 95, 200; Ar. Ph. 231, 135; Delondré J. Ph. [3] 27, 417; Weigel, O. C. 1872, 259; Schmidt, Ar. Ph. [3] 10, 611; B. 9, 1115; A. 185, 224). Occurs also in the root of *Sarracenia purpurea* (St. Martin, Z. [2] 2, 442; Hétet, C. A. 88, 185). Prepared by extracting

the seeds with boiling alcohol containing a little tartaric acid, concentrating the extract, adding water, filtering from resin, adding  $\text{Na}_2\text{CO}_3$ , and shaking with ether. The ethereal solution is shaken with dilute tartaric acid solution, and the acid solution mixed with  $\text{Na}_2\text{CO}_3$ , and extracted with ether. The ethereal extract is mixed with ligroin and allowed to evaporate spontaneously, when a viscid mass first separates, followed by crystals which are recrystallised from alcohol (Wright & Luff, C. J. 33, 838). If commercial veratrine [144°] be dissolved in alcohol at  $70^\circ$ , water added till turbidity ensues, and the solution evaporated at  $50^\circ$  to  $60^\circ$ , crystalline veratrine separates first, then a resinous mixture of veratrine and veratridine, while the mother-liquor contains veratridine and veratroin veratrate (Rosetti, Ar. Ph. [3] 21, 81).

**Properties**.—Needles (from alcohol), sol. ether, insol. water. Inactive to light. Very poisonous, a small quantity producing vomiting and purging. Introduced into the nose it produces sneezing. Alkaline to test papers. Conc.  $\text{H}_2\text{SO}_4$  forms a yellow colour changing to crimson, 1 pt. colouring 3,000 pts.  $\text{H}_2\text{SO}_4$  (Vasmer, Ar. Ph. 2, 74). Conc.  $\text{HClAq}$  forms a violet solution on warming.  $\text{HNO}_3$  forms a red solution, becoming yellow. Veratrine mixed with sugar (3 pts.) is coloured by  $\text{H}_2\text{SO}_4$  dark green and finally deep blue (Weypen, Fr. 13, 454). A solution of ammonium selenite (1 g.) in  $\text{H}_2\text{SO}_4$  (20 c.c.) gives a yellow colour at  $30^\circ$ ; in 3 hours a red pp. is formed, the liquid remaining yellow (Da Silva, C. R. 112, 1267). On heating with alcoholic potash or barys. it yields angelic acid and cevine (W. a. L.; Rosetti; Stransky, M. 11, 482).  $\text{ICl}$  forms a yellow flocculent pp., sol. hot  $\text{HClAq}$  (Dittmar, B. 18, 1612). Conc.  $\text{HClAq}$  yields tiglic acid. Veratrine yields tiglic acid and (8)-methyl-pyridine on distillation. On distilling veratrine with lime the products are (8)-methyl-pyridine and Ks hexahydrate and isobutyric acid (Ahrens, B. 23, 2705). Veratrine is not affected by boiling dilute  $\text{H}_2\text{SO}_4$ .

**Salts**.— $\text{B'HC l}$ . Amorphous.— $\text{B'H}_2\text{PtCl}_4$ : amorphous.— $\text{B'HAuCl}_4$ . Yellow needles (from alcohol).— $\text{B'HAuCl}_4$  2aq (Rosetti, J. 1883, 1351).— $\text{B'HHgCl}_2$ . Crystalline pp. v. sol. alcohol.— $\text{B'H}_2\text{SO}_4$  (dried at  $100^\circ$ ).— $\text{B'HI}$ . Reddish-brown amorphous solid (Bauer, J. 1874, 861).

**Benzoyl derivative**  $\text{C}_{22}\text{H}_{33}\text{BzNO}_7$ . [170°-180°]. Brown crystals (containing  $1\frac{1}{2}$  aq) (from ether).— $\text{B'HAuCl}_4$ .

**Tetrabromide**  $\text{C}_{22}\text{H}_{33}\text{Br}_4\text{NO}_7$ . Formed by allowing the tetrabromide to stand in contact with dilute  $\text{KOH Aq}$ . Light-yellow amorphous solid.

**Tetrabromide**  $\text{C}_{22}\text{H}_{33}\text{Br}_4\text{NO}_7$ . Formed by shaking veratrine with bromine-water. Yellow amorphous powder, insol. water, v. sol. alcohol (hard ether (Ahrens, B. 23, 2701).

**Cevine**  $\text{C}_{22}\text{H}_{33}\text{NO}_7$  (W. a. L.);  $\text{C}_{22}\text{H}_{33}\text{NO}_7$  (Rosetti). *Cevadine*. [145°] (W. a. L.); [182°-185°] (R.). Formed by boiling veratrine with alcoholic  $\text{NaOH}$  (W. a. L.). Yellow resin, v. sol. alcohol, sl. sol. ether. Its aqueous solution becomes turbid on warming. Does not attack the mucous membrane, gives a crimson colour with  $\text{H}_2\text{SO}_4$ , and a brown colour with cane-sugar and  $\text{H}_2\text{SO}_4$ . Its salts are amorphous.— $\text{B'HHgI}_2$  (dried at  $100^\circ$ ). Precipitate.

**Veratridine**  $C_{27}H_{45}NO_{11}$  (W. a. L.);  $C_{27}H_{45}NO_{11}$  (Rosetti). *Veratrine*. [180° cor.] (W. a. L.); [160°-165°] (R.). S. 3 at 15°. If the viscid mass which separates before veratrine when a solution of the crude base in alcohol-ligroin is evaporated be shaken with ether, cevadilline remains undissolved, while veratridine dissolves in the ether (Wright a. Luff). Amorphous resin, sl. sol. ether. Decomposed by alcoholic potash into veratric acid and verine  $C_{27}H_{45}NO_{11}$  [c. 95°] (W. a. L.) or veratrin  $C_{27}H_{45}NO_{11}$  [143°-148°] (R.), an amorphous base, sol. ether. Veratridine dissolves in boiling water, being converted into veratrin veratrate  $C_{27}H_{45}N_2O_{11}C_6H_5O_2$  2aq (Rosetti), which melts, when anhydrous, at 165°-170°.  $H_2SO_4$  forms a yellow solution which turns crimson.—Salts.— $B^+HAuCl_4^-$ . Amorphous.— $D^+H_2SO_4$  10aq, crystalline.

**Cevadilline**  $C_{27}H_{45}NO_{11}$ . Obtained as above (W. a. L.). Amorphous, sl. sol. ether, m. sol. benzene. Decomposed by alcoholic potash.

**Salts.**— $B^+HAuCl_4^-$ .— $B^+HHgCl_4^-$ . Gelatinous. Cevadilline is perhaps identical with the sabadilline  $C_{27}H_{45}N_2O_{11}$  of Wiegelin (C. C. 1872, 229), to which Hesse (A. 192, 186) assigns the formula  $C_{27}H_{45}NO_{11}$ ; while sabatrine  $C_{27}H_{45}N_2O_{11}$  (W.) or  $C_{27}H_{45}NO_{11}$  (H.) was probably a mixture of decomposition-products (Wright a. Luff).

**Veratrum album**. The alkaloids in the root of this plant, and in that of *V. viride*, are described under JERUINE.

#### VERATRUMIC ACID IS VERATRIC ACID.

#### VERINE v. VERATRUM ALKALOIDS.

**VERININ**  $C_{27}H_{45}N_2O_{11}$  3aq. Occurs in young vetch plants (*Vicia sativa*), in young red clover (*Trifolium pratense*), in pumpkin seeds, in ergot, and in the blossom of *Corylus avellana* and *Pinus sylvestris* (K. Schulze, J. pr. [2] 32, 47; J. 10, 80, 326). Separated from asparagin by crystallisation from hot water. Minute silky prisms, v. sol. hot water, insol. alcohol. Its aqueous solution is neutral, gives no pp. with  $Pb(OAc)_2$ , but is ppd. by  $AgNO_3$ , by picric acid, and by phosphotungstic acid in presence of HCl. Boiling hydrochloric acid forms guanine.— $Ag_2C_{27}H_{45}N_2O_{11}$ . Gelatinous pp.

**VERNONIN**  $C_{27}H_{45}N_2O_{11}$ . Occurs in the root of *Vernonia nigritiana*, used on the west coast of Africa as a febrifuge (Heckel a. Schlagenhaufen, C. R. 106, 1446). White powder, sl. sol. ether and chloroform, sol. alcohol. Conc.  $H_2SO_4$  gives a brown colour, changing to purple. Cardiac poison, 80 pts. being required to produce the effect of 1 pt. of digitalin. Decomposed by boiling dilute HCl into glucose and a resin  $C_{27}H_{45}O_2$ .

**VICIN**  $C_{27}H_{45}N_2O_{11}$ . S. 1 at 23°. Occurs in the seeds of *Vicia sativa*, *V. Faba*, and *V. Faba minor* (Ritthausen, J. pr. [2] 2, 333; 24, 202; 29, 359). Obtained by extracting the seeds with cold dilute  $H_2SO_4$  (1:50), neutralising with lime, filtering from  $CaSO_4$ , evaporating to dryness and crystallising from 85 p.c. alcohol. The yield is 25 p.c.

**Properties.**—Tufts of small needles, nearly insol. alcohol. Loses  $2H_2O$  at 160°. Sol. alkalis and alkaline earths, reppd. on neutralisation. Not affected by boiling baryta-water. Sol. dilute HCl and  $H_2SO_4$ , but after boiling the solution gives a deep-blue colour with  $FeCl_3$ , and

$NH_3$ , and a violet pp. with baryta. Boiling KOHAq (S.G. 1.1) also forms divicin. When evaporated with  $HNO_3$  (S.G. 1.2) the residue is edged with deep violet. Potash-fusion forms KCy.

**Salts.**— $B^+4H_2SO_4$ .— $B^+11HCl$ . Slender needles.

**Divicin**  $C_{27}H_{45}N_2O_{11}$ . By boiling vicin with water (5 pts.) containing  $H_2SO_4$  (1 pt.) at 0° there is formed crystalline  $(C_{27}H_{45}N_2O_{11})_2SO_4$ , which yields divicin on treatment with exactly the calculated quantity of KOHAq. Flat prisms (from water). Reduces  $AgNO_3$  at once. Not red. by baryta. A little  $FeCl_3$  followed by  $NH_3$  gives a splendid blue colour.  $B^+SHNO_3$ . Whetstone-shaped crystals, got by adding  $HNO_3$  to a solution of divicin.

**Convicin**  $C_{27}H_{45}N_2O_{11}$  2aq. Obtained from powdered vetch seeds by extracting with alcohol, allowing vicin to crystallise from the extract, pp. the mother-liquor with  $HgCl_2$  and potash, decomposing the pp. with aqueous  $H_2S$ , and evaporating. The mixture of vicin and convicin so obtained is treated with dilute  $H_2SO_4$ , which dissolves the vicin only. Thin plates (from water), often resembling leucine. Hardly sol. cold water, sl. sol. alcohol. Not decomposed by boiling KOHAq (S.G. 1.1). Potash-fusion gives off  $NH_3$ , but forms no KCy. Insol. cold dilute HCl and  $H_2SO_4$ . Its aqueous solution gives a flocculent pp. with  $Hg(NO_3)_2$ .

#### VINACONIC ACID v. TRI-METHYLENE D-CARBOXYLIC ACID.

**VINCETOXIN**  $C_{10}H_{12}O_6$  [59°].  $[a]_D = -50^\circ$ . Extracted by milk of lime from powdered asclepias root (Turret, C. R. 100, 277; Pl. [2] 43, 620). Occurs in two forms, one soluble and one insoluble in water. Both forms are levorotatory, amorphous, sl. alcohol, insol. ether. Boiling dilute HCl yields an amorphous, inactive sugar, which does not ferment with yeast.

**VINYL ALCOHOL**  $CH_2=CH.OH$ . This substance might be expected to be identical with aldehyde  $CH_2=CHO$ , but Poleck a. Thümmel (B. 22, 2863) suppose it to be present in ether that has been exposed to air and sunlight, and that its presence is indicated by the formation of a pp.  $C_2H_5OH.HgO.HgCl_2$  when a solution of mercury oxychloride in  $Na_2CO_3$  aq is added to commercial ether. This pp. is white, and is converted by boiling potash into explosive greenish-black 'acetylene mercury'  $C_2H_2.O.Hg$ , and by adding nitric acid to its alkaline solution into  $C_2H_3HgOCl_2$ , which is not explosive.  $H_2S$  passed into water containing the compound  $C_2H_2.O.HgCl_2$  yields (7)-tri-thio-acetic aldehyde [76°].

#### VINYL-DIACETONAMINE v. ACETONAMINES.

**VINYL-AMINE**  $CH_2=CH.NH_2$ . Formed by the action of moist  $Ag_2O$  or of KOHAq on bromo-ethylamine hydrobromide at 48° (Gabriel, B. 21, 1049, 2655). Known only in aqueous solution. Volatile with steam. Decomposes in aqueous solution even in the cold.  $SO_2$  converts it into taurine.

**Salts.**— $B^+HCl$ . Poisonous. Its aqueous solution is decomposed by heat.— $B^+3PiCl_4$ . Crystals, v. sol. water.— $B^+2BiCl_3$ . Minute scarlet hexagonal leaves.— $B^+HAuCl_4$ . Golden crystals.— $B^+C_2H_5N_2O_2$ . [142°]. Slender yellow needles.

**References.**—DI-iodovinylamine.VINYL BROMIDE *v.* Bromo-ethylene.Vinyl tribromide *v.* Tri-bromo-ethane.VINYL CHLORIDE *v.* Chloro-ethylene.VINYL ETHANE *v.* Butylene.VINYL-ETHYL-CARBINOL, *v.* PENTENYL ALCOHOL.VINYL-ETHYLENE *v.* Butene.

VINYL ETHYL OXIDE  $\text{CH}_2\text{CH}_2\text{OEt}$ . (35.5° i.v.). S.G.  $\frac{14.5}{17.5}$  7625. Formed by heating chloro-acetal  $\text{CH}_2\text{ClCH}_2\text{OEt}$  with sodium at 140° (Wialicenus, *A.* 192, 106). Liquid, smelling like ether mixed with allyl compounds. Combines with Cl and Br, forming di-chloro- and di-bromo-di-ethyl oxide. A small quantity (1 g.) of iodine converts large quantities of the oxide (200 g.) into a viscous liquid. Dilute (1:4)  $\text{H}_2\text{SO}_4$  forms aldehyde and  $\text{EtHSO}_4$ .

**Reference.**—CHLORO-VINYL-ETHYL OXIDE.

VINYL-ETHYL-PYRIDINE

$\text{C}_4\text{H}_5\text{NEtCH}_2\text{CH}_2$ . (98°–102° at 21 mm.). Formed by heating  $\text{C}_4\text{H}_5\text{NEtCH}_2\text{CH}_2\text{OH}$  with conc.  $\text{HCl}$  at 170° (Prausnitz, *B.* 25, 2394). Oil, v. sol. ether.— $\text{B}^*\text{H}_2\text{HgCl}_2$ . Needles, sl. sol. hot water.

VINYL IODIDE *v.* Iodo-ethylene.VINYL-MALONIC ACID *v.* TRIMETHYLENE DICARBOXYLIC ACID.

VINYL OXIDE  $(\text{C}_2\text{H}_3)_2\text{O}$ . (39°). Formed by the action of dry  $\text{Ag}_2\text{O}$  on vinyl sulphide (Semmler, *A.* 241, 90).

**Reference.**—HEXA-CHLORO-DI-VINYL OXIDE.o-VINYL-PHENOL  $\text{CH}_2\text{CH}(\text{C}_6\text{H}_4)\text{OH}$ .

*Methyl ether*  $\text{CH}_2\text{CH}(\text{C}_6\text{H}_4)\text{OMe}$ . o-Vinyl-anisole. (c. 198°). S.G.  $\frac{1.5}{1.0095}$ ,  $\frac{30}{30}$  1.0005. Formed from either of the methyl derivatives of o-oxy-phenyl-acrylic acid by successive treatment with  $\text{HI}$  and  $\text{Na}_2\text{CO}_3\text{aq}$  (Perkin, *C. J.* 83, 211; 89, 429). Oil. Polymerises readily (at 150°), forming a glassy mass, which, however, on distillation, regenerates the original oil. It smells like high-boiling coal-tar naphtha. It forms a colourless compound with bromine. Forms a red solid with  $\text{H}_2\text{SO}_4$ .

p-Vinyl-phenol. *Methyl ether*  $\text{CH}_2\text{CH}(\text{C}_6\text{H}_4)\text{OMe}$ . [3°]. (205°). S.G.  $\frac{1.5}{1.0029}$ ,  $\frac{30}{30}$  9956. Formed by distilling methoxy-phenyl-acrylic acid (*q. v.*) and from the same acid by successive treatment with conc.  $\text{HI}$  (S.G. 1.94) and  $\text{Na}_2\text{CO}_3$ .

**Reference.**—Bromo- and Nitro- VINYL-PHENOL.VINYL-PIPERIDINE  $\text{C}_4\text{H}_9(\text{C}_2\text{H}_5)_2\text{N}$  (?)

(147°). Formed by dehydration of oxy-ethyl-piperidine [32°] (Ladenburg, *B.* 22, 2587). Liquid, smelling like tropidine and coniine, v. sol. water.

**Reference.**—Bromo-VINYL-PIPERIDINE.

p-VINYL-ISOPROPYL-BENZENE  $\text{C}_{11}\text{H}_{14}$ , *i.e.*  $\text{C}_6\text{H}_5\text{PrCHCH}_2$ . (204°). S.G.  $\frac{1.5}{1.8902}$ . Formed by distilling cumyl-acrylic acid at 219° or by boiling  $\alpha$ -bromo- $\beta$ -cumyl-propionic acid with  $\text{Na}_2\text{CO}_3\text{aq}$  (Perkin, *C. J.* 1877, ii. 660). Oil, smelling like cumfural aldehyde. Partially polymerises on boiling, and also on keeping, forming a glassy mass, reconverted into the original hydrocarbon by heat. Yields  $\text{C}_{11}\text{H}_{11}\text{Br}$  [71°].

a-VINYL-PYRIDINE  $\text{C}_4\text{H}_5\text{N}$  *i.e.*

$\text{N} \begin{smallmatrix} \text{C}(\text{C}_2\text{H}_5)_2 \\ \text{CH} \end{smallmatrix} \text{CH} \text{CH}_2$ . (159°). S.G.  $\frac{2}{2}$  9985. Formed by passing a mixture of pyridine and

ethylene through a red-hot tube (Ladenburg, *B.* 20, 1648). Formed also by distilling oxy-ethyl-pyridine under high pressure or in presence of  $\text{KOH}$  (Ladenburg, *B.* 22, 2585), and by the action of  $\text{NaOHAq}$  on  $\beta$ -bromo- $\beta$ -pyridyl-propionic acid (Einhorn, *A.* 265, 229). Liquid smelling like conyryne, m. sol. water, v. sol. alcohol. Decomposed by distillation under atmospheric pressure, but boils at 81° under 29 mm. Oxidised by  $\text{KMnO}_4$  to picolinic acid, and reduced in alcoholic solution by  $\text{Na}$  to ethyl-pyridine.—Salts:  $\text{B}^*\text{H}_2\text{PtCl}_6$ . [174°]. Crystals, m. sol. water.— $\text{B}^*\text{HAuCl}_4$ . [144°]. Yellow needles.

Tetra-vinyl-pyridine  $\text{C}_4\text{H}(\text{C}_2\text{H}_5)_3\text{N}$ . (277°). S.G.  $\frac{2}{2}$  10515. Formed in the preparation of  $\gamma$ -ethyl-pyridine by heating pyridine ethyl-iodide in sealed tubes at 320° (Karan, *B.* 25, 2776). Sl. sol. water.— $\text{B}^*\text{H}_2\text{PtCl}_6$ . [175°].— $\text{B}^*\text{HAuCl}_4$ . [148°].— $\text{B}^*\text{HHgCl}_2$ . [146°]. Needles.

VINYL-QUINOLINE *v.* QUINOLYL-ETHYLENE.

VINYL SULPHIDE  $\text{C}_2\text{H}_3\text{S}$  *i.e.*  $\text{S}(\text{CH}_2\text{CH})_2$ . (101°). S.G. .913. Constitutes the chief part of the essential oil of *Allium ursinum* (Semmler, *A.* 241, 90). Liquid, smelling like allyl sulphide.

**Reactions.**—1. Dry  $\text{Ag}_2\text{O}$  forms vinyl oxide.—2. Moist  $\text{Ag}_2\text{O}$  gives aldehyde.—3. Alcoholic  $\text{HgCl}_2$  forms crystals of  $\text{C}_2\text{H}_3\text{ClHgS}$ , which, when heated with potassium sulphocyanide, yields vinyl sulphocyanide.—4.  $\text{PtCl}_4$  added to its alcoholic solution ppts.  $(\text{C}_2\text{H}_3)_2\text{Cl}_2\text{PtS}_2$ , which is decomposed by ammonium sulphide into vinyl chloride and dark-brown  $(\text{C}_2\text{H}_3)_2\text{PtS}_2$ .—5.  $\text{AgNO}_3$  forms  $(\text{C}_2\text{H}_3)_2\text{SAgNO}_3$ .—6.  $\text{Br}$  gives  $(\text{C}_2\text{H}_3)_2\text{SBr}_2$  [195°].—7. *Oxidising agents* yield  $\text{CO}_2$ , oxalic acid, and  $\text{H}_2\text{SO}_4$  only.

VINYL-TOLUIDINE so called is Br-p-TOLYL-DI-ETHYLENE-DIAMINE.

VIOLAQUERCITRIN *v.* this vol. p. 873.

VIOLANTIN  $\text{C}_8\text{H}_8\text{N}_2\text{O}$  4aq. Formed by mixing hot conc. solutions of nitroso- and nitro-barbituric acids (violuric and dilituric acids). Formed also by warming hydruilic acid with dilute  $\text{HNO}_3$  (Baeyer, *A.* 127, 223). Yellowish-white, crystalline powder, decomposed by water into its two component acids, but may be recrystallised from  $\text{HOAc}$  or 50 p.c. alcohol. It is also split up into its components by salts of the stronger acids.

VIOBURIC ACID  $\text{C}_4\text{H}_4\text{N}_2\text{O}$  *i.e.*

$\text{C}_2\text{O}_2 \begin{smallmatrix} \text{NH} \\ \text{NH} \end{smallmatrix} \text{C:NOH}$ . Nitroso-barbituric acid. Mpl.  $\gamma$ . 157.

**Formation.**—1. From hydruilic acid by the action of nitric acid (S.G. 1.2) or nitrous acid (Baeyer, *A.* 127, 200).—2. By heating dilituric (nitro-barbituric) acid with glycerin.—3. By warming ferrous diliturate with  $\text{KCy}$ .—4. By boiling an aqueous solution of alloxantin with hydroxylamine hydrochloride (Pellizzari, *G.* 17, 258).—5. By adding hydroxylamine to an aqueous solution of alloxan (Ceresole, *B.* 16, 1133).—6. By adding  $\text{KNO}_3$  to barbituric acid (Baeyer, *A.* 130, 140).

**Properties.**—Trimetric crystals (containing aq);  $\alpha$ :  $\beta$ :  $\gamma$  = 83:1:192. M. sol. cold water, sl. sol. alcohol. Its aqueous solution is p.p.d. by alcohol.  $\text{FeSO}_4$  gives a deep indigo-blue colour.  $\text{HNO}_3$  forms nitro-barbituric acid.  $\text{Br}$  forms di-bromo-barbituric acid and nitrous fumes. Reducing agents form uranil (amido-barbituric

acid). Conc. HClAq forms hydroxylamine on heating.

**Salts.**—NH<sub>4</sub>A'. Dark-blue prisms.—KA' 2aq. Deep-blue crystals, v. sol. water, forming a blue solution; turned red by excess of KOH. A solution of the K salt in conc. HClAq deposits (KA')<sub>2</sub>(HCl), 6aq. in colourless efflorescent prisms.—BaA', 4aq. Red dimetric tables, nearly insol. cold water.—MgA', 6aq. Purple-red crystals.—PbA', 4aq. Small red crystals.—AgA'.

• **Benzyl ether**  $\text{C}_6\text{H}_5\text{CH}_2\text{O} < \begin{smallmatrix} \text{NH} \cdot \text{CO} \\ \text{NH} \cdot \text{CO} \end{smallmatrix} > \text{C} \cdot \text{NOC} \cdot \text{H}_7$ . [226°]. Formed by the action of benzyl chloride on silver viridate (Conrad a. Guthzeit, *B.* 15, 2849). Silvery scales, sol. hot water and alcohol.

• **VIRIDIC ACID** v. CAFFEYANIC ACID.

**VIRIDINE** C<sub>12</sub>H<sub>15</sub>N. (251°). S.G. 1.024. A homologue of pyridine occurring in coal-tar (Thienius, *C. C.* 1862, 53). Yellowish oil, with slight greenish fluorescence, sl. sol. water, v. sol. alcohol and ether.—B'H<sub>2</sub>PCl<sub>4</sub>. Greenish brown, insol. water, alcohol, and ether. The mercuric chloride double salt melts at 85° and crystallises from water.

**Isomeride** C<sub>12</sub>H<sub>15</sub>N. (230°–235°). Obtained, with other bases, by heating methyl-ethyl-acrolein with alcoholic ammonia (Hoppe-Seyler, *M.* 9, 651).—B'H<sub>2</sub>HAuCl<sub>4</sub> (93°).—B'H<sub>2</sub>H<sub>2</sub>PCl<sub>4</sub> (135°).

**VISCIN** C<sub>10</sub>H<sub>11</sub>O<sub>4</sub> (?). The glutinous constituent of the stalk, leaves, and berries of the mistletoe (*Viscum album*). Extracted from the bark by kneading with water, washing the sticky mass with 90 p.c. alcohol, and extracting the viscin with cold ether. The residue consists of viscacoutchin and woody-fibre (Reinsch, *C. C.* 1861, 146). Colourless, tasteless, semi-fluid mass, S.G. 1.0, decomposed by distillation, yielding oily viscene (226°) S.G. .85, which forms a crystalline Na salt with conc. NaOH aq. Viscacoutchin is very glutinous. Its S.G. is

.978, and it is insol. alcohol and ether, sol. oil of turpentine.

**VISCOSE** is DEXTRANE (q. v.).

**VITELLIN** v. PROTEIDS.

**VITELLOSE** v. PROTEIDS.

**VOLUMES, SPECIFIC; v. SPECIFIC VOLUMES**, p. 498.

**VULPIC ACID** C<sub>10</sub>H<sub>11</sub>O<sub>4</sub>, i.e.

$\text{CPh} \cdot \text{C}(\text{OH}) \cdot \text{C}(\text{Ph}) \cdot \text{CO}_2\text{Me}$ . *Methyl pulvate*.  $\text{CO} \rightarrow \text{O}$

[148°]. Occurs in *Cetraria vulpina*, a lichen growing in Norway, and used there, mixed with nuxvomata, as poison for wolves (Bebert, *A.* 2, 342; Strecker a. Möller, *A.* 113, 56; Spiegel, *B.* 13, 1629; 14, 1686; *A.* 219, 15). The lichen contains 2½ to 4 p.c. of the acid, which may be extracted by warm milk of lime. Vulpic acid is also formed by dissolving pulvic anhydride in a solution of KOH in MeOH. It appears to occur in the lichen *Parmelia parietina* (Berzelius; Stein, *J.* 1864, 553).

**Properties.**—Yellow plates or needles, sol. alcohol and ether, v. c. sol. chloroform, nearly insol. boiling water. Decomposed above 200° into MeOH and pulvic anhydride. Boiling milk of lime converts it into pulvic acid. Boiling KOH aq. forms di-benzyl-glycollic acid and CO<sub>2</sub>.

**Salts.**—NH<sub>4</sub>A'. Yellow crystals, sol. water.—BaA', 2aq. Yellow needles (from water).—BaA', 7aq.—KA' aq. Light-yellow needles, sl. sol. water.—AgA'. Pp. Blackens at 190°.

**Acetyl derivative** C<sub>10</sub>H<sub>11</sub>AcO<sub>4</sub>. [156°]. Colourless needles, insol. NaOH aq.

**Methyl ether v. Di-methyl ether of Pulvic acid.**

**Isovulpic acid** C<sub>10</sub>H<sub>11</sub>MeO<sub>4</sub>. [124°]. Formed, in small quantity, together with pulvic anhydride, by heating vulpic acid at 200° (Spiegel). Thin golden plates (from alcohol). Forms orange solutions in alkalis.

## W

**WACKENRODER'S SOLUTION.** The solution obtained by passing H<sub>2</sub>S for a long time into nearly saturated SO<sub>2</sub> aq. The solution contains H<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, much H<sub>2</sub>S<sub>2</sub>O<sub>4</sub>, H<sub>2</sub>S<sub>2</sub>O<sub>5</sub>, and probably H<sub>2</sub>S<sub>2</sub>O<sub>6</sub>, along with H<sub>2</sub>SO<sub>3</sub>, dissolved colloidal S, and a little S in suspension; v. **CHLORIC ACIDS**, p. 638.

**WALDIVIN** C<sub>10</sub>H<sub>11</sub>O<sub>10</sub>. [230°]. S.G. 1.46. i. 17 at 15°; 8 at 100°. S. (alcohol) .53. Extracted by dilute alcohol from the powdered fruit of *Sinaba waldivia* (Tanret, *Bl.* [2] 35, 191; *J. R.* 91, 886). Hexagonal prisms (containing 4aq.), v. sol. chloroform, insol. ether. Neutral to amus. Inactive to light. Tastes bitter.

**WATER.** H<sub>2</sub>O. (*Hydrogen monoxide*). Mol. w. 17.96. (For physical data v. **Properties**.)

**Occurrence.**—Pure water is never found in nature. The properties of different specimens of naturally occurring waters depend on the impurities they contain, and these impurities are derived from the substances with which the water has come into contact; hence it is customary to classify natural waters in accordance with their origin, as *rain-water*, *surface-water*,

*well-water*, *mineral spring-water*, and *sea-water*.

The composition of the substances found in these waters, and the properties of the waters themselves—that is, of the various more or less dilute aqueous solutions—are discussed in pp. 983–960 of vol. iv. of the **DICTIONARY OF APPLIED CHEMISTRY**. Solid water, more or less pure, is found as ice and snow. Water vapour is a constant constituent of the atmosphere. A great many minerals, and also many organic substances, contain water combined with other compounds.

**Historical.**—In 1781 Cavendish showed experimentally that water was the only product of burning H and O mixed in certain proportions, and that almost the whole of the H and O disappeared. The account of the experiments made by Cavendish was published in 1784 (*T.* 1784, 116).

\*When a mixture of inflammable and dephlogisticated air [i.e. in modern language, hydrogen and oxygen] is exploded in such proportions that the burnt air is not much phlogisticated, the condensed liquor contains a little acid, which is always of the nitrous kind . . . ; but if the proportions be such that the burnt air is almost entirely phlogisticated, the condensed liquor is not at all acid, but

seems pure water, without any addition whatever; and as, when they are mixed in that proportion, very little air remains after the explosion, almost the whole being condensed, it follows that almost the whole of the inflammable and dephlogisticated air is converted into 'pure water' (*l.c.* p. 183).

Translated into modern language, this statement would be taken as asserting that water is formed by exploding a mixture of H and O in proper proportions. It is, however, worthy of note that Cavendish did not himself interpret his experimental results as we interpret them to-day. He regarded 'dephlogisticated air' [oxygen] as 'nothing but dephlogisticated water, or water deprived of its phlogiston.' He said: 'We must allow . . . that inflammable air [hydrogen] is either pure phlogiston . . . or else water united to phlogiston' (*l.c.* pp. 187, 140).

The formation of water by burning H and O was thought of by Cavendish as the restoration of phlogiston to water that had been deprived of this principle. 'Water,' he said, 'consists of dephlogisticated air united to phlogiston.' Cavendish evidently thought of H and O as what we might now call *forms of water*; one of these was water with too little phlogiston, and the other was water with too much phlogiston; the explosion restored the phlogistic balance, and the properties of water were apparent. When Lavoisier had interpreted Cavendish's results, Cavendish spoke of Lavoisier's explanation as an hypothesis: 'According to this hypothesis we must suppose that water consists of inflammable air united to dephlogisticated air' (*l.c.* p. 150). Cavendish established the fact that water is the product of burning a mixture of H and O in the ratio (approximately) of 2 vols. H to 1 vol. O; but he stated this fact, in language that no longer carries a definite meaning with it. Lavoisier added to the experimental basis whereon the fact rested, and he expressed the fact in language that still is clear, definite, and descriptive.

**Formation.**—1. By the direct union of H and O by igniting a mixture of these elements. 2. By deoxidising metallic oxides, and many other compounds that contain O, by heating with H.—3. By the decomposition of many compounds containing H and O, by heat, or by reactions with other substances.

According to Freyer & V. Meyer (*B.* 25, 622), a mixture of H and O in the ratio 2H:O does not explode when slowly passed through a glass tube at 606°, and the temperature of ignition of the wet, gaseous mixture is between 650° and 730°. Askenasy & V. Meyer (*A.* 269, 49) found that when pure, dry electrolytic gas was passed at a moderate rate through a glass tube heated to 518°, only 0.7 to 1.7 mgms. of water were produced in ten hours; and that a little more water, but still only a very small quantity, in proportion to the total quantity of H and O, was formed at 606°. Experiments made to determine the relation between the quantity of water formed and the time of the experiment showed that no constant relation could be arrived at, even when every precaution was taken to insure equality of conditions; the irregular action of the surfaces of the vessels was probably the cause of the irregularities in the results.

Davy (*T.* 1817) found that electrolytic gas did not explode when the pressure was so reduced

that the gas was rarefied to  $\frac{1}{3}$  of its ordinary density. Thomas (*O. J.* 36, 215) found that the gas exploded at 168 mm. pressure. L. Meyer & Seubert (*C. J.* 46, 586) found that the sparks from a Ruhmkorff coil caused the combination of 0.2 of a quantity of electrolytic gas at 0.70 mm. pressure, and that the remainder combined when the pressure was increased until it became the same as before the first explosion; this result is in keeping with Bunsen's determinations of the quantity of oxygen needed to prevent the explosion of 2H + O (*v. M. a. S.* 7, c. p. 588). Dixon (*T.* 1884, 634) noticed that electrolytic gas did not explode at a pressure under 70 mm., but that explosion occurred under 75 mm. pressure (*cf. D.*, *l.c.* p. 642).

According to the experiments of Dixon (*l.c.*), 'the union of oxygen and hydrogen is not affected by the presence or absence of water'; dry electrolytic gas exploded by the spark at a pressure between 70 mm. and 75 mm., and the wet gas exploded at the same pressure.

The velocity of explosion of electrolytic gas was found by Berthelot and Vieille (*C. R.* 95, 151) to be 2,810 metres per second (*cf. Explosion*, vol. ii. p. 530).

**Preparation.**—Stas (*Chem. Propert.* 110) prepared pure water as follows. When large quantities were required, spring-water was *very slowly* distilled through a long copper tube, bent into zigzag form, completely filled with pure copper turnings that had been oxidised by strongly heating in O, the copper tube being surrounded by alumina and sand, and heated to full redness; the distillate was then distilled in an apparatus of platinum.

The second method recommended by Stas, especially when comparatively small quantities of pure water are required, is based upon destroying the organic matter in distilled water by the action of K manganate and permanganate. The process is described by Stas as follows:—

I prepared potassium manganate by reacting on manganese oxide with caustic potash and potassium chlorate. I shook up the powdered product with water, just sufficient to dissolve the manganate that had been formed, and allowed the mixture to settle in a closed vessel. I then added 4 or 5 p.c. of the clear, dark-green solution to the spring water which was to be distilled, and allowed the components of this mixture to react for 24 hours. I then poured into the distillation vessel one or two litres of the conc. solution of potassium manganate that had been mixed with an equal volume of conc. caustic potash solution; this solution of potash was sufficiently conc. to make the salt so stable that its dilute solution could be heated for a long time without decomposition. I then filled the distillation vessel to  $\frac{2}{3}$  with the water which had been in contact with the potassium manganate, and distilled in the ordinary way. When boiling began I moderated the heat, in order to prevent the liquid, which frothed much for some minutes, from passing over. When the frothing had stopped, the water *slowly* boiled rapidly without the least inconvenience. When  $\frac{1}{2}$  of the water has distilled over, that which then distils is completely free from organic substances, and also from mineral substances, if the upper part of the distillation vessel is furnished with disengagers to hold back the extremely small drops that are always carried forward when a liquid is boiled vigorously.

Stas says that water thus prepared is perfectly free from organic matter. When he wished to obtain water absolutely free from any form of solid matter, Stas re-distilled the water that had been purified as described above, using as condenser a long tube of platinum soldered with gold. It is advisable to distil the water just before it is to be used.

On one occasion Stas used rain-water instead of well-water, and he found distinct quantities of ammonia in the distilled water thus prepared. To remove this he recommends to re-distil with this part of  $\text{NaHSO}_4$  or  $\text{KHSO}_4$ .

**Composition of water.**—The gravimetric composition of water was determined by Berzelius & Dulong (*A. Ch.* [2] 15, 86) and by Dumas (*A. Ch.* [8] 8, 189) by passing pure H over a weighed quantity of red-hot  $\text{CuO}$ , and weighing the water produced and the copper which remained. The results gave the ratio  $\text{H}:\text{O}=1:8$  (B. a. D.) and 1:7.98 (U.). An extended series of measurements by the same method, with many precautions, by Dittmar & Henderston (*C. N.* 67, 127, 139, 151, 164 [1893]) gave the ratio  $\text{H}:\text{O}=1:7.9827$ .

Several measurements have been made of the proportion by volume in which H and O combine to form water. Gay-Lussac in 1805, and Humboldt in 1805 (*A. Ch.* 53, 239), found the volumetric ratio of  $\text{H}:\text{O}$  to be 2:1. Morley, in 1891 (*Am. S.* [3] 41, 220, 276), determined the ratio of  $\text{H}:\text{O}$  to be 2.00023:1 by directly measuring the volumes of the gases. In 1892 Leduc (*C. R.* 116, 1248) found the ratio  $\text{H}:\text{O}=2.0037:1$ , from determinations of the relative densities of H, O, and electrolytic gas. In 1893 Scott (*T.* 184, 543) completed a most carefully performed series of syntheses of water by sparking mixtures of H and O, and determined the most probable value of the volumetric ratio  $\text{H}:\text{O}$  to be 2.00245:1.

**Properties.**—Water is a clear, transparent, almost colourless, tasteless, odourless liquid. A column of water appears slightly blue when looked at lengthwise. Bunsen (*A.* 72, 44) pointed out that the slight blue colour of water may be observed by looking at a shining white object through a column of water 2 metres long, contained in a tube blackened inside. V. Meyer (*B.* 15, 297) recommends to join five wide, thin-walled glass tubes, c. 40 mm. internal diameter, and each c. 1½ metres long, by wide caoutchouc tubing, and thus to form a tube c. 7½ metres long; to lay the tube perfectly horizontal, and to close the end by smooth glass plates held in position by metallic clasps; then to cover the tube with black cloth. On looking through the tube the field of view appears quite colourless, but on now filling the tube with pure water (by means of brass tubes passing through the metallic clasps) a deep-blue colour is seen on looking through the column of water.

The boiling-point of water is  $100^\circ$  under the pressure of 760 mm. Zeuner (*Grundzüge der mechanischen Wärmetheorie*, Tab. 19 [1877]) gives the following table, showing the increase of boiling-point with increase of pressure:—

Pressure in atmos.	Boiling-point.	Pressure in atmos.	Boiling-point.
1 . . .	100	8 . . .	179.81
2 . . .	120.6	9 . . .	176.77
3 . . .	133.91	10 . . .	180.31
4 . . .	144	11 . . .	184.60
5 . . .	152.22	12 . . .	188.41
6 . . .	159.22	13 . . .	192.08
7 . . .	165.84	14 . . .	195.53

An elaborate table is given by Broch (*Trav. et Mém. des Bureaux Internat. des Poids et Mes.*,

1, 46 [1891]) based on Regnault's determinations; the table gives the b.p. of water for each .1 mm. from 680 to 800 mm. pressure. (The table is given in Landolt & Börnstein's *Physikalisch-Chemische Tabellen* [Berlin, 1883], pp. 47-49.)

The melting-point of ice is slightly lowered by pressure. J. Thomson (*T. E.* 16) calculated that the m.p. would be lowered by  $n \cdot 0075^\circ$  for an increase of  $n$  atmospheres; W. Thomson (*P. M.* [3] 37, 123) confirmed this calculation by determining the m.p. of ice at 8.1 and 16.8 atmos. Mousson (*A. Ch.* [3] 56, 252) kept water liquid, at  $-5^\circ$  by greatly increasing pressure, and he found that at c. 13,000 atmos. pressure ice melted at  $-13^\circ$ .

The specific gravity of water is greater at  $4^\circ$  than at any other temperature. Exner gives the temperature of maximum density as  $3.946^\circ$  (older determinations are tabulated by Exner, *W. A. B.* 68 (ii), 463 [1873]). The following table, showing the density and volume of water from  $0^\circ$  to  $100^\circ$ , is given by Volkmann (*W.* 14, 260 [1881]); it is based on the determinations of Hagen, Matthiessen, Pierre, Kopp, and Jolly:

Temp.	Density (in vacuo) i.e. wt. of 1 c.c. water in grams.	Volume of 1 gram water in c.c.
0	.999878	1.000122
1	.999933	1.000067

100	.95856	1.04323

Rossetti (*P. Ergänzbd.* 5, 268 [1871]) gives the densities and volumes of water for each degree from  $-10^{\circ}$  to  $100^{\circ}$ , referred both to water at  $0^{\circ}$  and to water at  $4^{\circ}$  as unity. The S.G. of ice is c. .916 at  $0^{\circ}$  (water at  $0^{\circ}=1$ ); according to recent determinations by Zakrzewski (*W.* 47, 155 [1895]) the value is .916660.

The expansion of water for various intervals of temperature has been measured by various observers; putting  $V_t = V_0 (1 + at + bt^2 + ct^3)$ , the following values are given by Kopp (*P.* 72, 1 [1847]); cf. Pierre, *P.* 86, 451; Weidner, *P.* 123, 300; Matthiessen, *P. M.* [4] 31, 149; Rossetti, *P. Ergänzbd.* 5, 258; Hirn, *A. Ch.* [4] 10, 32):

Temp.	a
$0^{\circ}$ to $25^{\circ}$	.000061045
$25^{\circ}$ to $50^{\circ}$	.000065415
$50^{\circ}$ to $75^{\circ}$	.00005916
$75^{\circ}$ to $100^{\circ}$	.00008615

For the expansion of water above  $100^{\circ}$  v. Mendeleeff (*A.* 119, 1).

As water freezes it expands by c.  $\frac{1}{11}$  of its volume; one volume of water at  $0^{\circ}$  becoming 1.09082 volumes of ice at  $0^{\circ}$ .<sup>10</sup> It expands when heated at temperatures below  $0^{\circ}$ ; Zakrzewski (*W.* 47, 155) gives the co-efficient of expansion .000077 (v. also Brunner, *P.* 64, 116; Struve, *P.* 66, 298; Marchand, *J. pr.* 35, 254).

The compressibility of water is small. Röntgen a. Schneider (*W.* 33, 644) give the absolute compressibility at  $17.5^{\circ}$  as .0000462 per atmosphere of pressure (v. also Ramsay a. Young, *T.* 1892; and cf. Grassi, *A. Ch.* [3] 31, 437; and Rankine, *P. M.* [4] 1, 548; also Amaury a. Descamps, *C. R.* 68, 1564; and Calvetet, *C. R.* 75, 77).

A table showing the volume of 1 kilo. of

saturated water vapour and the weight (in kilos.) of 1 c. metre of the vapour, at temperatures from  $0^{\circ}$  to  $200^{\circ}$ , is given by Zeuner (*v. Landolt a. Börnstein's Physikalisch-chemische Tabellen* [Berlin, 1883], p. 53; cf. Dieterici, *W.* 38, 1). According to Dieterici (l.c.) water vapour saturated at  $0^{\circ}$  behaves like a perfect gas.

The vapour pressure of water varies from 1.0288 mm. at  $-19^{\circ}$  to 20926.4 mm. at  $230^{\circ}$ ; for complete tables calculated from Regnault's determinations v. Landolt a. Börnstein's *Physikalisch-chemische Tabellen* [Berlin, 1883] pp. 40-46 (the vapour pressure is given for each  $1^{\circ}$  from  $-19^{\circ}$

b	c
.0000077183	.00000003734
.0000077587	.000000035408
.0000031849	.000000072848
.0000031892	.000000024487

to  $101^{\circ}$ , and for each  $1^{\circ}$  from  $101^{\circ}$  to  $230^{\circ}$ ). Ramsay a. Young (*T.* 1892) give a table of the vapour pressures of water up to  $270^{\circ}$ . In connection with the vapour pressures of water and ice, v. R. a. Y. (*T.* 1884, 470). For an expression representing the vapour pressure of water at any temperature up to  $325^{\circ}$ , v. Antoine (*C. R.* 113, 328).

The spec. heat of water increases as temperature rises; the quantity of heat required to raise 1 g. of water from  $t^{\circ}$  to  $t^{\circ}+1$  is taken as unity in determinations of the spec. heats of other substances. The following table presents the data for S.H. of water at intervals of  $10^{\circ}$  from  $0^{\circ}$  to  $230^{\circ}$  (the memoirs by the different observers are: Regnault, *Acad.* 21, 729, [1847]; Jamin a. Amaury, *C. R.* 70, 661 [1870]; Bosscha, *P. Jubelbd.* 549 [1874]; von Münchhausen, *W.* 1,

$t^{\circ}$ (after therm.)	Regnault	Jamin a. Amaury	Bosscha	v. Münchhausen	Henrichsen	Baumgartner

592; 10, 284 [1877 and 1880]; Henrichsen, W. S. 83 [1879]; Baumgartner, W. S. 648 [1879].

The following values for S.H. of water, from 0° to 85°, are given by Bartoli a. Stracciati (*A. Ch.* [6] 29, 285); the values in the column 'calculated' were obtained by using the formula:

$$\begin{aligned} \text{S.H.} &= 1.006630 \\ &- .000593962t \\ &+ .000004338650t^2 \\ &+ .000000425520t^3 \\ &- .000000002819t^4 \end{aligned}$$

The unit is the quantity of heat given out by 1 gram water at 15° in cooling, to 14°.

°	S.H. calcd.	S.H. observed.

The S.H. of ice is considerably less than that of water; Regnault's determinations gave 47° between -75° and 0°; the determinations of Person a. Desains gave 504 between -20° and 0°; Ramsay a. Young (*T.* 1884, 475) give the value 5 as the mean of various experiments. S.H. of water gas at 100° is given by Strecker (*W.* 37, 85) as .37 referred to an equal weight of water = 1, and 1.36 referred to an equal volume of

air = 1; the ratio  $\frac{\text{S.H.p.}}{\text{S.H.v.}}$  given by S. is 1.4. Jaeger (*W.* 36, 165 [1889]) gave the value 1.33 to this ratio, and Cohen (*W.* 37, 628 [1889]) gave the value 1.287 for the temperature interval 144° to 800°.

The heat of vaporisation of water—i.e. the quantity of heat required to convert 1 g. of water at 100° into steam at 100°—is 835.77

gram-units, according to Favre a. Silbermann (*A. Ch.* [3] 87, 461). The following values are given for the heat required to convert 1 g. of water at  $t^\circ$  completely into water vapour; 606.5 when  $t = 0^\circ$ , 637 when  $t = 100^\circ$ , 676.6 when  $t = 230^\circ$  (Regnault, *Acad.* 21, 635); Dieterici (*W.* 38, 1) gives 596.8 when  $t = 0^\circ$ ; Regnault (*l.c.*) gives the formula  $\lambda = A + Bt$  for the total heat of vaporisation of water at different temperatures, and gives the values  $A = 606.5$ ,  $B = .305$ .

According to Sakhrat (*C. J.* 61, 495 [1892]), the temperature of the steam escaping from a boiling salt solution is exactly the same as that of the solution.

The heat of fusion of ice, i.e. the quantity of heat required to convert 1 g. of ice at  $t^\circ$  into 1 g. of water at  $t^\circ$  is given as follows by different observers (the values are in gram-units of heat): -79.24 and 79.06 when  $t^\circ = 0^\circ$  (Regnault, *A. Ch.* [3] 8, 19); 79.25 when  $t = 0^\circ$ , 74.2 when  $t = -10^\circ$ , 80.22 when  $t$  varies from  $-2^\circ$  to  $-21^\circ$  (Person, *A. Ch.* [3] 21, 295; 30, 73); 77.85 at  $-2.8^\circ$ , 76.75 at  $-4.995^\circ$ , 76.11 at  $-6.28^\circ$ , 76.0 at  $-6.6^\circ$  (Pettersson, *J. pr.* [2] 24, 129).

The thermal conductivity of water, from 10° to 18°, was determined by Winkelmann (*P.* 153, 481) to be 154; Bottomley (*Pr.* 31, 300) obtained nearly the same value; this figure means that heat sufficient to raise 154 mgm. water from 0° to 1° passes per second through a layer of water 1 mm. thick and 1 sq. mm. area, when the difference between the temperatures of the two surfaces of the layer is maintained at 1°. For electrical conductivity of water *v. Reactions*, No. 2.

The refractive indices of water at different temperatures, and for different lights of determinate wave-lengths, have been measured by many observers. The following values have been found for  $\mu_D$ : 1.33120 at 19.9°, 1.33001 at 23.7°, 1.33050 at 25° (Brühl, *B.* 24, 644). For detailed tabulation of the results obtained by Fraunhofer, van der Willigen, Baillé, Damien, Landolt, Wüllner, and Rühlmann, *v. Landolt a. Börnstein's Physikalisch-Chemische Tabellen* [Berlin, 1883] 205; *cf.* also Perkin (*C. J.* 61, 293), who gives values for  $\mu$  for the lines A C D and F, at 15° and 83.7°.

Observations have been made on the absorption spectrum of water and water-gas, but the matter has not been thoroughly investigated (*v. Vogel*, *P.* 156, 326; Jansen, *B.* A. 1866, 11).

Water crystallises, as ice, in rhombohedral forms; snow is generally found crystallised in six-sided stars derived from six-sided prisms.

Molecular weight of liquid water. Several observations have been made which tend to show that the molecular weight of liquid water is greater than 18. Paterno (*B.* 21, 3180), from measurements of the lowering of the freezing-point of water dissolved in acetic acid, concluded that the mol. w. might be 19, or might perhaps be 36. From the depression of the freezing-point of paratoluidine by water dissolved therein, Eykman (*Z. P. C.* 4, 510) concluded that the mol. w. of liquid water is probably 36, and this conclusion was strengthened by Walker's experiments on the connection between heats of fusion and solubility (*Z. P. C.* 5, 194). From measurements of the surface tension of water Ramsay and Shields (*C. J.* 68, 1069 [1893]) con-

clude that the mol. w. of liquid water is probably 72 at the ordinary temperature.

**Reactions.**—1. In 1847 Grove (*T.* 1847. 1) showed that water was decomposed into H and O by heat. Grove formed a little ball on the end of a Pt wire, by fusing the Pt, heated the globe of Pt to whiteness by an electric current, and plunged it into a little air-free water, nearly boiling, in a small basin, with a test tube full of air-free water arranged to collect any gas that might come off. Deville (*C. R.* 56, 195, 322 [1863]) found that H and O were given off in considerable quantities when molten Pt was plunged under water. D. noticed no decomposition when steam was passed through a Pt tube heated to bright redness, but by passing a current of an indifferent gas, such as CO, through the hot tube, and thus sweeping away the products of decomposition, H and O were obtained.—2. Water is scarcely decomposed by an electric current. Kohlrausch found the electrical conductivity of the purest water he could obtain by distillation *in vacuo* to be  $2.5 \times 10^{-6}$  in C.G.S. units, or c. 72 billionths of the conductivity of Hg (*P. M.* [5] 18, 542). By calculations based on this result, Ostwald concluded that in a litre of pure water the weight of water dissociated into H and OH ions, expressed in gram-molecules, is  $6 \times 10^{-8}$  (*Z. F. C.* 11, 521). By other methods of calculation, based on other data, Ostwald arrived at the value  $2$  to  $9 \times 10^{-6}$  for what has been called the *dissociation constant* of water (*Z. P. C.* 11, 521); Wijs, by calculations based on the hydrolysis of methyl acetate, obtained the values  $1 \times 10^{-14}$  (*Z. P. C.* 11, 492), and  $14 \times 10^{-14}$  (*ibid.* 12, 514); Arrhenius obtained the value  $1125 \times 10^{-16}$  (*ibid.* 11, 827); and Bredig, the value  $6 \times 10^{-16}$  (*ibid.* 11, 829). Later experiments on the conductivity of water by Kohlrausch and Heydweiller (*Z. P. C.* 14, 316 [1894]) with water that had been distilled *in vacuo* ten years ago, had then stood in a vessel filled with water, and been again distilled *in vacuo*, gave the following results:—conductivity (Hg = 1) .014 at 0°, .04 at 18°, .058 at 25°, .089 at 34°, .176; all these to be multiplied by  $10^{-10}$ . K. a. H. say that 1 mm. of this water at 0° had a resistance = that of 40 million kilometres of Cu wire of the same area. K. a. H. calculate that in 1 litre of the purest water at 18° there is .00008 mgm. H as free ions, and .000105 mgm. at 25°.—3. Steam is decomposed by electric sparks; for condition and details of results v. Thomson (*Pr.* 53, 90).

The reactions of water are so many that an approximate classification of them into groups is all that can be attempted here.—4. Many *metals* react with water, at temperatures varying from the ordinary to a full red heat, forming oxides or hydroxides and giving off H. The following metals decompose cold water: Ba, Sr, Ca, (Ce?), (La?), Li, K, Rb, Na, St. Al, Fe, Pb, Mg, (Mn), Mo, Si react at c. 100°; and most of the other metals at temperatures from c. 100° to a full red heat.—5. Many *non-metals* react, generally slowly, with water, forming acids and giving off O. F rapidly decomposes water at the ordinary temperature; Cl reacts slowly at the ordinary temperature, and somewhat more rapidly at a red heat; Br reacts more slowly than Cl; I has probably a very slight (any) action. S and P react slowly at 100°; Se is said not to

decompose water at 160°. Carbon gives off H at a red heat. Boron acts like a metal, giving off H at a red heat.—6. Many *haloid compounds* react with water, giving oxyhaloid compounds or oxides, and haloid acids.—7. Some *metallic sulphides* react with steam to form oxides and H<sub>2</sub>S. 8. A few of the *lower oxides* decompose water; e.g. CrO<sub>2</sub>·xH<sub>2</sub>O at the ordinary temperature, and CO at c. 600°.—9. Water reacts with many *oxides* to form hydroxides which are either basic or acidic; in some cases hydrates are formed. Hydrates of various *salts* are also produced by combining the salts with water (v. *HYDRATES*, vol. ii. p. 703; cf. *HYDROXIDES*, vol. ii. p. 733).—10. Water *dissolves* very many compounds of the most different properties (v. *SOLUTIONS*, vol. ix. p. 484).

Small quantities of water often bring about chemical changes that do not occur when the substances are perfectly dry; for instance, a mixture of dry CO and O is not exploded by sparks, but a trace of water suffices to start the change (v. Baker, *C. J.* 65, 611 [1894]).

The acidic and basic characters of water are so nearly balanced that the compound cannot be classed among either acids or basic bodies. The chemical relations of water to the compounds formed by reactions between it and other substances are determined chiefly by the chemical characters of the substances that react with it; thus the relations of HOH to M<sub>2</sub>(OH)<sub>2</sub>, formed by the interaction of water and metals, are those of an acid to its salts, whereas the relations of HOH to HX, formed by the interactions of water and non-metals, are those of a basic hydroxide to salts derived therefrom. The relations between both classes of derivatives of water and the parent compound are sometimes expressed by saying that the compounds belong to the *water type* (v. *TYPES*, vol. iv. p. 811). M. M. P. M.

**WAX.** A term applied to various natural solids more or less resembling bees'-wax. They are compound ethers, but differ from fats in yielding monovalent alcohols and not glycerin on saponification. They melt below 100°, are insol. water, sl. sol. or insol. alcohol, and sol. ether. They are not volatile.

**Bees'-wax.** [64°]. S.G. .965. Consists of a portion (about 5 p.c.) soluble in alcohol (cerin) and a portion insoluble in alcohol (myricin). Myricin is myricyl palmitate (Brodie, *A.* 67, 180; 71, 144). Cerin is chiefly composed of cerotic acid; but it contains small quantities of melissic acid C<sub>26</sub>H<sub>52</sub>O<sub>2</sub> [90°], and an acid melting at 78° (Schalfejeff, *B.* 9, 278, 1688; Natzger, *A.* 224, 246). There is also present one or more acids whose lead salts dissolve in ether and whose Ba salts dissolve in alcohol, and which therefore probably belong to the oleic series. Myricin may be saponified by alcoholic potash, and the myricyl alcohol separated from potassium palmitate by extraction with ligroin. Crude myricin yields CCl<sub>4</sub> and C<sub>2</sub>Cl<sub>4</sub> when heated with I and excess of SbCl<sub>5</sub> at 400° (Hartmann, *B.* 24, 1022). Bees'-wax containing two hydrocarbons, one of which [60°] (c. 275° at 11 mm.) is probably *n*-heptaicosane C<sub>27</sub>H<sub>56</sub>, and the other [68°] (c. 340° at 11 mm.) *n*-hentriacontane C<sub>31</sub>H<sub>62</sub> (Schwalb, *A.* 235, 106). According to Schwalb, the myricyl alcohol of bees'-wax has the formula C<sub>31</sub>H<sub>62</sub>O [85°], and is converted by heating with

soda-lime into an acid  $C_{11}H_{19}O_2$  [89°], which forms a methyl ether [71°] and an ethyl ether [70°]. Among the products of saponification of bees'-wax, ceryl alcohol  $C_{27}H_{54}O$  or  $C_{28}H_{56}O$ , and an alcohol  $C_{26}H_{52}O$  or  $C_{27}H_{54}O$  occur. The last-mentioned alcohol when heated with soda-lime gives an acid  $C_{26}H_{50}O_2$  or  $C_{27}H_{52}O_2$  [75.5°].

**Carnauba wax** v. vol. i. p. 710.

**Chinese wax**, which is produced by an insect, is almost entirely composed of ceryl cerotate ( $C_{27}H_{54}O_2$ ),  $C_{27}H_{54}O_2$  (Brodie, A. 67, 199).

**Cork wax** v. CORK.

**Pine wax** v. CROTOPIC ACID.

**Sugar-cane wax** v. CEROSEIN.

**Japan wax**. [42°-55°]. Obtained in the East from *Rhus succedanea*. It appears to be really a fat, since palmitin is its chief component. It also contains the ether of a fatty acid of higher melting-point than stearic acid (Sthamer, A. 43, 343; Buri, Ar. Ph. [3] 14, 403).

**Wax of Ficus gumiflua** of Java contains an alcohol  $C_{11}H_{22}O$  [73°], v. sol. ether, and a small quantity (5 p.c.) of isoceryl alcohol  $C_{27}H_{54}O$ , sl. sol. ether (Kessel, B. 11, 2112).

**Myrtle wax**. [49°]. Got by boiling the berries of *Myrica cerifera* of North America with water (Moore, J. 1862, 500). Consists of palmitic and some lauric acid and (20 p.c.) of palmitin.

**Opium wax**. Contains ceryl cerotate and ceryl palmitate (Hesse, B. 3, 637).

**Tobacco wax**. Contains  $C_{26}H_{52}O_2$  [63°], insol. cold alcohol, sol. ether and a small quantity of  $C_{26}H_{52}O_2$  [64.5°], nl. sol. cold ether (Kissling, B. 16, 2433).

**Coca leaf wax** (Hesse, A. 271, 214). The wax from Trujillo coca is palmityl-( $\beta$ )-amyrin  $C_{46}H_{90}O_2$  [ $\alpha_D = 54.5^\circ$ ]. On saponification it yields palmitic acid and ( $\beta$ )-amyrin  $C_{26}H_{50}O$  [196°] [ $\alpha_D = 94.2^\circ$ ], which yields an acetyl derivative [236°] and a benzoyl derivative [228°]. The wax from the broad-leaved coca of Peru and Bolivia melts at 70°; contains palmityl-( $\beta$ )-amyrin and a ketone, ( $\beta$ )-cerothinone  $C_{26}H_{50}O$  [66°], m. sol. alcohol, ether, and ligroin. The wax from Java coca contains the same substances, and also some ceryl cerotate and ethers of myristic acid and of oyceroic acid  $C_{27}H_{54}O_2$  [83°], which is v. e. sol. hot alcohol and ligroin, v. sl. sol. ether, and is converted by  $Ac_2O$  at 100° into cerotic acid  $C_{27}H_{54}O_2$  [70°].

**WHEY-PROTEID** v. MILK.

**WINE OIL**. Light oil of wine. An oil-obtained in the preparation of ether by distilling alcohol with  $H_2SO_4$ . The ether is shaken with milk of lime and fractionally distilled, the successive fractions being ether, alcohol, and wet alcohol. Light oil of wine (25 to 3 p.c. of the alcohol etherified) rises to the surface when the last fraction (90°-120°) is allowed to stand. When dried over  $CaCl_2$  it has S.G. 0.903. It contains  $C_{15}H_{32}$  (157),  $EtOC_8H_{17}$  (112°),

$Et.CO.O.C_8H_{17}$  (154°), and  $CH_3.CO.O.C_8H_{17}$  (164°) (Hartwig, J. pr. [2] 23, 449).

**Heavy oil of wine**, which passes over when the temperature is raised after the preparation of ether, consists of  $Et.SO_4$  mixed with olefines (Claesson, J. pr. [2] 19, 259; Serullas, A. Ch. [2] 89, 152).

**WINTERGREEN OIL** contains methyl o-oxymethylene.

**WINTERENE**  $C_{10}H_{18}$ . (260°-265°). S.G. 0.934. [ $\alpha_D$ ] 11.2° at 16°. A dextrorotatory sesquiterpene obtained by distilling winterbark (from *Dryas Winter-Forster*) with water (Arata a. Canzoneri, G. 18, 527). Coloured green by Br in  $CHCl_3$ .

**WOOD** v. LIGNONE.

**WOOD GUM** v. XYLEN.

**WOOD NAPHTHA** v. METHYL ALCOHOL.

**WOOD OIL**. *Gurjun Balsam*. Flows from incisions in the stem of *Dipterocarpus costatus*. It contains an essential oil, which gives a splendid violet colour when its solution in  $CS_2$  (20 pts.) is treated with a drop of a cold mixture of  $HNO_3$  and  $H_2SO_4$ . The same reaction is exhibited by the balsam itself, and also, in a more transient manner, by cod-liver oil and copaiba balsam (Flückiger, Ph. [3] 7, 2). The essential oil consists chiefly of a terpene (255°) (Werner, J. 1862, 461), which composes 65 p.c. of the balsam (Guibourt, J. 1876, 907). The resin contains a neutral substance,  $C_{26}H_{50}O_2$ , which crystallises from light petroleum in triclinic prisms [120°-130°]; it dissolves in conc.  $H_2SO_4$ , and is reprecipitated from the resulting reddish solution by adding water. It is not affected by potash-fusion (Flückiger, Ar. Ph. [3] 12, 59). A substance  $C_{26}H_{50}O_2$  [129°] is described by Brix (M. 2, 516) as ppd. by adding water to an alcoholic extract of wood oil. It is neutral and insol. alkalis, and yields a diacetyl derivative (75°). It is perhaps identical with the compound  $C_{26}H_{50}O_2$ . Wood oil also contains gurjunic acid  $C_{26}H_{50}O_2$  [220°], which crystallises from alcohol, distils with decomposition at 260°, and forms  $Ag_2A'$ .

**WOOD SPIRIT** v. METHYL ALCOHOL.

**WORMSEED OIL**. *Oleum Cins.* Obtained by steam-distillation from wormseed, the flower-buds of *Artemisia Vahlana*, A. Sieber, and *A. incalla* (Trommsdorff, Tr. N. J. 8, 812; Völckel, A. 33, 110; 87, 312; Hürzel, J. 1854, 591; 1855, 655; Kraut a. Wahlforss, A. 128, 293; Faust a. Homoyer, B. 7, 1429; Hell a. Ritter, B. 17, 2609; Wallach a. Brass, A. 225, 291). It consists chiefly of cineol  $C_{15}H_{26}O$ . Wormseed (*A. Gallica*) also contains betaine and choline (Jahns, B. 26, 1493).

**WRIGHTINE**  $C_{15}H_{26}N$ . [122°]. Occurs in the juice of *Wrightia antidysenterica* (Stenhouse, Ph. [2] 5, 493; Warnecke, B. 10, 60). Needs with bitter taste, sl. sol. water, v. sol. alcohol and ether. Conc.  $H_2SO_4$ , at 100° gives a dark green colour, turned dark blue by adding water. Wrightine is probably identical with conessine (q. v.).

## X

**XANTHALINE**  $C_8H_6N_2O_2$ . [506°]. Occurs in opium (T. a. H. Smith, *Ph.* [8] 23, 798). White crystalline powder, insol. water and alkalis, al. sol. hot alcohol, m. sol. benzene, v. e. sol. chloroform. Weak base, forming yellow salts from which it is ppd. by hot water. Conc.  $H_2SO_4$  forms a deep-orange solution, from which water ppts. the sulphate as yellow needles. Hot  $HNO_3$  does not decompose it. Zinc and  $H_2SO_4$  reduce it to hydroxanthaline  $C_8H_8N_2O_2$ , which forms white crystals [137°], nearly insol. water, v. sol. alcohol and benzene, and forms easily soluble crystalline salts. Hydroxanthaline is coloured deep-violet by  $H_2SO_4$  (even free from  $HNO_3$ ), the colour being destroyed by water, but reproduced by  $H_2SO_4$ .— $B^+H_2Cl_4$  aq.: yellow needles. Gives off all its acid at 156°.

**XANTHAMIDE** v. *Ethyl ether of (β)-Thio-carbamic acid*.

**XANTHATES**. The salts  $RS.CS.OEt$  where R is a metal; v. *ETHYL DITHIOCARBONATE*.

**XANTHIC ACID** v. *ETHYL DITHIOCARBONATE*.

**XANTHINE**  $C_4H_4N_4O_2$ , i.e.

$NH_2CH_2C(=NH)N_2CO$ . *Xanthic oxide*. Mol. w. 152. S. 007 in the cold; 08 at 100°. Occasionally found in urinary calculi (Marcet, *Essay on Calculi*, London, 1819; Liebig a. Wöhler, *A.* 26, 840; Lebon, *C. R.* 73, 47) and in urinary deposits (Bence Jones, *C. J.* 15, 78). Occurs in small quantity in the urine of man, in the pancreas, spleen, and liver of oxen, in the thymus gland of the calf, in muscle of mammals and fishes (Scherer, *A.* 107, 314; 112, 257; Städeler, *A.* 111, 28; 116, 102; Dürr, *A.* 184, 45; Kossel, *H.* 6, 422), in some kinds of guano (Unger a. Phipson, *C. N.* 6, 16), and in yeast (Schindler, *H.* 18, 432). Occurs also in lupin seeds (Salomon, *J.* 1881, 1012; Schulze a. Barbieri, *J. pr.* [2] 27, 358), in pumpkin-seeds (E. Schulze, *J. pr.* [2] 32, 457), and in tea (Baginsky, *H.* 8, 396).

**Formation**.—1. By the action of nitrous acid on guanine (Strecker, *A.* 108, 141; 118, 151; 121, 121; Balke, *J. pr.* [2] 47, 542).—2. In small quantity by heating a mixture of  $HOAc$  and aqueous  $HCl$  (Gautier, *Bl.* [2] 42, 141).

**Preparations**.—1. Separates as a crystalline powder when  $NaNO_2$  (8 g.) is added slowly to a solution of guanine (10 g.) in  $H_2SO_4$  (20 g.) and water (150 g.) at 75° (Fischer, *A.* 215, 309).—2. The aqueous extract of sprouting lupin seeds is evaporated, the residue treated with alcohol, and the alcoholic filtrate evaporated. The residue is dissolved in water, and  $AgNO_3$  and  $NH_3$  added. The gelatinous pp. is dissolved in hot  $HNO_3$  (S.G. 1.1), which yields on cooling a crystalline compound of hypoxanthine and silver nitrate, and on adding  $NH_3$  to the filtrate silver-xanthine is ppd. (S. a. B.).—3. Urine is ppd. with baryta-water; the filtrate is evaporated to a small bulk and boiled with cupric acetate. The pp. is dissolved in warm nitric acid and ppd. with  $AgNO_3$ ; the pp. is crystallised from hot diluted  $HNO_3$ , treated with ammoniacal  $AgNO_3$ , decomposed by  $H_2S$ , and the solution

evaporated.—4. A solution containing xanthine is treated with Fehling's solution and hydroxylamine hydrochloride, and the ppd. copper compound decomposed by  $H_2S$ . The xanthine may be further purified by preparing its lead salt and decomposing this with  $H_2S$  (Balke, *J. pr.* [2] 47, 552).

**Properties**.—Small scales (by evaporation) or powder composed of minute globules, nearly insol. cold water, insol. alcohol and ether. V. e. sol.  $KOH$  aq. and reppd. by  $CO_2$  and other acids. Weak base. Does not form an acetate. A cold saturated aqueous solution of xanthine gives white pps. with  $HgCl_2$  and  $AgNO_3$ , and a yellowish-green, flocculent pp. with hot cupric acetate. An ammoniacal solution of xanthine is ppd. by  $HgCl_2$ ,  $ZnCl_2$ ,  $CdCl_2$ , and  $AgNO_3$ . Xanthine reduces ammoniacal cupric chloride (Drechsel, *B.* 25, 2454). Xanthine evaporated with nitric acid leaves a yellow residue turned orange by  $KOH$  (but not by  $NH_3$ ), the colour becoming violet-red on warming. Solid xanthine added to a mixture of bleaching-powder and  $NaOH$  aq. on a watch-glass forms a dark-green spot, changing to brown and finally disappearing. Xanthine warmed with chlorine-water and a trace of  $HNO_3$ , as long as gases escape, and then evaporated to dryness, yields a residue which is coloured rose-red by gaseous  $NH_3$  (Weidel, *A.* 158, 365; Kossel, *H.* 6, 426).

**Reactions**.—1. Decomposed above 150°, giving off  $HCl$ ,  $NH_3$ , cyanogen, and  $CO_2$ .—2.  $KClO_4$  and  $HCl$  aq. at 60° form urea and alloxan.—3. Conc.  $HCl$  aq. at 230° forms glycocoll, formic acid,  $NH_3$ , and  $CO_2$  (E. Schmidt, *A.* 217, 311).—4.  $NaOH$  (2 mols.) and  $Pb(OAc)_2$  form a lead salt which, if dried and heated with  $MeI$  at 130°, yields theobromine (Fischer).—5. Slowly attacked by pure  $HNO_3$ , the gas evolved consisting of nitrogen (1 vol.),  $CO_2$  (4 vols.), and  $N_2O$  (11 vols.) (Franchimont, *R. T. C.* 6, 223).

**Salts**.— $B^+HCl$ . Nodular groups of silky needles.— $B^+H_2SO_4$  aq. Scales, decomposed by water.— $B^+BaH_2O_2$ . Sl. sol. water.— $B^+Cu_2O_2$ . Formed by the action of Fehling's solution and hydroxylamine hydrochloride (Balke).— $B^+Ag_2O$ . Yellowish-white flocculent pp., got by adding  $AgNO_3$  to an ammoniacal solution of xanthine. Blackens on boiling.— $NaC_4H_4N_4O_2$  aq. Minute needles.

**Bromo-xanthine**  $C_4H_3BrN_4O_2$ . Formed by heating xanthine with bromine at 100°, and also by the action of nitrous acid on bromoguanine (Fischer a. Reese, *A.* 221, 343). Crystalline powder, sol. conc.  $HCl$  aq. and  $H_2SO_4$ , but reppd. by water; sl. sol. hot water and hot alcohol; sol. alkalis.

**Isoxanthine**  $C_4H_4N_4O_2$ , i.e.

$NH.CO.C(=NH)N_2CO$ . Formed by reducing diazo-isopitosomethyl-uracil  $C_4H_4N_4O_2$  with  $SnCl_2$  and  $HCl$  aq. (Behrend, *A.* 245, 223). Needles (containing 1 aq.) sl. sol. hot water. Dissolves in  $Ac_2O$  without change. On evaporation with  $HNO_3$ , it leaves a residue coloured orange by

KOHAq. Yields  $C_8H_7BrN_3O_2$ , aq. crystallising from water in six-sided tables.

Pseudo-xanthine  $C_8H_7N_3O_2$ . A product of the action of  $H_2SO_4$  (2 pts.) on uric acid (1 pt.) at  $120^\circ$  (Schnitzler, A. F. 10, 150). Formed also by the action of nitrous acid on adenine (Kossel, H. 10, 258). Powder, sl. sol. water; HClAq. and  $NH_4$ Aq. v. sol. KOHAq. Its aqueous solution is acid in reaction, and on evaporation with  $HNO_3$  leaves a lemon-yellow residue, which is turned orange on warming with KOHAq.

The name pseudo-xanthine is also given by Gantier (*Bl.* [2] 48, 19) to a substance  $C_8H_7N_3O_2$  occurring in muscular tissue. This is a yellow powder, which forms a very soluble hydrochloride. Its aqueous solution is ppd. by  $HgCl_2$ ,  $AgNO_3$ , and ammoniacal  $Pb(OAc)_2$ , but not by  $Pb(OAc)_2$ . This pseudo-xanthine also gives an orange colour when the residue, after evaporation with  $HNO_3$ , is treated with potash.

Paraxanthine  $C_8H_7N_3O_2$ . [ $\alpha$ .  $284^\circ$ ]. Occurs in human urine (Salomon, B. 16, 195; 18, 3406; H. 13, 187; Thudichum, H. 11, 415; Kossel, H. 13, 302). Silky needles or monoclinic tables, insol. alcohol and ether, sl. sol. cold water, v. sol. hot water. Sol.  $NH_4$ Aq. and HClAq. Poisonous, acting like caffeine and theobromine.  $AgNO_3$  added to its solution in  $HNO_3$  or  $NH_4$ Aq. gives a gelatinous or flocculent pp. Picric acid forms a yellow crystalline pp. when added to its solution in HClAq. Gives a red colour (like xanthine) when the residue after evaporation with chlorine-water is exposed to gaseous  $NH_3$ . Does not give an orange colour when KOHAq. is added to the residue after evaporation with  $HNO_3$ . Conc. NaOHAq. forms a crystalline salt. KOHAq. does the same. A solution of paraxanthine is ppd. by  $Cu(OAc)_2$ , phosphotungstic acid,  $HgCl_2$ , and ammoniacal lead subacetate, but not by mercuric nitrate.

Heteroxanthine  $C_8H_7N_3O_2$ . Occurs in urine of men and dogs (Salomon, B. 18, 3407; H. 11, 412). Amorphous powder, v. sl. sol. cold water, sol.  $NH_4$ Aq. insol. alcohol and ether. Its solution in HClAq. is not ppd. by picric acid.  $AgNO_3$ ,  $HgCl_2$ ,  $Cu(OAc)_2$ , and ammoniacal lead subacetate give pps. When evaporated with chlorine-water and  $HNO_3$  it leaves a residue which is coloured red by gaseous  $NH_3$ , the colour changing to blue on addition of NaOHAq. NaOHAq. forms a salt crystallising in tables, v. sol. water, sl. sol. NaOHAq. The hydrochloride forms sparingly soluble crystalline aggregates, which lose  $HCl$  on treatment with water.

Hypoxanthine v. vol. ii. p. 745.

XANTHININE  $C_8H_7N_3O_2$ . S. 0025 in the cold;  $0.25$  at  $100^\circ$ . Formed by heating ammonium thionurate at  $200^\circ$  (Finck, A. 132, 298). Get also by heating pseudo-uric acid with  $H_2SO_4$  at  $150^\circ$  (Grimaux, *Bl.* [2] 81, 535). White powder, nearly insol. water, sol.  $NH_4$ Aq. forming a solution with blue fluorescence. Its solution gives a white pp. with  $HgCl_2$  and a yellow pp. with  $AgNO_3$ . Not attacked by  $HNO_3$ . Sol. KOHAq. and reppd. by  $CO_2$ . Sol. conc.  $H_2SO_4$ , forming a laminar sulphate, decomposed by water with separation of xanthine. —E'Aq. O. Bulky yellow pp. got by pouring an ammoniacal solution of xanthine into excess of aqueous  $AgNO_3$ .

XANTHOCHELIDONIC ACID v. CHELIDONIC ACID.

XANTHOCERATININE v. CERATININE and LEUCOCERATININE.

XANTHOGALLOL  $C_{12}H_7Br_3O_2$ , t. a.

$C_6H_4Br_2O \begin{smallmatrix} \diagup OCHBr_2 \\ \diagdown OCHBr_2 \end{smallmatrix} O$  (?). [ $132^\circ$ ]. Formed by adding pyrogallol (1 pt.) to bromine (10 pts.), leaving the mixture to stand for two hours, and then shaking with water and heating (Stenhouse a. Groves, C. J. 28, 1; A. 177, 191; 179, 287; Theurer, A. 245, 334). Tri-bromo-pyrogallol is an intermediate body in its preparation. Yellow laminae (from  $CS_2$  and ligroid), v. sol. ether and  $CS_2$ , m. sol. ligroid. Decomposed by boiling with water or alcohol. Very stable towards oxidising agents, even crystallising unaltered from conc.  $HNO_3$ . Not reduced by sodium-amalgam or by zinc and dilute  $H_2SO_4$ . Aniline in HOAc yields an anilide [ $205^\circ$ ], to which Theurer assigns the impossible formula  $C_{12}H_7Br_3(NHPh)_2O$ . p-Toluidine forms a corresponding p-toluide. Reacts with phenyl-hydrazine acetate.

Reactions. —1. NaOHAq. forms hexa-bromobenzene dihydride  $C_6H_2Br_6$  [ $189^\circ$ ], sl. sol. alcohol, which crystallises in prisms, while the mother-liquor contains a sodium salt of an acid  $C_6H_2Br_6O_2$  [ $124^\circ$ ], which forms BaA'', crystallising from dilute alcohol in large white plates (Theurer). By the action of dilute NaOHAq. on xanthogallol, Hantzsch a. Schmitter (B. 30, 2033) obtained  $C_{12}H_7Br_3(OH)_2O_2$ , which yields  $Ba_2(C_{12}H_7Br_3O_2)_2$ , and crystalline  $C_{12}H_7Br_3AcO_2$ . 2. Na $CO_3$ Aq. converts xanthogallol in the cold into  $C_{12}H_7Br_3O_2$ , crystallising from benzene in needles [ $72^\circ$ ] and prisms [ $131^\circ$ ], yielding the crystalline derivatives  $C_{12}H_7Br_3O_2NPhH$  and  $C_{12}H_7Br_3O_2NH_2.C_2H_5Me$ . —3. HBr passed into a cooled solution of xanthogallol in MeOH forms  $C_{12}H_7Br_3O_2(OMe)_2$ , crystallising from MeOH in prisms [ $113^\circ$ ], and converted by boiling dilute NaOHAq. into an acid  $C_{12}H_7Br_3O_2(OMe)$ , [ $105^\circ$ ], and by MeOH and hydrochloric acid into  $C_{12}H_7Br_3Cl(OMe)$ , [ $77^\circ$ ]. The brominated acid  $C_{12}H_7Br_3O_2(OMe)$ , reacts with aniline, forming crystalline  $C_{12}H_7Br_3O_2(OMe).NHPh$ . Conc.  $H_2SO_4$  converts  $C_{12}H_7Br_3O_2(OMe)$  into  $C_{12}H_7Br_3O_2$ , [ $65^\circ$ ]. —4. Hydrochloric acid gas passed into a cooled solution of xanthogallol in MeOH forms  $C_{12}H_7Br_3Cl_2O_2(OMe)$ , [ $86^\circ$ ], which is insol. water, v. sol. alcohol, does not react with aniline, and is decomposed by dilute alkalis. —5. HCl passed into an alcoholic solution of xanthogallol forms  $C_{12}H_7Br_3Cl_2O_2(OEt)_2$ , crystallising from alcohol in colourless prisms [ $75^\circ$ ], converted by NaOHAq. into a product [ $92^\circ$ ].  $C_{12}H_7Br_3Cl_2O_2$  [ $104^\circ$ ] is a bye-product in the action of alcohol and HCl on xanthogallol. It forms large yellow crystals, v. sol. alcohol.

XANTHOGENIC ACID v. ETHYL DITHIOCARBONATE.

XANTHOMETHYLIC ACID v. METHYL THIOCARBONATES.

XANTHON is DIPHTERINIC KETONE OXIDE. XANTHOPURPURIN is m-DI-OXY-ANTHRACINONE.

XANTHOQUINIC ACID v. OXY-QUINOLINIC CARBOXYLIC ACID.

XANTHOREAMNIN  $C_{12}H_7O_2$  (?). Obtained from Persian berries (the fruit of *Rhamnus infectoria*) by extracting with three times their

weight of 88 p.c. alcohol; the yield being 12 p.c. (Liebemann *a. Hörmann*, *B.* 11, 952, 1618; *A.* 196, 807; *cf. Kane*, *P. M.* 8, 23, 8; Gellatly, *N. E. P. J.* 7, 262; *C. N.* 8, 196; Hlasiwetz, *A.* 111, 108; Bolley, *A.* 115, 56; *U. J.* 18, 828; Stein, *Z.* 21, 5, 189, 568; Behrend, *J.* 11, 1859). Yellow needles (containing 2aq), v. sol. water and alcohol, insol. ether. Has little tinctorial power. Reduces Fehling's solution and ammoniacal  $\text{AgNO}_3$ , forming a mirror.  $\text{FeCl}_3$  gives a dark-brown pp. Ppd. by ammoniacal lead acetate. Boiling dilute  $\text{H}_2\text{SO}_4$  splits it up into rhamnetin (2 mols.) and isodulcetes (4 mols.).

Salts.— $C_{45}H_{22}K_2O_{20}$ . Yellow powder, v. e.  
sol. water.— $Pb_2Al^{17}$ . Yellow pp.

*Acetyl derivatives*  $C_{45}H_{48}Ac_{12}O_{28}$   
(Schützberger, Z. [2] 4, 668),  $-C_{48}H_{48}Ac_{11}O_{28}$ .  
Powder, v. e. sol. alcohol (Liebmann a. Bergami, B. 20, 2245).

**XANTHOCCELIN** v. **PICRO-ROCCELIN.**

**XANTHORRHŒA RESIN** is AGARIC RESIN.

**XANTHOXYLIN**·C<sub>10</sub>H<sub>16</sub>O<sub>4</sub>. [80%]. Occurs, together with xanthoxylene C<sub>10</sub>H<sub>16</sub> (162°) in the essential oil from japan-pepper (*Xanthoxylon piperitum*) (Stenhouse, *Ph.* [2] 13, 423; 17°19; *A.* 104, 237). Silky monoclinic crystals, insol. water, v. sol. alcohol and ether. Its alcoholic solution is not pptd. by AgNO<sub>3</sub> or lead acetate, even on addition of NH<sub>4</sub>Ac.

**XENYLAMINE** *v.* *p*-AMIDO-DIPHENYL.

**XENYDEN-8-DIAMINE v. p-p-DI-AMIDO-DI-PHENYL.**

**XERONIC ACID v. DI-ETHYL-MALEÏC ACID.**

**XYLAN**  $C_5H_8O_5$ . Tree gum. Wood gum. S. 2 at 100°.  $[\alpha]_D^{20} = -69.6^\circ$  (Tollens);  $-84^\circ$  (Thomsen). Obtained from the bark of trees (T. Thomsen, *J.ber.* [2] 19, 146; Pommard & Figuiet, A. 64, 388). Obtained, to the extent of 1.78 p.c., by extracting jute with dilute (5 p.c.) NaOH aq.; and got also by extracting beechwood or pine-wood sawdust with 5 p.c. NaOH aq. (Tollens, A., 254, 807, 320, 324, 326; *B.* [3] 1, 1102; Winterstein, *H.* 17, 881). Obtained also by extracting wheat-straw, first with 2 p.c. NH<sub>4</sub> aq. and then with 5 p.c. NaOH aq. (Tollens, A. 260, 291). The alkaline extract is ppd. with alcohol and HCl.

**Properties.**—Porous mass, insol. cold, sol. hot, in water; sol. NaOH aq. The hot aqueous solution becomes opalescent on cooling. Insol. in alcohol, but the aqueous solution is not pptd by alcohol unless an acid or the salt of an alkali is added. Insol.  $\text{NH}_4\text{aq}$ , lime- and baryta-water. Its aqueous solution is levorotatory. Gives no furfuraldehyde when distilled with  $\text{H}_2\text{SO}_4$  or boiled with dilute  $\text{H}_2\text{SO}_4$ . Gives no colour with iodine.  $\text{HNO}_3$  oxidises xylan to saccharic acid, but gives no mucic acid.

**p-XYLENE** C<sub>8</sub>H<sub>10</sub>, i.e. C<sub>6</sub>H<sub>4</sub>(Me)<sub>2</sub>[1,2]. *Dimethylbenzene*. Mol. w. 106. [ $\gamma$ -28°] (Clauson). A. Ch. [6], 6, 729. ( $d_4^{20}$ ) = 0.8923 (Pinette) (Pinette), A. 243.50,  $n_D^{20}$  = 1.4876 (Gladstone, G. J., 1876; 59, 290),  $n_D^{25}$  = 1.4928,  $n_D^{30}$  = 1.5328. C.E. (0°-10°) -00098. S.V. 139-3 (Schiff); 137-6 (Pinette). E.C. 1,084.274 ( $\rho_{20}$  = 94.000; H<sub>2</sub>O = 69.000) (Stohmann, J. pr. [2] 35, 41). M.M. 18-81 (Schnitzler, Z. F. C. 11, 758. Critical temperature: 858° (Altschul, Z. P. C. 11, 590). Occurs in coal-tar. The S.G.\* of crude xylene varies between .857 and .866; it contains 70 to 87 p.c. *m*-xylene, 8 to 20 p.c. *p*-xylene, 2 to 15 p.c.

*o*-xylene, and 3 to 10 p.c. fatty hydrocarbons (Levinstein, B. 17, 444; cf. Fittig, A. 143, 10). If 100 c.c. of the mixture are boiled for 45 minutes with 40 c.c. of HNO<sub>3</sub> (S.G. 1.42) diluted with 60 c.g. of water, the *p*- and *o*-xylene are oxidised, leaving the *m*-xylene and fatty hydrocarbons. If the residual hydrocarbons after washing with NaOH aq followed by steam distillation, be shaken for 30 minutes with 1½ volumes of H<sub>2</sub>SO<sub>4</sub>, the *m*-xylene will be sulphated and dissolved, while the fatty hydrocarbons remain. If 100 c.c. of crude xylene be shaken with 120 c.c. of H<sub>2</sub>SO<sub>4</sub>, the *o*- and *m*-xylene dissolve, leaving the *p*-xylene and fatty hydrocarbons. On crystallising the sodium salts of the dissolved sulphonic acids, sodium *o*-xylene sulphonate separates first, and may be converted into *o*-xylene by heating in a sealed tube with HCl aq at 190° (Jacobsen, B. 10, 1009), or by heating with diluted sulphuric acid. Nöling, Witt, and Forel (B. 18, 2668) found 25 p.c. of *p*-xylene in commercial xylene. According to Nöling and Palmer (B. 24, 1555), crude xylene may contain 10 p.c. of ethylbenzene. When a mixture of *o*-xylene and ethylbenzene is treated with Br (20 pts.) and I, tetra-bromoxylene is formed, together with a less highly brominated ethylbenzene (Crafts, C. R. 114, 1110).

**Formation.**—1. By distilling its carboxylic acids with lime.—2. From o-bromo-toluene, MeI, and Na (Jannasch, A. Hübner, A. 170, 117; Reymann, *B.* [2] 26, 532).—3. By heating cantharidin with P<sub>2</sub>S<sub>5</sub> (Piccard, B. 12, 680).—4. By passing MeI through a mixture of toluene and AlCl<sub>3</sub> at 85° (Jacobsen, *B.* 14, 2628).

**Properties.**—Oil, solidifying in a freezing-mixture at  $-28^{\circ}$ . Unlike *m*- and *p*-xylene it does not yield a solid nitro-derivative with a cold mixture of  $\text{H}_2\text{SO}_4$  and  $\text{HNO}_3$ . It is completely oxidised by chromic acid mixture.

**Reactions.**—1. Dilute  $\text{HNO}_3$  forms *o*-toluic acid.—2. Boiling aqueous  $\text{KMnO}_4$  oxidises it to phthalic acid.—3.  $\text{PCl}_5$  at  $200^\circ$  reacts, forming  $\text{C}_6\text{H}_4(\text{CCl}_2)\text{CHCl}_2$  (Colson a. Gautier, *Bt.* [2] 45, 507).—4. *Bromine* in the dark forms bromo-o-xylene  $\text{C}_6\text{H}_4\text{MeBr}$  [1:24]. In direct sunlight the products are  $\text{C}_6\text{H}_4\text{MeCH}_2\text{Br}$  and  $\text{C}_6\text{H}_4(\text{CH}_2\text{Br})_2$  (Schramm, *B.* 18, 1278).—5.  $\text{AlCl}_3$  and gaseous  $\text{HCl}$  at  $100^\circ$  yield benzene, *m*- and a little *p*-xylene, *p*-cumene and *m*-mesitylene (Hesse a. Tschl. 4, 270, 168).

***n*-Xylene**  $C_8H_{10}$ , [1.3]. V.D. 8.68 (calc. 8.67) (Schiff, A. 220, 92). (189°). S.G. 8.812 (Pissotte, A. 243, 50);  $\frac{100}{15}$  8715 (S.);  $\eta$  8655 (Brühl, A. 235, 13);  $n_D^{20}$  846 (Glaistone, C. J. 59, 290). C.E. (0°–10°) 00096.  $n_D^{1.495}$  (B.) 1.4876,  $n_D^{1.5277}$ . S.V. 139.8. H.C. 1.034, 168 (Stohmann, J. pr. [2] 85, 41). M.M. 127.8 at 20–30° (Schönrock, Z. P. C. 11, 756). *Critical temperature*: 846° (A.). Occurs in coal-tar (cf. o-Xylene).

**Formation.**—1. From *m*-iodo-toluene, MeI, and Na (Wroblewski, *A. 192*, 200).—2. From (1,3,4)-xylydine and amyl nitrite (Staedel, *A. Holz*, *B. 18*, 2919).—3. From toluene, MeCl, and AlCl<sub>3</sub> (Friedel & Crafts, *A. Ch.* [6] *1*, 461; Ador & Rilliet, *B. 11*, 1627).—4. By distilling mesityl-ene and xyllyic acids with time (Fittig, *A. 148*, 10; 156, 236).

**Properties.**—Liquid. Not attacked by dilute HNO<sub>3</sub>. Conc. HNO<sub>3</sub> on warming forms tri-nitro-xylene [176°], sl. sol. alcohol.

**Reactions.**—1. Oxidised by chromic acid mixture to isophthalic acid.—2. HCl, at 200° forms a hexachloride (Colson a. Gautier, *Bl.* [2] 45, 568).—3. Bromine in the dark forms C<sub>8</sub>H<sub>7</sub>Me.Br [1:3:4], while in direct sunshine C<sub>8</sub>H<sub>7</sub>Me.(CH<sub>2</sub>Br) and C<sub>8</sub>H<sub>7</sub>(CH<sub>2</sub>Br)<sub>2</sub> are produced (Schramm, *B.* 18, 1277; *M.* 8, 305).—4. AlCl<sub>3</sub> and gaseous HCl at 100° form benzene, mesitylene, and some *p*-xylene and *ψ*-cumene (Heise a. Töhl, *A.* 270, 168). On boiling with AlCl<sub>3</sub> the products are benzene, toluene, a little *p*-xylene, *ψ*-cumene, mesitylene, and durene (Anschütz, *A.* 235, 182).—5. On heating with MeI and I at 250° it yields *ψ*-cumene, mesitylene, and C<sub>8</sub>H<sub>14</sub> (Payman a. Preis, *A.* 223, 320).—6. Ethyl-malonyl chloride at 60° in presence of AlCl<sub>3</sub> forms the ketone C<sub>12</sub>H<sub>14</sub>O<sub>2</sub> [63°] (Béhal a. Auger, *Bl.* [3] 3, 122).—7. Benzoyl peroxide forms dixylylene C<sub>16</sub>H<sub>14</sub>, S.G. 21.9984 (Lippmann, *M.* 7, 528).—8. CrO<sub>2</sub>Cl<sub>2</sub> added to its solution in CS<sub>2</sub>, ppts. chocolate brown C<sub>8</sub>H<sub>7</sub>Me.2CrO<sub>2</sub>Cl<sub>2</sub>, which is converted by water into *m*-toluic aldehyde and at 200° yields C<sub>8</sub>H<sub>7</sub>Me.CH(CrO<sub>2</sub>Cl) (Étard, *A. Ch.* [5] 22, 244).—9. CH<sub>2</sub>Cl<sub>2</sub> and AlCl<sub>3</sub> form tetramethyl-anthracene [163°] (Friedel a. Crafts, *A. Ch.* [6] 11, 268).—10. PH<sub>3</sub>I forms C<sub>8</sub>H<sub>14</sub>, on heating (Baeyer, *Z.* [2] 3, 455). HIAq and P at 280° form *m*-xylene hexahydride.

***p*-Xylene** C<sub>8</sub>H<sub>6</sub>Me<sub>2</sub> [1:4]. [13°] (Reissert, *B.* 23, 2242); [15°] (Jannasch). (138°). S.G. 2.8801 (K);  $\rho_{20}^4$  860 (Gladstone, *C. J.* 59, 290). C.E. (0°-10°) 0.0098 (Pinette, *A.* 243, 51).  $\mu_{\text{H}}$  1.4854.  $\mu_{\text{D}}$  1.5253. S.V. 140 (Schiff). H.G. 1,084,274 (Stohmann, *J. pr.* [2] 35, 41). M.M. 12.79 at 20°-30° (Schönrock, *Z. P. C.* 11, 753). Critical temperature: 344°. Occurs in coal-tar (*v. supra*) and in Galician petroleum (Pawlewski, *B.* 18, 1915). Formed by the action of MeI and sodium on *p*-bromo-toluene (Fittig, *A.* 136, 303; Jannasch, *A.* 171, 79) and on *p*-di-bromo-benzene (V. Meyer, *B.* 3, 753). Monoclinic prisms;  $\alpha:b:c=2:32:1.2:34$ ;  $\beta=69.5^\circ$  (Baeyer, *A.* 245, 141).

**Reactions.**—1. Dilute HNO<sub>3</sub> forms *p*-toluic acid.—2. Chromic acid mixture yields terephthalic acid.—3. PCl<sub>5</sub> at 190° gives C<sub>8</sub>H<sub>4</sub>(CH<sub>2</sub>Cl)<sub>2</sub> and at 200° C<sub>8</sub>H<sub>4</sub>(CCl<sub>2</sub>)<sub>2</sub> (Colson a. Gautier, *Bl.* [2] 45, 5, 507).—4. Bromine in the dark forms C<sub>8</sub>H<sub>7</sub>BrMe, while in direct sunshine the products are C<sub>8</sub>H<sub>7</sub>Me.CH<sub>2</sub>Br and C<sub>8</sub>H<sub>7</sub>(CH<sub>2</sub>Br)<sub>2</sub> (Schramm, *B.* 18, 1276).—5. AlCl<sub>3</sub> and HCl at 100° act in the same way as with *o*-xylene.

**References.**—Bromo-, Bromo-nitro-, Chloro-, Dichloro-nitro-, Di-iodo-, Nitro-, and Oxyxylenes.

***m*-Xylene dicarboxylic acid** C<sub>8</sub>H<sub>6</sub>O<sub>4</sub>.  $\text{C}_8\text{H}_6\text{Me}_2(\text{CO}_2\text{H})_2$  [1:3:4:5]. Dimethyl-isophthalic acid.

( $\alpha$ )-Cumidic acid. Mol. w. 194. [above 320°]. Formed by heating di-bromo-*m*-xylene dissolved in ether under pressure with ClCO<sub>2</sub>Et and sodium-amalgam. Formed also, together with ( $\beta$ )-cumidic acid, by oxidation of durene with dilute HNO<sub>3</sub> or of durylic acid with KMnO<sub>4</sub> (Schnapsauff,

*B.* 19, 2508). Minute prisms (from water) or plates (by sublimation).—BA" 1:1aq: crystals, v. sol. water. Yields *m*-xylene on distilling with lime.

**Methyl ether Me<sub>2</sub>A".** [76°]. Crystals.

***m*-Xylene dicarboxylic acid**

C<sub>8</sub>H<sub>6</sub>Me<sub>2</sub>(CO<sub>2</sub>H)<sub>2</sub> [1:3:4:5]. Dimethyl-phthalic acid. Isocumidic acid. [280°]. Formed by oxidation of ( $\beta$ )- and ( $\gamma$ )-isodurylic acid (Jacobsen, *B.* 15, 1857). Small crystals. May be sublimed. Yields *m*-xylene on distillation with lime. The Ca salt crystallises in small plates. The Ba salt is amorphous.

***p*-Xylene dicarboxylic acid**

C<sub>8</sub>H<sub>6</sub>Me<sub>2</sub>(CO<sub>2</sub>H)<sub>2</sub> [1:4:2:5]. Di-methyl-terephthalic acid. ( $\beta$ )-Cumidic acid. Formed, together with ( $\alpha$ )-cumidic acid, by oxidation of *s*-durene with dilute HNO<sub>3</sub> or of durylic acid with KMnO<sub>4</sub> (S.). Minute six-sided prisms (from alcohol). Sublimes in small plates without melting. Nearly insol. hot water. Yields *p*-xylene on distilling with lime.—BA" 2:1aq: tables, v. sol. water.

**Methyl ether Me<sub>2</sub>A".** [114°]. (c. 297° cor.).

**Xylene dicarboxylic acid**

C<sub>8</sub>H<sub>6</sub>Me(CO<sub>2</sub>H)CH<sub>2</sub>CO<sub>2</sub>H [3:2:1]. [178°]. Formed by oxidation of C<sub>8</sub>H<sub>7</sub>Me(CO<sub>2</sub>Et)CH<sub>2</sub>CO<sub>2</sub>H (Béhal a. Auger, *C. R.* 109, 972). Gives off CO<sub>2</sub> on fusion.

**Xylene di- $\omega$ -carboxylic acid v. PHENYLENE-DIACETIC ACID.**

**Reference.**—OXY-XYLENE CARBOXYLIC ACID.

**XYLENE GLYCOL v. Di-oxy-xylene.**

***o*-Xylene dihydride v. CANTHARENE.**

***m*-Xylene dihydride** C<sub>8</sub>H<sub>10</sub>. (133°). S.G. 2.828. V.D. 3.74 (calc. 3.88).  $\rho_{20}^4$  1.4075. Formed, together with a polymeride C<sub>16</sub>H<sub>14</sub>, (280°-285°) S.G. 2.832, by heating the ketone C<sub>8</sub>H<sub>6</sub>O with ZnCl<sub>2</sub>. The ketone itself is obtained by distilling the anhydride C<sub>8</sub>H<sub>6</sub>O, which is got by the action of Ac<sub>2</sub>O on cineolic acid, formed by oxidation of eucalyptol (Wallach, *A.* 258, 827). Liquid, smelling like xylene. Yields, on nitration C<sub>8</sub>H<sub>7</sub>Me(NO<sub>2</sub>) [1:3:4].

***p*-Xylene dihydride** CMe<CH<sub>2</sub>.CH<CH<sub>2</sub>.CH<CMe.

(134°) at 720 mm. Formed by heating di-methyl-quinite dibromide C<sub>8</sub>H<sub>4</sub>Br<sub>2</sub> with quinoline (Baeyer, *B.* 25, 2122). Smells like turpentine. Forms a crystalline compound with HBr.

***m*-Xylene tetrahydride** C<sub>8</sub>H<sub>12</sub>Me<sub>2</sub>. (119°). S.G. 2.814;  $\rho_{20}^4$  1.794.

**Formation.**—1. By heating oxycamphoric anhydride C<sub>10</sub>H<sub>16</sub>O<sub>2</sub> with water at 180° or with H<sub>2</sub>O at 150° (Wreden, *A.* 163, 386).—2. By heating camphoric acid with syngas phosphoric acid at 200°.—3. By distilling camphoric acid with ZnCl<sub>2</sub> (Ballo, *A.* 197, 922).—4. By heating camphoric acid with HIAq at 200° (Wreden, *A.* 187, 171).

**Properties.**—Oil. Oxidised by chromic acid mixture to acetic, isobutyric, isophthalic, and terephthalic acids. HNO<sub>3</sub> forms tri-nitro-*m*-xylene.

**Xylene tetrahydride** C<sub>8</sub>H<sub>12</sub>. (181°). S.G. 2.816. Occurs among the products of the distillation of colophony (Renard, *A. Ch.* [6] 1, 236). Slightly dextrorotatory liquid. Yields oily di- and tri-bromo-derivatives. Sulphuric acid forms an oily polymeride C<sub>16</sub>H<sub>14</sub>, which is oxidised by fuming HNO<sub>3</sub> to succinic and oxalic acids. Absorbs oxygen. Does not reduce

ammoniacal  $\text{AgNO}_3$ . In ethereal solution it combines with Br, forming  $\text{C}_8\text{H}_8\text{Br}_2$ .

**m-Xylene tetrahydride** (?)  $\text{C}_8\text{H}_8$ . (120°). *Octonaphthylene*. Formed by the action of moist  $\text{Ag}_2\text{O}$  on  $\text{C}_8\text{H}_8\text{I}_2$ , which is got by the action of  $\text{CaI}_2$  at 60° on  $\text{C}_8\text{H}_8\text{I}_2\text{Cl}$  (175°), a product of the chlorination of octonaphthene (Jaskowkin, J. R. 16, ii. 294). Oil, smelling like turpentine. Combines with Br (2 atoms). An isomeric octonaphthylene (123°–129°) is got by distilling  $\text{C}_8\text{H}_8\text{I}_2\text{Cl}$  obtained by chlorination of iso-octonaphthene (Futochin, J. R. 16, ii. 295).

**m-Xylene hexahydride**  $\text{C}_8\text{H}_{10}$ , i.e.  $\text{C}_8\text{H}_8\text{Me}_2$  (1.3). *Octonaphthene*. (118°). S.G.  $\frac{1}{4}$  7814 (Lossen, A. 225, 110);  $\frac{1}{4}$  7706 (A.). C.E. (0°–26°) 001072. V.D. 3.87. S.V. 164.8.  $\mu_D = 1.419$  at 22° (Wallach, B. 25, 923). Occurs in Baku petroleum (Beilstein & Kurbatoff, B. 13, 1820; Markownikoff & Spady, B. 20, 1850), and among the products of the distillation of colophony (Renard, A. Ch. [6] 1, 229). Formed by heating heptanaphthene carboxylic acid with  $\text{HIAq}$  and P (Aschan, B. 24, 2718). Prepared by heating camphoric acid or m-xylene with  $\text{HIAq}$  at 200° (Wreden, A. 187, 557). Liquid. Not oxidised by aqueous  $\text{KMnO}_4$ ,  $\text{H}_2\text{SO}_4$ , and  $\text{HNO}_3$  form tri-nitro-m-xylene. Sulphur at 220° forms m-xylene.

**Isomeride**  $\text{C}_8\text{H}_{10}$ , i.e. *Iso-octonaphthene*. (122°). S.G.  $\frac{1}{4}$  7767  $\frac{1}{4}$  7637. Occurs in Caucasian petroleum (Futochin, J. R. 16, ii. 295). Liquid.

**p-Xylene hexahydride**  $\text{C}_8\text{H}_{10}\text{Me}_2$  (1.4). (138° cor.). V.D. 4.01 (obs.). S.G.  $\frac{1}{4}$  7956. Formed by heating bromo-camphor with  $\text{ZnCl}_2$  (R. Schiff, B. 13, 1407; G. 10, 320). Liquid, yielding tri-nitro-p-xylene [127°] on nitration.

#### m-XYLENE PHOSPHINIC ACID

**Chloride**  $\text{C}_8\text{H}_8\text{Me}_2\text{P(ONa)Cl}$  (1.34). (257°). Got from mercuric dixyl  $\text{Hg}(\text{C}_8\text{H}_8\text{Me}_2(4:1:3))_2$  and  $\text{PCl}_5$  at 235° (Weller, B. 20, 1720). Liquid, converted by water into the acid  $\text{C}_8\text{H}_8\text{Me}_2\text{P(OH)}_2$ . Chlorine forms the compound  $\text{C}_8\text{H}_8\text{Me}_2\text{P(ONa)Cl}$ , which is converted by water into  $\text{C}_8\text{H}_8\text{Me}_2\text{P(OH)}_2$ , [194°].

**m-Xylene-phosphinic acid**  $\text{C}_8\text{H}_8\text{Me}_2\text{P(OH)}_2$ , [98°] (Michaelis, A. 212, 237). Formed by the action of water on the chloride. Needles (from alcohol). Probably a mixture.

**Chloride**  $\text{C}_8\text{H}_8\text{Me}_2\text{P(ONa)Cl}$  (256°). S.G.  $\frac{1}{4}$  1.24. Formed from m-xylene,  $\text{PCl}_5$ , and  $\text{AlCl}_3$  (Weller, B. 20, 1720). It is a mixture of the preceding body and the 1,3,5 isomeride. Readily absorbs chlorine, forming  $\text{C}_8\text{H}_8\text{Me}_2\text{P(ONa)Cl}_2$ , whence  $\text{SO}_2$  forms  $\text{C}_8\text{H}_8\text{Me}_2\text{P(ONa)SO}_2\text{Cl}$  (280°–300°).

**p-Xylene phosphinic acid**  $\text{C}_8\text{H}_8\text{Me}_2\text{P(OH)}_2$ . Formed by treating the chloride with hot water (Weller, B. 21, 1494). Crystallises with difficulty.

**Chloride**  $\text{C}_8\text{H}_8\text{Me}_2\text{P(ONa)Cl}$  [–30°]. (254°). S.G.  $\frac{1}{4}$  1.25. Formed by heating p-xylene (150 g.) with  $\text{AlCl}_3$  (80 g.) and  $\text{PCl}_5$  (200 g.) for 36 hours with inverted condenser (Michaelis & Panssek, A. 212, 236). Strongly refracting liquid.

#### m-XYLENE c-SPHONIC ACID

**Chloride**  $\text{C}_8\text{H}_8\text{Me}_2\text{P(ONa)Cl}$ . **m-Xylene (a)-phosphinic acid**. [194°]. S. 1.5 at 20°; 6.9 at 100°. Formed by boiling the chloride  $\text{C}_8\text{H}_8\text{Me}_2\text{P(ONa)Cl}$  (v. supra) with water (Weller, B. 20, 1721). Needles, v. s. sol. alcohol. Decomposed into m-xylene

and phosphoric acid on heating with alkalis. Br added to dilute solutions forms bromo- and di-bromo-m-xylene. Yields two nitro-derivatives [182°] and [100°].

**Salts.** —  $\text{BaA}$  aq. Plates. —  $\text{CdH}_2\text{A}$  aq. Plates, more sol. cold than hot water. —  $\text{NiH}_2\text{A}$  aq. —  $\text{Ag}_2\text{A}$ : white pp.

**m-Xylene s-phosphinic acid**  $\text{C}_8\text{H}_8\text{Me}_2\text{PO(OH)}_2$ . **m-Xylene (b)-phosphinic acid**. [161°]. S. 1.8 at 15°; 117.8 at 100°. Prepared by boiling with water the mixture of chlorides  $\text{C}_8\text{H}_8\text{Me}_2\text{POCl}_2$  (280°–300°) which is got by the action of  $\text{SO}_2$  on the mixture of tetrachlorides  $\text{C}_8\text{H}_8\text{Me}_2\text{P(ONa)Cl}_2$  formed by combination of chlorine with the mixture of chlorides  $\text{C}_8\text{H}_8\text{Me}_2\text{P(ONa)Cl}$  obtained by heating m-xylene with  $\text{PCl}_5$  and  $\text{AlCl}_3$  (W.). Plates or needles, v. s. sol. alcohol and ether. Decomposed by alkalis into m-xylene and phosphoric acid.

**p-Xylene phosphinic acid**  $\text{C}_8\text{H}_8\text{Me}_2\text{PO(OH)}_2$ . [180°]. Formed by the action of water on  $\text{C}_8\text{H}_8\text{Me}_2\text{P(ONa)Cl}$  [c. 60°] which is got by passing  $\text{Cl}_2$  through the product of the action of  $\text{PCl}_5$  on p-xylene in presence of  $\text{AlCl}_3$  (Weller, B. 21, 1494). Needles, m. sol. water, v. sol. alcohol, al. sol. ether. Conc.  $\text{HNO}_3$  forms the compound  $\text{C}_8\text{H}_8\text{Me}_2(\text{NO}_2)_2\text{PO(OH)}_2$  [224°].  $\text{KMnO}_4$  yields  $\text{C}_8\text{H}_8\text{Me}_2(\text{CO}_2\text{H})_2\text{PO}_2\text{H}$  [278°].

**Salts.** —  $\text{KHA}$  —  $\text{BaA}$ . Pearly plates, more sol. cold than hot water.

**Chloride**  $\text{C}_8\text{H}_8\text{Me}_2\text{POCl}_2$ . (281°). S.G.  $\frac{1}{4}$  1.31. Oil. Formed by the action of  $\text{SO}_2$  on  $\text{C}_8\text{H}_8\text{Me}_2\text{P(ONa)Cl}$ .

**Reference.** — NITRO-XYLENE PHOSPHONIC ACID.

#### XYLENE PHTHALOYLIC ACID v. PHTHALYL KETONE CARBOXYLIC ACID

**o-XYLENE SULPHINIC ACID**  $\text{C}_8\text{H}_8\text{SO}_2$ , i.e.  $\text{C}_8\text{H}_8\text{Me}_2\text{SO}_2\text{H}$  (1:2:4). [83°]. Formed by the action of zinc-dust on o-xylene sulphochloride (Jacobsen, B. 10, 1011). Plates (from water).

**m-Xylene sulphinic acid**  $\text{C}_8\text{H}_8\text{Me}_2(\text{SO}_2\text{H})$  (1:3:4). [c. 50°]. Formed by reducing the sulphonic chloride  $\text{C}_8\text{H}_8\text{Me}_2\text{SO}_2\text{Cl}$  (Jacobsen; cf. Lindoff & Otto, A. 146, 233). Crystalline.

**p-Xylene sulphinic acid**  $\text{C}_8\text{H}_8\text{Me}_2(\text{SO}_2\text{H})$  (1:4:2). [85°]. Groups of needles (Jacobsen, B. 11, 22).

**o-XYLENE SULPHONIC ACID**  $\text{C}_8\text{H}_8\text{SO}_3$ , i.e.  $\text{C}_8\text{H}_8\text{Me}_2(\text{SO}_3\text{H})$  (1:2:4). Formed by warming o-xylene with  $\text{H}_2\text{SO}_4$  (Jacobsen, B. 10, 1011; 11, 22). Tables (containing 2aq) (from dilute  $\text{H}_2\text{SO}_4$ ). —  $\text{NaA}$  5aq. —  $\text{BaA}$ , 2aq. S. 5.8 at 0°; 33.6 at 100°.

**Chloride**  $\text{C}_8\text{H}_8\text{Me}_2\text{SO}_2\text{Cl}$ . [52°]. Prisms.

**Amide**  $\text{C}_8\text{H}_8\text{Me}_2\text{SO}_2\text{NH}_2$ . [144°]. Yields two acids  $\text{C}_8\text{H}_8\text{Me}_2(\text{CO}_2\text{H})_2\text{SO}_2\text{NH}_2$  on oxidation by  $\text{KMnO}_4$ .

**o-Xylene c-sulphonic acid**  $\text{C}_8\text{H}_8\text{Me}_2\text{SO}_3\text{H}$  (1:2:3). Formed by the action of sodium-amalgam on  $\text{C}_8\text{H}_8\text{Me}_2\text{Cl}(\text{SO}_2\text{H})$  [1:2:3:3] (Krüger, A. 18, 1760).

**Amide**  $\text{C}_8\text{H}_8\text{Me}_2\text{SO}_3\text{NH}_2$ . Granules.

**m-Xylene c-sulphonic acid**  $\text{C}_8\text{H}_8\text{Me}_2(\text{SO}_3\text{H})$  (1:3:2). **m-Xylene (b)-sulphonic acid**. Formed, together with a larger quantity of the (1,3,4)-isomeride, by dissolving m-xylene in fuming  $\text{H}_2\text{SO}_4$  (Jacobsen, A. 184, 183; B. 11, 18). It remains in the acid liquor after ppg. the (1,3,4)-isomeride by the proper quantity of water. Potash-fusion yields p-xyleneol [74.5°] (Jacobsen, B. 21, 3228). Its K salt heated with sodium

formate forms an acid  $C_6H_4O_2$  [99°].— $KA'$ .  
 $BaA'$ : minute needles.— $CaA'$  aq.

*Chloride*  $C_6H_4Me_2SO_2Cl$ . Oil.

*Amide*  $C_6H_4Me_2SO_2NH_2$  [98°]. Needles.

*m*-Xylene sulphonic acid  $C_6H_4Me_2(SO_3H)$  [1:3:4]. *m*-Xylene (a)-sulphonic acid. Formed as above. Long flat prisms (containing 2aq). Its  $K'$  salt heated with sodium formate yields xylylic acid.— $NaA'$ .— $BaA'$ . Small plates.— $CaA'$  9aq.— $CaA'$  6aq.

*Chloride*  $C_6H_4Me_2SO_2Cl$  [34°].

*Amide* [137°]. Needles (from water).  
 $3zCl$  at 160° forms  $C_6H_4Me_2SO_2NHBz$  [151°] Mahon, *Am.* 4, 194, which yields crystalline  $3a(C_6H_4N_2SO_2)_2$  aq and  $BaA'$ , sl. sol. water.

*p*-Xylene sulphonic acid  $C_6H_4Me_2(SO_3H)$  [1:4:2]. Formed by sulphonating *p*-xylene (Beilstein a. Wahlfors, A. 133, 38; Fittig a. Glinzer, A. 136, 305; Jacobsen, B. 10, 1009; 11, 22; Remsen a. Emerson, *Am.* 8, 265). Plates or prisms (containing 2aq). Oxidised by alkaline  $KMnO_4$  to sulpho-terephthalic and two sulpho-p-toluic acids.— $NaA'$  aq. [148°]. Trimetric plates;  $a:b:c = 1.077:1.1498$  (Moody a. Nicholson, *C. J.* 57, 978).— $KA'$  aq.— $BaA'$ . S. 2-27 at 0°; 5-53 at 100°.— $CaA'$  8aq. Light-blue triclinic prisms.— $ZnA'$  10aq.

*Chloride*  $C_6H_4Me_2SO_2Cl$  [26°]. Prisms.

*Amide* [148°]. Needles, m. sol. hot water.

*o*-Xylene disulphonic acid  $C_6H_4Me_2(SO_3H)_2$ . Formed by heating (1,2,4)-xylene sulphonic acid with  $ClSO_3H$  at 150° (Pfannenstill, *J. pr.* [2] 46, 155).— $KA'$  aq.— $BaA'$  3aq.— $PbA'$  3aq. Prisms.

*Chloride*  $C_6H_4Me_2(SO_3Cl)_2$  [79°]. Prisms.

*Amide*  $C_6H_4Me_2(SO_2NH_2)_2$  [239°].

*m*-Xylene disulphonic acid  $C_6H_4Me_2(SO_3H)_2$  [1:3:4:2]. Formed by heating *m*-xylene with fuming  $H_2SO_4$  at 150° (Wischin, B. 23, 2113), and by heating (1,3,4)-xylene sulphonic acid with  $SO_3$  at 150° (P.). Deliquescent needles, converted by potash-fusion into  $C_6H_4Me_2(OH)_2$  [146°].— $(NH_4)A'$ .— $NaHA'$  3aq.— $KA'$  2aq.— $BaA'$  3aq. Needles, v. sol. water.— $PbA'$  3aq.— $CaA'$ . Gummy mass.

*Ethyl ether Et.A'*. Plates.

*Chloride*  $C_6H_4Me_2(SO_2Cl)_2$  [129°]. Converted by  $PCl_5$  at 180° (2,4,1,3)-di-chloro-xylene. (220°).

*Amide*  $C_6H_4N_2S_2O_4$  [249°]. Needles. Oxidised by  $KMnO_4$  to  $C_6H_4(<SO>NH_2)_2$  [225°].

*Ethylamide*  $C_6H_4Me_2(SO_2NHEt)_2$  [135°].

*m*-Xylene disulphonic acid  $C_6H_4Me_2(SO_3H)_2$  [1:3:2:6?]. Formed in small quantity, together with the preceding isomeride, by heating (1,3,2)-xylene sulphonic acid with  $ClSO_3H$  at 150° (Pfannenstill, *J. pr.* [2] 46, 154). Needles.

*Chloride*  $C_6H_4Me_2(SO_3Cl)_2$ . Oil.

*Amide*. [210°]. More sol. water than its isomeride.

*p*-Xylene disulphonic acid  $C_6H_4Me_2(SO_3H)_2$  [1:4:2:6?]. Formed by heating (1,4,2)- $C_6H_4Me_2(SO_3Cl)_2$  with fuming  $H_2SO_4$  (Holmes, *Am.* 18, 372; Pfannenstill, *J. pr.* [2] 46, 156). Needles, v. a. sol. water.— $BaA'$  3aq.— $CaA'$  4aq.— $MgA'$  7aq.— $PbA'$  3aq.— $AgA'$  aq.

*Chloride*  $C_6H_4Me_2(SO_3Cl)_2$  [78°].

*Amide*  $C_6H_4Me_2(SO_2NH_2)_2$  [295°].

*References*.—Bromo-, Bromo-nitro-, Nitro- and Nitro-amido-, XYLENE SULPHONIC ACID.

**XYLENE THIOSULPHONIC ACID.**  $Xylyl$  ether  $C_6H_4SO_2S.C_6H_5$ . *Xylyl disulphide*. Formed by heating xylene sulphonic acid with water at 150°–160° (Otto a. Lindorf, A. 146, 289). Oil, v. sol. alcohol and ether.

**XYLENIC ALCOHOL** is TOLYL-CARRINOL.

**XYLENIC DIBROMIDE** v. Di-*o*-BROMOXYLENE.

**XYLENIC GLYCOL** v. Di-*o*-OXYXYLENE.

*o*-XYLENOL  $C_6H_4O$  i.e.  $C_6H_4Me_2OH$  [1:2:4]. Mol. w. 122. [62°]. (225° i.v.). H.F.p. 61,566 (Stohmann, *J. pr.* [2] 34, 316). Obtained by potash-fusion from the sulphenic acid (Jacobsen, B. 11, 238), and by the diazo-reaction from (1,2,4)-xylylidine (Jacobsen, B. 17, 161). Long needles (from water).  $SiCl_4$  yields  $Si(OC_6H_4)_2$ , crystallising in prisms (350°–360° at 120 mm.) (Hertkorn, B. 18, 1681). Ammoniacal  $ZnBr$ , at 800° from xylylidine and dicylamine.— $NaOC_6H_5$ . Flat needles, v. sl. sol.  $NaOH$  aq.

*Benzoyl derivative* [57°]. H.F. 77,768 (Stohmann, *J. pr.* [2] 36, 8).

*o*-Xylenol  $C_6H_4Me_2(OH)$  [1:2:3]. [75°]. (218° i.v.). Occurs in coal-tar (Schulze, B. 20, 410). Formed by the action of nitrous acid on *o*-xylylidine (Töhl, B. 18, 2562; Nöling a. Forel, B. 18, 2673). Slender needles. Its aqueous solution gives a blue colour with  $FeCl_3$ .  
*c-m*-Xylenol  $C_6H_4Me_2(OH)$  [1:3:2]. [49°]. Obtained from the crude xylylidine, or by the action of  $HCl$  on *p*-oxy-mesitylenic acid (Nöling; Jacobsen, B. 21, 2829). *p*-Xylenol is got instead of *m*-xylenol by potash-fusion from (1,3,2)-xylene sulphonic acid (Jacobsen, B. 11, 26; 21, 2328).

*m*-Xylenol  $C_6H_4Me_2(OH)$  [1:3:4]. [26°] (Jacobsen, B. 18, 3463; [73°] (Staedel a. Holz, B. 18, 2919). (211° i.v.). S.G. 2.10862. H.F.p. 59,501 (Stohmann, *J. pr.* [2] 34, 316).

*Formation*.—1. From *m*-xylene sulphonic acid by potash-fusion (Jacobsen, B. 11, 24, 375; cf. Wroblewski, B. [2] 10, 286; Warts, J. 1868, 459). 2. By heating oxy-mesitylenic acid with conc.  $HCl$  aq at 200° (Jacobsen, B. 11, 2052). 3. By reduction of nitro-*m*-xylene and treatment of the resulting xylylidine with nitrous acid (Harmsen, B. 13, 1558; S. a. S.; Hodgkinson a. Limpach, *C. J.* 63, 104).

*Properties*.—Needles, v. sl. sol. water, miscible with alcohol and ether. Volatile with steam.  $FeCl_3$  colours its aqueous solution blue and its alcoholic solution green, being changed to bright blue on dilution with water. Yields the corresponding xylylidine and di-xylylamine when heated with  $ZnBr$ ,  $AmCN$ , and  $NH_4Br$  at 315° (Müller, B. 20, 1041). Potash-fusion forms (4,1,3)-oxy-toluic acid. Yields oily  $P(OC_6H_4)_3$  (Kreysler, B. 18, 1703).  $SiCl_4$  forms  $Si(OC_6H_4)_2$  (455°) (Hertkorn, B. 18, 1690).

*Salts*.— $NaOC_6H_5$ . V. sol. water and conc.  $NaOH$  aq (dullish Na salts of other xylenols). *Methyl ether*  $MeOC_6H_4$  (192° i.v.) (J.). (186°) (S.). H.F.p. 46,336 (Stohmann, *J. pr.* [2] 35, 24).

*Acetyl derivative*  $C_6H_4OAc$  (226° i.v.). *o*-Xylenol  $C_6H_4Me_2(OH)$  [1:3:5]. [84°] (T.); [68°] (N. a. F.). Occurs in coal-tar (Schulze, B. 20, 410). Formed by the action of nitrous acid on *o*-xylylidine (Töhl, B. 18, 262; Nöling a. Forel, B. 18, 2679). Slender needles (from

water). Not coloured by  $\text{FeCl}_3$ — $\text{NaOAc}$ ,  $\text{H}_2\text{O}$ . Plates, sl. sol.  $\text{NaOH}$  aq.

*p*-Xylenol  $\text{C}_6\text{H}_4(\text{OH})_2$  [1:4:2]. [74:5°]. (211-5° i.v.). H.F.p. 61,362 (Stohmann, J. pr. [2] 84, 816). S.G. 24 971. Formed by potash-fusion from *m*- and from *p*-xylene sulphonic acid and from oxy-mesitylenic acid (Wurtz, A. 147, 878; Jacobsen, B. 11, 426). Formed also from *p*-xylydine by diazotisation followed by boiling with water (Nölting, Witt, a. Forel, B. 18, 2665). Long flat needles (from dilute alcohol). Volatile with steam. Its aqueous solution is not coloured by  $\text{FeCl}_3$ .

Potash-fusion gives (3,4,1)-oxy-toluic and oxy-terephthalic acid.  $\text{KNO}_3$  and  $\text{HOAc}$  yield a nitroso-derivative  $\text{C}_6\text{H}_3\text{Me}_2(\text{OH})(\text{NO})$  [1:4:3:6] [163°], which is the oxim of *p*-xyloquinone (Oliveri, G. 12, 162; Goldschmidt a. Schmid, B. 18, 568).

Salt.— $\text{NaOAc}$ ,  $\text{H}_2\text{O}$ . Large plates, sl. sol. cold  $\text{NaOH}$  aq.

*Methyl ether*  $\text{MeOC}_6\text{H}_4$ . (194° i.v.). Oil. *Ethyl ether*  $\text{EtOC}_6\text{H}_4$ . (199°) (S.); (205°) (N. W. a. F.). Oil. H.F.p. 54, 150.

*Acetyl derivative*  $\text{C}_6\text{H}_3\text{Me}_2\text{OAc}$ . (237° i.v.). S.G. 4 10264. Oil, not solid at -20°.

Xylenol. (220°). Occurs in beechwood-tar (Marasse, A. 152, 75; Tiemann a. Mendelssohn, B. 10, 57). Oil. Yields  $\text{C}_6\text{H}_4\text{OMe}$  (220°). On boiling with aqueous  $\text{KMnO}_4$  it yields an acid which is converted by potash-fusion into *u*-oxyisophthalic acid [300°].

References.—Bromo- and Nitro-XYLENOLS. XYLENOLIC ACID v. OXY-DI-METHYL-BENZOIC ACID.

*o*-XYLENOL SULPHONIC ACID  $\text{C}_6\text{H}_4(\text{SO}_3\text{H})_2$ , i.e.  $\text{C}_6\text{H}_3\text{Me}_2(\text{OH})\text{SO}_3\text{H}$ . Formed by sulphonation of (1,2,4)-xylenol (Jacobsen, B. 11, 24).  $\text{FeCl}_3$  gives a violet colour in neutral solutions.— $\text{NaA}$ . Slender prisms or small laminae.— $\text{BaA}$ . Nodular groups of minute laminae, sl. sol. cold water.

*m*-Xylenol (α)-sulphonic acid. Formed, together with the (β)-isomeride, by dissolving (1,3,4)-xylenol in  $\text{H}_2\text{SO}_4$  (J.).  $\text{FeCl}_3$  gives a violet-blue colour.— $\text{NaA}$ . Tables.— $\text{KA}$ . Plates.— $\text{BaA}$ . Leaflets.

*m*-Xylenol (β)-sulphonic acid  $\text{C}_6\text{H}_3\text{Me}_2(\text{OH})\text{SO}_3\text{H}$  [1:3:4:2] (Jacobsen, A. 195, 283). Formed as above. Coloured violet-blue by  $\text{FeCl}_3$ . Converted by potash-fusion into (2,5,1)-oxy-toluic acid.— $\text{NaA}$  4aq. Laminae.— $\text{BaA}$ . Minute needles, less soluble than the  $\text{Ba}$  salt of the (α)-acid. By sulphonating (1,3,4)-xylenol by  $\text{ClSO}_3\text{H}$ , Hodgkinson (C. J. 62, 110) obtained a xylenol sulphonic acid yielding  $\text{BaA}$ , aq.

*m*-Xylenol sulphonic acid  $\text{C}_6\text{H}_3\text{Me}_2(\text{OH})\text{SO}_3\text{H}$  [1:3:6:4]. Formed from  $\text{C}_6\text{H}_3\text{Me}_2(\text{NH}_2)\text{SO}_3\text{H}$  by the diazo-reaction (Sartig, A. 230, 386). Slender needles, v. sol. water and alcohol. The acid and its salts give with  $\text{FeCl}_3$  a bluish-violet colour turned green by alcohol.— $\text{KA}$ .— $\text{BaA}$ , aq. Needles, v. e. sol. water.— $\text{PbA}$ , 2aq.

*Ethyl derivative*  $\text{C}_6\text{H}_3\text{Me}_2(\text{OEt})\text{SO}_3\text{H}$ . Formed by heating diazo-*m*-xylene sulphonic acid with alcohol under pressure. Minute tables, v. sol. water and alcohol.— $\text{BaA}$ , 3aq. Minute plates, v. sol. water.

*p*-Xylenol sulphonic acid. Formed by dissolving *p*-xylenol in warm  $\text{H}_2\text{SO}_4$ . Hydrated

leaflets.— $\text{NaA}$  5aq. Tables.— $\text{BaA}$ . Minute needles.

XYLENYL ALCOHOL v. DI-OXY-XYLENE. XYLENYL CHLORIDE v. TETRA-*o*-CHLOROXYLENE.

XYLETIC ACID is OXY-DI-METHYL-BENZOIC ACID.

XYLIC ACID is DI-METHYL-BENZOIC ACID.

XYLIDIC ACID is TOLUENE DICARBOXYLIC ACID.

*c*-o-XYLYDINE  $\text{C}_6\text{H}_4\text{Me}_2(\text{NH}_2)$  [1:2:3].—*Di-methyl-phenyl-amine*. *Amido-xylylene*. Mol. w. 121. (223° i.v.) at 739 mm. S.G. 12 991. Obtained by reducing di-*o*-bromo-*c*-xylydine  $\text{C}_6\text{H}_2\text{Br}_2(\text{NH}_2)$  [1:2:4:5:3] with sodium-amalgam in the cold (Töhl, B. 18, 2562). Got also by heating (1,2,4)-xylenol with  $\text{NH}_4\text{Br}$  and ammonio-zinc bromide at 300° (Müller, B. 20, 1039). Prepared from *o*-xylene by nitration and reduction (Nölting a. Forel, B. 18, 2671; Wroblewski, B. 18, 2904). Oil. When oxidised by  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{H}_2\text{SO}_4$  it yields a small quantity of *o*-xyloquinone [55°]. Converted by the diazo-reaction into *o*-xylenol [73°].  $\text{H}_2\text{SO}_4$  and  $\text{HNO}_3$  give (4,1,2,3)-nitro-xylydine [114°] and (6,1,2,3)-nitro-xylydine [65°] (Nölting a. Stoecklin, B. 24, 567).—Salts:  $\text{B}^+\text{HCl}$  aq. Plates. Begins to sublime at 100°.— $\text{B}^+\text{HNO}_3$ . Needles.— $\text{B}^+\text{H}_2\text{SO}_4$ . Large plates, sl. sol. water.

*Acetyl derivative*  $\text{C}_6\text{H}_3\text{Me}_2\text{NHAc}$ . [134°] (N. a. F.); [131°] (T.; W.). Slender needles.

*i*-o-XYLYDINE  $\text{C}_6\text{H}_3\text{Me}_2(\text{NH}_2)$  [1:2:4]. [49°]. (226°). S.G. 12 10755. Prepared from *o*-xylene by nitration and reduction (Jacobsen, B. 17, 159). Got also by heating *m*-toluidine hydrochloride with  $\text{MeOH}$  at 300° (Limpach, B. 21, 643). Monoclinic crystals, not coloured by exposure to light and air. Gives no colour with bleaching powder. Its solutions colour pine-wood yellow. On nitration it yields (6,1,2,4)-nitro-xylydine [137°] and an isomeride [80°] (N. a. S.). Yields a saffranine on oxidation together with di-amido-di-phenyl-amine (Nietzki, B. 19, 3163).—Salt:  $\text{B}^+\text{HCl}$  aq. Prisms, v. sol. water. Yields  $\psi$ -cumidine when heated with  $\text{MeOH}$  at 310° (N. a. F.).

*Acetyl derivative*  $\text{C}_6\text{H}_3\text{Me}_2\text{NHAc}$ . [99°]. *c*-*m*-XYLYDINE  $\text{C}_6\text{H}_3\text{Me}_2(\text{NH}_2)$  [1:3:2]. (S). Xylydine (214° i.v.) at 739 mm. (N. a. F.). S.G. 12 9942 (W.). Formed by distilling *p*-amido-mesitylenic acid with lime (Schmitz, A. 193, 179) and by reducing *c*-nitro-*m*-xylene (Grovingk, B. 17, 2430). Obtained from commercial xylydine by crystallisation of the sulphate; the last mother-liquor depositing crystals which are converted into the acetyl derivative by distillation with  $\text{HOAc}$ . The acetyl derivative is saponified by treatment with dilute (25 p.c.)  $\text{H}_2\text{SO}_4$  (Nölting a. Pick, B. 21, 3150; cf. Wroblewski, B. 12, 1226). Gives *m*-xyloquinone [73°] on oxidation (Nölting a. Forel, B. 18, 2676). Yields (4,1,3,2)-nitro-xylydine [82°] on nitration (Nölting a. Stoecklin, B. [3] 6, 381).—Salts:  $\text{B}^+\text{HCl}$ — $\text{B}^+\text{HCl}$  aq. S. 9-7 at 18°. Monoclinic plates. Yields mesidine on heating with  $\text{MeOH}$  at 310°.— $\text{B}^+\text{HNO}_3$ . S. 6-2. Needles.— $\text{B}^+\text{H}_2\text{SO}_4$ . Very soluble needles.— $\text{B}^+\text{H}_2\text{SO}_4$ , 21aq. S. 60.

**Acetyl derivative**  $C_8H_7Me.NHAc$  [174°] (G.); [176-8°] (N. a. F.). Needles.

**Benzoyl derivative**  $C_8H_7Me.NHCO_2Ph$  [140°]. Needles. Yields benzoyl-nitro-xylylidine [178°] on nitration (Hübner, A. 208, 818).

***m*-Xylylidine**  $C_8H_7Me.NH_2$  [1:3:5]. (222° I.V.). S.G. 1.5 072. Formed by reduction of *s*-nitro-*m*-xylene [71°] (Thöl, B. 18, 362; Nölting a. Forel, B. 18, 2678). On oxidation by  $K_2Cr_2O_7$  and  $H_2SO_4$  it gives *m*-xyloquinone [73°]. By boiling the diazo-compound with water-xylenol [68°] is formed.  $ClCO_2Et$  forms  $C_8H_7Me.NH.CO_2Et$  [77-5°] (Frentzel, C. C. 1888, 1361).— $B^*HCl$ .  $MeOH$  at 250°–300° yields isocumidine  $C_8H_7Me.NH_2$  (5:4:3:1) (Limpach, B. 21, 643).— $B^*H_2SO_4$  aq.— $B^*HNO_3$  S. 4:66 at 13°.

**Acetyl derivative**  $C_8H_7Me.NHAc$  [140-5°] (N. a. F.); [138°] (T.); [144-6°] (W.). Colourless plates (from alcohol or ether).

***i*-m-Xylylidine**  $C_8H_7Me.NH_2$  [1:3:4]. (a). **Xylylidine** (215°) at 745 mm. (G.). S.G. 1.5 9184 (H.). S.V. 1483.

**Formation**.—1. By reducing *i*-nitro-*m*-xylene (Deumelandt, A. 144, 273; Tavildaroff, B. 2, 553; Wroblewski, A. 192, 215; 207, 91; Grevingk, B. 17, 2430; Wallach, A. 258, 331). It may be isolated from commercial xylylidine by conversion into hydrochloride and several crystallisations from water; the yield being about 40 p.c. (Nölting a. Forel, B. 18, 2677).—2. By heating *o*- and *p*-toluidine hydrochloride with  $MeOH$  at 300° (Hofmann, B. 9, 1295; Limpach, B. 21, 640).—3. By distilling (4,3,1,5)-amidomesitylic acid with lime (Schmitz, A. 193, 177).—4. By heating *i*-*m*-xylylidine with ammonium-zinc bromide and  $NH_4Br$  (Müller, B. 20, 1039).

**Reactions**.—1. When dissolved in  $H_2SO_4$  (10 pts.) it yields  $C_8H_7Me.NH_2(NO_2)$  [1:3:4:6] [123°] on nitration (Nölting a. Collin, B. 17, 265).—2. The hydrochloride heated with  $MeOH$  at 310° yields mesidine.—3.  $ClCO_2Et$  forms  $C_8H_7Me.NH.CO_2Et$  [57°] (Frentzel, C. C. 1888, 1361).—4. When mixed with di-amido-di-phenylamine it yields a saffranine on oxidation (Nietzki, B. 19, 8163).—5. When *m*-xylylidine (4 pts.) is heated with S (1 pt.) at 190° it gives off  $H_2S$  and forms a base  $C_8H_7Me.N_2S$  [107°] (285° at 14 mm.) which crystallises from alcohol in yellowish-white prisms and yields  $C_8H_7Me.AcN_2S$  [227°] (Anschütz a. Schultz, B. 22, 582). By further heating with sulphur a homologue of primuline is formed.—6. *Enanthol* forms oily  $C_8H_7Me.NO$  (Leeds, B. 16, 288).—7. *Acrolein* yields  $C_8H_7Me.N$ , a reddish-yellow mass which on distillation yields cryptidine  $C_{11}H_{11}N$  (270°) (Leeds, A. C. J. 5, 1).

• Salts.— $B^*HCl$ . Monoclinic prisms.— $B^*HCl$  aq. Plates (Staedel a. Holz, B. 18, 2649).— $B^*H_2PO_4$ .— $B^*HBr$ . Trimetric plates.— $B^*HNO_3$ .— $B^*H_2SO_4$  aq. Cubes. Loses xylylidine on evaporation of its solution (Nölting a. Pick, B. [2] 50, 606).— $B^*H_2PO_4$ . Only phosphate formed (Lewy, B. 19, 2728).— $B^*H_2CO_3$  S. 8:32 at 18°.— $B^*ZnCl_2$  (Lachovitch, M. 9, 514).— $B^*HgH(SO_4)$  aq.— $B^*Cu_2H_2(SO_4)$  (Denigès, C. R. 112, 970).

**Formyl derivative**  $C_8H_7Me.NH.CO_2O$ . [111°] (G.); [114°] (G. a. M.). Got by heating the base (12 g.) with formic acid (5 g.) at 150° (Gasiorowski a. Mers, B. 18, 1011; Gudemann,

B. 21, 2549). Crystals (from water). Converted by  $F_2S_2$  at 100° into the thioformyl derivative [105°].

**Mono-acetyl derivative**

$C_8H_7Me.NHAc$ . [129°]. Needles or plates (from dilute alcohol).  $P_2S_5$  forms the compound  $C_8H_7Me.NH.CSMe$  [95°] (Jacobsen a. Noy, B. 22, 907).

**Di-acetyl derivative**  $C_8H_7Me.NHAc_2$ . [60°]. Formed, together with the mono-acetyl derivative, by boiling the base with  $Ac_2O$  (Wallach, A. 258, 301).

**Benzoyl derivative**  $C_8H_7Me.NHCO_2Ph$ . [192°]. Needles (Hübner, A. 208, 818). Converted by  $HNO_3$  into the nitro-benzoyl derivative [184°] which is reduced by tin and  $HOAc$  to  $C_8H_7Me.NH_2$   $\left[ \begin{smallmatrix} NH \\ N \end{smallmatrix} \right] > C_6H_5$  [195°].

**Phthalyl derivative** [158°]. Prisms (from alcohol).

***p*-Xylylidine**  $C_8H_7Me.NH_2$  [1:4:2]. [15-5°] (Michael, Z. 26, 39). (215° i.V.) at 739 mm. (N. a. F.); (213-5° uncor.) (M.); (220°) (S.). S.G. 1.5 980. Obtained from *m*-xylene by nitration and reduction (Schaumann, B. 11, 1537; Nölting a. Forel, B. 18, 2664; 19, 2680). Occurs to the extent of about 25 p.c. in commercial xylylidine, from which it may be isolated by dissolving in warm  $H_2SO_4$  and pouring into hot water. The sparingly soluble *m*-xylylidine sulphonic acid crystallises out, and the mother-liquor, after successive treatment with  $CaCO_3$  and  $Na_2CO_3$ , yields on evaporation sparingly soluble, pearly plates of sodium *p*-xylylidine sulphonate, which on distillation with lime give *p*-xylylidine almost without loss. May also be got from crude xylylidine by means of its benzylidene derivative.

**Reactions**.—1. Oxidised by  $K_2Cr_2O_7$  and  $H_2SO_4$  to *p*-xyloquinone [123°], the yield being 70 p.c.—2. Converted by the diazo-reaction into *p*-xylenol [75°] (210°)—3. On heating with sulphur it yields  $C_8H_7Me.N_2S$  [144°], which crystallises from alcohol in yellowish needles, and yields an acetyl derivative [212°] (Anschütz a. Schultz, B. 22, 585).—4. The hydrochloride heated with  $MeOH$  at 290° under pressure forms  $\psi$ -cumidine (Limpach, B. 21, 646).—5. *Benzoic aldehyde* forms  $C_8H_7Me.N.CHPh$  [102°] (Pfug, A. 255, 166). The same body [98°] is got by adding benzoic aldehyde to an alcoholic solution of thionyl-*p*-xylylidine (Michaelis, A. 274, 237).

• Salts.— $B^*HCl$  aq. Leaflets, subliming at 125°–130° in needles.— $B^*HNO_3$ . Needles.— $B^*H_2SO_4$ . Plates, sl. sol. water.— $B^*H_2CO_3$ .

**Formyl derivative**  $C_8H_7Me.NH.CO_2O$ . [112°]. Needles (Pfug, A. 255, 168).

**Acetyl derivative**  $C_8H_7Me.NHAc$ . [189°]. Prisms. Yields on nitration acetyl-nitro-*p*-xylylidine [192°].

**Bromo-acetyl derivative**

$C_8H_7Me.NH.CO_2CH_2Br$ . [145°]. Formed from bromo-acetyl bromide and *p*-xylylidine in benzene (Abenius, J. pr. [2] 40, 435). Needles (from dilute alcohol). Boiling alcoholic potash converts it into an azine and the compound  $C_8H_7Me.NH.CO_2CH_2OEt$  [50°].

**Oxalyl derivative**  $C_8H_7Me.NH.CO_2O$ . Formed by heating the oxalate at 130°. Needles, subliming at 125°. An oxalyl-xylylidine [204°] was obtained by Gens (B. 8, 227) from crude, commercial xylylidine.

**Benzoyl derivative**  $C_6H_5Me_2NHBz$ . [140°]. Needles.

**References.**—BROMO-, CHLORO-, and NITROXYLIDINE.

**XYLIDINE SULPHONIC ACID** v. AMIDOXYLENE SULPHONIC ACID and BROMO- and NITROXYLIDINE SULPHONIC ACIDS.

**XYLIDINIC ACID** v. TOLUENE DICARBOXYLIC ACID.

**XYLINDEIN**  $C_{65}H_{10}O$ .  $Xylite$  oil. (252°) (Pinner, B. 15, 594; 16, 1729) (c. 240°) (Claisen & Ehrhardt, B. 22, 1013). S.G. 935. A product of the action of  $HCl$  on acetone (P.). Formed also by the action of  $NaOEt$  on methyl oxide in ether, and in the preparation of acetylacetone by the action of boiling  $EtOAc$  and  $NaOAc$  on acetone (C. A. E.). Oil, easily resinified by strong acids.

**Dixylitene**  $C_8H_{10}O_2$ . (310°–320°). A product of the action of  $HCl$  on acetone (Pinner).

**XYLOHYDROQUINONE** v. HYDROXYLOQUINONE.

**XYLOIC ACID** v. DI-METHYL-BENZOIC ACID.

**XYLONIC ACID**  $C_8H_{10}O_4$ . [ $\alpha$ ] = 17.48°. Formed by oxidising xylene with bromine (Tollens, A. 260, 367). Dextrorotatory. Its  $Ca$ ,  $Zn$ , and  $Ag$  salts are amorphous.  $—SrA_2$ . [ $\alpha$ ]<sub>D</sub> = +12.14°.

**XYLONITRILE** v. Nitrile of DI-METHYL-BENZOIC ACID.

**o-XYLOQUINONE**  $C_8H_6O_2$ , i.e.  $Q.H.Me_2O_2$  [1:2:3:6]. [55°]. Formed by oxidation of o-xylidine by  $K_2Cr_2O_7$  and  $H_2SO_4$ , the yield being about 10 p.c. (Nölting & Forel, B. 18, 2678). Yellow needles (by sublimation), v. sl. sol. water, m. sol. alcohol and ether.

**m-Xyloquinone**  $C_8H_6Me_2$  [1:3:2:5]. [78°]. Formed by oxidation either of m- or s-m-xylidine with  $K_2Cr_2O_7$  and  $H_2SO_4$  (Nölting & Forel, B. 18, 2679). Got also by oxidation of mesidine (Nölting & Baumann, B. 18, 1151). Yellow needles.

**p-Xyloquinone**  $C_8H_6Me_2O$  [1:4:2:5]. *Phlorone*. *Metaphlorone*. Mol. w. 136. [124°].

**Formation.**—1. Occurs, together with toluquinone and other bodies, among the products of the action of  $MnO_2$  and  $H_2SO_4$  on coal-tar and beechwood-tar (Rommier & Bouilhor, J. R. 55, 214; Görup-Besanez & v. J. Rad, Z. [2] 4, 580; Carstanjen, J. pr. [2] 23, 425).—2. By oxidation of p-xylene-diamine (Nietzki, B. 18, 472; A. 215, 168).—3. By oxidation of  $\psi$ -cupenol (Carstanjen, J. pr. [2] 23, 430).—4. By oxidation of  $\psi$ -cumidine by  $CrO_3$  (Nölting & Th. Baumann, B. 18, 1151; Sutkowski, B. 20, 977).—5. By distilling xylidine (218°) with  $H_2SO_4$  and  $MnO_2$ ; the yield being 5 p.c. (C.).—6. By oxidation of p-xylidine with  $K_2Cr_2O_7$  and  $H_2SO_4$ , the yield being over 70 p.c. (Nölting, Witt, & Forel,

B. 18, 2667).—7. By heating diacetyl with dilute  $NaOHAq$  (Van Pechmann, B. 21, 1490).

**Preparation.**—1. Commercial xylene (180°–140°) is heated with  $H_2SO_4$  at 100° for six days; the product poured into water; neutralised by  $CaCO_3$ ; treated with  $K_2CO_3$ ; and the  $K$  salts of the sulphonic acids fused with potash. The product is dissolved in water, acidified, and extracted with ether; and the mixture of xylenols so obtained is dissolved in warm  $H_2SO_4$ , and then diluted with water and distilled with  $MnO_2$ . Crystals of p-xyloquinone appear in the condenser and receiver (Carstanjen, J. pr. [2] 23, 427).—2. 'Yellow carboic acid' or 'creosote,' the mother-liquor from which phenol has crystallised, is dissolved in  $H_2SO_4$ , diluted with water, and then distilled with  $MnO_2$ . The solid found in the receiver is crystallised from alcohol when the first crop of crystals is xyloquinone (L. Carstanjen, J. pr. [2] 23, 423).

**Properties.**—Long yellow needles (from benzene), sl. sol. water and cold alcohol, v. sol. ether. May be sublimed. Volatile with steam.

**Reactions.**—1. Distilled with zinc-dust gives a hydrocarbon that oxidises to terephthalic acid.—2. Reduced by aqueous  $SO_2$  to hydroxyloquinone.—3. Conc.  $HCl$  converts it into a mixture of mono- and di-chloro-hydro-xyloquinones,  $C_8H_5ClMe_2(OH)$ , [147°] and  $C_8H_4Cl_2Me_2(OH)$ , [175°].

**Mono-oxim**  $C_8H_7Me_2O(NOH)$ . *Nitroso-p-xyleneol*. [168°]. Formed by heating p-xyloquinone (2 pts.) with an alcoholic solution of hydroxylamine hydrochloride (1 pt.) (Goldschmidt & Schmid, B. 18, 568; Sutkowski, B. 20, 978). Obtained also by adding  $KNO_3$  and excess of  $HOAc$  to an alkaline solution of p-xyleneol (Oliveri, G. 12, 162). Yellowish needles (from alcohol), v. sol. alcohol, ether, and benzene, insol. cold water. Alkalis form a deep orange-red solution. Reduced by  $SnCl_2$  to amido-p-xyleneol. Oxidised by alkaline  $K_2FeO_4$  to nitro-p-xyleneol.

**Di-oxim**  $C_8H_7Me_2(OH)_2$ . [272°]. Formed by boiling the quinone (1 mol.) with an alcoholic solution of hydroxylamine hydrochloride (2 mols.) (Sutkowski, B. 20, 977). V. sl. sol. alcohol, acetic acid, and benzene, insol. water. Dissolves in alkalis with a yellow colour. By tin and  $HCl$  it is reduced to xylene-p-diamine. Its di-acetyl derivative  $C_8H_5Me_2(NOAc)_2$  crystallises from acetic acid in small yellow prisms, [170°], v. sol. alcohol and benzene.

**References.**—DI-BROMO- and CHLOROXYLOQUINONE.

**XYLORCIN** v. DI-OXYXYLENE.

**XYLOSE** v. p. 538.

**XYLOSTEIN**. A glucoside in the berries of *Bonicera Xylospermum* (Hübichmann, J. 1856, 691; Enz, C. C. 1856, 393). Crystalline, insol. water, sol. alcohol and ether.

**XYLOYL-BENZOIC ACID** v. PHENYL XYLIL KETONE CARBOXYLIC ACID.

**XYLOYL-FORMIC ACID** v. XYLIL-GLYOXYLIC ACID.

**xy-DIXYLYL**  $C_8H_8$ , i.e.

[4:1:3]  $C_8H_8Me_2$ ,  $C_8H_8Me_2$  [3:4:1]. [125°]. Prepared by distilling mercury di-p-xylyl (Jacobsen, B. 14, 2112). Long needles (from alcohol).—**Dixylol**. (290°–295°). Formed from bromo-m (7)-xylene and  $Na$  (Pittig, A. 147, 35). Liquid.

**Di-xylyl** (so-called). (295°) (Oliveri, G. 12, 158). Is got by warming commercial xylene with  $\text{H}_2\text{SO}_4$  but never from xylene which has been made from xylene sulphonic acid. Hence it is probably not a benzene derivative (Armstrong, C. J. 45, 150). It is a colourless, fluorescent liquid, smelling like copaiba balsam.

**XYLYL-ACETAMIDE** v. *Acetyl derivative of Xylidine* and *Amide of Xylyl-acetic acid*.

**XYLYL-ACETIC ACID**

[1:3:4]  $\text{C}_6\text{H}_4\text{Me}_2\text{CH}_2\text{CO}_2\text{H}$ . [102°]. Formed from its amide, which is got by the action of yellow ammonium sulphide on xylyl methyl ketone (Willgerodt, B. 21, 534). Slender needles.

*Amide*  $\text{C}_6\text{H}_4\text{Me}_2\text{CH}_2\text{CONH}_2$ . [183°].

*References.*—Oxy-xylyl-acetic acid.

**XYLYL ALCOHOL** is **TOLYL-CARBINOL**.

**XYLYL-AMIDO-ACETIC ACID**  $\text{C}_6\text{H}_4\text{Me}_2\text{NO}_2$ , i.e.

[1:3:4]  $\text{C}_6\text{H}_4\text{Me}_2\text{NHCH}_2\text{CO}_2\text{H}$ . [134°]. Formed by boiling *m*-xylidine (2 mols.) with water and chloro-acetic acid (1 mol.) (Ehrlich, B. 16, 205). Prisms (from dilute alcohol). Insol. water, v. sol. acids.

*Xylide*  $\text{C}_6\text{H}_4\text{NHCH}_2\text{CO}_2\text{NHC}_6\text{H}_5$ . [128°]. Formed by boiling xylidine (2 mols.) with chloro-acetic ether (1 mol.). Thick needles (from alcohol), insol. water and  $\text{HCl}$  aq.

**XYLYL-AMIDO-CROTONIC ETHER**

[1:3:4]  $\text{C}_6\text{H}_4\text{Me}_2\text{NHCMcCH}_2\text{CO}_2\text{Et}$ . Formed from *m*-xylidine and acetoacetic ether (Conrad, A. Limpach, B. 21, 526). Decomposed on heating into (Py. 1, 3; B. 2, 4)-oxy-tri-methyl-quinoline, di-xylyl-urea, and alcohol.

**XYLYL-AMIDO-ETHYL-PHTHALIMIDE**

[1:3:4]  $\text{C}_6\text{H}_4\text{Me}_2\text{NHC}_6\text{H}_4\text{N}_2\text{C}_6\text{H}_4\text{O}_2$ . [123°]. Formed by heating bromo-ethyl-phthalimide with *m*-xylidine at 140° (Newman, B. 21, 2197). Small needles, v. e. sol. benzene, al. sol. cold alcohol.

**DI-*m*-XYLYL-DI-AMIDO-GLAZTHIOLE**

$\text{C}_6\text{H}_4\text{N}_2\text{S}$  i.e.  $\text{S} < \begin{matrix} \text{C}(\text{NHCH}_2)_2\text{N} \\ \text{C}(\text{NHCH}_2)_2\text{N} \end{matrix}$ . [79°]. Formed by oxidising (1,3,4)-xylyl-thio-urea with aqueous  $\text{H}_2\text{O}_2$  (Hector, B. 23, 368). Insol. water. Forms a very soluble hydrochloride.  $\text{B}^+\text{H}_2\text{P}(\text{Cl})_2$ . Decomposes at 214°–217°.  $\text{B}^+\text{AgNO}_2$ . Explodes on heating. Blackened by sunlight.  $\text{B}^+\text{C}_6\text{H}_5\text{N}_2\text{O}$ . [218°]. Yellow crystals, v. sol. alcohol. Cyanogen passed into its alcoholic solutions forms  $\text{C}_6\text{H}_4\text{N}_2\text{SCy}$ . [103°].

*Acetyl derivative*  $\text{C}_6\text{H}_4\text{AcN}_2\text{S}$ . Needles. *Benzoyl derivative*  $\text{C}_6\text{H}_4\text{BzN}_2\text{S}$ . [212°]. *Nitrosamine*  $\text{C}_6\text{H}_4(\text{NO})\text{N}_2$ . [146°].

**XYLYLAMINE** v. *Xylidine* and *Methyl-benzyl-amine*.

**Di-*o*-xylyl-amine**  $(\text{C}_6\text{H}_4)_2\text{NH}$ . (338°–345°). Formed, together with xylidine, by heating (1,3,4)-xylene with ammonio-zinc bromide and  $\text{NH}_4\text{Br}$  at 300° (Müller, B. 20, 1049). Liquid, solidified at a very low temperature.

**Di-*m*-xylyl-amine**. (305°–310°). Formed in like manner from *m*-xylidine. Oil.

**Di-xylyl-amine**. [162°]. Formed, together with a liquid isomeride, by heating xylidine with its hydrochloride (Girard, A. Vogt).

**XYLYL-BENZYL-AMINE**  $\text{C}_6\text{H}_4\text{N}_2$ , i.e.  $\begin{matrix} \text{C}_6\text{H}_4\text{Me}_2\text{NHCH}_2\text{Ph} \\ \text{C}_6\text{H}_4\text{Me}_2\text{NHCH}_2\text{Ph} \end{matrix}$ . (c. 205° at 15 mm.). Formed by heating *m*-xylidine with benzyl chloride at 160° (Joblin-Gohner, B. 18, 6, 21). Yellowish oil, sol. alcohol and benzene.

***p*-Xylyl-benzyl-amine**

[1:4:2]  $\text{C}_6\text{H}_4\text{Me}_2\text{NHCH}_2\text{Ph}$ . (322°) (Pflug, A. 256, 168).

***o*-XYLYL BENZYL KETONE**  $\text{C}_6\text{H}_4\text{O}$ , i.e.  $\text{C}_6\text{H}_4\text{Me}_2\text{COCH}_2\text{Ph}$ . [35°]. (210°–220° at 25 mm.). Formed from *o*-xylene, phenyl-acetic chloride, and  $\text{AlCl}_3$  (Wege, B. 24, 3540). Plates, sol. alcohol, v. sol. ether. Yields a crystalline oxim.  $\text{NaOEt}$  and benzyl chloride yield  $\text{C}_6\text{H}_4\text{Me}_2\text{COCH}(\text{CH}_2\text{Ph})\text{Ph}$  [75°].

***m*-Xylyl benzyl ketone**

[1:3:4]  $\text{C}_6\text{H}_4\text{Me}_2\text{COCH}_2\text{Ph}$ . (350°). Formed, together with a smaller quantity of an isomeride [93°], by the action of  $\text{AlCl}_3$  on a mixture of *m*-xylene and phenyl-acetic chloride (Sillscher, B. 15, 1681). Yields  $\text{C}_6\text{H}_4\text{Me}_2(\text{CO}_2\text{H})_2$  [3:4:1] on oxidation.  $\text{NaOEt}$  and benzyl chloride form oily  $\text{C}_6\text{H}_4\text{COCHPhCH}_2\text{Ph}$  (365°–375°).

***p*-Xylyl benzyl ketone**  $\text{C}_6\text{H}_4\text{COCH}_2\text{Ph}$ . (220°–230° at 26 mm.). Formed in like manner from *p*-xylene (Wege). Yields an oxim [99°] and a phenyl-hydrazone [96°].  $\text{NaOEt}$  and benzyl chloride yield  $\text{C}_6\text{H}_4\text{COCHPhCH}_2\text{Ph}$  [60–5°].

***m*-XYLYL-BENZYL-THIO-UREA**

$\text{C}_6\text{H}_4\text{NHCSNHCH}_2\text{Ph}$ . [85°]. Formed from benzyl-thiocarbimide and *m*-xylidine in alcohol (Dixon, C. J. 59, 558). Monoclinic prisms, v. sol. boiling alcohol and chloroform.

**XYLYL BROMIDE** v. **BROMO-XYLENE**.

**XYLYL-*tert*-BUTANE**  $\text{C}_6\text{H}_4\text{Me}_2\text{CMe}_2$ . [201°].

Formed from *m*-xylene, isobutyl bromide, and  $\text{AlCl}_3$  (Baur, B. 24, 2840). Got also from isobutyl alcohol, *m*-xylene, and  $\text{H}_2\text{SO}_4$  or  $\text{ZnCl}_2$  (Nölting, B. 25, 791). Oil, yields mesitylenic and trimetic acids on oxidation.

**XYLYL-BUTYL ALCOHOL**

[2:3:1]  $\text{C}_6\text{H}_4\text{Me}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{OH}$ . (above 270°). Got by reducing xylyl propyl ketone with zinc-dust and  $\text{KOH}$  aq, or with sodium-amalgam (Claus, J. pr. [2] 46, 474). Oil, v. sol. alcohol and ether. Tri-xylyl-butyl alcohol  $(\text{C}_6\text{H}_4)_3\text{CMe}_2\text{OH}$ . (above 300°). Formed from *m*-xylene, tri-chloro-*tert*-butyl alcohol, and  $\text{AlCl}_3$  (Willgerodt & Genieser, J. pr. [2] 37, 861). Oil, smelling like mushrooms.

***m*-XYLYL-*n*-BUTYRIC ACID**

[1:3:4]  $\text{C}_6\text{H}_4\text{Me}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$ . [70°]. Formed by saponifying the amide (Claus, J. pr. [2] 46, 476). Needles, v. sol. hot water. May be sublimed.  $\text{BaA}$ , 4aq.  $\text{CaA}$ , 4aq. Prisms, v. sol. water and alcohol.

*Amide*  $\text{C}_6\text{H}_4\text{Me}_2\text{CH}_2\text{CH}_2\text{CONH}_2$ . [124°]. Got by heating xylyl propyl ketone with  $\text{S}$  and ammonium sulphide in sealed tubes at 250°. Flat silky needles. May be sublimed.

***p*-Xylyl-*n*-butyric acid**

[1:4:2]  $\text{C}_6\text{H}_4\text{Me}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$ . [70°]. Needles, sl. sol. cold water.  $\text{BaA}$ , 4aq.  $\text{CaA}$ , 4aq. Needles, sol. water and alcohol.

*Amide*  $\text{C}_6\text{H}_4\text{Me}_2\text{CH}_2\text{CH}_2\text{CONH}_2$ . [125°]. Formed from *p*-xylyl propyl ketone (C). Flat needles, v. sol. hot water.

***m*-Xylyl-isobutyric acid**

[1:3:4]  $\text{C}_6\text{H}_4\text{Me}_2\text{CH}_2\text{CHMeCO}_2\text{H}$ . [70°]. Flat pearly needles, sol. hot water, alcohol, and ether. May be sublimed.

*Amide*  $\text{C}_6\text{H}_4\text{Me}_2\text{CH}_2\text{CHMeCONH}_2$ . [120°]. Got by heating xylyl isopropyl ketone with  $\text{S}$  and ammonium sulphide at 235° (Claus, J. pr. [2] 46, 483). Needles, sol. hot water.

**XYLYL-CARBAMIC ACID**

[1:3:4]  $C_6H_4Me_2.NH.CO.OH$ . *Ethyl ether EtA*. [58°]. Formed from *m*-xylylene and chloroformic ether (Hofmann, B. 3, 657; Frentzel, C. C. 1888, 1861). Needles.

**Xylyl-carbamic acid**

[1:3:5]  $C_6H_4Me_2.NH.CO.OH$ . *Ethyl ether EtA*. [77-5°] (Frentzel).

**Di-*p*-XYLYL-CARBINOL**

[(2:5:1)  $C_6H_4Me_2.CH.OH$ . [181°]. Formed by reducing di-*p*-xylyl ketone with zinc-dust and KOH (Elbs, J. pr. [2] 55, 484; B. 19, 408). White needles (from alcohol), nearly insol. Aq.

**XYLYL CYANATE** [1:3:4]  $C_6H_4Me_2.N.CO$ . [205°] (Frentzel, C. C. 1888, 1861).

**Xylylcyanate** [1:3:5]  $C_6H_4Me_2.N.CO$ . [208-5°].

**XYLYL CYANURATE**

[1:3:4]  $(C_6H_4Me_2)_3N_3C_3O_3$ . [162°] (Frentzel, C. C. 1888, 1861).

**XYLYLENE ALCOHOL v. Di-OXY-XYLYLENE.**

**XYLYLENE-DI-ALLYL-DI-THIO-DI-UREA**  $(CH_2)_2C_6H_4(NH.CS.NH.C_2H_5)_2$  [1:4:2:6]. [112-5°]. Made from *p*-xylylene diamine and allyl thiocarbimide (Lellmann, A. 238, 252). Needles (from alcohol). Not decomposed on melting.

***m*-XYLYLENE-*m*-DIAMINE**

$C_6H_4(CH_2)(NH_2)_2$  [1:3:4:6]. ***m*-Di-amido-*m*-xylylene** [105°]. Formed by reduction of nitro-xylylene [128°] or of di-nitro-xylylene [93°] (Fittig, A. 147, 18; Grevingk, B. 17, 2426; Witt, B. 21, 2419). White crystals. Sublimable. Does not yield a aurhodine on boiling with nitroso-dimethyl-aniline, NaOAc, and HOAc. —  $B''^2HCl$ . —  $B''^2H_2PtCl_4$ . —  $B''^2H_2SO_4$ . Crystalline, v. sq. Aq.

***m*-Xylylene-*o*-diamine**

$C_6H_4Me_2(NH_2)_2$  [1:3:5:6] [78-5°]. Formed by reduction of [2:4:1]  $C_6H_4Me_2.N_2$ ,  $C_6H_4Me_2.NH_2$  [1:3:5:6] (Nölting a. Forel, B. 18, 2685) and also by the action of tin and HClAq on di-bromo-di-nitro-*m*-xylylene [191°] (Jacobsen, B. 21, 2821), and on (5,1,3,6)-nitro-xylylene (Hofmann, B. 9, 1298). Plates (from water), sl. sol. cold benzene, sol. ether.

***m*-Xylylene-*m*-diamine**

$C_6H_4Me_2(NH_2)_2$  [1:3:4:2]. [64°]. Formed by reduction of nitro-xylylene [78°] or of di-nitro-*m*-xylylene [82°] (Grevingk, B. 17, 2426). White needles. Gives a Bismarck brown with nitrous acid and a chrysoidine with diazobenzene.

***p*-Xylylene-*o*-diamine**

$C_6H_4Me_2(NH_2)_2$  [1:4:2:3]. [75°]. Formed by reduction of *o*-di-nitro-*p*-xylylene (Lellmann, A. 228, 251; Nölting, B. 19, 145). White needles (by sublimation). Gives a deep-red colour with  $FeCl_3$ .

***p*-Xylylene-*m*-diamide**

$C_6H_4Me_2(NH_2)_2$  [1:4:2:6]. [102°]. Formed by reducing (2,6,1,4)-di-nitro-xylylene (L. a. N.). Needles (by sublimation). Behaves like a *m*-diamine.

***p*-Xylylene-*p*-diamine**

$C_6H_4Me_2(NH_2)_2$  [1:4:2:5]. [142°] (S.); [147°] (N. a. F.); [150°] (N.). **Formation**.—1. By reduction of xylylene-azoxylylene (amido-azo-xylylene) [2:5:1]  $C_6H_4Me_2.N_2$ ,  $C_6H_4Me_2.NH_2$  [1:2:5:4] by zinc and HClAq (Nietzki, B. 18, 471; Nölting a. Forel, B. 18, 2685).—2. By reduction of nitro-*p*-xylylene [142°] (Nölting, Witt, a. Forel, B. 18, 2666; von Kostanecki, B. 19, 2318; Marekwald, B. 23, 1021).—3. By reduction of the di-oxim of

*p*-xyloquinone  $C_6H_4Me_2(NO_2)_2$  with tin and HCl (Sutkowski, B. 20, 979).

**Properties**.—Colourless needles, sol. hot water and alcohol, m. sol. benzene and ether. Yields xylequinone [128°] on oxidation. Not oxidised by exposure to air. May be sublimed.

**Salts**.— $B''^2HCl$ . Colourless leaflets. —  $B''^2H_2SO_4$ . Crystalline meal.

***o*-Xylylene-*exo*-diamine**

[1:2]  $C_6H_4(CH_2.NH_2)_2$ . Formed by heating the phthalimide  $C_6H_4(CH_2.N:O_2.C_2H_5)_2$  with conc. HClAq at 200° (Strassmann, B. 21, 579). Alkaline liquid, smelling strongly like ammonia. Absorbs  $CO_2$ . Gives with  $FeCl_3$  a pp. of yellowish-red needles. —  $B''^2HCl$ . —  $B''^2H_2AuCl_4$ . Yellow plates. —  $B''^2C_2H_4N_2O_4$ . Yellow needles, decomposing above 170° without melting.

**Acetyl derivative**  $C_6H_4(CH_2.NHAc)_2$ . [146°].

**Benzoyl derivative**  $C_6H_4(CH_2.NH.Bz)_2$ . [168°].

***m*-Xylylene-*exo*-diamine**

[1:3]  $C_6H_4(CH_2.NH_2)_2$ . [247°]. Formed by the action of conc. hydrochloric acid at 220° on the  $C_6H_4(CH_2.N:C_2H_5O_2)_2$  [237°], which is got by heating potassium phthalimide with di-*o*-bromoxylene (Brömme, B. 21, 2705). Liquid, sol. water, miscible with alcohol and ether. Absorbs  $CO_2$ . —  $B''^2HCl$ . Needles (from water). —  $B''^2H_2PtCl_4$ . —  $B''^2C_2H_4N_2O_4$ . Yellow spangles, decomposing at 187°.

**Acetyl derivative**  $C_6H_4(CH_2.NHAc)_2$ .

[119°]. Crystalline mass, v. sol. hot water.

**Reference**.—NITRO-XYLYLENE-DIAMINE.

**XYLYLENE-BENZENYL-AMIDINE v. BENZ-****ENYL-XYLYLENE-DIAMINE.****XYLYLENE BROMIDE v. Di-BROMO-XYLYLENE.****XYLYLENE-CHLORO-MALONIC ETHER v.****CHLORO-XYLYLENE-MALONIC ETHER.**

**Xylylene-*exo*-di-chloro-malonic ether v. Di-**

**CHLORO-PHENYLENE-DI-METHYL-DI-MALONIC ETHER.****XYLYLENE-ETHENYL-AMIDINE**  $C_6H_4H_2N_2$ 

i.e.  $CMe < \text{N} > C_6H_4Me_2$ . Formed by reducing  $C_6H_4Me_2(NO_2)(NHAc)$  [1:3:5:4] with tin and HCl (Hobrecr, B. 5, 922). Resinous mass. —  $B''HCl$ . Large needles. —  $B''H_2PtCl_4$ . —  $B''HNO_3$ . Long needles.

**XYLYLENE IODIDE v. Di-IODO-XYLYLENE.****XYLYLENE-DI-MALONIC ACID v. PHENYL-****ENE-DI-METHYL-DI-MALONIC ACID.*****o*-XYLYLENE SULPHIDE**  $C_6H_4S$  i.e.

$C_6H_4 \begin{smallmatrix} CH \\ CH \end{smallmatrix} S$ . [0. 0°]. Formed by heating di-*o*-bromo-*o*-xylylene with  $K_2S$  (Leser, B. 17, 1824; Hjelt, B. 22, 2904). Oil, smelling like mercaptan. Very unstable, quickly turning into a black resin. —  $B''HgCl_2$ . Long needles.

**Methylo-iodide**  $B''MeI$ . [155°].

**Di-xylylene disulphide**

[1:3:4:5]  $C_6H_4Me_2.S_2.C_6H_4Me_2$  [5:4:3:1]. [118°]. Formed by heating xylylene-diazosulphide at 200°-250° (Jacobsen a. Ney, B. 22, 911). Conc.  $H_2SO_4$  forms a blue liquid, remaining blue on dilution.

***u*-DI-XYLYL-ETHANE**  $C_6H_4$  i.e.

$CH_2.OH(C_6H_4)_2$ . (314°). S.G. 0.966. Formed from ethylidene chloride, *m*-xylylene, and  $AlCl_3$  (Apschütz, B. 18, 865; A. 285, 826). Oil.

**Reference**.—CHLORO-DI-XYLYL-ETHANE.**DI-XYLYL-ETHYLENE**  $C_6H_4$  i.e.

$C_6H_4Me_2.CH.CHO.C_6H_4Me_2$ . **Tetra-methyl-stilbene**. [106°]. (325°-340°). Formed by distilling

$\text{O}_2\text{H}_2\text{Me}_2\text{CH}_2\text{OH}_2\text{Cl}$ , which is got from di-chloro-di-ethyl oxide, *m*-xylene, and  $\text{H}_2\text{SO}_4$  (Hepp, *B.* 7, 1416). Spangles (from alcohol), sol. ether and  $\text{CS}_2$ . Unites with bromine. Oxidised by dilute  $\text{HNO}_3$  to (1,3,4)-di-methyl-benzoic acid [129°].

**Di-xylyl-ethylene**  $\text{C}_6\text{H}_4\text{Me}_2\text{CH}:\text{CH}:\text{C}_6\text{H}_4\text{Me}_2$ . [157°]. Formed in like manner from *p*-xylene. Plates (from alcohol). Less soluble than the preceding isomeride.

**Tetra-xylyl-ethylene**  $(\text{C}_6\text{H}_4\text{Me}_2)_2\text{C}:\text{C}(\text{C}_6\text{H}_4\text{Me}_2)_2$ . [245°]. Formed from xylene,  $\text{CHCl}_3$ , and  $\text{AlCl}_3$  (Schwarz, *B.* 14, 1528). Yellow plates.

***m*-XYLYL-ETHYLENE-DIAMINE**  $\text{C}_6\text{H}_4\text{Me}_2\text{NH}_2\text{C}_2\text{H}_4\text{NH}_2$ . (274°). Formed from *m*-xylyl-amido-ethyl-β-thalimide and  $\text{HCl}$  (Newman, *B.* 24, 2197).— $\text{B}^+\text{HCl}$ . [173°].— $\text{B}^+\text{H}_2\text{PtCl}_4$ .— $\text{B}^+\text{C}_2\text{H}_5\text{N}_3\text{O}$ . [141°]. Reddish-yellow needles, v. s. sol. alcohol.

**DI-*m*-XYLYL-ETHYLENE DIKETONE**  $\text{C}_6\text{H}_4(\text{CO}_2\text{C}_2\text{H}_5)_2$ . [4:3:1]. [129°]. Formed from *m*-xylene, succinyl chloride,  $\text{AlCl}_3$ , and  $\text{CS}_2$  (Claus, *B.* 20, 1375). Needles, insol. water, v. sol. alcohol and ether. Dilute  $\text{HNO}_3$  oxidises it to (1,3,4)-di-methyl-benzoic acid.

*Oxim*  $\text{C}_6\text{H}_4(\text{C}(\text{NOH})(\text{C}_2\text{H}_5))_2$ . [140°].

**Phenyl-hydrazide**  $\text{C}_6\text{H}_4(\text{N}(\text{HPh})\text{C}_6\text{H}_5)_2$ . [189°]. Crystals.

**Di-*p*-xylyl-ethylene diketone**  $\text{C}_6\text{H}_4(\text{CO}_2\text{C}_2\text{H}_5)_2$ . [2:4:1]. [123°]. Formed from *p*-xylene, succinyl chloride,  $\text{AlCl}_3$ , and  $\text{CS}_2$  (Claus). Needles.

***m*-XYLYL ETHYL KETONE** [1:3:4]  $\text{C}_6\text{H}_4\text{Me}_2\text{CO}_2\text{C}_2\text{H}_5$ . (239°). Light oil, with aromatic odour, not solid at  $-10^\circ$  (Claus, *J. pr.* [2] 43, 140). Yields (1,3,4)-di-methyl-benzoic acid on oxidation.

**Phenyl-hydrazide** [126°]. Plates, v. sol. hot water, alcohol, and ether.

***p*-Xylyl ethyl ketone**

[4:1:2]  $\text{C}_6\text{H}_4\text{Me}_2\text{CO}_2\text{C}_2\text{H}_5$ . (238° uncor.). Formed from *p*-xylene,  $\text{AlCl}_3$ , and propionyl chloride (Claus a. Fickert, *B.* 19, 3182). Oil. Oxidised by  $\text{KMnO}_4$  to  $\text{C}_6\text{H}_4\text{Me}_2\text{CO}_2\text{CH}_2\text{CO}_2\text{H}$  [132°] and some (4,1,2)-di-methyl-benzoic acid.

***m*-XYLYL ETHYL KETONE CARBOXYLIC ACID** [4:2:1]  $\text{C}_6\text{H}_4\text{Me}_2\text{CO}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$ .

**Di-methyl-benzoyl-propionic acid**. [108°]. Formed from *m*-xylene, succinyl chloride,  $\text{AlCl}_3$ , and  $\text{CS}_2$  (Claus, *B.* 20, 1376). Needles, v. sol. hot water, insol. cold.— $\text{NH}_4\text{A}^+$ .— $\text{KA}^+$  4aq. V. sol. water.— $\text{NaA}^+$  4aq. Needles.— $\text{BaA}^+$  3aq. Needles.— $\text{PbA}^+$ : white pp.— $\text{AgA}^+$ : white crystalline pp.

***p*-Xylyl ethyl ketone carboxylic acid**

[4:1:2]  $\text{C}_6\text{H}_4\text{Me}_2\text{CO}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$ . [84°]. Formed from *p*-xylene in like manner ( $\text{C}_6\text{H}_4$ ). Colourless needles.

**XYLYL-DI-ETHYL-PHOSPHINE**

$\text{C}_6\text{H}_4\text{Me}_2\text{P}(\text{C}_2\text{H}_5)_2$ . (260°). Formed by the action of  $\text{ZnEt}_2$  on  $\text{C}_6\text{H}_4\text{Me}_2\text{P}(\text{Cl})_2$  (Czimatis, *B.* 15, 2016). Thick, colourless oil. Yields  $\text{B}^+\text{Me}^+$  [90°],  $\text{B}^+\text{Me}_2\text{PtCl}_4$  [202°], and  $\text{B}^+\text{Et}^+$  [186°].

***m*-XYLYL-GLYOXALINE**  $\text{C}_6\text{H}_4\text{N}(\text{CH}:\text{CH}:\text{CH}:\text{N})_2$ .

[35°]. (279°). Formed by the action of  $\text{HNO}_3$  on  $\text{C}_6\text{H}_4\text{N}(\text{CH}:\text{CH}:\text{CH}:\text{N})_2$  [192°], which is got by the action of  $\text{HCl}$  on the product of the action of amido-acetal on *m*-xylyl-thio-urea (Marck-

wald, *B.* 25, 2368). Sl. sol. water.—Aurochloride [165°].—Picrate. [159°]. Yellow needles, m. sol. chloroform.

***o*-XYLYL-GLYOXYLIC ACID**

[4:3:1]  $\text{C}_6\text{H}_4\text{Me}_2\text{CO}_2\text{CO}_2\text{H}$ . [92°]. Formed by oxidising *o*-xylyl methyl ketone with alkaline  $\text{K}_2\text{FeCy}$ , (Buckka a. Irish, *B.* 20, 1766).— $\text{BaA}^+$ .

***m*-Xylyl-glyoxylic acid**

[4:2:1]  $\text{C}_6\text{H}_4\text{Me}_2\text{CO}_2\text{CO}_2\text{H}$ . [54°]. Formed by oxidising *m*-xylyl methyl ketone with  $\text{KMnO}_4$  (Claus, *B.* 19, 231; *J. pr.* [2] 43, 149). Flat prisms. Yields (4,2,1) di-methyl-benzoic acid on boiling with dilute  $\text{HNQ}_3$ . Gives rise to  $\text{C}_6\text{H}_4\text{CH}(\text{OH})\text{CO}_2\text{H}$  [119°] on reduction.— $\text{CaA}^+$  2aq. Needles.— $\text{BaA}^+$  2aq.— $\text{AgA}^+$ . Needles, sol. hot water.

***p*-Xylyl-glyoxylic acid**

[5:2:1]  $\text{C}_6\text{H}_4\text{Me}_2\text{CO}_2\text{CO}_2\text{H}$ . [70°–80°]. Formed by oxidation of *p*-xylyl methyl ketone by aqueous  $\text{KMnO}_4$  (Claus a. Wollner, *B.* 18, 2859). Crystalline, v. sol. alcohol, ether, and  $\text{HOAc}$ , v. sl. sol. water. Splits up above 200° into  $\text{CO}_2$  and di-methyl-benzoic aldehyde. Oxidised by  $\text{HNO}_3$  to  $\text{C}_6\text{H}_4\text{Me}_2\text{CO}_2\text{H} \cdot \text{Ac}_2\text{O}$  and  $\text{NaOAc}$  yield di-methyl-cinnamic acid.— $\text{BaA}^+$  6aq: small felted needles.— $\text{CaA}^+$  3aq.— $\text{AgA}^+$ : crystalline pp.

**Ethyl ether EtA**. Oil.

**XYLYL GLYOXYLIC ALDEHYDE**

[1:3:4]  $\text{C}_6\text{H}_4\text{Me}_2\text{CO}_2\text{CHO}$ . *Oxim* [95°]. Formed from xylyl methyl ketone,  $\text{NaOEt}$ , and  $\text{C}_6\text{H}_5\text{NO}_2$  (Söderbaum, *B.* 25, 3163). Needles (from benzene-ligroin). Acetic anhydride gives the acetyl derivatives of the *syn*-oxim  $\text{C}_6\text{H}_4\text{Me}_2\text{CO}_2\text{CH}:\text{NOAc}$  [54°] decomposed by alkalis with formation of  $\text{C}_6\text{H}_4\text{Me}_2\text{CO}_2\text{H}$  [126°] and by hot  $\text{Ac}_2\text{O}$  yielding  $\text{C}_6\text{H}_4\text{Me}_2\text{CO}_2\text{CN}$  [47°].  $\text{AcCl}$  converts the oxim into  $\text{C}_6\text{H}_4\text{Me}_2\text{C}(\text{OH})_2\text{CH}:\text{NOAc}$  [142°], whence cold  $\text{NaOH}$  forms  $\text{C}_6\text{H}_4\text{Me}_2\text{CH}(\text{OH})\text{CO}_2\text{H}$  [103°], while  $\text{NaOHAq}$  at 50° forms 'xylyl formoin'  $\text{C}_6\text{H}_4\text{CO}_2\text{CH}(\text{OH})\text{CO}_2\text{CO}_2\text{C}_2\text{H}_5$  [155°].

**DI-XYLYL-GUANIDINE**

$\text{HN}:\text{C}(\text{NH}_2\text{C}_6\text{H}_4)_2$ . [1:2:4]. [158°]. Formed by the action of  $\text{PbO}$  and alcoholic ammonia on di-xylyl-thio-urea (Hofmann, *B.* 9, 1295). Needles, (from alcohol).

**XYLYL-HYDRAZINE**

[4:2:1]  $\text{C}_6\text{H}_4\text{Me}_2\text{NH}_2\text{NH}_2$ . [85°]. Formed from xylydine by diazotisation followed by reduction with  $\text{Na}_2\text{SO}_3$ , the resulting  $\text{C}_6\text{H}_4\text{Me}_2\text{NH}_2\text{SO}_3\text{Na}$  3aq being then treated with zinc-dust and  $\text{HOAc}$  (Klauber, *M.* 11, 282). Pale-yellow needles, v. sl. sol. water, v. sol. alcohol. Reduces Fehling's solution on warming. On heating with acetoacetic ether it yields a crystalline body [203°] reduced, in alcoholic solution by  $\text{Na}$  to oxy-xylyl-methyl-pyrazole.

**Salt**:— $\text{C}^+\text{HCl}^+$  2aq. [183°]. Small needles.

**Di-*o*-xylyl-hydrazine**

[3:2:1]  $\text{C}_6\text{H}_4\text{Me}_2\text{NH}_2\text{NH}_2$ . [1:2:3]. [141°]. *o*-Hydrazo-*o*-xylene. Got by heating nitro-*o*-xylene (20 g.) with  $\text{NaOH}$  (20 g.) alcohol (100 c.c.) and zinc-dust (25 g.) and reducing the product with alcoholic ammonium sulphide (Nöling a. Stricker, *Bl.* [2] 50, 618). White needles, sol. alcohol and ether. Easily oxidised by air.

***u*-Di-*o*-xylyl-hydrazine**

$\text{N}_2\text{H}_4(\text{C}_6\text{H}_4\text{Me}_2)_2$ . [1:3:4]. [107°]. Formed by reducing nitro-*o*-xylene with sodium-amalgam (N. a. S.). Yellowish white needles, sol. alcohol.

**Di-*m*-xylyl-hydrazine**  
 $N_2H_4(C_6H_4Me_2)_{1:2:5}$ . [125°]. Obtained from *s*-nitro-*m*-xylene (N. a. S.). Needles, easily oxidised by air.

***o*-Di-*m*-xylyl-hydrazine**  
 $N_2H_4(C_6H_4Me_2)_{1:2:4}$ . [122°]. Gp't by warming nitro-*m*-xylene (80 g.) with NaOH (80 g.), zinc-dust (40 g.), and alcohol (250 c.c.) and treating the xylene-azo-xylene so obtained with alcoholic ammonia and  $H_2S$  (N. a. S.). White needles, sol. alcohol and ether.

**Di-*p*-xylyl-hydrazine**  
 $N_2H_4(C_6H_4Me_2)_{1:2:5}$ . [145°]. Formed from nitro-*p*-xylene (N. a. S.). Needles, not affected by air.

**XYLYLIC ACID** *v.* DI-METHYL-BENZOIC ACID.

***o*-Xylylic acid** *v.* TOLYLACETIC ACID.

***p*-XYLYLIDENE-DI-IMINE**

$C_6H_4(CH.NH)_{1:4}$ . Formed by the action of alcoholic  $NH_3$  or dry  $NH_3$  gas upon terephthalic aldehyde (Oppenheimer, B. 19, 576). Glassy brittle crystals. V. cl. sol. alcohol and ether.

**DI-XYLYL-KETONE**  $CO(C_6H_4Me_2)_2$  (c. 340°). Obtained from (*m*?)-xylene,  $COCl_2$ , and  $AlCl_3$  (Ador a. Rilliet, B. 11, 399). Liquid, not solid at -60°. Split up by long boiling into  $H_2O$  and  $C_6H_4$ .

**Di-*p*-xylyl ketone**

[2:5:1]  $C_6H_4Me_2.CO.C_6H_4Me_2$  [1:2:5]. (327° uncor.). Formed from *p*-xylene,  $CS_2$ , and  $COCl_2$  in closed vessels; the yield being 55 p.c. (Elbs, J. pr. [2] 35, 481). Oil. Quickly decomposed by distillation into  $H_2O$  and (B. 2, 1'4')-tri-methyl-anthracene [227°]. Reduced by zinc-dust and alcoholic KOH to di-*p*-xylyl-carbinol [181°].

**Di-xylyl-tetraz ketone**

$C_6H_4.CO.CO.CO.CO.C_6H_4Me_2$  [4:3:1]. [150°]. Formed by the action of cold  $HNO_3$  (S.G. 1:4) on  $C_6H_4.CO.CH(OH).CO.CO.C_6H_4$  (Säderbaum, B. 25, 8475). Scarlet needles (from  $CS_2$ ). On dissolving in  $HOAc$  and ppg. by water it yields a dihydrate [100°]  $C_{12}H_{10}O_4$ .

**XYLYL MERCAPTAN**  $C_6H_4Me_2.SH$ . [214°]. S.G. 1:1.036. Got by treating xylene sulphonic chloride with Zn and dilute  $H_2SO_4$  (Ysells, Z. 1865, 860), and also by heating xylyl ethyl xanthate with alcoholic potash (Leuekart, J. pr. [2] 41, 192). Liquid. —  $Hg(E.C_6H_4)_2$ . —  $Pb(S.C_6H_4)_2$ . Yellow powder.

**TRI-*p*-XYLYL-METHANE**  $CH(C_6H_4Me_2)_3$ . [188°]. (above 360°). From di-*p*-xylyl-carbinol, *p*-xylene, and  $H_2O$  by boiling for four hours (Elbs, J. pr. [2] 85, 484). Crystalline grains (from alcohol), v. sol. ether and benzene.

***o*-XYLYL METHYL KETONE**

[4:3:1]  $C_6H_4Me_2.CO.CH_3$ . [246°]. Formed from *o*-xylene,  $AlCl_3$  and  $AlCl_3$  (Ullas, B. 18, 1856; 19, 232; J. pr. 1890, 410). Oil, smelling like coumarin (Armstrong a. Kipping, C. J. 83, 81). Yields (4,3,1)-di-methyl-benzoic acid on oxidation. Conc.  $HClAq$  forms  $C_{12}H_{10}O$  [114°].  $P_2O_5$  gives a body melting at 165°. Zinc-dust reduces the ketone to  $C_6H_4.CH(OH).CH_3$  (257°).

**Oxim**  $C_6H_4.Q(NOH).CH_3$ . [85°]. Prisms (from dilute alcohol), converted by  $AcCl$  into  $C_6H_4.C(N.OAc).CH_3$ . [72°].

**Phenyl-hydrazide**. Colourless prisms.

***m*-Xylyl methyl ketone**

[4:3:1]  $C_6H_4Me_2.CO.CH_3$ . [228°]. Formed from *m*-xylene,  $AlCl_3$ , and  $AlCl_3$  (Claus, B. 18, 280).

Obtained also by boiling *m*-xylene with  $HOAc$ ,  $ZnCl_2$ , and  $POCl_3$  (Frey, J. pr. [2] 48, 120). Oil smelling like peppermint. Not condensed by  $HClAq$ . Yields  $C_6H_4Br_2O$  [69°]. Reduction by  $HI$  yields  $C_6H_4Me_2.CH_2.CH_3$  (184°) (Claus, J. pr. [2] 45, 830).  $HNO_3$  gives  $C_{12}H_{10}N_2O_4$  [408°] (Claus, J. pr. [2] 41, 492).

***p*-Xylyl methyl ketone**

[5:2:1]  $C_6H_4Me_2.CO.CH_3$ . (225° uncor.). S.G. 1:1.0962. V.D. 4.93. Formed from *p*-xylene,  $AlCl_3$  and  $AlCl_3$  (Claus a. Wollner, B. 18, 1856). Oil, v. sol. alcohol and ether. Oxidised by hot aqueous  $KMnO_4$  to *p*-xylyl-glyoxylic acid. Dilute  $HNO_3$  forms di-methyl-benzoic and methyl phthalic acids.

**Oxim**  $C_6H_4.Q(NOH).CH_3$ . [58°].

***o*-XYLYL METHYL KETONE CARBOXYLIC ACID** *v.* METHYL-BENZOYL-ACETIC ACID.

**XYLYL-DI-METHYL-PHOSPHINE**

$C_6H_4Me_2.PMe_2$ . (230°). Formed from  $ZnMe_2$  and  $C_6H_4Me_2.PCl_2$  (Czimatis, B. 15, 2016). Oil Unites with  $CS_2$ , forming a compound [115°].

**XYLYL-METHYL-THIOHYDANTOIN**

[3:4]  $C_6H_4Me_2.N < \begin{matrix} CO.CH_2 \\ CS.NH \end{matrix}$ . [165°]. Formed from xylyl-thiocarbimide and alanine (Marckwald, B. 24, 3282). Needles, v. sol. alcohol.

**XYLYL PENTADECYL KETONE**

$C_6H_4Me_2.CO.C_{15}H_{31}$ . [87°]. (269° at 15 mm.). Formed from *m*-xylene, palmityl chloride, and  $AlCl_3$  (Krafft, B. 21, 2269). Small plates, yielding di-methyl-benzoic acid [126°] on oxidation.

**XYLYL PHENYLAMYL KETONE**

$C_6H_4Me_2.CO.CHPh.C_6H_5$ . [91.5°]. Formed by Friedel and Craft's method (Wege, B. 24, 8541).

**XYLYL-PHENYL- *v.* PHENYL-XYLYL-**

**TRI-XYLYL PHOSPHATE**  $PO(OC_6H_4Me_2)_3$ .

The *o*- and *p*-compounds are formed by heating *o*- and *p*-xylene with  $POCl_3$  (Kreyser, B. 18, 1702). They are oils, v. sol. ether, alcohol, and benzene.

***m*-XYLYL-PHTHALIDE**

$C_6H_4 \begin{matrix} \diagup CH(C_6H_4Me_2) \\ \diagdown CO \end{matrix} O$ . [84°]. Got by heating  $C_6H_4Me_2.CO.C_6H_4.CO.H$  with zinc and  $HCl$  (Gresly, A. 234, 237). Needles (from alcohol), sl. sol. benzene.

**XYLYL-PROPIONIC ACID**

[1:3:4]  $C_6H_4Me_2.CH_2.CH_2.CO_2H$ . [105°]. Formed by saponifying the amide. Silky needles, v. sol. hot water. —  $BaA$ , 6aq. Plates, m. sol. water. —  $CaA$ , 4aq. —  $AgA$ . White powder.

**Acide**  $C_6H_4Me_2.C_6H_4.CO.NH_2$ . [107°]. Got by heating the oxim of *m*-xylyl ethyl ketone with yellow ammonium sulphide under pressure (Claus, V. pr. [2] 46, 477). Needles, sol. hot water.

***m*-XYLYL PROPYL KETONE**  $C_6H_4Me_2.CO.C_3H_7$ .

[4:2:1]  $C_6H_4Me_2.CO.Pr$ . (251°). Formed from *m*-xylene, butyryl chloride and  $AlCl_3$  (Claus, J. pr. [2] 46, 474). Oil, v. sol. alcohol and ether. Yields *m*-xylyl-glyoxylic acid [54°] on oxidation with  $KMnO_4$ .

**Oxim**. Crystals, v. e. sol. alcohol.

***p*-Xylyl propyl ketone** [5:2:1]  $C_6H_4Me_2.CO.Pr$ . (249°). Formed in like manner from *p*-xylene. Light oil.

**Oxim** [47°]. Colourless needles.

***o*-Xylyl isopropyl ketone**

[4:3:1]  $C_6H_4Me_2.CO.Pr$ . (258°). Oil, smelling like

terpentine (Claus, *J. pr.* [2] 46, 484). Yields di-methyl-benzole acid [163°] on oxidation.

*Ozīm* [68°]. Large prisms.

*m*-Xylyl isopropyl ketone [4:2:1]  $C_8H_9Me.CO.Pr.$  (245°). Oil, yielding *m*-xylyl-glyoxylic acid on oxidation by  $KMnO_4$ .

*Ozīm* [97°]. Prisms (from alcohol).

*Phényl-hydrasie* [129°]. Crystals.

*p*-Xylyl isopropyl ketone

[8:2:1]  $C_8H_9Me.CO.Pr.$  (240°). Formed from *p*-xylene, isobutyryl chloride, and  $AlCl_3$  (Claus, *J. pr.* [2] 46, 484). Oil, smelling like mushrooms.

*Ozīm* [76°]. Plates and prisms.

**TETRA-*o*-XYLYL SILICATE**  $Si(OC_6H_4Me)_4$ . (c. 480°). Formed by heating *o*-xynol with  $SiCl_4$ , the yield being 85 p.c. of the theoretical amount (Hertkorn, *B.* 18, 1691). Large prisms.

**Tetra-*m*-xylyl silicate**  $Si(OC_6H_4Me)_4$ . (453°-457°). Formed, in like manner, from *m*-xynol. Oil.

***m*-XYLYL THIOCARBIMIDE**  $C_8H_9NS$  i.e. [4:2:1]  $C_8H_9Me.N:CS$ . Formed from di-xylyl-thio-urea and  $P_2O_5$  (Hofmann, *B.* 9, 1295). Crystals. Converted by  $PhOEt$  and  $AlCl_3$  into  $C_8H_9NH.CO.S.C_6H_4.OEt$  [140°] (Gattermann, *B.* 25, 3530).

**XYLYL ETHYL DITHIOCARBONATE**

$CS(OEt).SC_6H_4Me$ . Formed from potassium

xanthate and *m*-diao-xylene chloride (Louchart, *J. pr.* [2] 41, 192). Oil, converted by heating with alcoholic potash into xylyl mercaptan (214°).

**DI-XYLYL-THIO-UREA**

$CS(NH.C_6H_4Me.[1:2:4])_2$ . [158°]. Formed by digesting xylydine with  $CS_2$ , as long as  $H_2S$  escapes (Hofmann, *B.* 9, 1295). Crystals (from alcohol).

**XYLYL-UREA**  $NH_2.CO.NHO.C_6H_4Me.[1:2:4]$ . [186°]. Formed from crude xylydine sulphate and potassium cyanate (Genz, *B.* 8, 226). Needles (from alcohol).

*s*-Xylyl urea  $NH_2.CO.NHO.C_6H_4Me.[1:3:5]$ . [162°] (Frentzel, *C. C.* 1888, 1361).

Di-*s*-xylyl-urea  $CO(NHO.C_6H_4Me.[1:3:5])_2$ . [275°] (F.); [251°] (G. a. C.). Formed from *s*-xylydine and  $COCl_2$  (F.). Formed also from *m*-xylyl cyanate and xylydine (Gattermann a. Cantzler, *B.* 25, 1089). Needles.

Di-*m*-xylyl-urea  $CO(NH.C_6H_4Me.[1:2:4])_2$ . [263°]. A product of the distillation of *m*-xylyl-amido-crotonic acid (Conrad a. Limpach, *B.* 21, 527). Sublimes when melting.

Di-xylyl-urea  $CO(NHC_6H_4Me)_2$ . Formed by heating urea (1 pt.) with crude xylydine (8 pts.). Felted needles (from hot alcohol), not melted at 250° (Genz, *B.* 3, 226).

Reference. — METHYL-BENZYL-UREA.

## Y

**YTTTERBIUM.** Yb. At. w. c. 173. This name is given to the metal, not yet isolated, of an earth separated by Marignac, in 1878, from crude erbia obtained from *gadolinite* or *euxenite*. The claim of ytterbia to rank as a definite homogeneous compound is not yet satisfactorily established.

The discovery of a new earth in a mineral from Ytterby in Sweden was announced in 1788 by Gadolin; in 1797 Ekeberg confirmed the discovery. The new earth was named *yttria*, and the mineral from which it was obtained was called *gadolinite*. Researches into the nature of yttria were conducted by Berzelius in 1819 (*v. Lehrbuch* [5th ed.] 2), Mosander in 1839 and 1843 (*J. pr.* 30, 27), Scheerer in 1849, Clève and others. In 1878 Marignac made a careful examination of erbia (*M. Ch.* [5] 14, 247); he fractionally decomposed erbium nitrate by heat, and obtained an earth which he called *ytterbia*. The erbia used by Marignac was pink, and gave, in solution, an absorption spectrum; the new earth was white and showed no absorption spectrum. Nilson (*B.* 12, 554; 13, 1439 [1879-89]) prepared ytterbia, but found a reacting weight for the earth different from that assigned to it by Marignac. By repeated fractional decomposition by heat of the nitrate of ytterbium, Nilson separated another earth which he called *scandia* (*cf. Scandrium*, this vol., p. 481). Nilson (*B.* 13, 1430) in 1879 made a fuller examination of ytterbia, and determined the at. w. of the metal of this earth, and the properties of several salts of the metal. In this memoir Nilson asserted

that *erbia* was separable into seven distinct earths: erbia proper, scandia, terbia, thulia, ytterbia, yttria, and Soret's X (afterwards called holmia). (*cf. Erbium*, vol. ii. p. 456; and *Metals*, *RARE*, vol. iii. p. 245).

*Occurrence.* — Along with erbia, scandia, yttria, &c., in very small quantities in a few rare Scandinavian minerals, chiefly in *gadolinite* and *euxenite*. Nilson (*l.c.*) obtained c. 20 g. ytterbia from 6-7 kilos. of the crude earths prepared from c. 15 kilos. *gadolinite*.

*Preparation of ytterbia.* — Nilson (*B.* 13, 1430) mixed finely powdered *euxenite* or *gadolinite*, c. 400 g., at a time, with four times its weight of  $KHSO_4$ , fused over a powerful burner, pulverised the fused mass, and thoroughly exhausted with cold water; he ppd. the aqueous solution by ammonia, washed the ppd. separated oxides, and dissolved in  $HNO_3$  Aq; after boiling the solution for some time, and filtering, he ppd. by oxalic acid, washed the pp., dried it, and heated strongly until it was decomposed. The crude earth thus obtained was freed from  $K_2CO_3$  by boiling with water, and were then dissolved in  $HNO_3$  Aq; the solution was evaporated to dryness, and the residue was fused until red vapours began to come off. The reddish-yellow, opaque solid was then treated with boiling water, whereby a reddish-yellow pp. was formed, which was filtered off by means of a suction-pump. (This pp. contained oxide of Th. along with oxides of Ce, Fe, and U.) The reddish filtrate was evaporated to dryness, and the solid nitrates thus obtained were partly decomposed by heating, the soluble

(undecomposed) portion removed by solution in water, the residue dissolved in  $\text{HNO}_3\text{Aq}$ , the solution evaporated to dryness, the residue partly decomposed by heating, the undecomposed nitrates were removed by washing with water, the residue was dissolved in  $\text{HNO}_3\text{Aq}$ , and so on. After thirty repetitions of this process a solution was obtained that showed merely a trace of red colour after thirty-five repetitions the solution was quite colourless, and showed only two faint absorption bands, one in the green and the other in the red; after forty repetitions a solution was obtained which gave only the red band; and when the process of partial decomposition by heat had been repeated sixty-eight times a solution in  $\text{HNO}_3\text{Aq}$  was obtained which showed no trace of an absorption spectrum. This solution was saturated with  $\text{H}_2\text{S}$ , the small yellowish-brown pp. of  $\text{PtS}$  was filtered off, the filtrate was ppd. by pure oxalic acid, the pp. was washed, dried, and decomposed by heating strongly, and pure ytterbia was thus obtained. For a modification of this method of separating ytterbia from accompanying earths *v. Auer von Welsbach* (*M.* 4, 630).

**Atomic weight of ytterbium.**—The metal has not been isolated; the at. w. was determined by Nilson (*B.* 13, 1433) by dissolving pure  $\text{Yb}_2\text{O}_3$  (*v. supra*) in  $\text{HNO}_3\text{Aq}$ , adding a suitable quantity of  $\text{H}_2\text{SO}_4\text{Aq}$ , evaporating on a water-bath to drive off  $\text{HNO}_3$ , then on a sand-bath, and finally over a flame until all free  $\text{H}_2\text{SO}_4$  was removed, weighing the  $\text{Yb}_2(\text{SO}_4)_3$  thus obtained, and analysing it. Nilson dissolved pure  $\text{Yb}_2\text{O}_3$  in  $\text{HNO}_3\text{Aq}$ , evaporated to dryness, partially decomposed the nitrate by heat, treated with water, &c., as described *supra*, and in this way obtained seven fractions, each of which was converted into sulphate. The results are presented in the following table:—

Weight of $\text{Yb}_2\text{O}_3$ taken	Weight of sulphate formed	Pctge. composition of sulphate		Atomic w. of Yb.
		$\text{Yb}_2\text{O}_3$	$\text{SO}_3$	
1.0063	1.6186	62.171	37.829	173.21
1.0189	1.6314	62.149	37.851	173.03
8509	1.3690	62.155	37.845	173.08
7371	1.1861	62.145	37.855	173.00
1.0005	1.6099	62.147	37.853	173.01
8090	2.3022	62.126	37.874	173.84
1.0059	1.6189	62.134	37.866	172.91
Mean . . . . .		62.147	37.853	173.01

**Chemical relations of ytterbium.**—If Yb is really a homogeneous substance, it must be placed in Series 10 of Group III. in the periodic classification of the elements. This group contains the following elements:—

<i>Even series</i> —				
2	4	6	8	10
B (11)	Sc (14)	Y (89)	La (139)	Yb (173)
<i>Odd series</i> —				
3	5	7	9	11
Al (27)	Ga (70)	In (114)	—	Tl (204)

A comparison of the position of Yb with the positions of elements placed in Series 10 (*v. table on p. 811 of vol. iii.*) shows that Yb

ought to be decidedly more metallic than B, and somewhat more metallic than Al, Ga, or In; the data, however, are too meagre to allow a detailed comparison to be made. Little is known of the properties of compounds of Yb; but what is known broadly confirms the conclusions drawn from the position of the element in the periodic scheme of classification (*cf. EARTHS, METALS OF THE*, vol. ii. p. 424).

**Ytterbium oxide  $\text{Yb}_2\text{O}_3$ .** (*Ytterbia*.) A very heavy, white, infusible powder; slowly acted on by acids when cold or gently warmed, but readily dissolved by dilute acid solutions when boiling. Solutions in acids are colourless, and show no absorption spectra. The emission spectrum of a solution in  $\text{HClAq}$ , obtained by help of the spark, shows several lines, the most conspicuous of which have the wave-lengths 6221, 5556, 5476, 5352, and 5334 (*v. Lecoq de Boisbaudran, C. R.* 88, 1342). S.G. 9.175. S.H. ( $0^\circ$ – $100^\circ$ ) .0646 (Nilson, *l.c.*).

**Hydrated ytterbium oxide.** A white, gelatinous, but heavy pp. obtained by adding  $\text{NH}_3\text{Aq}$  to a solution of a salt of Yb; shrinks much when dried, and absorbs  $\text{CO}_2$  from the air. Easily soluble in acids (Nilson, *l.c.*).

**Ytterbium salts.** Nilson (*l.c.*) prepared an oxalate, an acid selenite, and a sulphate; and Marignac (*C. R.* 87, 578) prepared a formate.

**Ytterbium oxalate  $\text{Yb}_2(\text{C}_2\text{O}_4)_3$ .** 10aq. A white, microscopically crystalline powder; insoluble in water, scarcely soluble in dilute acids; unchanged in air; gives up part of its water at  $100^\circ$ . Prepared by adding oxalic acid to a warm solution of the sulphate.

**Ytterbium selenite  $\text{Yb}_2\text{O}_3 \cdot 4\text{SeO}_3 \cdot 5\text{aq}$ .** Obtained by adding  $\text{Na}_2\text{SeO}_3\text{Aq}$  to a solution of  $\text{Yb}_2(\text{SO}_4)_3$ , washing the ppd. normal selenite, dissolving in water containing a large excess of  $\text{H}_2\text{SeO}_3$ , evaporating nearly to dryness, and washing the residue with water. A white crystalline salt, insoluble in water. Loses  $4\text{H}_2\text{O}$  at  $100^\circ$ .

**Ytterbium sulphate  $\text{Yb}_2(\text{SO}_4)_3$ .** Prepared by dissolving  $\text{Yb}_2\text{O}_3$  in  $\text{HNO}_3\text{Aq}$ , adding  $\text{H}_2\text{SO}_4\text{Aq}$ , evaporating on a water-bath to drive off  $\text{HNO}_3$ , then on a sand-bath, and finally over a flame at low redness till all  $\text{H}_2\text{SO}_4$  is removed. An opaque, white solid. Dissolves in water when a large quantity is added at once; if a little is added much heat is produced, the salt combines with the water, and then dissolves very slowly when more water is added. Decomposed at a red heat, fully at a white heat. S.G. 3.793. S.H. .1039 at  $0^\circ$  to  $100^\circ$ .

**A hydrated sulphate  $\text{Yb}_2(\text{SO}_4)_3 \cdot 8\text{aq}$**  was obtained by Nilson in large, white, lustrous prisms by evaporating a solution of  $\text{Yb}_2(\text{SO}_4)_3$  in water at a gentle heat. M. M. P. M.

**YTTRIUM.** Y. At. w. c. 89.6. The name yttrium is given to the metal of an earth obtained from a few rare Swedish minerals. The separation of a new earth from a mineral found at Ytterby, in Sweden, was made by Gadolin in 1788. The existence of the new earth was confirmed in 1797 by Ekeberg, and the earth was called by him *yttria*. Subsequent researches carried on by Berzelius, Mosander, Scheerer, Berth, Delafontaine, Popp, Balf, a, Bunsen, Marignac, and others showed that the yttria of Gadolin and Ekeberg was a mixture of many oxides (*cf. EARTH, vol. ii. p. 456; SCANDIUM, vol.*

IV. p. 202; *YTTERIUM*, same vol. p. 879; and v. *infra*, *Homogeneity of Yttria*).

**Occurrence.**—About 80 to 85 p.c. of yttria, in combination with  $\text{SiO}_2$ , is found in the exceedingly rare Swedish mineral *gadolinite*; some specimens of *orthite* also contain yttria, and the earth has also been found, in combination with  $\text{Nb}_2\text{O}_5$  and  $\text{Ta}_2\text{O}_5$ , in specimens of *euxenite*. The oxides that generally accompany yttria in these rare minerals are ceria, didymia, erbia, lanthana, lime, magnesia, soda, and oxide of iron.

**Preparation of yttria.**—The crude oxides of yttrium, erbium, &c., are separated from *gadolinite* by the method of Bahr. a. Bunsen described under *Erbium* (vol. ii. p. 457). Marignac (*A. Ch.* [5] 14, 247) converted the oxides into nitrates, heated the nitrates in a Pt basin until red fumes came off freely; treated the residue with water, and separated the solution, which contained much Yt nitrate, from insoluble basic nitrates of Er, &c. He then evaporated the solution to dryness, heated again until partial decomposition was effected, again treated with water, poured off the solution, evaporated it to dryness, partially decomposed the solid nitrates by heat, and so on. After some hundred repetitions of these processes, approximately pure yttria was obtained. Auor von Welsbach (*M.* 4, 630) separated approximately pure yttria from the crude earths obtained from *gadolinite* by a long-continued series of operations based on the facts (1) that yttrium nitrate is less readily decomposed to basic salts than erbium nitrate when a fairly conc. solution of these nitrates is heated with the oxides of the metals made into a paste with water, and (2) that basic yttrium nitrates dissolve in a solution of the normal nitrates of Y and Er more readily than basic erbium nitrates.

**References.**—Gadolin (*Crell's Annal.* 1796 [1] 313); Ekeberg (*Scher. J.* 3, 187); Klaproth (*Scher. J.* 5, 531); Vauquelin (*Scher. J.* 5, 552); Berzelius (*Scher. J.* 16, 250, 404; and *Lehrbuch* [5th ed.], 2, 177); Berlin (*P.* 43, 105); Schoerer (*P.* 56, 483); Mosander (*P. M.* 23, 251); Popp (*A.* 131, 179); Delafontaine (*Ar. Sc.* [2] 21, 97; 22, 30; 25, 112; 51, 48; 61, 273); Bahr, (*A.* 135, 376); Bahr a. Bunsen (*A.* 137, 1); Cleve a. Höglund (*Bl.* [2] 18, 193, 279); Cleve (*Bl.* [2] 21, 844).

**Preparation of yttrium.**—The metal has not been obtained pure. Wöhler in 1828 (*P.* 13, 580) obtained impure yttrium by reducing the chloride by sodium. In 1864 Popp (*A.* 131, 179) dissolved yttria in  $\text{HClAq}$ , added  $\text{NH}_4\text{ClAq}$ , evaporated, separated and dried the double chloride of yttrium and ammonium thus formed, mixed this with Na, the double salt and the Na being arranged in alternate layers, heated the mixture in a closed crucible till action began and then allowed the reaction to proceed; washed the fused mass with water, separated unreacted yttria by levigation, washed the dark-grey powder that remained with water, and then with alcohol, and dried it over  $\text{H}_2\text{SO}_4$ . In 1890 Winkler (*B.* 23, 787) obtained a black powder that decomposed water by heating yttria and finely divided Mg in the ratio  $\text{Y}_2\text{O}_3:3\text{Mg}$  (*cf.* *Yttrium*, p. 882). Popp describes yttrium as a dark-grey powder resembling *ferrium redactum*, decomposing cold water slowly and hot water rapidly,

easily dissolved by dilute acids, including acetic acid, decomposing boiling  $\text{KOHAc}$ , and  $\text{NH}_4\text{ClAq}$  at the ordinary temperature, with evolution of H and  $\text{NH}_3$ ; the metal burns brilliantly when heated on Pt foil; when heated in O it burns with a very dazzling light.

An examination of the emission spectrum of yttrium was made by Thalen: the most prominent lines observed had the wave-lengths 6191, 6431, 5987, 5971, 5662, 5496, 5102, 5205, 5200, 5088, 4900, 4881, 4854, 4374, and 4309 (*Kongl. Sw. Vetens. Acad. Handl.* 12).

The atomic weight of yttrium was determined by Berzelius, Delafontaine, Popp, Bunsen a. Bahr (*v. supra*, *References*) by analyses of the sulphate, or by transforming yttria into the sulphate; the values varied from 92.2 to 102.3. In 1873 Cleve a. Höglund (*v. B.* 6, 1467) made more accurate determinations by analysing purer specimens of  $\text{Yt}(\text{SO}_4)_3$ , and obtained the value 89.6.

**Chemical relations of yttrium.**—Assuming yttrium to be a homogeneous element with at. w. c. 89, it must be placed in Series 6 of Group III. in the periodic arrangement of the elements. This group contains the earth metals; yttrium is preceded in the even series family by B and Sc, and is succeeded by La and Yb. A consideration of the position given to Y in the periodic classification shows that the element ought to closely resemble the other metals of the earths. Too little is known of the properties of many of the earth metals to allow of a detailed comparison of them one with another. A general account of the relations of these metals will be found in *EARTHS, METALS OF THE* (vol. ii. p. 424).

**The homogeneity of yttria.**—The properties described as belonging to yttria before 1885 were the properties of a mixture of at least five, and perhaps six, different bodies, according to Crookes (*C. N.* 51, 13, 155). Crookes subjected 'yttria' to a prolonged process of fractionation by ammonia (for a description of this method *v. Erbium*, vol. ii. p. 423), and he then examined the phosphorescence spectra of various fractions. Crookes concludes that yttrium is a compound, or perhaps a very intimate mixture, of simpler bodies. For details of the phosphorescence spectra of the substances obtained by fractionating 'yttria' *v. METALS, RARE* (vol. iii. p. 248). By thirty-two fractionations of 'yttria' by ppm. with  $\text{NH}_4\text{Aq}$ , followed by twenty-six fractionations by ppm. with oxalic acid, Lucq de Boisbaudran (*C. R.* 103, 619 (1887)) obtained a white specimen of yttria which gave no phosphorescence spectrum when mixed with lime, and which, when converted into chloride, gave a spark spectrum, showing only the lines of yttrium.

**Yttrium, bromide of,  $\text{YBr}_3 \cdot 9\text{H}_2\text{O}$ .** Colourless, very deliquescent tablets; obtained by dissolving  $\text{Y}_2\text{O}_3$  in  $\text{HBrAq}$  and concentrating (Cleve, *Bl.* [2] 18, 193). The anhydrous salt is obtained by Duboin (*C. R.* 107, 99, 248) by heating  $\text{Y}_2\text{O}_3$  to redness on a support of gas-carbon in a current of CO and Br vapour. Very soluble in water or alcohol; insoluble in ether.

**Yttrium, chloride of,  $\text{YCl}_3 \cdot 6\text{H}_2\text{O}$ .** Obtained by dissolving yttria in  $\text{HClAq}$ , evaporating to dryness on a water-bath; dissolving in alcohol, and evaporating over  $\text{H}_2\text{SO}_4$  (Cleve, *l.c.*). Crystallises in large, colourless, very deliquescent,

rhombic prisms (C., l.c.). The anhydrous compound is formed by heating yttria to redness on a support of gas-carbon in a slow stream of CO and Cl (Duboin, l.c.). By evaporating a solution of yttria in HClAq with addition of  $\text{NH}_4\text{Cl}$  a double compound of  $\text{YCl}_3$  and  $\text{NH}_4\text{Cl}$  is obtained; double compounds with  $\text{KCl}$  and  $\text{NaCl}$  are formed by fusing the constituent chlorides together. Popp (A. 181, 179) described the double compound  $\text{YCl}_3 \cdot 3\text{HgCl}_2 \cdot 9\text{H}_2\text{O}$ . Cleve (Bl. [2] 31, 105) described  $\text{YCl}_3 \cdot \text{SnCl}_4 \cdot 8\text{H}_2\text{O}$ .

Yttrium fluoride of  $2\text{YF}_3 \cdot \text{H}_2\text{O}$ . Obtained as a gelatinous pp. by adding  $\text{HFAq}$ , or solution of an alkali fluoride, to solution of a salt of yttrium (Cleve, Bl. [2] 18, 193).

Yttrium iodide of  $(? \text{YI}_3)$ . Deliquescent crystals, soluble in alcohol; obtained by evaporating a solution of yttria in  $\text{HKAq}$  (Berlin, P. 43, 105; no analyses given).

Yttrium oxides of. Besides yttria,  $\text{Y}_2\text{O}_3$ , there probably exists another oxide, containing more oxygen.

YTTRIA  $\text{Y}_2\text{O}_3$ . (Yttrium sesquioxide.) A hydrate, probably  $\text{Y}_2\text{O}_3 \cdot 6\text{H}_2\text{O}$  (1 pp., l.c.), is obtained, as a gelatinous pp. closely resembling hydrated alumina, by ppg. the solution of a salt of yttrium by ammonia. The oxide is formed by strongly heating this hydrate; also by decomposing by heat the carbonate, nitrate, or oxalate of yttrium in presence of air. Yttria is described as a heavy, white or almost white powder, S.G. 5.078 (Cleve, l.c.); 5.046 (Nilson a. Pettersson, B. 13, 1459). S.H. ( $0^\circ$ - $100^\circ$ ) 1026 (N. a. P., l.c.). By heating amorphous yttria with  $\text{CaCl}_2$  for some hours, and washing with warm water, Duboin (C. R. 107, 99, 243) obtained highly refractive crystals of  $\text{Y}_2\text{O}_3$ , scarcely acted on by acids or by fused  $\text{Na}_2\text{CO}_3$ . Yttria is a markedly basic oxide; it absorbs  $\text{CO}_2$  from the air, and decomposes solutions of ammonium salts, giving off  $\text{NH}_3$ . Yttria is insoluble in water; it dissolves slowly in cold  $\text{HClAq}$ ,  $\text{HNO}_3\text{Aq}$ , or  $\text{H}_2\text{SO}_4\text{Aq}$ , but more rapidly on warming. By heating a mixture of yttria and finely-powdered  $\text{Mg}$ , in the ratio  $\text{Y}_2\text{O}_3 : 3\text{Mg}$ , Winkler (B. 23, 787) obtained a black powder which slowly gave off  $\text{H}$  from cold water, rapidly from hot water, and dissolved in dilute  $\text{HClAq}$ , with violent evolution of  $\text{H}$ .

YTTRIUM PEROXIDE. By adding  $\text{H}_2\text{O}_2\text{Aq}$  and  $\text{NH}_4\text{Aq}$  to a solution of sulphate or nitrate of yttrium, Cleve (Bl. [2] 43, 53) obtained a white gelatinous pp. to which he gave the composition  $\text{Y}_2\text{O}_5$ ; but this formula cannot be regarded as final.

Yttrium salts of. The salts which are formed by replacing the  $\text{H}$  of acids by yttrium belong to the form  $\text{Y}_3\text{X}_3$ , where  $\text{X} = 2\text{ClO}_4$ ,  $2\text{NO}_3$ ,  $\text{SO}_4$ ,  $\text{SO}_3$ ,  $\text{CO}_3$ ,  $3\text{PO}_4$ , &c. Almost all the yttrium salts of oxyacids that have been prepared are normal salts; a basic nitrate, and an acid orthophosphate and selenate, are known. Many of the salts are obtained by dissolving yttria in acids and evaporating; those salts which are fusible, or but slightly soluble, in water are formed by ppn. from the nitrate or sulphate. The salts formed by ppn. are the arsenate, borate, carbonate, chromate, iodate and periodate, oxalate, phosphites, selenite and sulphite; besides these salts, the following salts of oxyacids are known, and are soluble in water: bromate, chlorate and perchlorate, nitrate, selenate, sulphate, thiosulphate and tungstate. A few double salts are known; the principal are  $\text{Y}_2(\text{CO}_3)_3 \cdot \text{M}_2\text{CO}_3 \cdot x\text{H}_2\text{O}$ ,  $\text{Y}_2(\text{C}_2\text{O}_4)_3 \cdot 3\text{M}_2\text{C}_2\text{O}_4 \cdot x\text{H}_2\text{O}$ , and  $\text{Y}_2(\text{SO}_4)_3 \cdot m\text{M}_2\text{SO}_4 \cdot x\text{H}_2\text{O}$ , where  $\text{M}$  = an alkali metal. Duboin (C. R. 107, 99, 243) obtained a silicate  $\text{Y}_2\text{O}_3 \cdot \text{SiO}_2$  by very strongly heating a mixture of 8 pts. yttria with 80 pts.  $\text{CaCl}_2$ , and washing with water. The yttrium salts of oxyacids have been examined, chiefly by Cleve (Bl. [2] 18, 193, 239; 21, 344; v. also Berlin, P. 43, 105; Högbon, Bl. [2] 42, 2; Popp, A. 131, 179).

Yttrium sulphide of. No compound of yttrium and sulphur has been isolated with certainty. Addition of  $(\text{NH}_4)_2\text{SAq}$  or  $\text{NH}_4\text{HSAq}$  to a solution of a salt of yttrium ppts. hydrated oxide. By fusing yttria,  $\text{S}$ , and an alkali carbonate, and washing the fused mass with water, a yellowish-green solid is obtained that is insoluble in water, but is partly decomposed thereby to hydrated oxide and  $\text{H}_2\text{S}$ ; this solid dissolves in acids, giving off  $\text{H}_2\text{S}$ . The same solid seems to be obtained by strongly heating yttria in  $\text{H}$  laden with  $\text{CS}_2$ . No compound of yttrium and  $\text{S}$  was obtained by heating yttria with  $\text{Na}_2\text{S}$ . By heating  $\text{YCl}_3$  in a stream of  $\text{H}_2\text{S}$ ,  $\text{HCl}$  is given off, and a yellow powder remains, which is decomposed by water, with evolution of much  $\text{H}_2\text{S}$  (v. Popp, A. 131, 179). According to Popp (l.c.), the composition of this substance is  $\text{Y}_2\text{S}_3$ .

By passing dry  $\text{H}_2\text{S}$  over a mixture of  $\text{YCl}_3$  with excess of  $\text{NaCl}$ , heated to c.  $1000^\circ$  in a boat of gas-carbon, Duboin (C. R. 107, 99, 243) obtained a greenish, crystalline solid, which when washed with water left transparent, greenish lamellae of the double compound  $\text{Y}_2\text{S}_3 \cdot \text{Na}_2\text{S}$ . M. M. F. M.

#### ZANZALÖIN & ALÖIN.

ZEORIN  $\text{C}_{12}\text{H}_{18}\text{O}$ . [231?]. Occurs in the ethereal extract from *Zeora sordida* (Paterno, G. 7, 281, 508). Small pyramids with hexagonal base (from ether-alcohol), v. al. sol. alcohol and ether, insol. water. Neutral. Not attacked by alkalis or dilute acids.

#### ZINC. Zn. At. w. c. 65.8 (v. infra).

Mol. w. c.  $65.8$  at c.  $1400^\circ$ ; probably the same in solution in  $\text{Hg}$  (v. infra). Melts at  $419^\circ$  (determined by air thermometer; v. Meyer a. Riddle, B. 26, 243); at  $417.77^\circ$  (determined by platinum thermometer, Callendar & Griffiths, C. N. 66, 1); for older determinations, giving

m.p. from  $440^{\circ}$  to  $450^{\circ}$ , v. Carnelley's *Melting and Boiling-point Tables* (1, 14). Boils between  $980^{\circ}$  and  $954^{\circ}$  (Deville a. Troost, *C. R.* 90, 773); at  $930^{\circ}$  (Vielle, *C. R.* 94, 720; cf. Troost, *C. R.* 94, 788). S.G. c. 6.9 to 7.2 (v. Schölin, *A.* 107, 59; Kelscher, *B.* 14, 2750; Quinke, *P.* 135, 642; Spring, *B.* 16, 2724). V.D.  $34.8$  at c.  $1400^{\circ}$  (Mensching a. V. Meyer, *B.* 19, 3295). S.H. ( $0^{\circ}$  to  $100^{\circ}$ ) .0935 (Bunsen, *P.* 141, 1); ( $19^{\circ}$  to  $47^{\circ}$ ) .0932 (Kopp, *T.* 155, 71; cf. Schüller a. Wartha, *B.* 8, 1016). C.E.; if length of bar at  $0^{\circ} = l^{\circ}$ , then length at  $t^{\circ} = (1 + \beta l)$ ; if volume at  $0^{\circ} = V$ , then volume at  $t^{\circ} = (1 + \beta V)$ ;  $\beta = .00002976$  from  $0^{\circ}$  to  $100^{\circ}$  (Matthiessen, *P. M.* [4] 32, 472). Heat of fusion for 1 kilo = 28,130 (Pérson, *A. Ch.* [3] 24, 129). T.C. (Ag = 100) 28.1 (Wiedemann, *P. M.* [4] 19, 243). E.C. (Hg at  $0^{\circ} = 1$ ) 16.1 at  $0^{\circ}$ , 16.92 at  $100^{\circ}$  (Benoit, *P. M.* [4] 45, 314); 14.83 at  $100^{\circ}$  (Kirchoff a. Hanseemann, *W.* 13, 406). Chief lines in emission spectrum 6360, 6100, 4924, 4911, 4809, 4722, 4679 (Huggins, *T.* 154, 139; cf. Thülen, *Determin. des Longueurs d'Ondes des Raies Mécaniques* [Upsala, 1868]; and Ames, *P. M.* [5] 30, 33); for wave-lengths of lines of high refrangibility, v. Hartley a. Adeney (*T.* 1884 [1], 97). Zinc crystallises in tabular hexagonal plates,  $a : c = 1.356425$  (Williams a. Burton, *Am.* 11, 219; cf. Schölin, *J. pr.* 89, 122; 96, 178; Sharples, *Am. S.* [3] 7, 223; Nöggerath, *P.* 39, 324; Nickles, *A. Ch.* [3] 22, 37; G. Rose, *B. B.* 1852, 26; *P.* 107, 448; Storer, *P. Am.* 4, 6; Cooke, *Am. S.* 31, 191). The metal is probably dimorphic. H.C. [Zn, O] = 85,430 (Thomsen, *Th.* 8, 275). Refraction equivalent = 9.8 (Gladstone, *Ph.* 18, 49).

**Historical.**—That copper acquired a reddish colour, and that its properties were modified, by melting with certain ores, was known to the ancients and the alchemists; the ore with which copper was generally melted to form brass was called *cadmia fossilis*. The fact that a lustrous solid could be obtained by heating *cadmia fossilis* seems to have been known to the ancient writers on mineralogy. According to Kopp (*Geschichte der Chemie*, 4, 116), the earliest use of the word *zinc* is found in a writing of the fifteenth century attributed to Basil Valentine. Paracelsus, in the sixteenth century, speaks of zinc as a definite metal-like substance, and assigns it to the class of bastard or semi-metals. The name 'zinc' was applied during the seventeenth and eighteenth centuries alike to zinc ores and to the metal-like substance obtained from these ores. Boyle speaks of zinc, and also uses the word *spelter*, or *splauter*, a term of Indian origin according to Kopp. Tolerably pure zinc seems to have been obtained from zinc ores about 1720; probably by Henckel (v. Percy's *Metallurgy*, 1, 220).

**Occurrence.**—Zinc is found in small quantities; Becker (*J. M.* 1857, 698) and Phipon (*C. R.* 55, 218) noticed the occurrence of native zinc in Victoria. Considerable quantities of compounds of zinc occur in many places; the commonest are *calamine* (carbonate), *siliceous calamine* (silicate), *blende* (sulphide), and *red zinc ore* (oxide); aluminate, arsenate, phosphate, and sulphate of zinc are also found, but in smaller quantities. Small quantities of Cd compounds occur in most zinc ores. The

ash of a plant that grows on the waste heaps of the zinc works in Rhenish Prussia (*Viola calaminaria*) is said to contain compounds of zinc (Braun, *P.* 927, 175). Zinc compounds have been found in some springs (v. Hillebrand, *U. S. Geology Survey Bull.* No. 113 (1898)). Traces of zinc compounds have been found, according to Lechartier a. Bellamy (*C. R.* 84, 687), in the human liver, in calves' liver, in beef, hens' eggs, wheat, barley, maize, beans, and vetches.

**Formation.**—Zinc ore, generally carbonate or sulphide, is roasted in reverberatory calciners; the roasted ore is mixed with half its weight of powdered charcoal, coke, or anthracite, and heated in crucibles or retorts arranged so that the reduced metal distils from the impurities; the metal is condensed and collected in suitable vessels, and CO passes off. For details and descriptions of the different forms of apparatus, v. *DICTIONARY OF APPLIED CHEMISTRY*, vol. iii. p. 1042.

**Preparation.**—Commercial zinc generally contains from .5 to 3.3 p.c. lead, with c. .2 to .5 p.c. iron and cadmium, and small traces of arsenic.

Pure zinc was prepared by Reynolds a. Ramsay (*C. J.* 51, 854 (1887)) by dissolving zinc sold as free from common impurities in dilute  $H_2SO_4$ , evaporating, crystallising the sulphate several times, electrolysis a solution of this salt, the metal being deposited on an electrode of Pt wire, dissolving the metal in dilute  $HClAq$ , ppg.  $ZnO, H_2$  by  $NH_4Aq$ , dissolving the pp. in excess of  $NH_4Aq$ , and ppg.  $ZnS$  by  $H_2S$ ; the  $ZnS$  was dissolved in  $HClAq$ , and again ppg. from an ammoniacal solution by  $Li_2S$ ; the pp. was well washed, dissolved in pure dilute  $H_2SO_4$ , and the sulphate obtained on crystallisation was re-crystallised several times; an aqueous solution of this sulphate was then electrolysed, using a Pt wire as electrode, and the metal was melted in a tube of hard glass from which the air had been exhausted. By distilling this metal *in vacuo* in a tube of hard glass, very pure zinc was obtained. Pullinger (*C. J.* 57, 816 (1890)) distilled zinc sold as 'chemically pure' in a hard glass tube, bent slightly towards the closed end, placed in a combustion furnace, the open end being connected with a good water-pump. By melting the distilled zinc in a tube of hard glass with a small bulb blown on the end, the part of the tube between the bulb and the wider portion containing the zinc being capillary, and the open end being connected with a water-pump, he obtained the zinc imperfectly bright, smooth, lustrous spheres free from hollows; the pump was stopped while the zinc was molten, and the increased pressure caused the molten metal to filter through the capillary tube into the bulb. For the preparation of pure zinc by electrolysis of an ammoniacal solution of the sulphate, v. Myers (*C. R.* 74, 195).

Solba (*C. C.* 1834, 419) says that zinc can be obtained free from As and nearly free from iron by the combined interaction of  $As_2S_3$  and water vapour. He mixes burnt gypsum with one-fourth its weight of  $As_2S_3$  powder, moulds the moistened mixture into spheres about 5 cm. diameter, and sinks these to the bottom of a crucible containing molten zinc; vapours of

H<sub>2</sub>S and S are given off, and the molten metal is thereby briskly agitated. When the reaction is completed, the little balls are taken out, the upper crust is removed, and the operation is repeated if necessary.

*Zinc-dust* is obtained either in the distillation of the metal, or, is not such fine division, by crushing and powdering the metal in an iron mortar at a temperature somewhat below the m.p. of zinc. The ZnO.H<sub>2</sub> always present in specimens of zinc-dust may be removed by digesting with NH<sub>4</sub>ClAq and then with NH<sub>4</sub>Aq, and drying on a porous tile *in vacuo* (Carnegie, C. J. 53, 471).

*Properties.*—Zinc is a white metal, with a slight shade of blue; it is very lustrous when polished. Commercial zinc is brittle at the ordinary temperature, but it becomes malleable between 100° and 150°; at 210° it again becomes brittle, and at that temperature it can be finely powdered in a mortar. Pure zinc is said to be malleable at the ordinary temperature. Commercial zinc that has been heated to 100°–150° retains its malleability when it cools. Kahlischer (B. 14, 2747) noticed that rolled zinc ceased to give a ringing sound when struck after it was heated to c. 160°–300°, that it could then be bent easily, and that when bent it emitted a sound like the 'cry' of tin; he found that the zinc became crystalline, and the crystalline structure was more decided the higher the temperature; the S.G. was very slightly increased, and the electrical resistance was reduced by c. 3 p.c. Zinc is a softer metal than copper; its hardness is increased by rolling. The tensile strength of zinc varies much with the mode of preparation. Zinc crystallises easily, especially when pure; the form is that of hexagonal plates (for references *v. supra*, beginning of this article). Zinc melts at c. 420°, and boils somewhat below 1000° (*v. supra*). Molten zinc expands somewhat during solidification. The metal can be distilled at a full red heat; the vapour takes fire in the air, and burns with formation of ZnO and the production of a bright white light. Zinc exposed to the ordinary air becomes very gradually covered with a thin film of a basic carbonate which protects the mass of the metal from further corrosion; in pure dry air zinc is unchanged. Zinc dissolves in dilute acids, generally with evolution of H (*v. infra*, *Reactions with sulphuric and nitric acids*); it also dissolves in solutions of caustic potash or soda. When impure zinc is amalgamated it resists the action of acids. Zinc is not acted on by mineral lubricating oils; some of the commoner animal oils attack it slightly (*v. Redwood, C. S. I. 5, 362*). Zinc ppts. most of the other metals from their solutions; if a piece of impure zinc is dissolved in an acid, most of the metallic impurities (As, Cd, Cu, Pb, &c.) remain undissolved as long as undissolved zinc is present. Zinc combines directly with O, S, Se, Te, the halogens, and P; it forms alloys with many metals. Pure zinc does not decompose boiling water, but the commercial metal reacts and gives off H. Zinc-dust usually contains some ZnO.H<sub>2</sub>; it is said also to contain H, produced by the interaction of Zn and ZnO.H<sub>2</sub> (*v. Greville Williams, C. N. 52, 205, 268*).

*Atomic and molecular weights of zinc.* In 1809 Gay-Lussac (*Mém. S. d'A., 2, 174*) deter-

mined the weight of ZnO obtained by dissolving a determinate weight of zinc in nitric acid, evaporating to dryness, and strongly heating the residue; Berzelius in 1811 repeated the experiment of Gay-Lussac (G. A. 37, 400; *v. also P., 8, 184*); and in 1843 Erdmann made similar experiments (*v. Berzelius' Lehrbuch, 3, 1219*). The values obtained for the at. w. of zinc were 65.39 (G.-L.), 65.41 (B.), and 64.94 and 64.88 (E.). In 1844 Favre decomposed ZnC<sub>2</sub>O<sub>4</sub> by heating in air, and determined the weights of ZnO and CO<sub>2</sub> produced; the value 65.85 was thus obtained for the at. w. of zinc. In the same year Favre obtained the value 66.78 by dissolving zinc in dilute H<sub>2</sub>SO<sub>4</sub>Aq, burning the H given off by passing it over hot CuO, and weighing the water thus produced (A. Ch. [3] 10, 163). In 1884 Marignac determined the Cl and the Zn in ZnCl<sub>2</sub>.2KCl, and obtained the value 65.18 for the at. w. of zinc (A. Ch. [6] 1, 309; *v. also* Baubigny, C. R. 97, 908 [1883]). By dissolving zinc in dilute H<sub>2</sub>SO<sub>4</sub>Aq and measuring the H given off, van der Plaats concluded that the at. w. of zinc is 65.18 (C. R. 100, 52 [1885]). Reynolds a. Ramsay, in 1887, by measuring the H given off by the interaction between very pure zinc and H<sub>2</sub>SO<sub>4</sub>Aq, obtained the value 65.48 (C. J. 51, 854). By oxidising zinc to ZnO, by HNO<sub>3</sub>Aq, in 1888, Moxse a. Burton, obtained the value 65.1 (Am. 10, 311). In 1889 Gladstone a. Hibbert (C. J. 55, 443) determined the ratio of zinc dissolved to silver deposited by one and the same electric current; taking the at. w. of silver as 107.66 (the value adopted in this Dictionary) the at. w. of zinc was found to be 65.29.

In 1886 Mensching a. V. Meyer (B. 19, 8295) found the V.D. of zinc at c. 1400° to be 34.3, a number which shows that the gaseous molecule of zinc is monatomic. Ramsay, in 1889, determined the lowering of the vapour pressure of Hg produced by dissolving zinc therein (C. J. 55, 521); assuming that equal volumes of dilute solutions contain equal numbers of molecules, and that the molecular weight of liquid Hg is 200, Ramsay's results indicate that the molecules of zinc in dilute solutions of this metal in Hg are monatomic. The experiments of Heycock a. Neville (C. J. 57, 376 [1890], and 61, 888 [1892]) on the lowering of the freezing-points of Bi, Cd, Pb, Sn, and Na by solution of zinc in these metals tend to confirm the conclusion that the molecule of zinc in dilute solutions in these metals is monatomic.

*Chemical relations of zinc.* Zinc is the second odd-series member of Group II. in the periodic classification of the elements. Zinc is preceded in the odd series of this group by Mg and is followed by Cd, —, and Hg; the members of the even series of Group II. are Be, Ca, Sr, Ba, —. Zinc is the second member of series 5; it is preceded in this series by Cu, and is succeeded by Ga, Ge, As, Se, and Br. The general chemical character of zinc is that of a metal; its oxide ZnO is basic, its chloride ZnCl<sub>2</sub> is volatilisable without decomposition. No acids are known containing zinc, and the molecule of the element is monatomic. The fact that compounds of ZnO and K<sub>2</sub>O are obtained by dissolving ZnO.H<sub>2</sub> in KOHAq and adding alcohol shows that the hydroxide of the metal has feebly marked acidic properties, and the iso-

tion of a number of oxychlorides and basic carbonates, nitrates, and sulphates illustrates the fact that zinc is less positive than Mg, which is the first member of the zinc family of Group II. For a general account of the properties of the family of which zinc forms a member v. MAGNESIUM GROUP OF ELEMENTS, vol. iii. p. 163. The atom of zinc is divalent in the gaseous molecules of its compounds.

**Reactions and Combinations.**—1. Zinc is unchanged in pure dry air; in ordinary air the surface layers are slowly converted into a basic carbonate, which protects the metal beneath. Heated strongly in air or oxygen, zinc burns to ZnO.—2. Heating zinc in bromine, chlorine, or iodine produces  $\text{ZnBr}_2$ ,  $\text{ZnCl}_2$ , or  $\text{ZnI}_2$ .—3. When zinc is heated in phosphorus vapour, phosphide of zinc (q. v., p. 890) is formed.—4. By heating zinc with selenium vapour, a compound of Zn and Se is formed (v. ZINC SELENIDE, p. 890).—5. Zinc combines with tellurium when the elements are heated together (v. ZINC TELLURIDE, p. 891).—6. Sulphur and zinc combine when a mixture of these elements is very strongly compressed (Spring, B. 16, 1000).—7. Zinc decomposes water at a red heat. Commercial samples of zinc decompose water at  $100^\circ$  (L'Hôte, C. R. 101, 1153).—8. ZnS is formed by strongly heating zinc in a stream of hydrogen sulphide; when hydrogen selenide is used the product is ZnSe, and by heating the metal in hydrogen telluride ZnTe is formed (v. Margottet, C. R. 84, 1293).—9. Zinc is said to reduce carbon monoxide at a very high temperature.—10. Zinc is superficially oxidised by heating to dull redness in nitric oxide (Säbater a. Senderens, C. R. 114, 1429). Oxidation in nitrogen dioxide ( $\text{NO}_2$ ) is effected at  $300^\circ$  (S. a. S., C. R. 115, 236).—11. Many metallic oxides are reduced by heating with zinc.—12. Zinc reacts with sulphurous acid solution; according to Schweizer (v. C. N. 23, 293), the products are  $\text{ZnSO}_4$ , along with  $\text{H}_2\text{S}_2\text{O}_4\text{Aq}$ ,  $\text{H}_2\text{S}_2\text{O}_6\text{Aq}$ , and S.—13. Zinc dissolves in hydrochloric acid, giving off H and forming  $\text{ZnCl}_2$ . Reynolds a. Ramsay (C. J. 51, 857) say that pure zinc scarcely reacts with boiling hydrochloric acid. For reactions of zinc with sulphuric and nitric acids, v. *infra*.—14. Zinc dissolves slowly in hot solutions of caustic soda or potash, giving off H, and forming  $\text{ZnO} \cdot x\text{H}_2\text{O}$  (cf. ZINC HYDROXIDE, p. 888); the reaction is much hastened by adding iron or Pt along with the zinc.—15. Many metallic salts in solution are reduced by zinc, with ppn. of the metals, e.g. salts of As, Cd, Cu, and Pb.—16. When Zinc dust is shaken with an aqueous solution of ferric chloride, the whole of the ferric salt is very rapidly reduced to ferrous chloride (for details of the application of this reaction in the estimation of ferric iron, v. Carnegie, C. J. 53, 468 [1898]).—17. According to Siersch (J. 1897, 257), zinc dissolves in sodium chloride solution, forming  $\text{ZnCl}_2 \cdot 2\text{NaClAq}$ , ZnO, and H.—18. Pommard (J. pr. 73, 496) says that nearly all chlorides and fluorides are reduced by reacting with vapour of zinc in an atmosphere of H.—19. By heating to redness a mixture of zinc filings and sodium metaphosphate, Hoeslet (A. 100, 99) probably obtained phosphides of zinc (v. ZINC PHOSPHIDES, p. 890).—20. Zinc reacts with sodium hydrogen sulphite solution,

forming  $\text{ZnSO}_4$ ,  $\text{Na}_2\text{S}_2\text{O}_4\text{Aq}$ , and  $\text{Na}_2\text{SO}_4\text{Aq}$  (v. HYPOSULPHITES, this vol. p. 593).—21. By heating zinc with zinc sulphide in an exhausted tube, some of the ZnS is carried forward and deposited in the front part of the tube; probably at a high temperature ZnS is decomposed, and there exist offy Zn and S, and at a lower temperature these recombine to form ZnS (Morse a. White, Am. 11, 348). A similar phenomenon is noticed on heating zinc with zinc oxide (M. a. W., Lc. p. 258).—22. ZnS is formed by strongly heating zinc and mercuric sulphide or zinc and potassium polysulphides (v. ZINC SULPHIDE, p. 890).

When strips of zinc-foil are immersed in  $\text{CuSO}_4\text{Aq}$ , a deposit of finely-divided Cu is formed on the zinc. This copper-zinc couple is an energetic reducing agent;  $\text{KClO}_4\text{Aq}$  is reduced to  $\text{KClAq}$ ,  $\text{KNO}_3\text{Aq}$  to  $\text{KNO}_2\text{Aq}$  and  $\text{NH}_4\text{Aq}$ ,  $\text{K}_2\text{FeCy}_6\text{Aq}$  to  $\text{K}_2\text{FeCy}_4\text{Aq}$ ,  $\text{SO}_2\text{Aq}$  to S,  $\text{As}_2\text{O}_3\text{Aq}$  to  $\text{AsH}_3$ ,  $\text{C}_2\text{H}_5\text{NO}_2$  (in alcohol) to  $\text{C}_2\text{H}_5\text{NH}_2$ , &c. (v. Gladstone a. Tribe, C. J. 33, 306).

**Reactions of zinc with sulphuric and nitric acids.** Commercial zinc dissolves easily in dilute  $\text{H}_2\text{SO}_4\text{Aq}$ , with formation of  $\text{ZnSO}_4\text{Aq}$  and evolution of H. In 1830 De la Rive noticed that very little action took place between approximately pure zinc and  $\text{H}_2\text{SO}_4\text{Aq}$ ; this fact has been confirmed by other experimenters. Reynolds a. Ramsay (C. J. 51, 857 [1887]) found that zinc prepared by repeated electrolysis of the sulphate and distillation *in vacuo* scarcely reacted with  $\text{H}_2\text{SO}_4\text{Aq}$ ; L'Hôte (C. R. 101, 1153) also asserted that pure zinc does not react with  $\text{H}_2\text{SO}_4\text{Aq}$ . Divers a. Shimidzu (C. J. 47, 698 [1885]) observed very great differences between the rate of action of the same  $\text{H}_2\text{SO}_4\text{Aq}$  on sheets of commercial zinc of the same size. Pullinger in 1890 (C. J. 57, 815), and Weeren in 1891 (B. 24, 1785), made somewhat elaborate investigations into the connections between the conditions and the rate of the interaction of zinc and  $\text{H}_2\text{SO}_4\text{Aq}$ .

Pullinger used 'pure' sulphuric acid diluted with three times its weight of water; and zinc prepared by distilling that sold as 'chemically pure' *in vacuo* and casting in balls under pressure to prevent the formation of cracks or hollows (v. *supra*, Preparation of zinc, p. 885). He found that when the surface of the zinc was very smooth this was best accomplished by immersing in aqua regia for 10 or 15 seconds, and washing with water—and the acid was boiled for some hours before the experiment, there was practically no reaction at  $20^\circ$ – $25^\circ$  (spheres of zinc weighing c. 2½ g. lost from 5 to 6 mgns. in 20 hours). Pullinger found that the presence of small quantities of  $\text{H}_2\text{S}$ ,  $\text{SO}_2$ , or  $\text{H}_2\text{S}_2\text{O}_4\text{Aq}$  did not affect the weight of zinc dissolved by the boiled  $\text{H}_2\text{SO}_4\text{Aq}$ ; addition of some  $\text{H}_2\text{O}_2$  materially increased the rate of action; and  $\text{H}_2\text{SO}_4\text{Aq}$  that had been electrolysed before use dissolved from four to ten times more zinc than some of the same acid that had not been electrolysed; addition of a few drops of  $\text{HNO}_3\text{Aq}$  considerably increased the action; when a few drops of  $\text{HClAq}$  were added to the  $\text{H}_2\text{SO}_4\text{Aq}$  practically no action occurred. P. supposed that all the 'pure' acid used by him contained traces of an oxidising substance, probably  $\text{H}_2\text{S}_2\text{O}_8$ , and that the solvent action was due to this. P.

insists on the important connection between the rate of action and the smoothness or roughness of the surface of the zinc used. But he concludes that 'in all probability pure dilute sulphuric acid would, at ordinary temperatures, be entirely without action upon metallic zinc, whether the surface of the latter were rough or smooth.'

Weeren used zinc which he found to be chemically pure by analysis; he gives no account of his method of preparation nor any details of his analytical results. W. found that the weight of pure zinc dissolved by pure  $\text{H}_2\text{SO}_4$  (1:20) at the ordinary temperature, and under a pressure of 10 mm., was c. ten times greater than the weight dissolved at 760 mm. pressure; but the weights of impure zinc dissolved at the two pressures were almost the same. The pure zinc used by W. dissolved fairly rapidly in boiling  $\text{H}_2\text{SO}_4$ ; in one case when 2.1 mgm. dissolved at  $0^\circ$  after thirty minutes' action, 122 mgm. dissolved in the boiling acid. W. found that the solubility of his pure zinc increased very slowly as temperature rose up to within  $1^\circ$  of the b.p. of the acid used, but that when ebullition actually began the solubility of the zinc suddenly increased; the weight of pure zinc dissolved by  $\text{H}_2\text{SO}_4$  at  $100^\circ$  and boiling, was c. sixteen times greater than the weight of the same zinc dissolved by the same acid at  $100^\circ$  but kept from actually boiling by pressure. On the other hand, W. noticed that as much impure zinc dissolved at  $100^\circ$  when the acid was boiling as when it was prevented by pressure from boiling. Addition of oxidisers,  $\text{CrO}_3$  or  $\text{H}_2\text{O}_2$ , enormously increased (c. 300 times) the solubility of pure zinc in  $\text{H}_2\text{SO}_4$  at  $18^\circ$ - $20^\circ$ , but only slightly increased (c. six times) the solubility of impure zinc. W. supposes that when pure zinc is immersed in pure  $\text{H}_2\text{SO}_4$  a slight reaction occurs, and that the H produced is attracted to and held firmly on the surface of the zinc, and that the reaction ceases because the surface of the metal is protected by the layer of H. Increase of temperature does not appreciably affect the rate of action, because the layer of H remains fixed to the surface of the zinc, but when the acid boils the H is removed and rapid dissolution occurs; any conditions which remove the layer of H increase the solubility of the zinc. W. supposes that the rate of dissolution of impure zinc in  $\text{H}_2\text{SO}_4$  is not much affected by boiling, presence of oxidisers, &c., because H is not given off at the surface of the zinc, but at the surface of the more negative impurities. The rapid solution of zinc in  $\text{HNO}_3$  is connected, according to W., with the rapid oxidation of the H produced at the surface of the zinc, and hence the production of a layer of water on the surface of the metal which destroys the attraction between the zinc and any H that may escape oxidation.

As regards the products of the interaction of zinc and sulphuric acid, when the acid is fairly concentrated (c.  $\text{H}_2\text{SO}_4$ ,  $\text{H}_2\text{O}$  to c.  $\text{H}_2\text{SO}_4$ ),  $\text{SO}_2$  is given off, and at moderately high temperatures  $\text{H}_2\text{S}$  and S are also produced (v. Calvert & Johnson, *C. J.* [2] 4, 435 [1867]). A qualitative examination of the products by Pattison Muir & Adie (*C. J.* 58, 47 [1889]) showed that  $\text{ZnSO}_4$  is the only salt of zinc produced, with any concen-

tration of acid, and at any temperature up to the b.p. of the acid used; that with approximately pure zinc little or no  $\text{SO}_2$  or  $\text{H}_2\text{S}$  is formed unless the temperature be high; and that the purer the zinc the less is the quantity of S produced (*cf.* Ditte, *A. Ch.* [6] 19, 68).

The products of the interaction of zinc and nitric acid are  $\text{Zn}(\text{NO}_3)_2$ ,  $\text{Zn}(\text{NO}_2)_2$ ,  $\text{NH}_4\text{NO}_3$  and  $\text{NH}_4\text{NO}_2$ , and  $\text{NO}$ ,  $\text{N}_2\text{O}$ , and  $\text{N}_2$ . Acworth found that when  $\text{HNO}_3$  reacts with zinc in presence of  $(\text{NH}_4)_2\text{NO}_2$ , the chief gaseous product is N (along with some  $\text{N}_2\text{O}$  and  $\text{NO}$ ) (*C. J.* 28, 828 [1875]). Acworth & Armstrong studied the reaction of  $\text{HNO}_3$  and Zn more fully in 1878 (*C. J.* 32, 54), and found that the only gaseous products were  $\text{N}$ ,  $\text{N}_2\text{O}$ , and  $\text{NO}$  (*cf.* Deville, *C. R.* 70, 22, 550 [1870]). According to Divers (*C. J.* 43, 443 [1883]), a little  $\text{NH}_4\text{OH}$  is formed when cold  $\text{HNO}_3$  and quickly poured off again. Divers & Shimidzu (*C. J.* 47, 597 [1885]) found that considerable quantities of  $\text{NH}_4\text{OH}$  are produced by the combined reaction of  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$ , or  $\text{HNO}_3$  and  $\text{HCl}$ , on zinc (v. HYDROXYLAMINE, *Formation*, vol. ii. p. 734). Divers (*loc.*) thought that zinc does not form  $\text{Zn}(\text{NO}_3)_2$  by a direct reaction with  $\text{HNO}_3$ , but by interacting with some of the  $\text{Zn}(\text{NO}_2)_2$  formed by the primary action of the metal on the acid. The products of the interaction of zinc and  $\text{HNO}_3$  have been examined recently by Montemartini (*G.* 22 [1], 277 [1892]), who says that free H is not produced (he also says that no  $\text{NH}_4\text{OH}$  is formed), and that in addition to nitrate and nitrite of zinc and ammonium, hyponitrite is also produced; the gaseous products, according to M., are  $\text{N}_2\text{O}$ ,  $\text{NO}$ ,  $\text{NO}_2$ , and  $\text{N}$ ; there is no nitrous acid formed, says M., if the  $\text{HNO}_3$  contains more than 80 p.c.  $\text{HNO}_2$ , and no  $\text{NO}_2$  if less than 80 p.c.  $\text{HNO}_2$  is present. M. also gives determinations of the quantities of the various products at different temperatures, and of the rate of reaction with different concentrations of  $\text{HNO}_3$  (*Abstract in C. J.* 62, 1279 [1892]).

**Zinc alloys of.** Alloys of zinc have been formed with most metals by fusing the constituents together; the alloys are generally hard, some of them are brittle. With antimony, two crystalline alloys are formed by melting the metals together, in the ratios  $3\text{Zn}:2\text{Sb}$  and  $\text{Zn}:\text{Sb}$ , and allowing to cool very slowly; Cooke (*Ann. S.* [2] 18, 229; 20, 222) formulates these alloys as  $\text{Zn}_3\text{Sb}_2$  and  $\text{ZnSb}$ , respectively. These alloys react with water and give off H. Alloys with arsenic are formed by heating together Zn and As, or Zn and  $\text{As}_2\text{O}_3$ , or by heating Zn in vapour of  $\text{As}$  and H; by the last method Descamps (*C. R.* 86, 1022, 1065) obtained crystals agreeing in composition with the formula  $\text{Zn}_3\text{As}_2$ . Spring (*B.* 16, 324) formed an alloy by compressing Zn and As, in the ratio  $3\text{Zn}:2\text{As}$ , at 6,500 atmospheres. Zinc alloys with bismuth when the metals are melted together, but on cooling two layers are formed, the upper containing zinc with c. 2 p.c. Bi, and the lower Bi with from 5 to 14 p.c. zinc. An alloy of zinc with bismuth and lead (3 pts. Zn, 5 pts. Bi, and 5 pts. Pb) melts at  $94.5^\circ$ . For descriptions of alloys with calcium, v. Caron (*C. R.* 48, 440 & 50, 547); Wöhler (*Z.* 133, 253); and Norton & Tritschell

(*Ann. J. 10, 70*). Brass is composed of alloys of zinc with copper (v. vol. ii. p. 254; and for details v. *DICTIONARY OF APPLIED CHEMISTRY*, vol. iii. p. 1052). Alloys of zinc with copper and nickel form German silver; most modern bronzes are alloys of zinc with copper and tin (v. vol. ii. p. 254; and for details v. *DICTIONARY OF APPLIED CHEMISTRY*, vol. iii. p. 838). Zinc alloys with iron (for details v. *DICTIONARY OF APPLIED CHEMISTRY*, vol. iii. p. 1051). For alloys with lead v. vol. iii. p. 125 (also Krant, *S. U. J. 5, 537*). Alloys with lead and tin are mentioned in vol. iii. p. 125 (v. also Wright a. Thompson, *Pr. 48, 25*). For alloys with magnesium v. Parkinson (*J. pr. 101, 375*). Zinc and mercury form a number of amalgams, which are brittle when a little Hg is present and paste when much Hg is present (for references v. *S. C. I. 9, 512*). For alloys with platinum v. this vol. p. 288. For alloys with silver v. Wright a. Thompson (*Pr. 48, 25*).

For an account of the formation of zinc alloys by immersing zinc in various metallic solutions v. Mylius a. Fromm (*B. 27, 630* [1894]).

**Zinc, amide of,  $Zn(NH_2)_2$ .** This compound was obtained by Frankland (*Pr. 8, 502*) by passing dry  $NH_3$  into an ethereal solution of  $ZnEt_2$ . A white, amorphous powder; unchanged at  $200^\circ$ , but decomposed at a red heat to  $Zn_3N_2$  (v. *ZINC NITRIDE*, p. 889) and  $NH_3$ ; reacts with water to form  $ZnO, H_2$  and  $NH_3$ .

**Zinc, bromide of,  $ZnBr_2$ .** Formula probably molecule, from analogy of  $ZnCl_2$ . S.G. 3.643 at  $10^\circ$  (Bödeker). Melts at  $394^\circ$  (Carnelley, *C. J. 33, 277*). Boils at  $695^\circ$  to  $699^\circ$  (C. a. Williams, *C. J. 33, 283*); at  $650^\circ$  (Freyer a. V. Meyer, *B. 25, 622*). H.F. [ $Zn, Br$ ] = 75,930 (*Th. 3, 275*).

**Preparation.**—1. Zinc filings are heated to dull redness in a stream of  $H_2$  vapour.—2. Zinc, or  $ZnO, H_2$ , is dissolved in a slight excess of  $HBrAq$ , the solution is evaporated to dryness, and the dry residue is sublimed out of contact with air.

**Properties and Reactions.**—White needles; very deliquescent. Easily soluble in water, alcohol, or ether (v. Berthelot, *J. Ph. 14, 610*). Thomsen gives [ $ZnBr_2, Aq$ ] = 15,030 (*Th. 3, 275*). Aqueous solutions of  $ZnBr_2$  of different concentrations have the following specific gravities according to Kremers (*P. 108, 115*):—

S.G. $ZnBr_2, Aq$ at $19.5^\circ$ .	P.c. $ZnBr_2$ .
1.1849	18.3
1.3519	31.7
1.5276	43.2
1.7082	52.6
1.8525	59.1
2.1027	68.0

• **Combinations.**—1. With ammonia to form a series of compounds. These compounds were examined by Rammelsberg (*P. 55, 240*), and, more recently, by André (*Bl. [2] 89, 398* [1883]). By dissolving  $ZnBr_2$  in  $NH_3$  under different conditions, A. obtained (1)  $ZnBr_2 \cdot 2NH_3 \cdot H_2O$ , (2)  $3ZnBr_2 \cdot 8NH_3 \cdot 2H_2O$ , (3)  $3ZnBr_2 \cdot 10NH_3 \cdot H_2O$ , and (4)  $ZnBr_2 \cdot 5NH_3$ ; by saturating hot  $NH_3$  with  $ZnO$ , he obtained  $3ZnBr_2 \cdot 6NH_3 \cdot 2H_2O$ .—2. With caesium bromide, to form  $ZnBr_2 \cdot 8CsBr$  and  $ZnBr_2 \cdot 2CsBr$  (Wells a. Campbell, *Zeit. f. anorg. Chemie*, 5, 278).

**Zinc, chloride of,  $ZnCl_2$ .** Mol. w. c. 136. Melts at  $262^\circ$  (Braun, *P. 154, 190*). Boils at  $708^\circ$ – $719^\circ$  (Carnelley a. Williams, *C. J. 33, 284*); at  $730^\circ$  (Freyer a. V. Meyer, *B. 25, 622*). S.G. 2.753 at  $13^\circ$  (Bödeker). V.D. at  $890^\circ$  to  $907^\circ$  = 66 (F. a. M., 4.c.). H.F. [ $Zn, Cl$ ] = 97,210 (*Th. 3, 275*).

**Formation.**—1. By heating zinc filings in  $Cl_2$ .—2. By heating a mixture of 2 pts.  $HgCl_2$  and 1 pt. zinc filings in a retort.—3. By distilling a mixture of equal pts.  $ZnSO_4$  and  $CaOH_2$ , or a mixture of 1 pt.  $ZnO$  and 2 pts.  $NH_4Cl$ .—4. By dissolving zinc, or  $ZnO, H_2$ , in  $HClAq$ , evaporating to dryness, and heating the residue in a retort.

**Preparation.**—1. Zinc filings are heated in a small retort in a stream of  $Cl_2$ ; the product is distilled.—2. Zinc, or  $ZnO, H_2$ , is dissolved in a slight excess of  $HClAq$ ; the solution is evaporated to dryness, and the residue is distilled from a small retort.

**Properties and Reactions.**—A white, semi-transparent, crystalline, very caustic solid; very deliquescent. Easily soluble in water, also in alcohol. Thomsen gives [ $ZnCl_2, Aq$ ] = 15,630 (*Th. 3, 275*). Sublimes at a red heat. An aqueous solution is partly decomposed on evaporation, giving oxychlorides (q.v.). Oxychlorides are also formed by heating a solution of  $ZnCl_2$  in  $HClAq$  with  $ZnO$ , also with  $HgO$  or  $PbO$ . Kremers (*P. 105, 360*) gives the following data:

S.G. $ZnCl_2, Aq$	P.c. $ZnCl_2$
1.1275	13.8
1.2466	25.8
1.3869	37.5
1.5551	49.2

A conc. solution of  $ZnCl_2$  is often used as a bath for maintaining fairly high constant temperatures. Dry  $ZnCl_2$  is used as a caustic; also as a dehydrating agent; a dilute aqueous solution is employed as an antiseptic.

**Combinations.**—1. With water. By keeping  $ZnCl_2, Aq$  containing 70.5 p.c.  $ZnCl_2$  at  $0^\circ$  for 24 hours, Engel (*C. R. 102, 111*) obtained large crystals of the trihydrate,  $ZnCl_2 \cdot 3H_2O$ , melting at  $7^\circ$ . When  $ZnCl_2, Aq$  containing 79.9 p.c.  $ZnCl_2$  at  $0^\circ$  is kept for a long time it solidifies; on heating to  $16^\circ$  a part melts and a part remains solid; the liquid part is the dihydrate  $ZnCl_2 \cdot 2H_2O$ , and the solid part is the hydrate  $2ZnCl_2 \cdot 3H_2O$  (E., l.c.). By heating a syrupy solution of  $ZnCl_2$  with a little  $HClAq$ , Schindler (*Mag. Pharm. 36, 45*) obtained octahedral crystals of the monohydrate  $ZnCl_2 \cdot H_2O$ . According to Engel (l.c.), the hydrate obtained by S. was  $2ZnCl_2 \cdot 3H_2O$ .—2. With hydrogen chloride and water. Engel (*M. 5, 432*) obtained the compounds  $2ZnCl_2 \cdot HCl \cdot 2H_2O$  and  $ZnCl_2 \cdot HCl \cdot 2H_2O$  by passing  $HCl$  gas into  $ZnCl_2, Aq$ , and adding zinc from time to time, and, when the solution had the S.G. of 2.0, cooling to  $0^\circ$ .—3. Various compounds of  $ZnCl_2$  with ammonia have been described; the formulas  $ZnCl_2 \cdot NH_3$ ,  $ZnCl_2 \cdot 2NH_3$ ,  $2(ZnCl_2 \cdot 2NH_3) \cdot H_2O$ ,  $ZnCl_2 \cdot 4NH_3 \cdot H_2O$ , and  $ZnCl_2 \cdot 6NH_3 \cdot H_2O$  have been given to compounds obtained by dissolving  $ZnCl_2$  in  $NH_3, Aq$ , passing in  $NH_3$ , and evaporating under different conditions (v. Marignac, *Ann. M. 56* 12, 1; Divers, *C. N. 18, 13*; Puzoznik, *P. 142, 467*; Davis, *C. N. 25, 265*; André, *A. Ch. [6] 3, 84, 98*; Thoms, *B. 20,*

748).—4. Lang (*B.* 21, 1578) described a compound with pyridine,  $\text{ZnCl}_2 \cdot 2\text{C}_5\text{H}_5\text{N}$ .—5.  $\text{ZnCl}_2$  combines with *alkali chlorides*. Compounds,  $\text{ZnCl}_2 \cdot \text{NH}_4\text{Cl} \cdot \text{H}_2\text{O}$ ,  $\text{ZnCl}_2 \cdot 2\text{NH}_4\text{Cl} \cdot \text{H}_2\text{O}$ , and  $\text{ZnCl}_2 \cdot 8\text{NH}_4\text{Cl}$  are described by Schindler (*Mag. Pharm.* 36, 46), Marignac (*J.* 1857, 217), Rammeisberg (*P.* 94, 508), and Hantz (*A.* 68, 287). A compound  $\text{ZnCl}_2 \cdot 2\text{KCl}$  is described by R. (*l.c.*) and M. (*l.c.*); and a compound  $\text{ZnCl}_2 \cdot 2\text{NaCl} \cdot 3\text{H}_2\text{O}$  by M. (*l.c.*). Wells & Campbell (*Zeit. f. anorg. Chem.* 6, 273) describe two compounds with  $\text{CsCl}$ , to which they give the formulae  $\text{ZnCl}_2 \cdot 2\text{CsCl}$  and  $\text{ZnCl}_2 \cdot 3\text{CsCl}$ .—6. With *zinc oxide*, v. *Oxychlorides*, p. 891.

A solution of zinc in conc.  $\text{HCl}$  aq. to which as much  $\text{NH}_4\text{Cl}$  has been added as the weight of zinc dissolved, is used for cleaning the surfaces of metals that are to be soldered together; any oxide on the metallic surfaces reacts with the  $\text{NH}_4\text{Cl}$  present to form chloride which dissolves in the  $\text{ZnCl}_2$  solution.

Zinc, cyanide of, and double zinc cyanides; v. vol. ii. p. 347. For details regarding the conditions of formation and the properties of *zinc-mercuric cyanide*, v. Dunstan, *C. J.* 61, 666 [1892].

Zinc, ferrocyanide of; v. vol. ii. p. 337.

Zinc, fluoride of,  $\text{ZnF}_2$ . Formula probably molecular, from analogy of  $\text{ZnCl}_2$ . Formed by heating zinc or  $\text{ZnO}$  to redness in a stream of dry  $\text{HF}$ ; also by the interaction of fused  $\text{ZnCl}_2$  and dry  $\text{HF}$  at  $800^\circ$  to  $900^\circ$ ; also by heating the hydrated salt to redness in dry  $\text{HF}$  (Poulenc, *C. R.* 116, 581 [1893]). The *tetrahydrate*  $\text{ZnF}_2 \cdot 4\text{H}_2\text{O}$  is obtained by evaporating a solution of zinc in  $\text{HFAq}$ , and crystallising. The salt  $\text{ZnF}_2$  crystallises in colourless needles, probably monoclinic. S.G. 4.84 at  $15^\circ$ ; the crystals act strongly on polarised light (P., *l.c.*). Clarke (*Ann. S.* [3] 13, 201) gives S.G. of  $\text{ZnF}_2$  as 4.556 at  $17^\circ$ , and 4.612 at  $12^\circ$ ; and the S.G. of  $\text{ZnF}_2 \cdot 4\text{H}_2\text{O}$  as 2.567 at  $10^\circ$  and 2.535 at  $12^\circ$ .  $\text{ZnF}_2$  is slightly soluble in cold, more soluble in hot water; it is insoluble in alcohol at  $95^\circ$ ; soluble in boiling  $\text{HClAq}$ ,  $\text{H}_2\text{SO}_4\text{aq}$ , or  $\text{HNO}_3\text{aq}$  (P., *l.c.*). Heated in air, or to redness in steam, it is wholly changed to  $\text{ZnO}$ ; fusion with alkali carbonates produces  $\text{ZnO}$  and alkali fluorides; heating with  $\text{H}_2\text{S}$  forms  $\text{ZnS}$ , and with  $\text{HCl}$  forms  $\text{ZnCl}_2$ . It is reduced by  $\text{H}$  at a red heat (P., *l.c.*).  $\text{ZnF}_2$  forms *double salts* with  $\text{AlF}_3$  and with alkali fluorides. Berzelius (*P.* 1, 26) described the salts  $\text{ZnF}_2 \cdot 2\text{AlF}_3$  and  $\text{ZnF}_2 \cdot 2\text{KF}$ ; and Wagner (*B.* 19, 896) the salts  $\text{ZnF}_2 \cdot 2\text{NH}_4\text{F}$ ,  $\text{ZnF}_2 \cdot 2\text{LiF}$ ,  $\text{KF}$ , and  $\text{ZnF}_2 \cdot \text{NaF}$ . The compound  $\text{ZnF}_2 \cdot \text{ZrF}_4 \cdot 6\text{aq}$  ( $= \text{ZnZrF}_6 \cdot 6\text{aq}$ ) is described by Marignac (*A. Ch.* [3] 60, 257); S.G. 2.255 at  $12^\circ$  (Topsøe, *C. C.* 4, 76). For  $\text{ZnF}_2 \cdot \text{SiF}_4$ , v. *Zinc silicofluoride*, p. 890.

Zinc, hypophosphide of,  $\text{ZnPH}_2$ . A white, friable solid having this composition was obtained by Dr. Fehsel & Finkelstein (*B.* 4, 352) by passing dry  $\text{PH}_3$  into a cooled ethereal solution of  $\text{ZnEt}_2$ . The compound can be kept in a closed vessel; in air it absorbs moisture and rapidly decomposes, giving off  $\text{PH}_3$ .

Zinc, hydrosulphide of. According to Thomsen (*B.* 11, 2044 [1878]), the pp. obtained by mixing  $\text{NaHSaAq}$  and  $\text{ZnSO}_4\text{aq}$  in equivalent quantities, is probably a hydrosulphide of zinc (no analysis or formula given). Addition of

two equivalents of  $\text{NaSH}$  in solution to an equivalent of  $\text{ZnSO}_4$  in solution produces no pp., but the solution gives a pp. of  $\text{ZnS}$  or hydrosulphide on standing, or on addition of acid or soda (T., *l.c.*). According to von Zotta (*M.* 10, 807 [1890]), the pp. supposed by Thomsen to be zinc hydrosulphide has the composition  $\text{ZnS} \cdot \text{H}_2 \cdot 2\text{ZnS}$ . When four equivalents of  $\text{NaSH}$  are added to one equivalent of  $\text{ZnSO}_4$ , both in solution, and the clear solution is boiled, or treated with acid or alkali, a pp. of  $\text{ZnS} \cdot \text{H}_2 \cdot 2\text{ZnS}$  is obtained (von Z., *l.c.*). Linder & Picton (*C. J.* 61, 130 [1892]) obtained evidence in favour of the existence of compounds of  $\text{Zn}$ ,  $\text{S}$ , and  $\text{H}$ , probably  $7\text{ZnS} \cdot \text{H}_2 \cdot \text{S}$  and  $12\text{ZnS} \cdot \text{H}_2 \cdot \text{S}$ , by passing  $\text{H}_2\text{S}$  into water at  $0^\circ$  with  $\text{ZnO} \cdot \text{H}_2$  in suspension; they failed to isolate a definite compound with certainty.

Zinc, hydroxide of,  $\text{ZnO} \cdot \text{H}_2$ . (*Zinc hydrate*, *hydrated zinc oxide*.) Obtained, as a white flocculent pp., by adding to solution of a salt of zinc rather less  $\text{KOHaq}$  than is sufficient to decompose the whole of the salt, washing thoroughly, and drying at a low temperature. According to Ville (*C. R.* 101, 375),  $\text{ZnO} \cdot \text{H}_2$  is obtained in crystals by shaking very finely-powdered  $\text{ZnCO}_3$ , or basic carbonate, with twice as much  $\text{KOH}$  in 10 p.c. solution as is theoretically required for the decomposition of the carbonate; formation of crystals of  $\text{ZnO} \cdot \text{H}_2$  begins at once, and is complete after twenty to thirty minutes.  $\text{ZnO} \cdot \text{H}_2$  is said to be obtained in lustrous rhombic prisms by immersing zinc in contact with iron or copper in  $\text{NH}_4\text{aAq}$  (Nickles, *A. Ch.* [3] 22, 31; Carnu, *Bl.* 5, 64 [1863]). Bödeker (*A.* 94, 358) obtained the *monohydrated hydroxide*  $\text{ZnO} \cdot \text{H}_2 \cdot \text{H}_2\text{O}$  in very lustrous octahedra by keeping a saturated solution of the hydroxide in  $\text{NaOHaq}$  in a closed vessel for some weeks. S.G. of  $\text{ZnO} \cdot \text{H}_2$  is given by Nickles (*l.c.*) as 2.677, and by Filhol (*A. Ch.* [5] 21, 415) as 3.053. Thomsen gives  $[\text{ZnO} \cdot \text{H}_2\text{O}] = 82,680$  (*Th.* 3, 275).  $\text{ZnO} \cdot \text{H}_2$  dissolves easily in acids, forming salts  $\text{ZnX}^+$ .

$\text{ZnO} \cdot \text{H}_2$  also dissolves in caustic alkali solutions, and in  $(\text{NH}_4)\text{CO}_3\text{aq}$ . By adding alcohol to a solution of  $\text{ZnO} \cdot \text{H}_2$  in  $\text{KOHaq}$ , Laux (*A.* 9, 183) obtained small lustrous crystals ( $? \text{ZnO} \cdot \text{K}$ ); Fremy (*C. R.* 15, 1106) obtained (?)  $\text{ZnO} \cdot \text{K}$ ,  $\text{ZnO}$ ; by using  $\text{NaOHaq}$  Combe & Jackson (*B.* 21, 1589 [1888]) obtained two compounds derived from  $\text{ZnO} \cdot \text{H}_2$  by replacing  $\text{H}$  by  $\text{Na}$ . They shook a solution of  $\text{ZnO} \cdot \text{H}_2$  in conc.  $\text{NaOHaq}$  with alcohol; separated the upper (alcoholic) layer and allowed it to crystallise, and treated the lower (watery) layer repeatedly with alcohol until it solidified. The crystals from the lower layer had the composition

$\text{Zn}_2\text{O}_2\text{Na}_2\text{H}_2 \cdot 17\text{H}_2\text{O}$  ( $= \text{Zn}_2(\text{OH})_2(\text{ONa})_2 \cdot 17\text{H}_2\text{O}$ ), agreeing, except in water of crystallisation, with an ammonium compound described by Malaguti (*C. R.* 62, 413 [1866]); this compound melts at  $c. 70^\circ$ , rapidly absorbs  $\text{CO}_2$  from the air, loses  $12\text{H}_2\text{O}$  at  $100^\circ$ , is insol. in ether, and is decomposed by water, but not in presence of excess of  $\text{NaOH}$ , with formation of  $\text{ZnO}$  and a little  $\text{ZnO} \cdot \text{H}_2$ . The crystals from the upper layer had the composition

$22\text{ZnO} \cdot \text{NaH}_2\text{O} \cdot 7\text{H}_2\text{O}$  ( $= 22\text{Zn}(\text{OH})_2(\text{ONa}) \cdot 7\text{H}_2\text{O}$ ), corresponding with the compound described by Fremy (*l.c.*); this compound forms white shining needles, which do not melt at  $300^\circ$ ; it

absorbs  $\text{CO}_2$  from the air more slowly than the other compound, is decomposed by alcohol or water, and does not lose  $\text{H}_2\text{O}$  until heated above  $200^\circ$  (v. *Am.* 11, 145 [1899]). C. A. J. failed to obtain compounds derived from  $\text{ZnO}_2\text{H}_2$  by replacing H by  $\text{NH}_4$  or Mg. Compounds of ZnO with  $\text{BaO}$ ,  $\text{CaO}$ , and  $\text{MgO}$  are described by Bertrand (*C. R.* 115, 999); these compounds are of the forms  $2\text{ZnO} \cdot \text{MO} \cdot x\text{H}_2\text{O}$ .

**Zinc iodide of  $\text{ZnI}_2$ .** Formula probably molecular, from analogy of  $\text{ZnCl}_2$ . Formed by heating together zinc and iodine, and subliming; also by digesting I with water and excess of zinc until the liquid is colourless and evaporating over  $\text{H}_2\text{SO}_4$  (Rammelsberg, *P.* 43, 665). Crystallises in white octahedra; S.G. 4.696 (Bödeker); melts at  $c. 446^\circ$  (Carnelley, *C. A.* 33, 278); and boils at  $c. 624^\circ$  (C. A. Williams, v. Carnelley's *Melting- and Boiling-point Tables*, 1, 23). H.F. ( $\text{ZnI}_2$ ) = 49,230; [ $\text{ZnI}_2$ , Aq] = 60,540 (*Th.* 3, 275). Heated in air  $\text{ZnI}_2$  gives off I, and ZnO remains. Kremers (*P.* 111, 61) gives the following data:—

S.G. $\text{ZnI}_2$ , Aq	P.c. $\text{ZnI}_2$	S.G. $\text{ZnI}_2$ , Aq	P.c. $\text{ZnI}_2$
1.2310	23.1	1.9746	63.5
1.5121	42.6	2.3976	76.0
1.7871	56.3		

Hot  $\text{ZnI}_2$  Aq is said to dissolve zinc in contact with the air, and on filtering an oxyiodide is said to be deposited (Müller, *J. pr.* 26, 141).  $\text{ZnI}_2$  Aq also dissolves I; Baup (*J. Ph.* 9, 37 [1823]) says enough I is dissolved to form  $\text{ZnI}_3$ .

$\text{ZnI}_2$  combines with  $\text{NH}_3$ . By allowing a solution of  $\text{ZnI}_2$  in  $\text{NH}_4$  Aq to evaporate, Rammelsberg (*P.* 48, 152) obtained lustrous, four-sided prisms of  $\text{ZnI}_2 \cdot 4\text{NH}_3$ , decomposed by water with production of ZnO. Various double compounds with other iodides have been described:  $\text{ZnI}_2 \cdot 2\text{MI}$ , where M =  $\text{NH}_4$ , K or Na (Rammelsberg, *l.c.*; also *P.* 43, 665);  $\text{ZnI}_2 \cdot 2\text{CsI}$  and  $\text{ZnI}_2 \cdot 3\text{CsI}$  (Wells a. Campbell, *Zeit. f. anorg. Chemie*, 5, 273);  $2\text{ZnI}_2 \cdot \text{BaI}_2$  (R., *l.c.*);  $\text{ZnI}_2 \cdot 2\text{BiI}_3$ , 12aq (Linan, *P.* 111, 240).

**Zinc nitride of  $\text{Zn}_3\text{N}_2$ .** Obtained by Frankland (*Pr.* 8, 502) by heating zinc amide ( $\text{Zn}(\text{NH}_2)_2$ ; v. p. 887) to low redness. A grey, pulverulent solid; unchanged by heating to redness out of contact with air; reacts violently with water to give  $\text{ZnO}$ ,  $\text{H}_2$ , and  $\text{NH}_3$ .

**Zinc nitroprusside of  $\text{v. vol. ii. p. 341}$ .**

**Zinc oxides of.** Besides the normal basic oxide ZnO, there seems to be another higher (? superoxide) of zinc.

**Zinc oxide ZnO.** Formula not certainly molecular.

**Occurrence.**—With oxides of Mn, and Fe, as red zinc ore and franklinite.

**Formation.**—1. By burning zinc in air or  $\text{O}_2$ . By strongly heating  $\text{ZnO}_2\text{H}_2$ ,  $\text{Zn}(\text{NO}_3)_2$ ,  $\text{ZnCO}_3$ , or another salt of zinc with a volatilisable acid.

**Preparation.**—Pure  $\text{ZnSO}_4$ , prepared as described under ZnO, Preparation (p. 883), is dissolved in water, and the solution is very slowly added to a boiling solution of pure  $\text{Fe}_2(\text{CO}_3)_3$  containing rather less  $\text{Na}_2\text{CO}_3$  than suffices to decompose all the  $\text{ZnSO}_4$ . The pp. of basic zinc carbonates washed by decantation with boiling water until the washings are free from carbonates

and sulphates; it is then dried, powdered, and heated either in a Hessian crucible, or better, in a flask of hard glass, until a portion taken from the middle dissolves, when cold, in acid without effervescence. The solid is now finely powdered, sifted through a fine sieve, again heated, and then rubbed up with water, and washed and dried. ZnO is prepared in crystals by heating  $\text{ZnCl}_2$  to redness in steam (Daubrée, *C. R.* 39, 153); also by heating the amorphous oxide slowly in a stream of H (Regnault, *A. Ch.* [2] 62, 350; Deville, *A. Ch.* [3] 43, 277); also by heating the amorphous oxide to whiteness in a stream of  $\text{O}_2$  (Sidot, *C. R.* 69, 202); also by heating  $\text{Zn}(\text{NO}_3)_2$  to redness (Brügelmann, *W.* 4, 283).

**Properties.**—A slightly yellow, powdery solid; becomes darker yellow when heated, but recovers its original colour on cooling. S.G. 5.5 to 5.7 (v. Brügelmann, *B.* 13, 1741; Filhol, *A. Ch.* [8] 21, 415; Hierapath, *C. J.* 1, 45; Karsten, *S.* 65, 394). S.G. crystalline (at  $15^\circ$ ) 5.782 (Brügelmann, *W.* 4, 286). ZnO crystallises in slightly yellow, lustrous, hemimorphous pyramids belonging to the hexagonal system (B., *l.c.*). Thomsen (*Th.* 3, 275) gives H.F. ( $\text{ZnO}$ ) = 85,480. Richards a. Rogers (*Am.* 15, 567 [1893]) found that ZnO, prepared by heating  $\text{Zn}(\text{NO}_3)_2$ , gave off some gas when dissolved in dilute acids; the maximum amount of gas from 10 g.  $\text{ZnO}$  was 20 c.c.; the gas consisted chiefly of N, with a little O; the higher the temperature to which the  $\text{Zn}(\text{NO}_3)_2$  had been heated the less was the quantity of gas obtained; but some N always came off, even from ZnO which had been heated to the softening temperature of porcelain. Moissay (*C. R.* 115, 1031 [1893]) states that ZnO volatilises readily when heated in an electric furnace, and condenses again in transparent crystals. ZnO is not decomposed at  $c. 1750^\circ$  (Read, *C. J.* 65, 313 [1894]).

**Reactions and Combinations.**—1. ZnO is a basic oxide. It interacts with most acids to form salts  $\text{ZnX}$  ( $\text{X} = 2\text{NO}_3$ ,  $\text{SO}_4$ ,  $\text{PO}_4$ , &c.) and water. 2. With fairly conc. caustic soda or potash, salts are formed which are most simply regarded as derived from  $\text{ZnO}_2\text{H}_2$ , with H replaced by Na or K (v. Zinc hydrosulphate, p. 889). 3. ZnO is reduced to Zn, with explosive violence, by heating with magnesium (v. Winkler, *B.* 23, 123). 4. Morse a. White (*Am.* 11, 258) heated a mixture of ZnO and zinc in an exhausted tube, and found that a deposit of ZnO formed in the front part of the tube. They suppose that some of the original ZnO is decomposed by the combined action of heat and zinc, and that zinc and O exist together in the hot part of the tube, but combine in the cooler parts of the tube to form  $\text{ZnO}_2$ . 5. Oxychlorides, oxybromides, and probably oxyiodides of zinc are formed by heating ZnO with zinc chloride, bromide, and iodide respectively. 6. ZnO is reduced to zinc by heating with carbon or in carbon monoxide. 7. ZnO does not directly interact with water;  $\text{ZnO}_2\text{H}_2$  is produced by ppg. a zinc salt solution by an alkali (v. Zinc hydrosulphate, p. 889). 8. By heating ZnO with oxides of aluminium, chromium, and iron along with  $\text{B}_2\text{O}_3$  in a pottery furnace until the  $\text{B}_2\text{O}_3$  was volatilised, Ebelsen (*A. Ch.* [8] 32, 34) obtained the compounds  $\text{ZnO} \cdot \text{Al}_2\text{O}_3$ ,  $\text{ZnO} \cdot \text{Cr}_2\text{O}_3$ , and  $\text{ZnO} \cdot \text{Fe}_2\text{O}_3$ .

**ZINC PEROXIDE.** In 1818 Thénard (*A. Ch.* [2] 9, 56) obtained what he called 'deutoxide de zinc' by the action of  $\text{H}_2\text{O}_2\text{Aq}$  on gelatinous  $\text{ZnO}\cdot\text{H}_2\text{O}$ , and also by adding  $\text{KOH}\cdot\text{Aq}$  to a solution of  $\text{ZnO}\cdot\text{H}_2\text{O}$  in  $\text{HClAq}$  to which  $\text{H}_2\text{O}_2$  had been added. In 1884 Haas (*B.* 27, 2249) obtained a white, tasteless, neutral, gelatinous pp. by adding  $\text{H}_2\text{O}_2\text{Aq}$  to solutions of zinc salts and then adding  $\text{NH}_4\text{Aq}$ ; after washing and drying at  $100^\circ$ , the solids had approximately the compositions  $\text{Zn}_2\text{O}_3$  and  $\text{Zn}_2\text{O}_4$ . H. thinks it probable that the substances obtained by him were compounds of  $\text{ZnO}$  and  $\text{ZnO}_2$ ; the formula  $2\text{ZnO}\cdot 3\text{ZnO}_2$  agrees well with some of his analyses.

**Zinc oxybromides of.** Oxybromides of zinc are formed by heating solutions of  $\text{ZnBr}_2$  with  $\text{ZnO}$ , and by partially ppg.  $\text{ZnBr}_2\text{Aq}$  by  $\text{NH}_4\text{Aq}$ . Several compounds have been described by André (*Bl.* [2] 39, 398 [1884]):

- (1)  $\text{ZnBr}_2\cdot 4\text{ZnO}\cdot x\text{H}_2\text{O}$ ,  $x = 10, 13$ , and  $19$ ;
- (2)  $\text{ZnBr}_2\cdot 5\text{ZnO}\cdot 6\text{H}_2\text{O}$ ; (3)  $\text{ZnBr}_2\cdot 6\text{ZnO}\cdot 36\text{H}_2\text{O}$ .

**Zinc oxychlorides of.** These compounds are formed by adding to  $\text{ZnCl}_2\text{Aq}$  a quantity of  $\text{NH}_4\text{Aq}$  less than sufficient for complete ppg.; also by boiling  $\text{ZnCl}_2\text{Aq}$  with  $\text{ZnO}$ , or with certain other metallic oxides. Schindler (*Mag. Pharm.* 36, 45) obtained  $\text{ZnCl}_2\cdot 3\text{ZnO}\cdot 4\text{H}_2\text{O}$  by boiling  $\text{ZnCl}_2\text{Aq}$  with  $\text{ZnO}$  and the same compound by partially ppg.  $\text{ZnCl}_2\text{Aq}$  by  $\text{NH}_4\text{Aq}$ . By adding to  $\text{ZnCl}_2\text{Aq}$  so much  $\text{NH}_4\text{Aq}$  that the pp. which formed at first partly dissolved, and also by treating  $\text{ZnCl}_2\cdot 4\text{NH}_3$  with water, Kane (*A. Ch.* 72, 296) obtained  $\text{ZnCl}_2\cdot 6\text{ZnO}\cdot 10\text{H}_2\text{O}$ . André (*C. R.* 106, 854) obtained  $2\text{ZnCl}_2\cdot 3\text{ZnO}\cdot 11\text{H}_2\text{O}$  by boiling  $\text{ZnCl}_2\text{Aq}$  with  $\text{HgO}$  and letting the solution cool; using  $\text{P}^\circ$  he obtained another oxychloride, probably  $\text{ZnCl}_2\cdot 3\text{ZnO}$ , combined with  $\text{ZnCl}_2\cdot \text{PbO}$ .

**Zinc oxyiodides of.** According to Müller (*J. pr.* 20, 441 [1842]),  $\text{ZnI}_2\text{Aq}$  dissolves zinc when warmed therewith in the air; on cooling, an oxyiodide,  $\text{ZnI}_2\cdot 3\text{ZnO}\cdot 2\text{aq}$ , is ppg.

**Zinc oxysulphides of.** The compound  $4\text{ZnS}\cdot \text{ZnO}$  occurs native as *voltzite*, as spherical globules in some specimens of *galena*. A compound having the same composition was found in a furnace due at Freiberg by Karsten (*S.* 57, 186). By heating dry  $\text{ZnSO}_4$  to redness in  $\text{H}$ , Arfvedson obtained a yellow-coloured oxysulphide  $\text{ZnS}\cdot \text{ZnO}$  (*P.* 1, 69).

**Zinc perbromoplatinocyanide of.** v. vol. ii. p. 845.

**Zinc phosphides of.** Zinc and P combine when heated together, forming a greyish, lustrous, somewhat malleable compound. By heating finely powdered zinc in vapour of P, Schrötter obtained a compound, with S.G. 4.76, having the composition  $\text{Zn}_3\text{P}_2$  (*W. A. B.* 1359, 301). Vigier obtained the same compound by heating zinc in  $\text{P}$ , until distillation began, and then passing  $\text{H}$  laden with vapour of P over the zinc. The same compound was formed by Regnault (*A. Ch.* [4] 9, 162) by heating to whiteness a mixture of  $\text{MgHPO}_4$ ,  $\text{ZnS}$  and  $\text{O}$ ; along with the  $\text{Zn}_3\text{P}_2$  were formed crystals of another phosphide, probably  $\text{ZnP}$ ; and by treating  $\text{ZnP}$  with dilute acid, an amorphous, yellow solid remained which detonated when mixed with  $\text{KClO}_4$  and struck, and which was perhaps  $\text{ZnP}$ . The compound  $\text{Zn}_3\text{P}_2$  was obtained by

Hvörslet (*A.* 100, 99) by strongly heating a mixture of  $\text{ZnO}$ ,  $\text{P}_2\text{O}_5$ , and  $\text{O}$ . By heating a mixture of  $\text{NaPO}_3$  and zinc shavings in a retort, H. (loc.) obtained a yellowish red, loose sublimate which contained  $\text{Zn}$  and  $\text{P}$ ; and by heating the fused mass in the retort with  $\text{HClAq}$ , grey lustrous tablets of  $\text{ZnP}_2$  remained. Lüpke (*C. O.* 1890 [ii.] 642) formed zinc phosphide ( $1\text{ZnP}_2$ ) by adding amorphous P to molten zinc covered with  $(\text{NH}_4)_2\text{CO}_3$ ; this phosphide was not decomposed by water, but was slowly decomposed by dilute  $\text{HClAq}$ , giving off  $\text{PH}_3$ .

For the compound  $\text{ZnP}_2$  v. **ZINC HYDROPHOSPHIDE**, p. 838.

**Zinc, platinocyanide of.** v. vol. ii. p. 844.

**Zinc, salts of.** Many salts are obtained by replacing the H of acids by zinc. The greater number of the salts of zinc are normal salts; several basic carbonates, nitrates, and sulphates are known. The following are the chief salts of zinc derived from oxyacids:—*Argentite* and *arsenate*, *borate*, *bromate*, *carbonates*, *chlorate* and *perchlorate*, *chromates*, *iodate* and *periodates*, *molybdates*, *nitrates* and *nitrites*, *phosphates* and *phosphites*, *selenate* and *selenite*, *silicate*, *sulphates* and *sulphite*, *thiosulphate*, *tungstates*, *vanadates* (v. **CARBONATES**, **NITRATES**, **SULPHATES**, &c.).

**Zinc, selenide of.**  $\text{ZnSe}$ . This compound, is formed, in reddish-yellow, regular crystals, S.G. 5.40, by heating zinc to redness in a stream of  $\text{H}_2\text{Se}$ , and then subliming in a slow stream of  $\text{H}$  (Margottet, *C. R.* 84, 1293).

**Zinc, selenocyanide of.** v. vol. ii. p. 848.

**Zinc, silicofluoride of.**  $\text{ZnSiF}_6\cdot 6\text{H}_2\text{O}$ . Obtained in hexagonal plates, easily sol. in water, by evaporating to a small bulk a solution of  $\text{ZnO}$  in  $\text{H}_2\text{SiF}_6\text{Aq}$  (Berzelius). S.G. 2.104 (Topsøe, *C. C.* 4, 76).

**Zinc, stannifluoride of.**  $\text{ZnSnF}_6\cdot 6\text{H}_2\text{O}$ ; v. this vol., p. 724.

**Zinc, sulphocyanide of.** v. vol. ii. p. 853.

**Zinc, sulphide of.**  $\text{ZnS}$ . This compound is not formed by heating together zinc and  $\text{S}$ , as the  $\text{S}$  volatilises before the temperature of combination is reached.

**Occurrence.**—As *zinc blende*.

**Preparation.**—1. By repeatedly subjecting a mixture of zinc and  $\text{S}$  in the ratio  $\text{Zn}:\text{S}$ , to a great pressure; the product resembled zinc blende (Spring, *Z.* 16, 1,000).—2. By rapidly heating a mixture of zinc filings and cinnamon in a retort; formation of  $\text{ZnS}$  occurs with detonation;  $\text{Hg}$  distils off.—3. By heating  $\text{ZnO}$  with  $\text{S}$ .—4. By heating  $\text{ZnO}$ , or  $\text{ZnO}\cdot\text{H}_2\text{O}$ , in a stream of  $\text{H}_2\text{S}$ ; in the case of  $\text{ZnO}\cdot\text{H}_2\text{O}$ , formation of  $\text{ZnS}$  takes place very slowly (v. Wagner, *D. P. J.* 197, 334).—5.  $\text{ZnS}$  is also formed by heating dry  $\text{ZnSO}_4$  with  $\text{S}$  and  $\text{O}$ .—6.  $\text{ZnS}$  is obtained by passing  $\text{H}_2\text{S}$  into a neutral or alkaline solution of a zinc salt, or into a solution in a weak acid, such as acetic acid, washing the pp., drying it at  $100^\circ$ , and heating in a stream of dry  $\text{H}_2\text{S}$ . The pp. dried at  $100^\circ$  is said to be  $2\text{ZnS}\cdot \text{H}_2\text{O}$  (Geiger, a. Reimann, *Mag. Pharm.* 31, 178; cf. Squibay, *Fr.* 7, 78).

**Properties and Reactions.**—S.G. of  $\text{ZnS} = 3.93$  (Karsten, *S.* 65, 894); S.G. of *blende* = 4.03 to 4.07 (v. Neumann, *P.* 23, 1). Thomsen (*Zh.* 3, 276) gives H.F. of  $\text{ZnS}\cdot \text{H}_2\text{O}$  as  $[\text{ZnS}\cdot \text{H}_2\text{O}] = 41,680^\circ$ .  $\text{ZnS}$  prepared by ppg. is a yellowish

solid; easily sol. in acid, forming salts of Zn and giving off  $H_2S$ . Zinc blende is a grey to black crystalline solid; slowly acted on by acids. By repeatedly washing ppd.  $ZnS$ , also by passing  $H_2S$  into water containing pure  $ZnO \cdot H_2O$  in suspension, Winssinger (*B.* [2] 49, 452 (1888)) obtained colloidal  $ZnS$ , sol. in water; the solution could be boiled until all excess of  $H_2S$  was expelled without ppn. of  $ZnS$ .  $ZnS$  prepared by adding excess of  $NH_4Ac$  to  $ZnCl_2$  aq. pp. all the zinc as  $ZnS$  by  $H_2S$ , washing and drying the pp. and then heating nearly to whiteness in a Hessian crucible inside a plumbago crucible, is very phosphorescent (*v.* Henry, *C. R.* 115, 503).

By heating  $ZnS$  with zinc in a vacuum tube, Morse a. White (*Am.* 21, 348) found that some of the  $ZnS$  was carried forward and deposited on the cooler part of the tube; they supposed that some of the  $ZnS$  was decomposed, and that Zn and S existed in the hottest part of the tube and combined in the cooler portions. By heating blende with I and a little water some  $ZnSO_4$  is formed (Filhol a. Melhies, *A. Ch.* [4] 22, 68; Lasaulx, *J.* 1870, 1272).

According to Schiff (*A.* 115, 74), a polysulphide of zinc, probably  $ZnS_2$ , is formed by pp. a neutral solution of a salt of zinc by  $K_2S_2A_8$  and drying the pp. over  $H_2SO_4$ . Spring (*B.* 16, 1000) thought that a polysulphide of zinc was probably formed by strongly compressing a mixture of zinc with excess of S.

Zinc, telluride of,  $ZnTe$ . Obtained, in large ruby-red, regular crystals, by strongly heating zinc in a stream of  $H_2Te$ , and then subliming in a slow current of  $H$  (Margottet, *C. R.* 84, 1293).

Zinc, titanifluoride of,  $ZnTiF_6$ ; *v.* this vol., p. 742. M. M. P. M.

#### ZINC, ORGANIC COMPOUNDS OF.

Zinc methyl or Zinc methide  $ZnCH_3$ , *i.e.*  $ZnMe$ . Mol. w. 95. V.D. 3.29 (calc. 3.30).  $[-40^\circ]$  (Haase, *B.* 26, 1053).  $(40^\circ)$ . S.G. 1.886.

**Formation.**—1. By heating methyl iodide with zinc in sealed tubes at  $150^\circ$ . The compound  $IZnMe$  is formed as an intermediate product. The reaction takes place more easily when the  $MeI$  is mixed with two-thirds of its volume of ether and heated to  $100^\circ$ , but it is then difficult to separate the ether from the  $ZnMe_2$  (Frankland, *A.* 85, 346; 111, 62; Wanklyn, *C. J.* 13, 124; Butlerow, *A.* 144, 2; Ladenburg, *A.* 173, 147).—2. By heating finely granulated zinc with  $HgMe$ , in a sealed tube for 24 hours, at  $120^\circ$ , and distilling the product (Frankland a. Duppa, *C. J.* 17, 30).—3.  $IZnMe$  is formed in 24 hours if  $MeI$  is left in contact with a large amount of copper-zinc couple (Gladstone, *C. J.* 35, 109).

**Preparation.**—Zinc filings (5 pts.) are heated with reduced copper (1 pt.) till the copper-zinc couple is produced, and the product treated with  $MeI$  (Gladstone, *C. J.* 35, 569).

**Properties.**—Colourless mobile liquid, taking fire on exposure to air. Decomposed by water into  $CH_4$  and  $Zn(OH)_2$ . By very careful oxidation it appears to yield  $Zn(OMe)_2$ , and crystalline  $ZnMe(OMe)$ , which is split up by water into  $Zn(OH)_2$ , methyl alcohol, and  $CH_4$ .

**Reactions.**—1. *Acetyl chloride* (1 mol.) forms  $CH_3COI(OZnMe)CH_3$ , which is slowly converted, by further treatment with  $ZnMe_2$ , into

$CH_3CMe(OZnMe)CH_3 + ClZnMe$ , crystallising in prisms, and converted by water into *tert*-butyl alcohol,  $CH_3$ , zinc chloride, and  $Zn(OH)_2$ . The compound  $CH_3COI(OZnMe)CH_3$  yields acetone on addition of water (Butlerow, *Z.* 1864, 365, 702; Pawlow, *N. Petersb. Acad. Bull.* 22, 497; Bogomeletz, *A.* 209, 88).—2. *Bromoacetyl bromide*, followed by water, yields methyl-isopropyl carbinol (Winogradoff, *A.* 191, 127).—3. In ethereal solution *secondary hexyl iodide* has no action at  $100^\circ$ ; but at  $125^\circ$  the products appear to be  $CH_3$ , ethyl iodide, and hexylene (Purdie, *C. J.* 39, 464).—4. *Chloral* followed by water forms  $COI_2CHMe.OH$ , while butyric chloral yields  $CH_3CH_2CH_2CHMe.OH$ .—5. *Nitric oxide* passed into  $ZnMe$ , forms  $CH_3N_2O_2(ZnMe)$ , which is decomposed by water, yielding crystalline  $(CH_3N_2O_2)_2Zn$  aq. from which the Na salt  $CH_3N_2O_2Na$  aq. of 'di-nitro-methyl' acid may be obtained (Frankland, *A.* 99, 346).

**Zinc ethyl or Zinc ethide  $ZnEt$ .** Mol. w. 123.  $[-28^\circ]$  (Haase, *B.* 26, 1053). (118°). S.G. 1.182. H.F. = 31,800 (Guntz, *C. R.* 105, 673). V.D. 4.26 (obs. and calc.).

**Formation.**—1. By heating zinc or zinc-sodium alloy with  $EtI$  or a mixture of  $EtI$  and ether (Frankland, *C. J.* 2, 297; 8, 44; *Tr.* 142, 431; 145, 259; *A.* 95, 28; Wanklyn, *C. J.* 13, 121; Pebal, *A.* 118, 22; 121, 105; Rieth a. Beilstein, *A.* 123, 215; 126, 248; Chapman, *Laboratory*, 1, 195; Alexejeff a. Beilstein, *C. R.* 63, 171; Rathke, *A.* 152, 230; Wichelhaus, *J.* 1868, 425).—2. By heating granulated zinc with  $HgEt$ , in sealed tubes for 36 hours at  $100^\circ$  (Frankland a. Duppa, *C. J.* 17, 3).—3. From zinc filings and  $EtBr$  (Wichelhaus, *A.* 152, 321).

**Preparation.**—Clean zinc filings (180 g.) are mixed with copper (20 g.) reduced from the oxide at a dull-red heat by coal gas; the mixture is rapidly heated over a very large Bunsen flame, and is well shaken meanwhile. As soon as the filings begin to cake together and the copper is no longer visible, the copper-zinc couple has been made. The flask is now connected with an inverted condenser, inclined slightly upwards, and when it is cold ethyl iodide (175 g.) is added. Dry  $CO_2$  is passed through the apparatus, and the flask heated by a water-bath; in half an hour the  $EtI$  ceases to run back from the condenser, for it has been converted into  $IZnEt$ . The apparatus is now tilted so that the condenser is inclined downwards, and heated in a bath of paraffin. The reaction  $2IZnEt = ZnI_2 + ZgEt$ , now takes place, and  $ZnEt_2$  (60 g.) is collected in a receiver kept full of  $CO_2$  (Gladstone a. Tribe, *C. J.* 26, 446; 35, 569).

**Properties.**—Colourless, mobile liquid, fuming in the air, and quickly taking fire, burning with a luminous green-edged flame, and giving off clouds of  $ZnCl_2$ . Immediately decomposed by water into  $Zn(OH)_2$  and ethane. In like manner it attacks organic compounds containing hydroxyl or amidogen, with elimination of ethane. It causes india-rubber to swell remarkably.

**Reactions.**—1. Gradually treated with dry oxygen, it appears to produce  $ZnEt(OEt)$  and  $Zn(OEt)_2$ , successively (Frankland). According to Demuth a. Meyer (*B.* 23, 894), the passage of oxygen through a solution of  $ZnEt$  in ligroin

(7 vols.) yields  $\text{EtZn.O.O.Et}$ , which is decomposed by heat, sometimes with explosive violence. The compound  $\text{EtZn.O.O.Et}$  sets free I from a solution of KI and yields alcohol when distilled with dilute  $\text{H}_2\text{SO}_4$ .—2. *Sulphur* forms zinc mercaptide  $\text{Zn(SET)}_2$ . It appears to act in like manner (Chabrie, *Bl.* [3] 2, 788).—3. *Iodine* forms  $\text{IZnEt}$  and  $\text{ZnI}_2$  successively, together with  $\text{EtI}$ . Bromine acts in like manner. Zinc ethyl takes fire in chlorine.—4. Dry *ammonia* forms  $\text{Zn(NH}_3)_2$ , and ethane (Frankland, *Pr.* 8, 502).—5. *Nitric oxide* is absorbed by an ethereal solution of  $\text{ZnEt}_2$ , forming crystalline  $\text{ZnEt}_2(\text{NO})_2$ , which melts below  $100^\circ$  and is split up by water into ethane and  $\text{C}_2\text{H}_5\cdot\text{N}_2\text{O}_2\cdot\text{ZnOH}$ . Carbon dioxide passed into an aqueous solution of this salt ppts. zinc carbonate, while zinc 'dinitroethylate' ( $\text{C}_2\text{H}_5\text{N}_2\text{O}_4$ ) $_2\text{Zn}$  remains in solution (Frankland, *Tr.* 1857, 59; A. 90, 342; C. J. 37, 570). The salt ( $\text{C}_2\text{H}_5\text{N}_2\text{O}_4$ ) $_2\text{Zn}$  crystallises in prisms, yields  $\text{NH}_3$  and  $\text{NH}_4\text{Et}$  on treatment with sodium-amalgam (Zuckschwerdt, A. 174, 302), and  $\text{HNO}_3$  and  $\text{NH}_4\text{Et}$  on treatment with alcoholic potash (Zorn, B. 15, 1008). The dinitroethylates  $\text{NaA}$ ,  $\text{BaA}$ ,  $\text{CaA}$ ,  $\text{ZnA}$ ,  $\text{MgA}$ ,  $\text{CuA}$ ,  $\text{AgA}$ , and  $\text{AgA}(\text{NO}_3)$  were prepared by Frankland.—6.  $\text{SO}_2$  forms zinc ethane sulphinate (Hobson, C. J. 10, 456).—7.  $\text{PCl}_5$  yields  $\text{PEt}_2$  (Hofmann a. Cahours, *Tr.* 1857, 578).—8.  $\text{SiCl}_4$  gives  $\text{SiEt}_4$ .—9. Heated with  $\text{EtI}$  at  $170^\circ$  it forms *n*-butane and  $\text{ZnI}_2$ . Ethane and ethylene are also formed (Brodie, C. J. 3, 405).  $\text{ZnEt}_2$  does not act on amyliodic.—10. Displaces halogens in organic compounds by ethyl.—11. Adds itself to a carbonyl group. Thus with *diethylketone* it forms  $\text{Et}_2\text{C(OZnEt)}_2$ , which is converted by water into tri-ethyl-carbinol. *Di-propyl ketone* forms, in like manner, ethyl-di-propyl-carbinol. Ketones containing the group  $\text{CO.CH}_3$  act differently, forming condensation-products; thus acetone yields mesityl oxide and phorone (A. Saytzeff, *J. pr.* [2] 31, 319). Zinc ethyl has no action on paraldehyde (Wedensky, *J. pr.* [2] 39, 568). With acetic aldehyde it forms  $\text{CH}_3\text{CH(OZnEt).OZnEt}$ , which is converted by water into *sec*-butyl alcohol.—12. In some cases it can add  $\text{ZnEt}_2$  and H to a carbonyl group,  $\text{C}_2\text{H}_5$  being evolved. Thus  $\text{ZnEt}_2$  converts *chloral*, dissolved in pure ether, into crystalline  $\text{CCl}_3\text{CH}_2\text{OZnEt}$ , which is converted by water into tri-chloro-ethyl alcohol (Delacoe, *Bl.* [2] 48, 784). Further action of zinc ethide on chloral yields  $(\text{CCl}_3\text{CH}_2\text{O})_2\text{Zn}$ , a white powder. In like manner butyric chloral is converted into  $\text{C}_4\text{H}_9\text{Cl}_3\text{CH}_2\text{O.H}$ . In this splitting off of Zn olefine,  $\text{ZnEt}_2$  differs from  $\text{ZnMe}_2$ , but resembles zinc propyl and zinc isobutyl (Garzaroli, A. 225, 162).—13. Can displace oxygen by two ethyl radicles; thus it converts *oxalic ether* into  $\text{CO}_2\text{Et.CEt.CO}_2\text{Et}$  (Frankland a. Duppa, A. 142, 1; *Pr.* 12, 396).—14. Can displace ethoxyl by ethyl. Thus it converts *formic ether* into  $\text{HCEt(OZnEt).OEt}$  and then into  $\text{HOEt(OZnEt).Et}$ , which is turned by water into di-ethyl-carbinol (Wagner a. Saytzeff, A. 175, 851).—15. Can displace chlorine by hydrogen. Thus with *chloro-benzoic acid* the first product is probably  $\text{C}_6\text{H}_4(\text{ZnEt).CO}_2\text{Et}$ , which is converted by water into benzoic ether,  $\text{C}_6\text{H}_5$ , and  $\text{ZnO}$ .—16. With *benzonitrile* at  $150^\circ$ , and subsequent treatment with alcohol, cyanophenol is formed (Frankland a. Evans, C. J. 37, 563). It

polymerises phenyl-acetonitrile in the same way, forming cyanobenzene.—17. *Cyanogen* forms  $\text{ZnCy}_2$ , and  $\text{EtCN}$  (Frankland a. Graham, C. J. 37, 740).—18. *Azobenzene* is reduced by  $\text{ZnEt}_2$ , followed by water, to aniline (Frankland a. Louis, C. J. 37, 563).—19. Acts on primary and secondary amines, giving off ethane, but has no action on tertiary amines (Frankland, *Pr.* 8, 502; *Gal. J. Ph.* [5] 7, 484).  $\text{ZnEt}_2$  has no action on *nicotine* or *quinoline*, but forms with many alkaloids containing O compounds from which the alkaloids are regenerated by water.—20. *Acetamide* gives  $(\text{AcNH})_2\text{Zn}$ , while oxamide gives  $\text{C}_2\text{O}_2(\text{NH})_2\text{Zn}$ .—21. Acts on  $\text{HgCl}_2$ , forming  $\text{ClHgEt}$  and  $\text{HgEt}_2$  (Buckton, A. 109, 218).  $\text{HgCl}_2$  yields  $\text{HgEt}_2$ , mercury, and  $\text{ZnCl}_2$ .—22.  $\text{AgCl}$  forms  $\text{ZnCl}_2$ , silver, and butane.—23.  $\text{CCl}_4$  forms  $\text{EtCl}$ , ethylene, and propylene (Rieth a. Beilstein, A. 124, 242).—24. *Chloroform* yields amylene (H. a. B.), while bromoform gives propylene and  $\text{EtBr}$  (Alexejeff a. Beilstein, C. R. 58, 172).  $\text{CHCl}_3$  produces ethylene, butane, and hydrogen (Borodine, A. 126, 239).

Zinc bromo-ethylide  $\text{ZnBrEt}$ . [62]. Formed by the action of the copper-zinc couple on  $\text{EtBr}$  at  $100^\circ$  (Gladstone a. Tribe, C. J. 27, 410). Pearly scales, decomposed by heat partly into  $\text{ZnBr}_2$  and  $\text{ZnEt}_2$ , and partly into  $\text{Zn}$ ,  $\text{ZnBr}_2$ ,  $\text{C}_2\text{H}_4$ , and  $\text{C}_2\text{H}_6$ .

Zinc iodo-ethylide  $\text{ZnIEt}$ . Formed in like manner. Crystalline. Split up by heat into  $\text{ZnI}_2$  and  $\text{ZnEt}_2$ .

Zinc propyl  $\text{ZnPr}$ . ( $148^\circ$ ) (S.); ( $146^\circ$ ) (Gladstone a. Tribe, B. 6, 1136); ( $150^\circ$ ) (Pape, B. 14, 1873). Formed by heating propyl iodide with zinc and a small quantity of an alloy of zinc and sodium (Stoherbakoff, *Bl.* [2] 37, 345). Heavy liquid, with disagreeable odour. Reacts with aldehydes, forming propylene and such compounds as  $\text{RCH}_2\text{OZnPr}$ , which yield secondary alcohols on addition of water.

Zinc isopropyl  $\text{ZnPr}$ . ( $136^\circ$ ) with decomposition; ( $96^\circ$  at 40 mm.). Got by heating  $\text{PrI}$  (170 g.) with ether (100 g.), zinc (100 g.), and zinc-sodium (3 g.) at  $100^\circ$  (Ragozin, J. R. 24, 549). Fuming liquid. Yields crystalline  $\text{Zn(OPr)}$ , on exposure to air. Split up at  $132^\circ$  into Zn and hydrocarbons (Gladstone a. Tribe, C. J. 39, 6).

Zinc isobutyl  $\text{Zn(C}_4\text{H}_9)$ . ( $166^\circ$ ) at 734 mm. (Garzaroli-Thurnlackh a. Popper, A. 228, 167). Formed from zinc and  $\text{Pr.CH}_3\text{I}$ . Got also from Zn and  $\text{Hg(C}_4\text{H}_9)_2$  (Cahours, *Bl.* [2] 21, 357).

Zinc isocamyl  $\text{Zn(C}_5\text{H}_{11})$ . ( $220^\circ$ ). S.G. 1.022. V.D. 6.95 (calc. 6.87). Prepared by heating zinc with  $\text{Hg(C}_5\text{H}_{11})_2$  (Frankland, A. 85, 360; 130, 122). Liquid, fuming in the air but not taking fire. Takes fire in oxygen. When added to cooled aldehyde it yields, after addition of ice-cold water, methyl-isocamyl-carbinol, isopropyl-ethylene, and ethyl and isocamyl alcohols (Sokoloff, C. C. 1587, 988).

ZINCATES. Compounds derived from  $\text{ZnO.H}_2$  by replacing H by positive metals; v. ZINC HYDROXIDES, p. 888.

\* ZERCONATES v. under ZINCONIUM HYDROXIDE, p. 896.

ZINCONIUM, *oxide of zinc* (v. p. 886).  $\text{ZnZnCONIUM}$ . *Zr.* At. w. 69.90 (v. p. 894). Mol. w. not known. Melts above m.p. of Si (i.e. above  $c. 1300^\circ$ ) (Troost, J. 1865, 158). S.G. 4.15 (Troost, *Lo.*); 4.25 (Moissan, C. R. 116,

1722). S.H. ( $0^{\circ}$ – $100^{\circ}$ ) 065 (Mixer a. Dana, *M.* 169, 388 [1873]).

**Historical.**—Klaproth in 1789 (*Beiträge*, 1, 208, 227) announced the discovery of a new earth, in combination with silica, as the rare mineral, *zircon*. The same earth has been found in a few other rare minerals, such as *eudialyte*, *polyignite*, *ferrysomite*, &c. Bright-coloured varieties of zircon are generally called *hyacinth*, the greyish or brown kinds are called *zirconite*, and a variety which is nearly colourless is known as *jargon*.

In 1845 Svanberg (*A.* 56, 223) stated that zirconia was a mixture of at least three oxides, but Berlin (*J. pr.* 58, 147), Marignac (*A. Ch.* [3] 60, 257), and Hermann (*J. pr.* 31, 75; 97, 331) failed to obtain any evidence of the composite character of zirconia. At a later time, Sorby (*B.* 2, 126, 193 [1869]), and also Forbes (*B.* 2, 337, 383), thought they had obtained spectroscopic indications of the presence of another earth in *zircon*; but it was shown that the abnormalities observed were due to traces of compounds of uranium (Sorby, *C. N.* 21, 73; Knop, *A.* 159, 44; cf. Hannay, *C. J.* 26, 703).

**Occurrence.**—Never uncombined. The principal naturally occurring compound of Zr is *zirconite*, which is more or less pure  $\text{ZrSiO}_4$ . This mineral is found in small quantities in the sand and alluvial deposits of certain rivers in Ceylon, and in the older rocks in many parts of the world; it has been found in the granites of Sweden, Switzerland, Tyrol, and North America (*v. J. M.* 1877, 97).

**Formation.**—1. By heating  $\text{K}_2\text{ZrF}_6$  with K (Berzelius, *P.* 4, 117 [1825]).—2. By passing vapour of  $\text{ZrF}_4$  over Na in a red-hot tube (Troost, *C. R.* 61, 109 [1865]).—3. By heating  $\text{ZrO}_2$  with Mg (Phipson, *J. pr.* 96, 353 [1865]).—4. By melting  $\text{ZrO}_2$  in a carbon crucible in an electric furnace; or by mixing  $\text{ZrO}_2$  with carbon, melting in an electric furnace, then mixing the Zr carbides thus formed (*v. Carbides*, p. 894) with excess of  $\text{ZrO}_2$  and again melting (Moissan, *C. R.* 116, 1222 [1893]).

**Preparation.**—1. Finely powdered *zirconite* ( $\text{ZrO}_2 \cdot \text{SiO}_2$ ) is thoroughly mixed with an excess of finely powdered carbon, the mixture is compressed into small cylinders which are placed in a closed carbon crucible and heated in an electric furnace (with a current of 30 to 35 amperes and 70 volts), while a stream of  $\text{CO}_2$  is sent through the crucible; the greater part of the  $\text{SiO}_2$  is thus volatilised (Troost, *C. R.* 116, 1428). The carbides of Zr in the crucible are now mixed with excess of  $\text{ZrO}_2$  and melted in the electric furnace (Moissan, *C. R.* 116, 1222).—2. Finely powdered and sifted *zirconite* is mixed with 2 to 3 times its weight of  $\text{KHF}_4$ , the mixture is heated to bright redness for c. 15 mins., and after cooling, is boiled with water containing a little dilute  $\text{HFAg}$ ;  $\text{K}_2\text{SiF}_6$  is removed by filtration, the filtrate deposits  $\text{K}_2\text{ZrF}_6$  on cooling. The  $\text{K}_2\text{ZrF}_6$  is re-crystallised from water, then dried, mixed with K, and heated in a vessel of glass or iron; the product is washed with water, digested for a long time with conc.  $\text{HClAg}$  at  $40^{\circ}$ , then washed with water containing  $\text{NH}_4\text{Cl}$ , and finally with alcohol (Berzelius, *Lc.*; Troost, *A.* 136, 353). This method yields *amorphous zirconium*. According to Bailey (*Pr.* 46, 74 [1889]), the only

method that gives nearly pure amorphous Zr is to heat  $\text{ZrO}_2$  with Mg foil (not powder) and treat with  $\text{HClAg}$ .—3. One part dry  $\text{K}_2\text{ZrF}_6$  is mixed with 1½ pts. Al, and the mixture is heated to the melting-point of iron in a crucible made of gas coke; the product is digested with conc.  $\text{HClAg}$  diluted with twice its volume of water, when the crystalline leaflets of Zr, that have formed on the surface of the Al, separate from the mass of Al before the latter is wholly dissolved. When the whole of the Al has dissolved an alloy of Zr and Al remains, besides the crystalline leaflets of Zr; if the temperature of reduction is not sufficiently high, the main product is the Zr-Al alloy (Troost, *Lc.*; cf. Franz, *B.* 8, 58). This method yields *crystalline zirconium*.

Various methods have been used for decomposing *zirconite* and obtaining compounds of Zr. Franz (*B.* 3, 58) fuses the powdered mineral with  $\text{KHSO}_4$ , treats the fused material with boiling water containing a little  $\text{H}_2\text{SO}_4$ , washes the insoluble  $3\text{ZrO}_2 \cdot \text{SO}_3$  thus formed, and adds it, in small portions at a time, to molten  $\text{NaOH}$ ; he then lixivates with cold water, dissolves the  $\text{ZrO}_2$  that remains in hot conc.  $\text{H}_2\text{SO}_4$ , dilutes, pptts. by  $\text{NH}_4\text{Aq}$ , washes, dries, and decomposes the  $\text{ZrO}_2 \cdot \text{rH}_2\text{O}$  by heat. The method of fusing with  $\text{KHF}_4$  used by Marignac (*v. supra*, No. 2) yields pure  $\text{K}_2\text{ZrF}_6$  very readily;  $\text{Zr(SO}_4)_2$  may be obtained by heating the  $\text{K}_2\text{ZrF}_6$  with conc.  $\text{H}_2\text{SO}_4$  (*v.* Hiortdahl, *A.* 137, 34; cf. *J. pr.* 88, 201). For other methods *v.* Hermann (*J. pr.* 97, 330); Scheerer (*P.* 59, 48); Stromeyer (*A.* 113, 727); Chancel (*J. pr.* 74, 471); Berlin (*J. pr.* 58, 145); Henneberg (*J. pr.* 38, 508); Bailey (*Pr.* 46, 74 [1889]).

**Properties.**—Zirconium has been isolated as black amorphous powder, and also as a greyish crystalline solid.

**Amorphous zirconium** (*v. Preparation*, No. 2) is a black powder, which is extremely porous and resembles powdered charcoal; when pressed with a burnisher it agglomerates to graphite-like laminae. After being heated strongly, and then cooled, *in vacuo*, it is said to glow and burn when exposed to air. The porous amorphous metal is said not to conduct electricity. Amorphous Zr is stated to be insoluble in ordinary acids, including *aqua regia*; but, according to Bailey (*Pr.* 46, 74 [1889]), it dissolves in cold conc.  $\text{H}_2\text{SO}_4$ ;  $\text{HFAg}$  dissolves it readily, H being given off. It is oxidised by heating in the air, when it burns to  $\text{ZrO}_2$  with a brilliant white light; oxidation is also effected by fusion with caustic or carbonated alkalis, or with  $\text{KNO}_3$  or  $\text{KClO}_4$ .

**Crystalline zirconium** (*v. Preparation*, No. 3) is a very lustrous, greyish, brittle, solid, which resembles Sb in appearance; very hard, easily scratching glass and ruby (Moissan, *C. R.* 116, 1222). S.H. 415 (Troost, *J.* 1865, 183); 425 (Moissan, *Lc.*). S.H. ( $0^{\circ}$  to  $100^{\circ}$ ) 066 (Mixer a. Dana, *A.* 169, 388 [1873]). Crystalline Zr burns in the  $\text{O-H}$  flame; it is not oxidised in O until heated to whiteness; it dissolves slowly in hot conc.  $\text{HClAg}$ , and is very slightly acted on by  $\text{HNO}_3\text{Aq}$  or  $\text{H}_2\text{SO}_4$ , even when warm; cold  $\text{HFAg}$  dissolves it readily. Molten  $\text{KClO}_4$ , or  $\text{KNO}_3$ , is said to be without action; molten  $\text{KOH}$  dissolves the metal as long as any moisture is present.

According to Troost (*J.* 1865, 188), Zr melts above the m.p. of Si (i.e. above c. 1800°). The emission-spectrum of Zr has been mapped by Thalén; the chief lines are 6127 in the red, and in the blue, 4816, 4771, 4788, 4709, and 4886.

The at. w. of Zr was determined, (1) by Berzelius (*P.* 4, 126; 8, 186, [1825]), by finding the ratio of  $ZrO_2$  to  $SO_2$  in the sulphate; (2) by Hermann (*J. pr.* 81, 77 [1844]) by analysing  $ZrCl_2$ ; (3) by Marignac (*A. Ch.* [3] 80, 270 [1860]), by analysing  $K_2ZrF_6$ ; (4) by Bailey (*Pr.* 46, 74 [1889]), by decomposing  $Zr(SO_4)_2$  by heat and weighing the  $ZrO_2$  produced; (5) by Mixer a. Dana (*A.* 169, 888 [1873]), by determining the S.H. of Zr; (6) by Deville a. Troost (*P.* 108, 636; 641 [1859]), by determining the V.D. of  $ZrCl_4$ . The results of Berzelius gave the at. w. of Zr as 89.2; those of Hermann, 88.5 to 90.7; those of Marignac, 90.3 to 90.6; and the results obtained by Bailey gave 90.4 as the at. w. of the metal.

Zirconium is the third member of the even-series family of Group IV. in the periodic classification of the elements. This group contains the following elements:—

Even Series	2	4	6	8	10	12
	C	Ti	Zr	-	-	Th
Odd Series	3	5	7	9	11	
	Ni	Ge	Sn	-	Pb	

As is to be expected from its position in the classificatory system, Zr is a metal with some non-metallic properties; the oxide  $ZrO_2$  forms corresponding salts, many of which are basic salts; the haloid compounds,  $ZrX_4$ , are probably all volatilisable without decomposition (the V.D. of  $ZrCl_4$  only has been determined), but aqueous solutions yield oxyhalides on evaporation; hydrated  $ZrO_2$  reacts as a weak acid towards strong bases, forming zirconates; salts are known derived from the acid  $H_2ZrF_6$ ; there is an oxide higher than  $ZrO_2$ , probably  $ZrO_3$ . For a more detailed comparison of Zr with the other even-series elements of Group IV. v. TITANIUM GROUP OF ELEMENTS (this vol. p. 749), and cf. TIN GROUP OF ELEMENTS (this vol. p. 735). The atom of Zr is tetravalent in the gaseous molecule  $ZrCl_4$ .

**Reactions and Combinations.**—1. Heated in air, or oxygen, Zr burns to  $ZrO_2$ , giving out dazzlingly white light; amorphous Zr burns easily, crystalline only at a white heat, and then merely superficially.—2. Both amorphous and crystalline Zr dissolve readily in *hydrofluoric acid*, giving off  $H_2$  and forming  $ZrF_4$ .—3. According to Bailey (*Pr.* 46, 74), amorphous Zr dissolves in cold conc. *sulphuric acid*. Both forms dissolve in *aqua regia*.—4. Conc. *hydrochloric acid* reacts with Zr, when warm, forming  $ZrCl_4$  solution. Crystalline Zr is said to interact with *gaseous hydrogen chloride*, at dull redness, forming  $ZrCl_4$ .—5. Amorphous Zr is oxidised by *molten potash* or *soda*, also by *molten nitre* or *potassium chlorate*; the crystalline form of Zr is said not to be acted on by molten  $KNO_3$  or  $KClO_3$ , and by molten caustic alkalis only as long as there are traces of moisture present.—6. Zr combines directly with the *halogens*, to form  $ZrX_4$ , and probably with *sulphur* (v. *Sulphide*, p. 897).

**Detection and Estimation.**—Addition of hot

ed.  $K_2SO_4$  to solutions of salts of Zr ppt. white basic sulphate of Zr, which is insoluble in water and nearly insoluble in much  $HClAq$ . Turmeric paper becomes reddish-brown when immersed in a solution of a salt of Zr in  $HClAq$ ; the reaction is completely masked by the presence of boric acid (v. Brush, *J. pr.* 62, 7). Bailey (*C. J.* 49, 481 [1886]) found that addition of  $H_2O_2Aq$  to a slightly acid solution containing salts of Zr, along with salts of Fe, Nb, and Ti, ppt. the whole of the Zr as  $ZrO_2$  (or  $Zr_2O_3$ ), but none of the other metals. Troost makes use of the comparatively small volatility of  $ZrO_2$  at a very high temperature, to separate this oxide from  $SiO_2$  (v. *C. R.* 116, 1428).

Zr is generally estimated as  $ZrO_2$ ; salts of volatilisable acids are decomposed by heat; or solutions may be ppt. by  $NH_4Aq$  and the pp. washed, dried, and strongly heated.

**Zirconium, alloys of.** An alloy of Zr with aluminium is obtained in the preparation of Zr by reducing  $K_2ZrF_6$  by Al (v. *Preparation of Zirconium*, No. 3). Mellis (*Z.* [2] 6, 296) obtained crystals having the composition  $ZrAl_3$  (or perhaps  $Zr_2Al_3Si$ ) by heating to whiteness a mixture of 1 pt. powdered *zirconite* with 5 pts. *cryolite* powder, 10 pts. mixed  $KCl$  and  $NaCl$ , and 1 pt. Al, treating with dilute  $HClAq$ , and separating the larger crystals of the alloy from the finer crystals of Si.

**Zirconium, bromide of,  $ZrBr_4$ .** Formula probably molecular, from analogy of  $ZrCl_4$ . Obtained by mixing finely powdered  $ZrO_2$  with sugar charcoal, making into balls with starch paste, drying, and heating to bright redness in a current of dry  $CO_2$ , and dry Br (Mellis, *Z.* [2] 6, 296).  $ZrBr_4$  is a white, microscopically crystalline, hygroscopic powder; it is easily volatilised; heated in H it is not reduced to a lower bromide. Contact with moist air or water produces the oxybromide  $ZrOBr_2$ ; evaporation of an aqueous solution gives the heptahydrate of this compound  $ZnOBr_2 \cdot 7H_2O$  in large needle-shaped, transparent crystals (M., l.c.).

**Zirconium, carbides of.** By heating an intimate mixture of  $ZrO_2$  and C in the electric arc, in an atmosphere of  $CO_2$ , Troost (*C. R.* 116, 1227 [1893]) obtained a very hard, steel-grey solid, approximating closely to the composition  $ZrC$ . By using less C, other carbides seem to be produced (cf. Moissan, *C. R.* 116, 1222), but analyses of other compounds are not given.  $ZrC$  dissolves easily in dilute  $HFAq$ , but is not acted on by other acids. Moissan (l.c.) says that carbides of Zr containing more than 5 p.c. O ( $ZrC$  contains c. 2½ p.c. O) take fire fairly easily when exposed to the air; Troost says that carbides with a small proportion of O are only superficially oxidised by heating to redness, but that those with much O burn brilliantly at this temperature.

**Zirconium, chloride of,  $ZrCl_4$ .** Mol. w. c. 231.5. V.D. 117 at 440° (Deville a. Troost, *P.* 108, 636).

**Formation.**—1. By heating Zr in  $Cl_2$ .—2. By heating an intimate mixture of  $ZrO_2$  and C in  $Cl_2$ .—3. By passing vapour of  $SiCl_4$  over heated  $ZrO_2$  (Troost a. Hautefeuille, *C. R.* 76, 1819).

**Preparation.**—A mixture of  $ZrO_2$  with c. its own weight of lampblack is made into a paste with oil, little balls, c. the size of hazel-nuts

are formed on this, and these are covered with powdered charcoal, and heated to full redness in a closed crucible until the oil is completely charred; the pellets are then heated to bright redness in a tube of hard glass, while a current of dry Cl is passed through the tube; the ZrCl<sub>4</sub> which forms on the cooler parts of the tube is sublimed, in a stream of dry Cl, into a tube drawn out into bulbs, which are sealed off when the operation is finished (v. Bailey, *Pr.* 46, 74).

**Properties, Reactions, and Combinations.**—A white solid; volatilises unchanged at c. 400°. Dissolves in water, with production of heat; the solution on evaporation gives *corychlorides* (q. v.). Does not interact with *silethide* at 180° (Hinsberg, *A.* 239, 253). Combines with ammonia to form ZrCl<sub>4</sub>.NH<sub>3</sub>; with sodium chloride to form ZrCl<sub>4</sub>.2NaCl (Paykull, *B.* 6, 1467).

**Zirconium, ferrocyanide of.** According to Hornberger (*A.* 181, 232), the pp. formed by adding K<sub>4</sub>FeCy<sub>6</sub>Aq to a solution of a salt of Zr, when washed and dried, has the composition Zr<sub>3</sub>(FeCy<sub>6</sub>)<sub>2</sub>(?) it is a blue powder with a greenish tinge, insoluble in water, decomposed by acids, giving off HCN.

**Zirconium, fluoride of, ZrF<sub>4</sub>.** Formula probably molecular, from analogy of ZrCl<sub>4</sub>.

**Formation.**—1. The hydrated compound ZrF<sub>3</sub>.3aq is formed by slowly evaporating a solution of ZrO<sub>2</sub>.H<sub>2</sub>O or ZrF<sub>3</sub> in HFAq.—2. By heating ZrO<sub>2</sub> with twice its weight of (NH<sub>4</sub>)HF<sub>2</sub> to dull redness, till all the ammonium salt is volatilised (Marignac, *A. Ch.* [3] 60, 263).

**Preparation.**—Deville (*A. Ch.* [3] 49, 84) obtained ZrF<sub>4</sub> by heating to whiteness a mixture of finely powdered *sirconite* and *fluorspar* in a stream of HCl (ZrSiO<sub>4</sub> + 2CaF<sub>2</sub> + 2HCl = ZrF<sub>4</sub> + CaCl<sub>2</sub> + CaSiO<sub>3</sub> + H<sub>2</sub>O).

**Properties and Reactions.**—Prepared as described, ZrF<sub>4</sub> is a colourless, transparent, crystalline (probably hexagonal) solid; volatilisable at white heat; insoluble in water and acids. ZrF<sub>4</sub>, prepared by heating ZrO<sub>2</sub> with (NH<sub>4</sub>)HF<sub>2</sub>, is said to be soluble in water and in dilute HFAq. The crystals of ZrF<sub>4</sub>.3aq are partially decomposed on drying. Heated to full redness in air, ZrF<sub>4</sub> gives ZrO<sub>2</sub> and HF.

**Combinations.**—1. With water (v. *Formation*, No. 1) to form ZrF<sub>4</sub>.3aq.—2. With various metallic fluorides to form compounds of the form ZrF<sub>4</sub>.xMF<sub>y</sub>.H<sub>2</sub>O. These salts are often called *sircono-fluorides*, or *fluo-sirconates*; they are better named *sirconio-fluorides*. The zirconio-fluorides have been examined chiefly by Marignac (*A. Ch.* [3] 60, 267); they are obtained either by gradual evaporation of solutions containing the constituent fluorides, or by adding hydroxides or carbonates of the various metals to solutions of ZrF<sub>4</sub> in HFAq, and evaporating.

**Ammonium zirconio-fluorides.** The salts are described: (1) 2NH<sub>4</sub>F.ZrF<sub>4</sub> = (NH<sub>4</sub>)<sub>2</sub>ZrF<sub>6</sub>, rhombic crystals, isomorphous with K<sub>2</sub>ZrF<sub>6</sub>; (2) 8NH<sub>4</sub>F.ZrF<sub>4</sub>, small octahedra showing simple refraction (Baker, *C. J.* 35, 762).

**Cadmium zirconio-fluorides.** Two salts seem to exist: (1) 2CdF<sub>2</sub>.ZrF<sub>4</sub>.6aq, monoclinic crystals, isomorphous with the Mn salts; (2) CdF<sub>2</sub>.2ZrF<sub>4</sub>.6aq, laminar, fan-shaped groups of crystals.

**Manganese zirconio-fluorides.** (1) MnF<sub>2</sub>.ZrF<sub>4</sub>.6aq; and (2) 2MnF<sub>2</sub>.ZrF<sub>4</sub>.6aq.

**Nickel zirconio-fluorides.**

(1) NiF<sub>2</sub>.ZrF<sub>4</sub>.6aq, hexagonal prisms; S.G. 2-227 (Topsøe, *C. C.* 4, 76); and (2) 2NiF<sub>2</sub>.ZrF<sub>4</sub>.12aq, monoclinic crystals. The first salt forms a double salt with K<sub>2</sub>ZrF<sub>6</sub>, viz. NiZrF<sub>6</sub>.K<sub>2</sub>ZrF<sub>6</sub>.8aq.

**Potassium zirconio-fluorides.**

(1) K<sub>2</sub>ZrF<sub>6</sub>; obtained by strongly heating *sirconite* with two or three times its weight of KHF<sub>4</sub>, boiling with very dilute HFAq, filtering from K<sub>2</sub>SiF<sub>6</sub>, and allowing the filtrate to cool. Crystallises in rhombic crystals, terminated by six-sided pyramids; solubility = 78 at 2°, 1.4 at 15°, 2.7 at 100° and 25 at 100°. S.G. 3.082 (Topsøe, *L.c.*); (2) KF.ZrF<sub>4</sub>.aq (= KZrF<sub>5</sub>.aq); obtained, in monoclinic crystals, by dissolving the preceding salt in water containing a large excess of ZrF<sub>4</sub>; (3) 3KF.ZrF<sub>4</sub> (= K<sub>3</sub>ZrF<sub>7</sub>); obtained by crystallising K<sub>2</sub>ZrF<sub>6</sub> from a solution containing excess of KF; small, brilliant, regular octahedra, with simple refraction (v. Baker, *C. J.* 35, 762). Soluble in water; the hot conc. solution deposits K<sub>2</sub>ZrF<sub>6</sub> on cooling.

**Sodium zirconio-fluorides.** The salt 5NaF.2ZrF<sub>4</sub> is said to be always formed in whatever proportion the constituent fluorides are mixed. Small, monoclinic crystals; solubility at 18° = 38, and at 100° = c. 1.6.

**Zinc zirconio-fluorides.** (1) ZnZrF<sub>6</sub>.6aq, isomorphous with ZnSiF<sub>6</sub>.6aq and ZnSnF<sub>6</sub>.6aq, crystallising in regular hexagonal prisms, easily soluble in water. S.G. 2.255 (Topsøe, *L.c.*). (2) 2ZnF<sub>2</sub>.ZrF<sub>4</sub>.12aq; deposited from a solution containing excess of ZnF<sub>2</sub> in monoclinic crystals, isomorphous with 2NiF<sub>2</sub>.ZrF<sub>4</sub>.12aq.

**Zirconium, hydride of.** By heating ZrO<sub>2</sub> and Mg powder, in the ratio ZrO<sub>2</sub>.2Mg, in an atmosphere of H, Winkler (*B.* 24, 888; cf. *B.* 23, 2666) obtained a black powder which burnt in O, and contained c. 73 p.c. H. On treating this with dilute HClAq, Mg and MgO dissolved, H being given off, and a black residue was left which W. regarded as ZrH<sub>3</sub>. Supposing the reduction of the ZrO<sub>2</sub> had proceeded in accordance with the equation ZrO<sub>2</sub> + 2Mg + 2H = 2MgO + 2ZrH<sub>3</sub>, the product would have contained 53.44 p.c. ZrH<sub>3</sub>, and, therefore, would have given 1.15 p.c. H; as only .78 p.c. H was found, W. concluded that c.  $\frac{1}{3}$  of the ZrO<sub>2</sub> had been reduced.

**Zirconium, hydroxide of, (?) ZrO<sub>2</sub>.H<sub>2</sub>O.** Addition of NH<sub>4</sub>Aq to a solution of a salt of Zr produces a white, bulky, gelatinous pp. of ZrO<sub>2</sub>.xH<sub>2</sub>O. According to Berzelius, the dry pp. has the composition ZrO<sub>2</sub>.H<sub>2</sub>O = ZrO<sub>2</sub>.H<sub>2</sub>O. Hermann (*J. pr.* 97, 318) gave the formula ZrO<sub>2</sub>.2H<sub>2</sub>O = ZrO<sub>2</sub>.H<sub>2</sub>O, to the pp. dried at 17.5°; Paykull (*B.* 12, 1718) said that after drying *in vacuo*, the composition was ZrO<sub>2</sub>.3H<sub>2</sub>O, and after drying at 100° ZrO<sub>2</sub>.H<sub>2</sub>O. A detailed examination of the dehydration of the pp. formed by adding NH<sub>4</sub>Aq to a cold solution of Zr(NO<sub>3</sub>)<sub>3</sub> was made by Carnelley a. Walker (*C. J.* 53, 68, 82 (1888)). The loss of water by the air-dried pp. was fairly regular to c. 90°, when the pp. had approximately the composition ZrO<sub>2</sub>.2H<sub>2</sub>O; the loss was then less rapid, but very regular, up to c. 885°, whereat the composition was approximately 2ZrO<sub>2</sub>.H<sub>2</sub>O; somewhere between 885° and 415° there was a sudden increase in the percentage loss of water.

for a rise of  $10^\circ$ , this increase being accompanied by a change of colour from grey to pure white; at  $415^\circ$  the composition was approximately  $24\text{ZrO}_2 \cdot \text{H}_2\text{O}$ ; water was then given off very regularly, until at c.  $560^\circ$  dehydration was completed. C. a. W. conclude that probably no definite hydrate of  $\text{ZrO}_2$ , unchanged throughout a fair range of temperature, is formed by heating  $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$  ppd. from a salt of Zr; they think that the change of colour which accompanies the comparatively large percentage loss of water at c.  $400^\circ$  is an accompaniment of a condensation of molecules chiefly of the composition  $n(2\text{ZrO}_2 \cdot \text{H}_2\text{O})$  to molecules chiefly of the composition  $n(24\text{ZrO}_2 \cdot \text{H}_2\text{O})$ . There is a distinct resemblance between the phenomena of the dehydration of  $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$  and those of the dehydration of  $\text{SiO}_2 \cdot x\text{H}_2\text{O}$ ,  $\text{SfO}_2 \cdot x\text{H}_2\text{O}$ , and  $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ .

Hydrated  $\text{ZrO}_2$  ppd. cold, and washed with cold water, dissolves easily in the ordinary acids, including oxalic acid (Bailey, C. 7, 49, 481), forming salts  $\text{ZrX}^+$ , and  $\text{ZrX}^{++}$ ; when ppd. hot, or washed with hot water, the pp. is only slowly dissolved by the ordinary acids. According to Paykull (B. 12, 1719), moist  $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$  absorbs  $\text{SO}_2$  from the air. Digestion with  $\text{Zr}(\text{SO}_4)_2$  Aq produces basic sulphates  $3\text{ZrO}_2 \cdot 4\text{SO}_3$ , 15aq and  $6\text{ZrO}_2 \cdot 7\text{SO}_3$ , 19aq (P., Lc.).

**Zirconates.**  $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$  behaves as a weak acid towards the stronger bases. A few salts have been prepared which are most simply regarded as derived from  $\text{Zr}(\text{OH})_2$  by replacing H by alkali and alkaline earth metals; these zirconates are obtained by heating  $\text{ZrO}_2$  with bases; they have been examined chiefly by Hiortdahl (A. 137, 34, 236 [1865]).

**Sodium zirconates.** (1)  $\text{Na}_2\text{ZrO}_3$  ( $= \text{Na}_2\text{O} \cdot \text{ZrO}_2$ ); obtained by heating  $\text{ZrO}_2$  with  $\text{Na}_2\text{CO}_3$  in the ratio  $\text{ZrO}_2 : \text{Na}_2\text{CO}_3$ ; the crystalline mass thus formed is gradually decomposed by water with separation of amorphous  $\text{ZrO}_2$ . (2)  $\text{Na}_4\text{ZrO}_4$  ( $= 2\text{Na}_2\text{O} \cdot \text{ZrO}_2$ ); obtained by heating  $\text{ZrO}_2$  with a considerable excess of  $\text{Na}_2\text{CO}_3$  to whiteness for a considerable time; decomposed by water, with formation of (3)  $\text{Na}_4\text{O} \cdot 8\text{ZrO}_2$ , 12aq, which forms hexagonal tablets.

**Zirconates of calcium and magnesium** were obtained by H (Lc.) by heating to redness mixtures of  $\text{ZrO}_2$  with  $\text{SiO}_2$  and  $\text{CaCl}_2$  or  $\text{MgCl}_2$ . Ouvrard (C. R. 112, 1444 [1891]) describes **lithium zirconate**,  $\text{Li}_2\text{ZrO}_3$ , obtained by fusing  $\text{ZrO}_2$  with  $\text{LiCl}$  and cooling slowly; when  $\text{Li}_2\text{CO}_3$  was used, and the fused mass was treated with boiling water containing a little acetic acid, pure  $\text{ZrO}_2$  remained.

**Zirconium, nitride of.** In fusing amorphous Zr with Al in a cracked lime crucible, Mallet (Am. S. [2] 28, 346 [1858]) obtained a dark grey, porous solid, which gave yellowish lustrous microscopic cubes when treated with  $\text{HClAq}$ ; the crystals were unchanged by *aqua regia* or alkali solutions; when fused with  $\text{KOH}$  they gave off  $\text{NH}_3$ . The yellow crystals were probably a nitride of Zr.

**Zirconium, oxides of.** Besides zirconia,  $\text{ZrO}_2$ , there exists a higher oxide, probably  $\text{ZrO}_3$ ; and, possibly, also a lower oxide (?)  $\text{ZrO}$ .

**Zirconium dioxide  $\text{ZrO}_2$  (Zirconia. Zirconia anhydride.)** Mol. w. not known.

**Preparation.**—There are many methods for

preparing  $\text{ZrO}_2$  from *zirconite*. 1. The mineral is heated to redness and thrown into water, and the least-coloured pieces are finely powdered and levigated; the powder is very strongly heated with four times its weight of  $\text{Na}_2\text{CO}_3$  in a Pt crucible, and the product is heated with excess of  $\text{HClAq}$ ; the whole is evaporated to dryness; the residue is digested with water, filtered from  $\text{SiO}_2$ , and  $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$  is ppd. by  $\text{NH}_4\text{Aq}$ . The pp. is washed and dissolved in  $\text{HClAq}$ , and the solution is nearly saturated with  $\text{Na}_2\text{CO}_3$ , and boiled with  $\text{Na}_2\text{S}_2\text{O}_3$  Aq as long as  $\text{SO}_2$  is given off, whereby  $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$  is ppd. (Berzelius, P. 4, 124; 8, 186; Hermann, J. pr. 31, 77; Chancel, A. 108, 237; Stromeyer, A. 113, 127).—2. Very finely powdered *zirconite* is boiled with conc.  $\text{HClAq}$ , and the residue is washed with water and dried; 100 g. of the dried powder are added to 400 g. molten  $\text{NaOH}$ , with which 20 g.  $\text{NaF}$  have been mixed, and the whole is heated in a nickel crucible until the action ceases, when the molten mass is poured on to a sheet of nickel, and, after solidification, is plunged into water; the portion insoluble in water is dissolved in  $\text{HClAq}$ , the solution is evaporated to dryness, and treatment with  $\text{HClAq}$  and evaporation to dryness are repeated several times to remove  $\text{SiO}_2$  and  $\text{HF}$ . The solution in  $\text{HClAq}$  is then ppd. by  $\text{NH}_4\text{Aq}$ ; the  $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$  is thoroughly washed by decantation, dissolved in the smallest possible quantity of conc.  $\text{HClAq}$ , and the solution is evaporated to dryness; the residue is washed in a funnel with conc.  $\text{HClAq}$  mixed with 4 pts. of alcohol; the washed solid is then repeatedly crystallised from conc.  $\text{HClAq}$ . The white, lustrous crystals of  $\text{ZrOCl}_2 \cdot x\text{H}_2\text{O}$  thus obtained are dissolved in water, and  $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$  is ppd. by  $\text{NH}_4\text{Aq}$  (Venable, C. N. 64, 315 [1891]; cf. Bailey, Pr. 46, 74 [1889]; cf. Preparation of Zirconium, p. 893). By heating ppd.  $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$  to c.  $560^\circ$ ,  $\text{ZrO}_2$  is obtained.

**Crystalline zirconia** is obtained from the amorphous form (1) by fusing with borax at a very high temperature, and washing with  $\text{HClAq}$  (Nordenskjöld, P. 114, 612; Knop, A. 187, 363); (2) by fusion with *microcosmic salt* (K., Lc.); (3) by heating to dull redness in dry  $\text{HCl}$  at a pressure of three atmospheres (Hautefeuille a. Perrey, C. R. 110, 1638); (4) by melting and volatilising in an electric furnace, using a current of 360 amperes and 70 volts (Moissan, C. R. 116, 1232 [1893]); (5) by heating, to dull redness, a salt of Zr with an acid that can be removed by heating, in a current of dry  $\text{HCl}$  (H. a. P., Lc.).

**Properties.**—Amorphous zirconia is a white, tasteless, odorless powder; S.G. c. 5.0 insoluble in acids, except in conc.  $\text{H}_2\text{SO}_4$  (v. Reactions, No. 7) or  $\text{HFAq}$ . Crystalline zirconia is a transparent, colourless solid; S.G. 5.1 (Moissan, Lc.), 5.42 (Knop, Lc.), 5.7 (Nordenskjöld, Lc.). The crystals are described by N. (Lc.) as quadratic prisms, isomorphous with  $\text{SnO}_2$  (*tin stone*) and  $\text{TiO}_2$  (*rutile*). The crystals are extremely hard; they scratch glass easily (Moissan, Lc.). It is generally said that when  $\text{ZrO}_2$  is heated to incipient redness it glows brightly, and becomes denser; but the experiments of Carnellep a. Walker (C. J. 58, 82 [1888]) on the action of heat on  $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$

Make it probable that the glowing is an accompaniment of the dehydration from approximately  $2\text{ZrO}_2 \cdot \text{H}_2\text{O}$  to approximately  $24\text{ZrO}_2 \cdot \text{H}_2\text{O}$ . Zirconia reacts towards acids as a basic oxide, forming salts  $\text{ZrX}_4$  and  $\text{ZrX}_3$  (many of which are basic salts); it also decomposes alkali carbonates and some other alkali and alkaline earth salts, when fused therewith, forming zirconates  $m\text{ZrO}_2 \cdot n\text{M}_2\text{O}$  (v. *Zirconates*, p. 896).

**Reactions.**—1. When  $\text{ZrO}_2$  is heated to a very high temperature it melts, boils, and volatilises, condensing in crystals; Moissan (*C. R.* 116, 1222 [1893]) effected the volatilisation in a crucible heated in the electric furnace using a current of 300 amperes and 70 volts.

2. When very strongly heated with excess of carbon, carbides are formed (v. *Carbides*, p. 894). Heating in a carbon crucible in the electric furnace produces  $\text{Zr}$  (M., l.c.). 3. Heating with magnesium produces  $\text{Zr}$ , perhaps also an oxide lower than  $\text{ZrO}_2$  (Winkler, *B.* 23, 2642; 24, 888; Phipson, *Pr.* 96, 353; Bailey, *Pr.* 46, 74; cf. *Zirconium monoxide*). When heated with magnesium in an atmosphere of hydrogen, spongy  $\text{ZrH}_2$  is perhaps produced (v. *Zirconium hydride*, p. 895).—4.  $\text{ZrCl}_4$  is formed by heating  $\text{ZrO}_2$  mixed with carbon in a stream of chlorine; using bromine produces  $\text{ZrBr}_4$  (v. *Bromide and Chloride*, p. 894).—5.  $\text{ZrF}_4$  is formed by heating  $\text{ZrO}_2$  to dull redness with excess of ammonium fluoride.—6.  $\text{K}_2\text{ZrF}_6$  is formed by slightly heating  $\text{ZrO}_2$  with excess of potassium hydrogen fluoride, boiling with very dilute  $\text{HFAg}$ , and filtering.—7.  $\text{Zr(SO}_4)_2$  is obtained by heating  $\text{ZrO}_2$  with excess of a mixture of 2 pts. conc. sulphuric acid and 1 pt. water.

**ZIRCONIUM PEROXIDE.** By adding  $\text{H}_2\text{O}_2\text{Aq}$  and  $\text{NH}_4\text{Ag}$  to a solution of  $\text{Zr(SO}_4)_2$ , Clève (*B.* [2] 43, 53) obtained an oxide containing more O than  $\text{ZrO}_2$ ; to this oxide he gave the formula  $\text{ZrO}_2$ . Bailey in 1886 (*C. J.* 49, 149, 481) examined the pp. obtained by adding  $\text{H}_2\text{O}_2\text{Aq}$  to solution of  $\text{Zr(SO}_4)_2$ ; according to B., the moist pp. has the composition  $\text{Zr}_2\text{O}_5$ , and this composition is unchanged after keeping (moist) for some months. In Bailey's paper in 1889 (*Pr.* 46, 74) he gives the composition  $\text{Zr}_2\text{O}_5 \cdot 3\text{H}_2\text{O}$  to the oxide ppd. by  $\text{H}_2\text{O}_2\text{Aq}$ , either from an acid or an alkaline solution of  $\text{Zr(SO}_4)_2$ , after drying over  $\text{P}_2\text{O}_5$ ; and the composition  $\text{Zr}_2\text{O}_5$  after drying at  $100^\circ$ . The oxide  $\text{Zr}_2\text{O}_5 \cdot 2\text{H}_2\text{O}$  was obtained (*C. J.* 49, 485) by preparing a solution of  $\text{Zr(SO}_4)_2$  by heating  $\text{K}_2\text{ZrF}_6$  with  $\text{H}_2\text{SO}_4$ , and at once adding  $\text{H}_2\text{O}_2\text{Aq}$ .  $\text{Zr}$  peroxide is insol. in very dilute (1 p.c.)  $\text{H}_2\text{SO}_4\text{Aq}$  or  $\text{HClO}_4\text{Aq}$  (B., l.c.). Bailey (l.c.) employed the ppn. of  $\text{Zr}_2\text{O}_5 \cdot 3\text{H}_2\text{O}$  to separate  $\text{Zr}$  from Fe, Nb, and Ti.

**ZIRCONIUM MONOXIDE (?)  $\text{ZrO}$ .** By heating  $\text{ZrO}_2$  and powdered Mg, in the ratio  $\text{ZrO}_2\text{:Mg}$ , in a stream of H, Winkler (*B.* 23, 2658 [1890]) obtained a black powder, which he allowed to cool in H, then kept for some time in  $\text{CO}_2$  from Mg by treatment with dilute  $\text{HClAq}$ , washed with water containing HCl, then with alcohol, and finally with ether and dried in *vacuo*. He thus obtained a deep black powder, which was unacted on by  $\text{HClAq}$ ,  $\text{HNO}_3\text{Aq}$  or  $\text{H}_2\text{SO}_4\text{Aq}$ , even on warming, and which burst to  $\text{ZrO}_2$  when heated in air. W. supposed this black powder to be  $\text{ZrO}$ .

VOL. IV.

**Zirconium, oxyacid of.** Hydrated zirconia,  $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$ , reacts as a weak acid towards strong bases (v. *Zirconates*, p. 896).

**Zirconium, oxybromide of,  $\text{ZrOBr}_2 \cdot x\text{H}_2\text{O}$ .**  $\text{ZrBr}_4$  dissolved in water; on evaporation, transparent needle-shaped crystals are formed, to which Mellis (*Z.* [2] 6, 296) gave the composition  $\text{ZrOBr}_2 \cdot 7\text{H}_2\text{O}$ . By dissolving  $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$  in  $\text{HBrAq}$  and evaporating, Weibull (*B.* 20, 1394 [1887]) obtained lustrous needles of  $\text{ZrOBr}_2 \cdot 8\text{H}_2\text{O}$ , isomorphous with  $\text{ZrOCl}_2 \cdot 8\text{H}_2\text{O}$ .

**Zirconium, oxychlorides of.** Various oxychlorides have been described. (1)  $\text{ZrOCl}_2 \cdot x\text{H}_2\text{O}$ ; prepared by dissolving  $\text{ZrO}_2 \cdot \text{H}_2\text{O}$  in  $\text{HClAq}$  and evaporating (for details as to the best conditions v. Weibull, *B.* 20, 1394). Hermann (*J. pr.* 81, 77) gave the formula  $\text{ZrOCl}_2 \cdot 9\text{H}_2\text{O}$ ; and Weibull (l.c.)  $\text{ZrOCl}_2 \cdot 8\text{H}_2\text{O}$  (cf. also Paykull, *B.* 6, 1467; and Bailey, *Pr.* 46, 74). (2)  $\text{Zr}_2\text{OCl}_4$ ; prepared by Troost a. Hautefeuille (*C. R.* 73, 563) by passing steam and vapour of  $\text{ZCl}_4$  through a red-hot tube. (3)  $2\text{Zr}_2\text{O}_3\text{Cl}_4 \cdot 15\text{H}_2\text{O}$ ; prepared by Endemann (*J. pr.* [3] 31, 219) by adding ether to a warm alcoholic solution of  $\text{ZrOCl}_2 \cdot x\text{H}_2\text{O}$ .

**Zirconium, oxydides of.** By adding the calculated weight of  $\text{BaI}_2$  in solution, to  $\text{Zr(SO}_4)_2$  dissolved in a slight excess of  $\text{H}_2\text{SO}_4\text{Aq}$ , filtering, evaporating over  $\text{H}_2\text{SO}_4$ , and removing free I from the residue by  $\text{CS}_2$ , Hinshelwood (*A.* 239, 253 [1887]) obtained a white, amorphous powder, easily soluble in water, giving off I in moist air, to which he gave the formula  $\text{ZrHO}_2 \cdot \text{H}_2\text{O} \cdot x\text{H}_2\text{O}$  ( $x$  probably = 3).

**Zirconium, oxysulphide of; v. ZIRCONIUM SULPHIDES (infra).**

**Zirconium, salts of.** The salts formed by the replacement of H of acids by Zr belong to the forms  $\text{ZrX}_4$  and  $\text{ZrX}_3$ ; many basic salts are known. The following are the chief salts of Zr derived from oxyacids: Arsenates, borates, carbonates, nitrates, oxalates, phosphates, selenites, silicates, sulphates, and sulphites.

**Zirconium, silicofluoride of, (?)  $\text{ZrSiF}_6$ ;** probably obtained by Berzelius by evaporating a solution (?) of  $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$  in  $\text{H}_2\text{SiF}_6\text{Aq}$  (v. *Lehrbuch*, 3, 505 [5th ed.]).

**Zirconium, sulphides of.** According to Berzelius (v. *Lehrbuch*, 2, 189 [5th ed.]), a compound of Zr and S is formed by heating the elements together in *vacuo*, or with H. The compound, to which no formula is assigned, is described by B. as a dark-brown coloured powder; unacted on by  $\text{H}_2\text{SO}_4\text{Aq}$ ,  $\text{HNO}_3\text{Aq}$ , or  $\text{HClAq}$ ; slowly attacked by boiling *aqua regia*; dissolved easily by  $\text{HFAg}$ , giving off  $\text{H}_2\text{S}$ ; insol. in  $\text{KOHAg}$ , and decomposed by fusion with  $\text{KOH}$  to  $\text{K}_2\text{S}$  and  $\text{ZrO}_2$ . By strongly heating  $\text{ZrO}_2$  in vapour of  $\text{CS}_2$ , Fremy (*A. Ch.* [3] 33, 326 [1853]) obtained a graphite-like solid, which was rapidly acted on by  $\text{HNO}_3\text{Aq}$ , with separation of S; Fremy supposed that the substance might be an oxy-sulphide.

**Zirconium, sulphocyanide of.** By adding  $\text{Ba(SCN)}_2$  to  $\text{Zr(SO}_4)_2$  solution, Hornberger (*A.* 181, 232 [1876]) obtained a solution which, he said, contained  $\text{Zr(SCN)}_2$ ; this solution quickly decomposed, depositing a yellow solid, while  $\text{Zr(SCN)}_2$  remained in solution.

# ADDENDA

[DESCRIPTIVE INORGANIC CHEMISTRY ONLY.]

**ALUMINIUM** (vol. i. p. 141). *Preparation*.—By electrolysis a molten mixture of  $\text{AlF}_3 \cdot 3\text{NaF}$  with  $\text{NaCl}$  (Minet, *C. R.* 111, 603 [1890]). The best results are obtained by using the salts in the ratio  $\text{AlF}_3 \cdot 3\text{NaF} : 6\text{NaCl}$ ; details of the quantities to be used, the strength of current, &c., are given by M.

*Properties*.—Minet (*C. R.* 111, 603 [1890]) gives m.p. of Al as  $675^\circ$ ; and S.G. at  $820^\circ$  as 1.76. The S.H. of Al is given by Richards (*C. N.* 65, 97 [1892]) as  $22\frac{1}{2}$  at  $20^\circ$ ,  $232$  at  $100^\circ$ , and  $2845$  at the m.p. =  $625^\circ$ ; the S.H. of molten Al at  $650^\circ$  = 308, according to Pionchon (*C. J.* 115, 162 [1892]). The molecule of Al in dilute solution in tin is perhaps diatomic (Heycock & Neville, *C. J.* 57, 376 [1890]).

*Reactions*.—Volatilises in electric furnace, with current of 250 amperes and 70 volts (Moissan, *C. R.* 116, 1429 [1893]). Not appreciably acted on by  $\text{NO}_2$  at  $500^\circ$  (Sabatier & Senderens, *C. R.* 115, 236 [1892]). An amalgam is formed by bringing Al into a solution of a mercuric salt (Klandy, *C. C.* 1893 [1] 201; abstract in *C. J.* 61 [11] 376 [1893]). Heated with  $\text{NaPO}_3$  in a current of  $\text{H}_2$  from 28 to 31 p.c. of the P distils over; P is also obtained by heating Al with any phosphate of Ca or Mg (Rossel a. Frank, *B.* 27, 52 [1894]). According to Lunge (*C. N.* 65, 110 [1892]), vessels made of Al may be used for holding articles of food, at least at the ordinary temperature, without danger of the metal being dissolved; this result is confirmed by K. Iland (*C. R.* 114, 1536 [1892]).

**Aluminium, alloys of** (vol. i. p. 143). For an alloy with gold,  $\text{Al}_2\text{Au}$ , v. Heycock & Neville (*C. J.* 65, 74 [1894]).

**Aluminium, chloride of** (vol. i. p. 144). Nilson & Pettersson (*Z. P. C.* 4, 306 [1889]) made a number of determinations of the V.D. of  $\text{AlCl}_3$ ; they find that the compound gradually dissociates above its b.p. until c.  $800^\circ$ , when its V.D. becomes constant and corresponds with the formula  $\text{AlCl}_3$ .  $\text{AlCl}_3$  may be prepared by heating an alloy of Al and Cu nearly to redness in dry  $\text{HCl}$ ;  $\text{AlCl}_3$  distils over unmixed with any Cu compound (Mabery, *B.* 22, 2658 [1889]). Sabatier (*B.* [3] 1, 98 [1889]) says that crystals of the hydrated chloride after being *in vacuo* for three months at  $20^\circ$  over  $\text{H}_2\text{SO}_4$ , have the composition  $\text{AlCl}_3 \cdot 6\text{H}_2\text{O}$ .

**Aluminium, oxides of** (vol. i. p. 146). By heating  $\text{Al}_2\text{O}_3$  with Mg, in the ratio  $\text{Al}_2\text{O}_3 : \text{Mg}$ , Winkler (*B.* 23, 780 [1890]) obtained a brownish-black powder which, he says, contained a considerable quantity of an oxide lower than  $\text{Al}_2\text{O}_3$ , probably  $\text{AlO}$ . By the incomplete combustion of Al, Pionchon obtained a dark-grey powder, said by P. to have the composition  $\text{Al}_2\text{O}_3 = 2\text{Al}_2\text{O}_3 \cdot \text{Al}_2\text{O}$  (*C. R.* 117, 828; abstract in *C. J.* 64 [11] 572 [1893]). By heating amorphous  $\text{Al}_2\text{O}_3$  to in-

ipient redness in  $\text{HCl}$  gas at a pressure of three atmos., Hautefeuille a. Perrey (*C. R.* 110, 1038 [1890]) obtained crystals of corundum. According to Reafl (*C. J.* 65, 815 [1894]),  $\text{Al}_2\text{O}_3$  is unchanged at c.  $1750^\circ$ .

**Aluminium, phosphide of** (vol. i. p. 146). A grey crystalline powder,  $\text{Al}_2\text{P}_3$ , was obtained by Rossel a. Frank (*B.* 27, 52 [1894]) by heating Al in vapour of P, and then heating the product till P ceased to come off.

**AMMONIA** (vol. i. p. 196). *Formation*.—According to Loew (*B.* 23, 1443 [1890]), traces of  $\text{NH}_3$  are formed by shaking Pt black with very dilute  $\text{NaOH}$  in the air.  $\text{NH}_3$  is also formed by the combined action of Pt black and dextrose on  $\text{KNO}_3$  (L., *loc. cit.*, p. 675).

*Properties*.—Ludeking a. Starr (*Am. S.* [8] 45, 200 [1892]) give S.H. of liquid  $\text{NH}_3$  as 8857. For measurements of the wave-lengths of the lines in the emission spectrum of  $\text{NH}_3$ , v. Magnanini (*Z. P. C.* 4, 435 [1889]). Perkin (*C. J.* 65, 689, 728 [1889]) gives M. M. of  $\text{NH}_3$  in aqueous and alcoholic solutions; also Mol. W. of various  $\text{NH}_3$  salts in solution. Tables showing the solubility of  $\text{NH}_3$  in alcohol of various concentrations, at  $10^\circ$ ,  $20^\circ$ , and  $30^\circ$ , are given by Delépine (*J. Ph.* [5] 25, 496; v. abstract in *C. J.* 62, 1049 [1892]). For the freezing-points of aqueous solutions of  $\text{NH}_3$ , v. Pickering (*C. J.* 63, 151 [1893]).

*Reactions*.—Dry  $\text{NH}_3$  does not combine with dry hydrogen chloride when these gases are mixed (Baker, *C. J.* 65, 611 [1894]). Nor do dry  $\text{NH}_3$  and dry carbon dioxide combine (Hughes & Soddy, *C. N.* 69, 138 [1894]). Michel a. Grandmougin (*B.* 26, 2565 [1893]) say that the products of passing  $\text{NH}_3$  over heated peroxide of Ba, Pb, Mn, or  $\text{N}_2$ , are N with a little  $\text{HNO}_2$  and  $\text{HNO}_3$ , and oxide or hydroxide of the metal. The reactions of liquid  $\text{NH}_3$  with  $\text{CrCl}_3$  and  $\text{FeCl}_3$  are described by Christensen (*Zeit. f. anorg. Chemie*, 4, 227; abstract in *C. J.* 64 [11] 469 [1893]).

**AMMONIUM COMPOUNDS** (vol. i. p. 200).

**Ammonium amalgam** (vol. i. p. 201). From measurements of the polarisation given by this substance in a solution of  $\text{NH}_4\text{Cl}$  against zinc amalgam, and a comparison of these measurements with the polarisations given by metallic amalgams, Le Blanc concludes that ammonium amalgam really exists (*Z. P. C.* 5, 467; abstract in *C. J.* 58, 2204 [1890]).

**Ammonium chloride** (vol. i. p. 202). Baker (*C. J.* 65, 611 [1894]) asserts that the V.D. of the dry salt at  $350^\circ$  is 28.7, corresponding with that required by the formula  $\text{NH}_4\text{Cl}$ . B. also says that no reaction occurs when dry  $\text{NH}_4\text{Cl}$  and dry  $\text{CaO}$  are heated together.

**ANTIMONY** (vol. i. p. 282). *Reactions*.—Montecatini (*G.* 22, 384, 426) finds that no

appreciable quantity of  $\text{NH}_3$  is formed by the interaction of Sb and  $\text{HNO}_3$  varying from 2 to 70 p.c.  $\text{HNO}_3$ ;  $\text{NO}_2$  is practically the only gaseous product of the reaction; when 70 p.c.  $\text{HNO}_3$  is used, the residue probably has the composition  $(\text{SbO})\text{NO}_2$ .

**Antimonates** (vol. i. p. 285). Several salts have been prepared, by double decomposition from the K salt, by Beilstein and O. v. Biase (C. C. 1889. 803; abstract in C. J. 56, 1123). All the compounds are salts of  $\text{HSbO}_3$ ; R. a. J. conclude that the only well-marked antimonates are derived from this acid. Ebel (B. 22, 3044 [1889]) describes several metantimonates.

**Antimonites** (vol. i. p. 285). For antimonites of K and Na v. Corninbauf (C. R. 115, 1305; abstract in C. J. 61 [11], 171 [1893]).

**Antimony, bromide of** (vol. i. p. 286). The b.p. of  $\text{SbBr}_3$  is given as  $275^\circ$  by Freyer a. V. Meyer (Zeit. f. anorg. Chemie, 2, 1 [1892]).

**Antimony, trichloride of** (vol. i. p. 286). Boils at  $223^\circ$  (Freyer a. V. Meyer, loc.).

**Antimony, pentachloride of** (vol. i. p. 287). The V.D. at  $218^\circ$  and 58 mm. pressure was found to be 1417 (corresponding with the formula  $\text{SbCl}_5$ ) by Anschütz a. Evans (J. 253, 95 [1890]). Double compounds of  $\text{SbCl}_5$  with  $\text{HCl}$  and  $\text{CsCl}$  are described by Saunders (Ann. 14, 152 [1892]), and by Wheeler (Am. S. [3] 46, 269 [1893]).

**Antimony, fluoride of** (vol. i. p. 287). The double compound  $\text{SbF}_5 \cdot 2\text{AnF}$  is described by H. von Helmholtz (Zeit. f. anorg. Chemie, 3, 115 [1893]).

**Antimony, hydride of** (vol. i. p. 288). The temperature whereat decomposition of  $\text{SbH}_3$  begins is given by Braun (B. 22, 3202 [1889]) as c.  $150^\circ$ . For the reactions of  $\text{SbH}_3$  with  $\text{AgNO}_3$  a. Vitali (abstract in C. J. 61 [11], 206 [1893]).

**Antimonic oxide** (vol. i. p. 290). When heated to dull redness  $\text{Sb}_2\text{O}_5$  gives off  $\text{O}_2$ , forming  $\text{Sb}_2\text{O}_3$ , which at c.  $1750^\circ$  is further reduced to  $\text{Sb}_2\text{O}_3$  (Reud, C. J. 65, 314 [1891]).

**Antimonious sulphide** (vol. i. p. 291). Black  $\text{Sb}_2\text{S}_3$  is formed, according to Mitchell (C. N. 67, 291 [1893]), by passing  $\text{CO}_2$  into boiling water with ordinary  $\text{Sb}_2\text{S}_3$  in suspension. Picton (C. J. 61, 142 [1892]) obtained a colloidal  $\text{Sb}_2\text{S}_3$  in very fine suspension in water, by allowing solution of tartar emetic to flow into saturated  $\text{H}_2\text{SAq}$ .

**Antimony, thio-chlorides and thio-iodides of** (vol. i. pp. 292-3). Ouvrard (C. C. 116, 1516 [1889]) describes  $\text{SbSCl}$  and  $\text{Sb}_2\text{S}_2\text{Cl}_2$  obtained by the action of  $\text{H}_2\text{S}$  on  $\text{SbCl}_3$ ; and  $\text{SbSI}$  formed by heating  $\text{SbI}_3$  to  $150^\circ$  in dry  $\text{H}_2\text{S}$ , and  $\text{Sb}_2\text{S}_2\text{I}_2$  formed by heating  $\text{Sb}_2\text{S}_3$  with 1 and crystallising from  $\text{CS}_2$ .

• **ARSENIC** (vol. i. p. 301). A full account of the different forms of As obtained, along with  $\text{As}_2\text{O}_3$ , by subliming As in a tube is given by Retgers (Z. P. C. 4, 403; abstract in C. J. 61 [11], 570 [1893]). Petersen gives the following heats of oxidation, and atomic volumes, of the allotropic forms of As (Z. P. C. 8, 601 [1891]):—

Grey, rhombic	[As $_2$ O $_3$ ] At. volume
Grey-black, amorphous	56.830 26.1
Grey-black, amorphous	154.840 15.91
Brown, amorphous	163.503 15.99

**Arsenic, bromide of** (vol. i. 309).  $\text{AsBr}_3$  combines with  $\text{NH}_3$  to form  $\text{AsBr}_2 \cdot 3\text{NH}_3$  (Besson, C. R. 110, 1258 [1890]).

**Arsenates** (vol. i. p. 307). For arsenates of Cd v. A. de Schullen (Bl. [3] 1, 473 [1889]); for arsenates of Cu, and of Cu and Na, v. Hirsch (C. C. 1891 [1], 15; abstract in C. J. 60, 644); many double arsenates of K, and of Na, with Cd, Co, Mg, Mn, Ni, and Zn are described by Lefèvre (C. R. 110, 405 [1890]).

For this arsenate of Cu, Hg, Zn; and Zn and Na, v. Preis (A. 257, 174 [1890]).

**Arsenites** (vol. i. p. 306). For the preparation, by double decomposition from the salt  $2\text{K}_2\text{AsO}_4 \cdot \text{As}_2\text{O}_3$ , and properties of the arsenites of the following metals v. Hefehard (B. 27, 1019 [1891]):—Al, Ba, Cd, Ca, Cr, Co, Cu, Au, Fe, Pb, Mg, Mn, Ni, Pd, Pt, Ag, Sr, Sn, Ti, U, and Zn (references and criticisms of former investigations are given). Stavenhagen (Zeit. f. anorg. Chemie, 1891, 165) obtained the double salt of K arsenite and sulphate,  $\text{K}_2\text{AsO}_3 \cdot 10\text{K}_2\text{SO}_4$ , by evaporating solutions of the constituents alternatingly.

**Arsenic acid** (vol. i. p. 307). For a detailed account of the reaction of  $\text{H}_2\text{S}$  with solutions of  $\text{H}_3\text{AsO}_4$ , v. Brauner a. Tomczak (C. J. 53, 145 [1888]).

**Arsenious chloride** (vol. i. p. 310). According to Besson (C. R. 109, 919 [1890]),  $\text{AsCl}_3$  solidifies at  $-18^\circ$ , forming white needles; at  $-30^\circ$   $\text{AsCl}_3$  absorbs much  $\text{Cl}$ , forming a liquid which does not solidify at  $-60^\circ$ , and which with water gives off much  $\text{Cl}$  and forms  $\text{As}_2\text{O}_3 \cdot \text{AsCl}_3$ . Besson (C. R. 110, 1258 [1890]) says that the compound formulated by Rose as  $2\text{AsCl}_3 \cdot 7\text{NH}_3$  is really  $\text{AsCl}_3 \cdot 4\text{NH}_3$ .

• **Arsenious fluoride** (vol. i. p. 310). Moissan (J. Ch. [6] 19, 280 [1891]) prepared  $\text{AsF}_3$  by heating  $\text{As}_2\text{O}_3$  with  $\text{HF}$ ; he gives b.p. as  $63^\circ$  at 750 mm., and says that it solidifies to white crystals at  $-8.5^\circ$ . Besson (C. R. 110, 1258 [1890]) describes the compound  $2\text{AsF}_3 \cdot 5\text{NH}_3$ .

**Arsenic, trihydride of** (vol. i. p. 310). Brun (B. 22, 3202 [1889]) finds that the first products of the action of air, or  $\text{O}_2$  on  $\text{AsH}_3$  are solid  $n\text{AsH}_3$  and  $\text{H}_2\text{O}$ , and the next products are  $\text{As}$  and  $\text{H}_2\text{O}$ .  $\text{AsH}_3$  and  $\text{H}_2\text{S}$  do not react in absence of air at the ordinary temperature, either as gases or in solution (B., loc.).  $\text{AsH}_3$  begins to decompose at c.  $230^\circ$  (B., loc.). For the reactions of  $\text{AsH}_3$  with  $\text{AgNO}_3$  a. Vitali (abstract in C. J. 61 [11], 206 [1893]).

• **Arsenious iodide** (vol. i. p. 311). Besson (C. R. 110, 1253 [1890]) describes the compounds  $\text{AsI}_3 \cdot 4\text{NH}_3$  and  $\text{AsI}_3 \cdot 12\text{NH}_3$ .

**Arsenious sulphide** (vol. i. p. 315). Picton (C. J. 61, 140 [1892]) obtained an aqueous solution of colloidal  $\text{As}_2\text{S}_3$ , containing also some very finely divided sulphide in suspension, by allowing  $\text{As}_2\text{O}_3$  to flow into saturated  $\text{H}_2\text{SAq}$ , to which  $\text{H}_2\text{S}$  was continually passing, and removing  $\text{H}_2\text{S}$  by a stream of  $\text{H}$ .

**Arsenic pentasulphide** (vol. i. p. 315)  $\text{As}_2\text{S}_5$  is obtained, according to McCay (Am. 12, 547 [1891]), by passing  $\text{H}_2\text{S}$  for a long time into a hot solution of an alkali dihydrogen arsenate, and then ppg. by a mineral acid.

**Arsenic, thiochlorides and thio-iodides of** (vol. i. p. 316). Ouvrard (C. R. 116, 1516 [1893]) obtained  $\text{As}_2\text{S}_2\text{Cl}_2$  by passing  $\text{H}_2\text{S}$  into

$\text{AsCl}_3$ , and washing the pp. with  $\text{CS}_2$ . By heating 1 pt.  $\text{As}_2\text{S}_3$  with 10 pts.  $\text{AsCl}_3$  to  $150^\circ$  he obtained  $\text{As}_2\text{S}_3\text{Cl}_3$ .

**AZO-IMIDE** (v. *Hydrazoic acid*, p. 219, *Addenda*).

**BARIUM** (vol. i. p. 440). Richards, in 1893, made an elaborate experimental revision of the at. w. of Ba (*P. Am. A.* 28, 1; 29, 55). As a mean result of the most trustworthy experiments, R. adopts 137.1 as the at. w. of Ba ( $O=15.96$ ). Limb (*C. R.* 112, 1434 [1891]) failed to obtain any Ba by electrolysis fused  $\text{BaCl}_2$ , or  $\text{BaCl}_2$  mixed with  $\text{NaCl}$ .

**Barium, carbide of.** By heating a mixture of Ba amalgam and powdered charcoal in H, Maquenne (*C. R.* 114, 361 [1892]) obtained grey  $\text{BaC}_2$ ; decomposed by water, giving  $\text{BaO}$ ,  $\text{H}_2\text{Aq}$  and  $\text{C}_2\text{H}_2$ ; v. also Moissan, *C. R.* 118, 683 (*abstract in C. J.* 66 [1], 314 [1894]).

**Barium, chloride of** (vol. i. p. 441). By bringing  $\text{BaCl}_2$  into contact with liquid  $\text{NH}_3$ , and allowing the gas to escape at  $0^\circ$  and 760 mm., Joannis obtained  $\text{BaCl}_2 \cdot 8\text{NH}_3$  (*C. R.* 112, 337 [1891]).

**Barium, fluoride of** (vol. i. p. 441).  $\text{BaF}_2$  is obtained in microscopic crystals by adding  $\text{BaCl}_2\text{Aq}$  (3.6 p.c.) to boiling  $\text{KFAq}$  (1 p.c.), boiling, washing, drying, and heating strongly (Moissan, *Bull.* [3], 6, 152 [1891]). Poulenc (*C. R.* 116, 987 [1893]) obtained  $\text{BaF}_2$  in well-formed octahedra by fusing amorphous  $\text{BaF}_2$  with  $\text{KHF}_4$  and  $\text{KCl}$ .

**Barium, nitrides of.** Maquenne (*C. R.* 114, 220 [1892]) obtained a mixture, probably containing some  $\text{Ba}_3\text{N}_2$ , by heating Ba amalgam to redness in a current of N. Berthelot & Matignon (*A. Ch.* (7) 2, 144 [1894]) say that  $\text{Ba}_3\text{N}_2$  is formed by heating  $\text{AmN}_3\text{Aq}$  with  $\text{BaO}$ ,  $\text{H}_2\text{Aq}$ .

**Barium monoxide** (vol. i. p. 442).  $\text{BaO}$  is unchanged at c.  $1750^\circ$  (Read, *C. J.* 65, 313 [1894]); it liquefies at c.  $2,000^\circ$ , but is not decomposed at c.  $2,500^\circ$  (Moissan, *C. R.* 115, 1034 [1892]).

**Barium dioxide** (vol. i. p. 443).  $\text{BaO}_2$  is decomposed by salts of Al, Cr, Co, Fe, &c.; some salts—e.g. those of Ca, Li, K, Na—do not react with  $\text{BaO}_2$  (v. Kwasnik, *B.* 25, 65). For decomposition of  $\text{BaO}_2$  by heat v. Le Chatelier (*C. R.* 115, 654; *abstract in C. J.* 64 [1], 71 [1893]).

**BERYLLIUM** (vol. i. p. 504). Krüss & Morath (*B.* 23, 727 [1890]) obtained hexagonal crystals of Be, mixed with BeO, by heating  $\text{BeF}_2 \cdot 2\text{KCl}$  to redness with Na. K. a. M. (*L.c.* p. 2552) obtained the value 9.03 for the at. w. of Be by converting BeO into  $\text{BeSO}_4 \cdot 4\text{H}_2\text{O}$ , and this again to BeO. Gibson (*C. J.* 63, 909 [1893]) describes methods for preparing BeC from *beryl*.

**Beryllium, fluoride of** (vol. i. p. 506). Petersen (*Z. F. C.* 5, 263 [1890]) gives the thermal data  $\text{H}_2$ . [ $\text{BeO} \cdot \text{H}_2\text{O} \cdot 2\text{HFAq}$ ] =  $-19.783$ . The *double compound*  $\text{BeF}_2 \cdot \text{AmF}$  is described by H. von Helmholtz (*Zeit. f. anorg. Chemie*, 3, 115 [1893]).

**Beryllium, oxide of** (vol. i. p. 506). By dissolving BeO in  $\text{KOH Aq}$ , Krüss & Morath (*B.* 23, 727 [1890]) obtained *potassium beryllate*  $\text{BeO} \cdot \text{K}_2\text{O}$  (?), mixed with  $\text{K}_2\text{CO}_3$ , as a snow-white, silky solid.

**BISMUTH** (vol. i. p. 509). The at. w. of Bi was re-determined by Claassen in 1890 (*B.* 23, 928 [1890]), by converting Bi into nitrate, and

this into  $\text{Bi}_2\text{O}_3$ ; the mean result was 209.86 ( $O=15.96$ ). Schneider (*J. pr.* [2] 42, 553; 44, 23 [1891]) criticises Claassen's results and maintains that Marignac's value (almost exactly 208) is as trustworthy as that obtained by C. The molecule of Bi in dilute solution in tin is perhaps diatomic (?) (Heycock & Nevill, *C. J.* 57, 376 [1890]).

**Preparation.**—Claassen (*L.c.*) says that pure Bi is best prepared by electrolysis a solution of the metal in  $\text{HNO}_3\text{Aq}$ , using a cone of Pt as the negative electrode, then washing with alcohol, and fusing with  $\text{KCl}$ .

**Properties.**—Melts at  $264^\circ$ , according to Claassen (*L.c.*): at  $269.22^\circ$ , according to Callendar & Griffiths (*C. N.* 63, 1 [1891]). S.G. 9.7474 (*C.*, *L.c.*; no temperature given!; 9.787 at  $0^\circ$ , 9.673 solid at the m.p., 10.004 liquid at the m.p. (Vicentini, *Rend. Acad. Lincei*, 6 [1], 121, 147 [1891]). For S.G. of liquid Bi from  $235^\circ$  to  $280^\circ$  v. Cattaneo (*Rend. Acad. Lincei*, 7, [1], 88 [1892]). For electrical resistance v. E. v. Aubel (*C. R.* 108, 1102 [1889]).

**Reactions.**—According to Völey (*Pr.* 48, 458 [1891]), Bi does not dissolve in 30 p.c.  $\text{HNO}_3\text{Aq}$  at  $30^\circ$  if  $\text{HNO}_3$  is absent; but Bi dissolves readily in 1 p.c.  $\text{HNO}_3\text{Aq}$ .

**Bismuth, bromide of** (vol. i. p. 511).  $\text{BiBr}_3$  boils at  $453^\circ$  (V. Meyer, *A.* 264, 122 [1891]). Cavazzi & Tivoli (*G. Z.* [1], 306 [1892]) describe a lustrous, black, hygroscopic solid,  $\text{FBrH}(\text{BiBr}_3)$ , obtained by allowing  $\text{BiBr}_3$  to fall gradually into  $\text{PH}_3$  (*abstract in C. J.* 62, 279).

**Bismuth, chloride of** (vol. i. p. 512). Boils at  $435^\circ$ – $441^\circ$  (uncor.) (V. Meyer, *L.c.*). The only *double chloride* of Bi and K of those hitherto described that exists is  $\text{BiCl}_2 \cdot 2\text{KCl}$ , 2aq, according to Brigham (*Am.* 14, 164 [1892]). B. has also prepared  $\text{BiCl}_2 \cdot \text{KCl}$  aq.

**Bismuth, fluoride of** (vol. i. p. 512). H. von Helmholtz describes the *double fluoride*  $\text{BiF}_3 \cdot \text{AmF}$  (*Zeit. f. anorg. Chemie*, 3, 115 [1893]).

**Bismuth, iodide of** (vol. i. p. 513). Astre (*C. R.* 110, 525 [1890]) obtained the *double iodide*  $2\text{BiI}_3 \cdot \text{KI}$  by keeping I,  $\text{KCl}$ , Bi, and water in contact for some weeks, and then crystallising from Et acetate.

**Bismuthous oxide** (vol. i. p. 513). Claassen (*B.* 23, 938 [1890]) gives S.G. as 9.044. Read (*C. J.* 65, 313 [1894]) found  $\text{Bi}_2\text{O}_3$  to be unchanged at c.  $1750^\circ$ .

**Bismuth, oxysulphide of** (vol. i. p. 516). By passing dry  $\text{H}_2\text{S}$  into boiling benzene containing  $\text{Bi}_2\text{O}_3$  in suspension, P. v. Scherpenberg (*C. R.* 1889, [1] 643) obtained  $\text{Bi}_2\text{O}_3\text{S}$ .

**Bismuth, selenide of** (vol. i. p. 516). The *double compound*  $\text{Bi}_2\text{Se}_3 \cdot \text{K}_2\text{Se}$  is described by P. v. S. (*L.c.*).

**Bismuth, sulphide of** (vol. i. p. 516). P. v. S. (*L.c.*) obtained the *double compound*  $\text{Bi}_2\text{S}_3 \cdot \text{K}_2\text{S}$  by fusing  $\text{Bi}_2\text{O}_3$  with K polysulphide.

**BORON** (vol. i. p. 524). The at. w. of B has been determined by Abrahall by the analysis of  $\text{BBr}_3$  (*C. J.* 61, 650 [1892]); the value obtained was 10.67 ( $O=15.96$ ). Also by Ramsay & Aston (*C. J.* 63, 207 [1893]) by finding the percentage of water in crystalline borax, and by distilling fused borax with  $\text{HCl Aq}$ , and  $\text{d CH}_3\text{OH}$  and weighing the residual  $\text{NaCl}$ ; the values varied about 11, but showed considerable differences.

Himbach (*B.* 26, 164 [1893]), by titrating solutions of borax with standard HClAq, using methyl orange as indicator, obtained the value 10.91 (O=15.96). The following values for S.H. of amorphous B are given by Moissan & Gautier (*C. R.* 116, 924 [1893]): 0° to 100° = 3066, 0° to 192° = 3407, 0° to 234° = 3573. For atomic refraction of B v. Ghira (*C. R.* 23 [1], 452; *abstract* in *C. J.* 64 [11], 517 [1893]).

**Preparation.**—According to Moissan (*C. R.* 114, 819 [1892]), the methods employed to give amorphous boron yield substances containing from c. 45 to c. 72 p.c. of B. M. (*l.c.* p. 392) says that nearly pure amorphous B is obtained by heating to redness a mixture of one pt. powdered Mg with 3 pts. fused B<sub>2</sub>O<sub>3</sub>, washing with HClAq, KOH in alcohol, HFaq, and water (the process is tedious, details are given); by fusing this product with 50 pts. B<sub>2</sub>O<sub>3</sub>, and washing with HClAq &c., a brown powder is obtained containing c. 98.5 p.c. B, with traces of Mg and small quantities of other impurities.

**Properties and Reactions.**—The properties of amorphous boron are described by Moissan (*C. R.* 114, 617 [1892]). Brown powder; S.G. 2.45. Does not fuse in electric arc, but volatilises (*M.*, *C. R.* 117, 423 [1893]); increases in density when heated to c. 1500° in H<sub>2</sub>. Specific electrical resistance = 801 megohms. Burns in air at c. 700°. Combines directly with Br, Cl, (not I), N at c. 1200°, Se, S, (not Te); also with Al, Fe, Mg, Pt, and Ag. Reduces many oxyacids and oxides when heated therewith; HClO<sub>4</sub>, HIO<sub>3</sub>, HNO<sub>3</sub>, and H<sub>2</sub>SO<sub>4</sub> are rapidly reduced; As<sub>2</sub>O<sub>3</sub> and As<sub>2</sub>O<sub>5</sub>, CO, N<sub>2</sub>O, P<sub>2</sub>O<sub>5</sub>, SiO<sub>2</sub>, steam, and SO<sub>2</sub> are also reduced; many metallic oxides are reduced to metals, often with explosive violence; molten KOH gives off H; metallic fluorides are generally decomposed, giving BF<sub>3</sub>; many other metallic salts, both in solution and when heated as solids, are reduced by amorphous boron.

**Boron, bromide of** (vol. i. p. 525). BBr<sub>3</sub> boils at 90° (Freyer & V. Meyer, *Zeit. f. anorg. Chemie*, 2, 1). Ghira (*Z. P. C.* 12, 768 [1893]) gives S.V. 94.72; and S.G.  $\frac{d}{4}$  = 2.64985. According to Besson (*C. R.* 112, 1001 [1891]), when a mixture of gaseous HI and BBr<sub>3</sub> is passed through a glass tube at 300°–400° the products are BBr<sub>3</sub>, BBr<sub>2</sub>I, and BI. BBr<sub>3</sub> and BBr<sub>2</sub>I are colourless liquids, distilling at c. 125° and 180°; they are rapidly decomposed by air and light. Tarble (*C. R.* 116, 1524 [1893]) says that BBr<sub>3</sub> combines with PBr<sub>3</sub> and PBr<sub>5</sub> to form compounds easily decomposed by water, Cl, or NH<sub>3</sub> in the cold. Besson (*C. R.* 114, 542 [1892]) describes BBr<sub>3</sub>·4NH<sub>3</sub>, obtained by passing dry NH<sub>3</sub> into BBr<sub>3</sub> in dry CCl<sub>4</sub>.

**Boron, carbide of**, B<sub>2</sub>C. Moissan (*C. R.* 118, 556 [1894]) says that B and C combine when amorphous B is mixed with c.  $\frac{1}{2}$  its weight of sugar charcoal, and the mixture is heated in the electric furnace for some minutes, using a current of 250–300 amperes and 70 volts. After treating the product with HNO<sub>3</sub>Aq, and then with KClO<sub>4</sub> and HNO<sub>3</sub>Aq, the carbide remains as a very hard, lustrous, black, crystalline powder; S. G. 2.57; burns very slowly in O at 1000°; acted on by Cl below 1000° but not by Br, I, S, P, N, or mineral acids; reacts with molten KOH or KNaCO<sub>3</sub> (*abstract* in *C. J.* 66 [11], 249 [1894]).

**Boron, chloride of** (vol. i. p. 525). BCl<sub>3</sub>, boiling at 17° (Freyer & V. Meyer, *Zeit. f. anorg. Chemie*, 2, 1). Ghira (*Z. P. C.* 12, 768 [1893]) gives S.G.  $\frac{d}{4}$  = 1.48386, and S.V. 81.94.

**Boron, fluoride of** (vol. i. p. 526). According to Besson (*C. R.* 110, 80 [1890]), BF<sub>3</sub> unites with PH<sub>3</sub> at c. –30° to form 2BF<sub>3</sub>·PH<sub>3</sub>, decomposed by water giving off H and PH<sub>3</sub>.

**Ammonium borofluoride** is described by Stolba (*C. R.* 1896, [1] 211; *abstract* in *C. J.* 58, 560).

**Boron, hydride of** (vol. i. p. 526). Sabatier (*C. R.* 112, 865 [1891]) says that the gas produced by adding HClAq to the brown powder formed by heating B<sub>2</sub>O<sub>3</sub> with Mg in H has a very disagreeable odour, burns with a green flame, gives a brown ppt. with AgNO<sub>3</sub>Aq, deposits B when passed through a glass tube, at a dull red heat (H coming off), and is decomposed by electric sparks, giving pure H. The gas contains a little B hydride, according to S. (*l.c.*); cf. Winkler (*B.* 23, 772 [1890]).

**Boron, iodide of** (vol. i. p. 527). BI<sub>3</sub>. Prepared by Moissan (*C. R.* 112, 717 [1891]), (1) by heating I and B to 700°–800°; (2) by heating amorphous B (dried in H<sub>2</sub> at 200°), in a stream of dry HI, in a tube of hard glass until the glass nearly softens; (3) by passing HI and BCl<sub>3</sub> vapours through a porcelain tube heated to redness. The product is dissolved in CS<sub>2</sub>, shaken with Hg, and allowed to crystallise. Colourless crystals, very hygroscopic, rapidly become coloured in light. Melts at 43° and boils at 210°. Decomposed by water, giving HIAq and H<sub>2</sub>BO<sub>3</sub>Aq. (For other reactions v. *abstract* in *C. J.* 60, 979 [1891].) For compounds with NH<sub>3</sub>, v. Besson (*C. R.* 114, 542 [1892]; *abstract* in *C. J.* 62, 771).

**Boron, oxide of** (vol. i. p. 527). B<sub>2</sub>O<sub>3</sub>. For reduction by Mg powder, giving Mg boride, v. Winkler (*B.* 23, 772 [1890]). The compound B<sub>2</sub>O<sub>3</sub>·P<sub>2</sub>O<sub>5</sub> (= B<sub>2</sub>P<sub>2</sub>O<sub>7</sub>) is obtained by evaporating H<sub>2</sub>BO<sub>3</sub>Aq mixed with H<sub>2</sub>P<sub>2</sub>O<sub>7</sub>, heating to redness, and washing with hot water (G. Meyer, *B.* 22, 2919 [1889]).

**Borates** (vol. i. p. 529). For some new borates of Li, Rb, and Cs v. Reischle (*Zeit. f. anorg. Chemie*, 4, 166 [1893]). For remarks on the classification of alkali and alkaline earth borates v. Le Chatelier (*C. R.* 113, 1034 [1891]). For a full account of Mn borate, v. Hartley & Ramage (*C. J.* 63, 129 [1893]). The compounds 6FeO·FeBr<sub>3</sub>·8B<sub>2</sub>O<sub>3</sub> and 6ZnO·ZnBr<sub>2</sub>·5B<sub>2</sub>O<sub>3</sub> are described by Rousseau & Allaire (*C. R.* 116, 1446; *abstract* in *C. J.* 64 [11], 518 [1893]).

**Boron, phosphide of**. According to Besson (*C. R.* 113, 78 [1891]), a phosphide of B is obtained by passing PH<sub>3</sub> into BBr<sub>3</sub>, and heating the product, BBr<sub>3</sub>·PH<sub>3</sub>, to 300°, when it gives HBr and B phosphide. The phosphide is said to be a brown powder, insoluble in water, reacting with boiling conc. alkali solutions to give PH<sub>3</sub>; gives off P when heated to redness in N (for other reactions v. *abstract* in *C. J.* 60, 1418 [1891]).

**Boron, selenide of**. (B<sub>2</sub>Se<sub>3</sub>). Obtained, as a yellowish grey powder, decomposed violently by water, giving H<sub>2</sub>Se and some Se, by heating B to full redness in a current of H<sub>2</sub>Se (Sabatier, *C. R.* 112, 1000 [1891]).

Boron, sulphides of (vol. i. p. 531). For heat of formation of  $B_2S_3$ , v. Sabatier (*C. R.* 112, 862; abstract in *C. J.* 60, 981 [1891]). Moissan (*C. R.* 115, 203 [1892]) gives details of various methods of preparing  $B_2S_3$ , and describes the reactions of this compound (v. abstract in *C. J.* 62, 1393 [1892]). According to M. (l.c. p. 271), boron pentasulphide,  $B_2S_5$ , is obtained by heating  $BI_3$  with rather less than one equiv. of S in  $CS_2$  solution at  $60^\circ$  for many hours. M. describes the compound, which was not obtained pure, as a light white crystalline powder, S.G. 1.85.

**BROMHYDRIC ACID** (vol. i. p. 532). The V.D. has been determined by Biltz at  $-15^\circ$  and  $-28^\circ$  (*Z. P. C.* 10, 354 [1892]); the results agree with the V.D. required by the formula HBr. The M. Ms. of HBrAq from 15.47 to 65.59 p.c. HBr have been measured by Perkin (*C. J.* 55, 706 [1889]).

**Preparation.**—1. By the interaction of P, Br, and  $H_2O$ , v. Filoti a. Crosa (*G.* 21, 64 [1891]; cf. Gassman, abstract in *C. J.* 64 [11], 453 [1893]). 2. By passing  $H_2S$  into Br covered with water (Recoura, *C. R.* 110, 784 [1890]).—3. By adding  $H_2SO_4$  Aq S.G. 1.41 to KBr (Feit a. Kubierschky, *J. Ph.* [5] 24, 159; abstract in *C. J.* 60, 1320 [1891]; v. also Addyman, *C. J.* 61, 97 [1892]; cf. Léger, abstract in *C. J.* 64 [11], 114 [1893]).

**Hydrates.**—Pickering (*P. M.* [5] 36, 11 [1894]) has isolated  $HE \cdot 3H_2O$  and  $HBr \cdot 4H_2O$ ; the former melting at  $-48^\circ$  and the latter at  $-55.4^\circ$ .

**Reactions.**—For the decomposition of HBrAq by  $H_2SO_4$  Aq of different concentrations v. Addyman (*C. J.* 61, 98 [1892]).

**BROMINE** (vol. i. p. 534). Mol. w. in solution in water or acetic acid = 159.5 (Br.) (Paterno a. Nasini, *B.* 21, 215 [1888]). The V.D.s of Br from  $15^\circ$  to  $280^\circ$ , and at pressures from 75 to 760 mm., have been determined by Perman (*Tr.* 48, 45 [1891]); no indications of dissociation were obtained. For measurements of the absorption of light by Br v. Camichel (*C. R.* 117, 807; abstract in *C. J.* 64 [11], 561 [1893]).

**Bromates** (vol. i. p. 538). **Lithium bromate**  $LiBrO_3$ ; prepared by the interaction of  $Li_2O$  Aq and  $Li_2SO_4$  Aq (Potilitzin, *J. R.* 22, 392; abstract in *C. J.* 62, 1275 [1892]). **Potassium bromate**  $KBrO_3$ . The decomposition of this salt by heat has been studied by Cook (*C. J.* 65, 802 [1894]); decrepitation occurs at c.  $180^\circ$ , with evolution of Br; the salt fuses at a higher temperature, and O is evolved, without any Br, until KBr remains; no oxy-compounds are formed.

**Strontium bromate** behaves to decompose at c.  $240^\circ$ ; the principal change is to SrBr and O, but SrO is also formed (Potilitzin, *J. R.* 22, 454; abstract, with summary of quantitative results, in *C. J.* 64 [11], 11 [1893]).

**CADMIUM** (vol. i. p. 354). Determinations of the at. w. have been made by Partridge (*Am. S.* [3] 40, 377 [1891]), and by Morse a. Jones (*Am. S.* 14, 261 [1892]), P. converted  $CdCl_2O$  into CdO by heating,  $CdSO_4$  into CdS by heating in  $H_2S$ , and  $CdCl_2O$  into CdS by heating in  $H_2S$ . M. a. J. converted Cd into  $Cd(NO_3)_2$ , and this into CdO by heating. The results all lie about 112 (v. abstract in *C. J.* 60, 399; cf. Clarke, *ibid.* 390 [1891], and 62, 1397 [1892]). Lorimer a. Smith

(*Zeit. f. anorg. Chemie* [1, 364 [1892]) obtained values varying from 112.182 to 111.908 (O = 16). The molecule of Cd in dilute solution in tin may be diatomic (v. Heycock a. Neville, *C. J.* 57, 376 [1890]). Cd melts at  $320.68^\circ$ , according to Callendar a. Griffiths (determined by Pt thermometer, *C. N.* 63, 1 [1891]). For the infra-spectrum of Cd v. Ames (*P. M.* [5] 30, 33 [1890]). According to Williams (*Ann.* 14, 273 [1892]), Cd crystallises in hexagonal and polyhedral forms; axial ratio  $a:c = 1:1.6554$ . Cd is superficially oxidised at a dull-red heat by nitric oxide (Sabatier a. Senderens, *Cr. R.* 114, 1429 [1892]). Montemartini (*G.* 22 [1] 250; v. abstract in *C. J.* 62, 1278 [1892]) has analysed the gases produced by the interaction of Cd and nitric acid, with excess of  $HNO_3$  Aq (27.5 p.c.) at  $8^\circ$ , N,  $N_2O$ ,  $N_2$  and  $NH_3$  are produced.

**Cadmium, alloys of** (vol. i. p. 655). For an alloy with gold, CuAu, v. Heycock a. Neville (*C. J.* 61, 914 [1892]; cf. *ibid.* 65, 65 [1894]). For alloys with copper, gold, and silver, prepared by immersing Cd in solutions of salts of the other metals, v. Milius a. Fromm (*B.* 27, 630 [1894]).

**Cadmium, bromide of** (vol. i. p. 655). For the double compounds  $CdBr_x \cdot xCsBr$ ,  $x = 1, 2$ , and 3, v. Wells a. Walden (*Zeit. f. anorg. Chemie*, 5, 266 [1893]).

**Cadmium, chloride of** (vol. i. p. 655). Kwasnik (*Ar. Ph.* 229, 569; abstract in *C. J.* 62, 566 [1892]) describes  $CdCl_2 \cdot 2NH_3$  and  $CdCl_2 \cdot NH_3$ . For the double compounds  $CdCl_2 \cdot xCsCl$  and  $CdCl_2 \cdot 2CsCl$ , v. Wells a. Walden (*l.c.*). Double compounds with  $HCl$ ,  $NH_4Cl$ ,  $LiCl$ , and  $KCl$ , of the form  $CdCl_2 \cdot MCl$ , aq., are described by Clusaveant (*A. Ch.* [6] 30, 5; v. abstract in *C. J.* 66 [11], 18 [1894]).

**Cadmium, fluoride of** (vol. i. p. 655).  $CdF_2$  is obtained by (1) the interaction of HF and Cd at a red heat; (2) the interaction of HF and fused  $CdCl_2$ , or CdO at a red heat; it is a colourless, transparent solid; S.G. 6.64; somewhat soluble water, insoluble alcohol of  $95^\circ$  (Poulenc, *C. R.* 116, 581 [1893]).

**Cadmium, iodide of** (vol. i. p. 656). For the double compounds  $CdI_x \cdot xCsI$ , when  $x = 1, 2$ , and 3, v. Wells a. Walden (*l.c.*).

**Cadmium, oxides of** (vol. i. p. 656). CdO is unchanged at c.  $1750^\circ$  (Read, *C. J.* 65, 313 [1894]).

According to Kouriloff (*J. R.* 22, 171; abstract in *C. J.* 62, 1278 [1892]), the compound  $CdO \cdot CdO \cdot H_2O$  is obtained by heating  $CdO \cdot H_2O$  with  $H_2O$  Aq. Moré a. Jones (*Am.* 12, 488; abstract in *C. J.* 58, 1376 [1890]) obtained small crystals, which they say were cadmium oxide  $CdO$ , by gently heating  $CdOH$ ; the hydroxide was obtained by heating  $CdCl_2$ ,  $CdBr_2$ , or  $CdI_2$  with excess of Cd, to the melting-point, in N, or *vacuo*, and heating with water, when  $CdCl_2$ ,  $CdBr_2$ , or  $CdI_2$  dissolved, a little  $CdO \cdot H_2O$  separated, and  $CdOH$  remained as a white amorphous powder.

**Cadmium, salts of** (vol. i. p. 656). For the electrical conductivities of very dilute solutions of  $CdBr_2$ ,  $CdCl_2$ ,  $CdI_2$ ,  $K_2CdF_6$ ,  $Cd(NO_3)_2$ , and  $CdSO_4$ , v. Wershoven (*Z. P. C.* 5, 481 [1890]).

**Cadmium, sulphide of** (vol. i. p. 657). Two forms (and perhaps more) of CdS seem to exist, one lemon-yellow and the other red; they differ

inguity in S.G., and in crystalline form; the yellow is said to change to the red by friction (v. Buehner, *Chem. Zeit.* 11, 1087, 1107; 15, 778; von Klobukoff, *J. pr.* [2] 39, 412; *abstracts* in *C. J.* 54, 234 [1888]; 56, 946 [1889]; 62, 778 [1892]). A solution of colloidal C.S. was obtained by Prost (*Ca C.* 1888, 32; *abstract* in *C. J.* 54, 653 [1888]) by completely ppg. an ammoniacal solution of  $\text{CaSO}_4$  by  $\text{H}_2\text{S}$ , washing well, suspending the pp. in water and passing in  $\text{H}_2\text{S}$ . A solution with 4 grms.  $\text{CaS}$  per litre remained clear for many days; one with 11 grms. coagulated in 2½ hours.

**CESIUM** (vol. i. p. 657). According to Beketoff (*n. abstract* in *C. J.* 62, 274 [1892]), Cs is obtained by heating  $\text{CsOH}$  with c. ½ its weight of Al.

**Cesium, haloid compounds of** (vol. i. p. 658). A series of compounds of the form  $\text{CsX}_n$ , where  $\text{X} = \text{Br}$ ,  $\text{I}$ , or  $\text{Br}$  and  $\text{I}$ ,  $\text{Cl}$ ,  $\text{Br}$  and  $\text{I}$ , &c., is described by Wells & Penfield (*Am. S.* [3] 43, 17; *abstract* in *C. J.* 62, 773 [1892]). Double compounds of Cs haloids with haloid compounds of Cd, Cu, Mg, Hg, Pb, and Zn are described by Wells (and others) (*Am. S.* [3] 41, 221; *Zeit. f. anorg. Chemie*, 3, 195; 5, 266, 273, 300, 304, 306; *abstracts* in *C. J.* 64 [11], 67, 322 [1893]; 66 [11], 45, 47 [1894]).

**Cesium, hydroxide of** (vol. i. p. 658). S.G.  $d_{40}^{20}$  4.0178;  $[\text{CaOH}, \text{Al}] = 15, 876$ ;  $[\text{CsOH}, \text{Al}] = 13, 790$  (Beketoff, *C. C.* 1891, [1] 451).

**Cesium, oxide of** (vol. i. p. 658). According to Beketoff (*J. R.* 25, 433; *abstract* in *C. J.* 60 [11], 234 [1894]),  $\text{Cs}_2\text{O}$  reacts with slightly moist H to give Cs and  $\text{CsOH}$ .

**CALCIUM** (vol. i. p. 663). The molecule in dilute solution in tin may be diatomic (v. Heycock & Neville, *C. J.* 57, 376 [1890]).

**Calcium, carbide of**. By heating 120 g.  $\text{CaCO}_3$  with 70 g. sugar charcoal in the electric furnace with a current of 350 amperes and 70 volts, Moissan (*C. R.* 118, 501 [1894]) obtained lustrous, yellow crystals of  $\text{CaC}_2$ ; S.G. 2.22 at 18°; insoluble in most solvents; reacts with  $\text{Cl}$ ,  $\text{Br}$ , and  $\text{I}$  at 250°–350°; burnt to  $\text{CaCO}_3$  by  $\text{O}$  at a red heat; interacts violently with water, giving off pure acetylene, and with steam giving  $\text{CaCO}_3$ ,  $\text{C}_2\text{H}_2$ , and  $\text{C}_2\text{H}_4$  (*abstract* in *C. J.* 66 [1], 313 [1894]).

**Calcium, oxide of** (vol. i. p. 666).  $\text{CaO}$  is unchanged at c. 1750° (Read, *C. J.* 65, 313 [1894]). According to Veley (*C. J.* 63, 821 [1893]; 66, 1 [1894]), dry  $\text{CaO}$  does not appreciably combine with dry  $\text{CO}_2$ ,  $\text{SO}_2$ , or  $\text{Cl}_2$  below 300°. Baker (*C. J.* 65, 611 [1894]) says that dry  $\text{CaO}$  does not react with dry  $\text{SO}_2$ , nor with dry  $\text{NH}_3$ . Moissan (*C. R.* 115, 1034 [1892]) obtained crystals of  $\text{CaO}$  by heating ordinary lime in the electric furnace.

**Calcium, oxychloride of** (vol. i. p. 666). Prepared by boiling  $\text{CaO}$  with conc.  $\text{CaCl}_2$ ; crystallises in thin, lustrous needles; decomposed by water, alcohol, &c.; dissolves in glycerin. Composition is probably  $3\text{CaO} \cdot \text{CaCl}_2 \cdot 15\text{aq}$  (Zahorsky, *Zeit. f. anorg. Chemie*, 3, 34 [1893]).

**Calcium, oxyiodide of**. By heating  $\text{CaO}$  with  $\text{CaI}_2$  in a sealed tube at 150° for 6 hours, Tassilly (*Bl. [3]* 9, 629 [1893]) obtained needles of  $\text{CaI}_2 \cdot 3\text{CaO} \cdot 18\text{aq}$ .

## CARBON (vol. i. p. 684).

**Diamond**. Moissan (*C. R.* 116, 218; 118, 320; *abstracts* in *C. J.* 64 [11], 275; 66 [11], 184 [1893 and 1894]) obtained grey-black carbonado by dissolving  $\text{C}$  in iron, heating to 2000°–3000°, and rapidly cooling the exterior by water or by plunging into a bath of melted lead; the liquid interior expands as it cools and produces a very high pressure. Diamond blackens, swells, and changes to graphite in the electric furnace (*M. C. R.* 117, 423 [1893]). For various reactions of diamond, v. Moissan (*C. R.* 116, 460; *abstract* in *C. J.* 64 [11], 319 [1893]).

**Graphite**. For accounts of graphites prepared in different ways, the compositions of the graphitic oxides obtained, and the H.F.s of these oxides, v. Berthelot & Petit (*C. R.* 110, 101, 106; *abstract* in *C. J.* 64, 448 [1890]). For the action of conc.  $\text{HNO}_3$  on various graphites, v. Luzi (*B.* 24, 4085; 26, 1412 [1892 and 1893]).

**Amorphous carbon**. Mixer (*Am. S.* [3] 45, 363; *abstract* in *C. J.* 61 [11], 671 [1893]) describes the interactions of charcoal and N, S, O, and the halogens. According to Ernst (*J. pr.* [2] 48, 31; *abstract* in *C. J.* 64 [11], 461 [1893]), the composition of the products of combustion of coke (CO and  $\text{CO}_2$ ) depends almost wholly on the temperature; the maximum formation of  $\text{CO}$  is at c. 700°, at 1,000°  $\text{CO}$  is the only product.

**Allotropy of carbon**. The following heats of combustion, and atomic volumes, are given by Petersen (*Z. P. C.* 8, 601 [1891]):—

	[C.O.].	At. volume.
Amorphous . . .	96,530 to 96,980	6.7 to 8
Graphite . . .	93,360	5.8
Diamond . . .	93,240 to 94,550	3.4

For the reactions of various forms of  $\text{C}$  with  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{H}_2\text{SO}_4$ , v. Wiesner (*M.* 13, 371; *abstract* in *C. J.* 62, 1273 [1892]); and with  $\text{HNO}_3$  and  $\text{KClO}_4$ , v. Schutzenberger (*C. R.* 111, 774; *abstract* in *C. J.* 60, 265 [1891]).

**Carbon, tetrabromide of** (vol. i. p. 688). Collie (*C. J.* 65, 262 [1891]) finds that very many compounds of carbon give  $\text{CBr}_4$  when heated with  $\text{NaOH}$  and  $\text{Br}$ .

**Carbon, bromochlorides of** (vol. i. p. 688). The three compounds  $\text{CBrCl}_3$ ,  $\text{CBr}_2\text{Cl}_2$ , and  $\text{CCl}_3\text{Br}$  are formed by heating  $\text{CHCl}_3$  and  $\text{Br}$  to 225° in a sealed tube (Besson, *C. R.* 114, 222 [1892]).

**Carbon, tetrafluoride of**,  $\text{CF}_4$ . Mol. w. 88.37. V.D. 44.6. Prepared by the direct union of  $\text{C}$  (purified lampblack) and  $\text{F}$  at the ordinary temperature; by the reaction of  $\text{F}$  with  $\text{CCl}_4$ , slightly heated, or with  $\text{CHCl}_3$  at 100°, or with  $\text{CHI}_3$  (Moissan, *C. R.* 110, 296, 951; *abstracts* in *C. J.* 58, 557, 944 [1890]); also by heating  $\text{AgF}$  with  $\text{CCl}_4$  to 220° in a sealed tube (Chabrie, *C. R.* 110, 279 [1890]). M. recommends to pass vapour of  $\text{CCl}_4$  over  $\text{AgF}$  at 195°–200°, to let the vapours pass through a serpentine tube kept at –23°, and to collect the gas over  $\text{Hg}$ ; the gas is kept in contact with fragments of caoutchouc (to remove  $\text{CCl}_4$ ), then shaken with absolute alcohol, in which it dissolves, and then expelled by heat, collected and shaken with  $\text{H}_2\text{SO}_4$  (to remove alcohol vapour); metal vessels must be used.  $\text{CF}_4$  is a colourless gas, liquefying at –75° and 760 mm. pressure, or at 20° under

a pressure of 4 atmos. Other fluorides seem to be formed along with  $\text{CF}_4$ ; Chabré (L.c.) says that  $\text{AgF}$  and  $\text{C}_2\text{F}_4$  yield  $\text{C}_2\text{F}_6$ .

Carbon; tetra-iodide of (vol. i. p. 689). Moissan (C. R. 113, 19; abstract in C. J. 60, 1420 [1891]) prepares  $\text{CI}_4$  by heating  $\text{CCl}_4$  (free from  $\text{CHCl}_3$ ) with excess of  $\text{HI}$  to  $90^\circ$  in a sealed tube, washing the crystals with  $\text{NaHSO}_4$  aq, drying, and slowly subliming *in vacuo*.  $\text{CI}_4$  reacts with  $\text{Cl}$  to form  $\text{CCl}_4$  and chlorides of  $\text{I}$ ; reduced to  $\text{CHI}_3$  by  $\text{H}$  at  $140^\circ$  (for other reactions v. M., L.c.).

Carbon monoxide (vol. i. p. 689). For some experiments on the sparking of  $\text{CO}$ , with the formation of brown solids, v. Berthelot (C. R. 110, 609) and Schutzeberger (C. R. 110, 560; abstracts in C. J. 58, 691 [1890]). Winkler (B. 24, 878 [1891]) finds that  $\text{CO}$  is reduced to  $\text{C}$ , at a full red heat, by  $\text{Mg}$ ; carbides of  $\text{Mg}$  are probably formed (cf. W., B. 23, 2612 [1890]).

Carbon dioxide (vol. i. p. 691). For S.H. of  $\text{CO}_2$ , v. Kurnakoff (J. R. 22, 493; abstract in C. J. 64 [11], 5 [1893]).  $\text{CO}_2$  is reduced by heating to redness with  $\text{Mg}$ , amorphous  $\text{C}$ , and some  $\text{CO}$  being formed (Winkler, B. 23, 2642; 24, 878 [1890-91]). Dry  $\text{CO}_2$  is said not to combine with dry  $\text{NH}_3$  (Hughes & Soddy, C. N. 69, 133).

Carbon, oxychloride of (vol. i. p. 692).  $\text{COCl}_2$  becomes viscid, but remains clear, at  $-75^\circ$  (Haase, B. 26, 1052 [1893]).

Carbon disulphide (vol. i. p. 693). The contractions observed when mixtures of  $\text{CS}_2$  and air are exploded show that the reaction is more complicated than is shown by the equation  $\text{CS}_2 + 3\text{O}_2 = \text{CO}_2 + 2\text{SO}_2$ ; the volume of  $\text{CO}_2$  formed is, practically, in accordance with the equation, but the volume of  $\text{SO}_2$  is smaller; some of the  $\text{N}$  of the air is oxidised (v. Podler, C. J. 57, 625 [1890]). By heating  $\text{CS}_2$  with excess of *aqua regia*, Schlagdenhauffen & Bloch (J. Ph. [5] 28, 241 [1893]) obtained  $\text{SO}(\text{OCCl}_2)\text{Cl}$ . Decomposition of  $\text{CS}_2$ , heated in dry  $\text{N}$ , begins at  $216^\circ$ , and explosion with  $\text{O}$  at a higher temperature (Baker, C. J. 65, 611 [1894]).

Tricarbon disulphide  $\text{C}_3\text{S}_2$ . B. von Lengyel (Z. 26, 2960 [1893]) obtained this compound by keeping the vapours of  $\text{CS}_2$  in an electric arc between  $\text{C}$  poles for some hours, filtering off the black substance formed, allowing the red filtrate to stand over  $\text{Cu}$  for 6 to 8 days, and evaporating in a current of dry air.  $\text{C}_3\text{S}_2$  is a deep-red liquid, B.G. 1-27389; the vapour, even in minute quantities, causes violent catarrh; can be distilled, with partial change to a black solid, at  $60^\circ$ - $70^\circ$  and reduced pressure; insoluble in water, but dissolved by  $\text{EtOH}$ ,  $\text{Et}_2\text{O}$ ,  $\text{CS}_2$ ,  $\text{CHCl}_3$ , or  $\text{C}_2\text{H}_6$ . A conc. solution in  $\text{CS}_2$  deposits a black solid; the same solid is formed by gently heating the liquid, if heating to  $100^\circ$ - $120^\circ$  is rapid the change is explosive. The black solid is probably a polymeride. A solution of  $\text{C}_3\text{S}_2$  in  $\text{CS}_2$  reacts with  $\text{Br}$  to form  $\text{C}_3\text{S}_2\text{Br}_2$ . (For other reactions, v. abstract in C. J. 66 [11], 91 [1894].)

Carbon, thiobromide of,  $\text{C}_3\text{S}_2\text{Br}_2$ ; formed by the action of  $\text{Br}$  on a solution of  $\text{C}_3\text{S}_2$  in  $\text{CS}_2$  (v. supra).

Carbon, thiochloride of (vol. i. p. 695). The polymeride of thio-carbonyl chloride has the molecular formula  $(\text{OSCl})_n$ , according to the

cryoscopic determinations of Carrara (v. supra, 12; abstract in C. J. 66 [11], 15 [1894]).

CEBIUM (vol. i. p. 723). For details regarding the preparation of  $\text{Ce}$  compounds free from compounds of  $\text{Di}$  and  $\text{La}$ , v. Schottländer (B. 28, 378 [1892]); also Bricout (C. R. 113, 146 [1894]).

Cerium, hydride of. According to Winkler (B. 24, 873 [1891]), a compound of  $\text{Ce}$  and  $\text{H}$ , probably  $\text{CeH}_3$ , is formed by reducing  $\text{CeO}_2$  by  $\text{Mg}$  in presence of  $\text{H}$ .

Cerium dioxide (vol. i. p. 725).  $\text{CeO}_2$  is unchanged at c.  $1750^\circ$  (Kead, C. J. 65, 813 [1894]).

CHLORHYDRIC ACID (vol. ii. p. 5). Biltz (Z. P. C. 10, 854 [1892]) finds that the V.D. at  $-77^\circ$  agrees with the formula  $\text{HCl}$ . Perkin (C. J. 55, 793, 795 [1889]) has determined M. M. of  $\text{HCl}$  aq and  $\text{HCl}$  in iso-amyl oxide; the values obtained for  $\text{HCl}$  in aq are c. double those for  $\text{HCl}$  in iso-amyl oxide. For measurements of the E.C. of  $\text{HCl}$  in different solvents, v. Kablukoff (Z. P. C. 4, 429 [1889]). For revised tables giving S.G. of  $\text{HCl}$  aq, v. Lunge & Marchlewski (Zeit. f. anorg. Chemie, 1891, 135).

For the relations between the number of molecules of  $\text{HCl}$  required to ppt. one mol of different chlorides, and the reduction of the freezing-points of solutions of the chlorides and of  $\text{HCl}$ , v. Engel (C. R. 117, 845; abstract in C. J. 66, 40 [1894]).

Bailey & Fowler (C. J. 53, 755 [1888]) find that when  $\text{HCl}$  stands over  $\text{P}_2\text{O}_5$  the gas is absorbed, with production of  $\text{POCl}_3$  and  $\text{HPO}_3$ ; and that when  $\text{HCl}$  and  $\text{O}$  stand over  $\text{Hg}$  an oxychloride, probably  $\text{Hg}_2\text{OCl}_2\text{H}_2\text{O}$ , is formed. Bijker (C. J. 65, 611 [1891]) states that dry  $\text{HCl}$  does not combine with dry  $\text{NH}_3$  when the gases are mixed.

CHLORINE (vol. ii. p. 10). For the S.G. of liquid chlorine from  $-80^\circ$  to  $77^\circ$ , and the vapour pressures from  $-88^\circ$  to  $146^\circ$ , v. Knietsch (A. 259, 100 [1890]). For the preparation of  $\text{Cl}$  for use in the laboratory, v. Klason (B. 23, 330; abstract in C. J. 53, 415 [1890]). Shenstone (C. J. 61, 445 [1892]) finds that  $\text{Cl}$  obtained by heating  $\text{PbCl}_2$  always contains some  $\text{HCl}$  and  $\text{O}$ , with water, and perhaps a trace of  $\text{N}$ .  $\text{Cl}$  expands when brought into sunlight. Richardson (P. M. [5] 32, 277 [1891]) has constructed an instrument wherein the expansion is used to measure the intensity of light. Baker (C. J. 65, 611 [1894]) found that no explosion occurred when a mixture of equal vols. of dry  $\text{Cl}$  and dry  $\text{H}$  was exposed to bright sunlight; and that after exposure to bright sunshine for two days, and to diffused light for two days, more than a quarter of the mixture remained unchanged.

Podler (C. J. 57, 618 [1890]) has examined the interaction of  $\text{Cl}$  and water in tropical sunlight; he finds that there is very little action, unless there is an extremely large excess of water. With very much water and little  $\text{Cl}$ , exposed to the full light of the sun in the hot season in India, the main reaction is  $2\text{H}_2\text{O} + 2\text{Cl}_2 + \text{Aq} = 4\text{HCl}$  aq +  $\text{O}_2$ ; with diffused sunlight  $\text{HCl}$  aq and  $\text{HClO}$  aq are formed at first, and finally  $\text{HCl}$  aq,  $\text{HClO}$  aq, and  $\text{O}_2$ . Harker (Z. P. C. 9, 673 [1892]), from an extended investigation of the explosion of mixtures of  $\text{Cl}$ ,  $\text{H}$ , and  $\text{O}$ , concluded that when there is insufficient  $\text{H}$  to

decomposition of the H between the Cl and O occurs; and that the product of the numbers of molecules of HCl and O, divided by the product of the numbers of molecules of H<sub>2</sub>O and Cl<sub>2</sub>, is a constant, or, in other words, that the law of Guldberg and Waage holds good. According to Gautier and Charpy (C. R. 113, 597 [1891]), there is no reaction between Mg or Zn and liquid Cl at the ordinary temperature, very little reaction with Fe or Ag, and rather more with Cu.

Chlorates (vol. i., p. 18). Spring and Prost (Bl. [3] 1, 340 [1893]) have determined the quantities of Cl obtained by decomposing by heat chlorates of Al, Ba, Cu, Pb, Hg, K, Ag, Na, and Zn; the amount of Cl varied from .02 p.c. from KClO<sub>3</sub> to 13.45 p.c. from Zn(ClO<sub>3</sub>)<sub>2</sub>.

Calcium chlorate. Dry Ca(ClO<sub>3</sub>)<sub>2</sub> melts between 300°-350°, having previously given off from 8 to 5 p.c. of its weight of O; the rate of evolution of O increases, at 330°, until c. 60 p.c. of the total O is given off, after which the rate decreases. For the quantities of O evolved, of Ca(ClO<sub>3</sub>)<sub>2</sub> decomposed, and of CaCl<sub>2</sub> and Ca(ClO<sub>2</sub>)<sub>2</sub> formed, v. abstract in C. J. 62, 1275 [1892].

Potassium chlorate. McLeod (C. J. 55, 184 [1890]) concluded from his experiments that when KClO<sub>3</sub> is heated with MnO<sub>2</sub> some KMnO<sub>4</sub> is formed and again decomposed (v. MANGANESE PEROXIDE, vol. iii. p. 183), and that Cl is always given off in this reaction. In 1893 (B. 26, 1790) Brunck stated that Cl is not given off when KClO<sub>3</sub> and MnO<sub>2</sub> are heated together, but that ozone is produced. McLeod (C. J. 65, 202 [1894]) has proved that Cl is produced in the reaction. Fowler and Grant (C. J. 57, 272 [1890]) have studied the influence of various oxides on the decomposition of KClO<sub>3</sub> (references are given to older memoirs); they support McLeod's view of the reaction with MnO<sub>2</sub>, and think that the oxides of Fe, Co, Cu, and Ni react similarly to MnO<sub>2</sub>; acidic oxides, such as V<sub>2</sub>O<sub>5</sub>, U<sub>2</sub>O<sub>5</sub>, and WO<sub>3</sub>, cause evolution of O accompanied by much Cl, a vanadate, uranate, or tungstate being also formed; powdered glass or sand also assists the reaction, but only when very finely divided (v. summary of conclusions, C. J. 57, 281-2). According to Thompson and Perry (C. J. 61, 925 [1892]), the main reaction which occurs when an intimate mixture of KClO<sub>3</sub> and iodine is heated is 2KClO<sub>3</sub> + I<sub>2</sub> = 2KIO<sub>3</sub> + Cl<sub>2</sub>, and some of the Cl reacts with unchanged I to form ICl and ICl<sub>3</sub>. Basset (C. J. 57, 760 [1890]) examined the reactions between KClO<sub>3</sub>, water, and iodine; he concluded that the main reaction, at 60°, in the presence of a very small quantity of HNO<sub>3</sub>, is as shown by the equation 6I<sub>2</sub> + 10KClO<sub>3</sub> + 6H<sub>2</sub>O + Aq = 6KHIO<sub>3</sub> + 4KClAq + 6HClAq; in evaporating the solution to dryness Cl was given off, and the results of several experiments led to the representation of the change produced by evaporation to dryness as 12KHIO<sub>3</sub> + 8KCl + 12HCl = 11KHIO<sub>3</sub> + 9KCl + 6H<sub>2</sub>O + ICl + ICl<sub>3</sub>HCl + 4Cl<sub>2</sub>. For determinations of the quantities of oxidising gases (Cl and oxides of Cl) removed by passing air through FClO<sub>3</sub>Aq mixed with HClAq, v. Pendlebury and McKillop (C. S. Proc. 1893-4, [No. 123] 211).

Strontium chlorate. For experiments on the

decomposition of this salt by heat, giving SrCl<sub>2</sub>, Sr(ClO<sub>3</sub>)<sub>2</sub>, and O, v. Potilitzin (J. R. 21, 451; abstract in C. J. 58, 698 [1890]).

CHROMIUM (vol. ii. p. 162). S.H. of pure Cr (0° to 99°) = 12162 (Jäger and Krüss, B. 22, 2028 [1889]). The at. w. of Cr was re-determined by Rawson in 1889 (C. J. 55, 219), by strongly heating (NH<sub>4</sub>)<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, measuring the N given off, and weighing the Cr<sub>2</sub>O<sub>3</sub> that remained; also by reducing (NH<sub>4</sub>)<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>Aq to CrCl<sub>3</sub>Aq by HClAq and alcohol, pp. by NH<sub>4</sub>Aq, and weighing Cr<sub>2</sub>O<sub>3</sub> produced; the mean value thus obtained was 52.06, or 51.98 reduced to 0° and a vacuum (O = 15.96). Menckie in 1891 (A. 261, 339; abstract in C. J. 60, 882 [1891]) re-determined the at. w. of Cr by estimating (1) Ag and Cr, and also O, in Ag<sub>2</sub>CrO<sub>4</sub> and in Ag<sub>2</sub>CrO<sub>4</sub>NH<sub>4</sub>, (2) O in K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, (3) Cr and Cr in (NH<sub>4</sub>)<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>; the extreme values, from thirty-six experiments, were 52.12 and 51.83; twenty-eight of the experiments gave values between 51.9 and 52. According to Prinz (C. R. 116, 392 [1893]), Cr crystallises in minute cubes with pyramidal faces. For the absorption spectra of salts of Cr, v. Lapraik (J. pr. [2] 47, 308 [1893]).

Preparation.—Glatzel (B. 23, 3127 [1890]) says that almost perfectly pure Cr can be obtained by reducing CrCl<sub>3</sub>KCl by Mg powder (for details v. abstract in C. J. 60, 152 [1891]). Huet (C. R. 115, 945 [1892]) prepares Cr by electrolysis a solution of Cr alum, containing an alkali sulphate and H<sub>2</sub>SO<sub>4</sub>. Moissan (C. R. 116, 349 [1893]) says that Cr can be obtained by reducing a mixture of Cr<sub>2</sub>O<sub>3</sub> and C in the electric furnace, using a current of 50 volts and 100 amperes, and then breaking up the product, which contains from 8.6 to 12.9 p.c. C, and heating it, mixed with more Cr<sub>2</sub>O<sub>3</sub>, again in the electric furnace in a carbon crucible.

Chromic acid (vol. ii. p. 54). Miss Field (C. J. 61, 405 [1892]) has found that only Cr<sub>2</sub>O<sub>3</sub> is obtained by working according to Moissan's directions for preparing H<sub>2</sub>CrO<sub>4</sub>. Determinations of the increase in the b.p. of water caused by solution of Cr<sub>2</sub>O<sub>3</sub> led to the conclusion that an aqueous solution of Cr<sub>2</sub>O<sub>3</sub> contains some H<sub>2</sub>CrO<sub>4</sub>, and probably also H<sub>2</sub>CrO<sub>3</sub>.

Chromic bromide CrBr<sub>3</sub> (vol. ii. p. 161). Recoura (C. R. 110, 1029, 1193) obtained green CrBr<sub>3</sub>·6H<sub>2</sub>O by boiling saturated CrO<sub>3</sub>Aq with a large excess of HBrAq and concentrating; deliquescent crystals, soluble alcohol, insoluble ether. Unchanged when kept solid, but solution soon becomes blue and then violet, with rise of temperature. By boiling a green solution, then saturating with HBr while cold, filtering, and drying the pp. thus formed on porous plates, crystals of the blue variety, CrBr<sub>3</sub>·6H<sub>2</sub>O, were obtained; very soluble water, insol. alcohol. Heat of solution of blue crystals = 28,700; and of green = 13,600. The blue solid changed to the green at 100°. (For more details v. abstract in C. J. 58, 1063 [1890].)

Chromic chloride CrCl<sub>3</sub> (vol. ii. p. 161). Marchetti (G. 22 [11], 375 [1892]) finds that the molecular lowering of the freezing-point of water by the violet form of CrCl<sub>3</sub> is considerably greater than that caused by the green form.

Chromic fluoride, CrF<sub>3</sub> (vol. ii. p. 162). Fabrig (G. 20, 582 [1890]) obtained CrF<sub>3</sub>·9H<sub>2</sub>O as a green crystalline pp., by adding excess c

$\text{NH}_4\text{FAq}$  gradually to a cold solution of violet  $\text{Cr}_2(\text{SO}_4)_3$ . Slightly sol. water; insoluble  $\text{NH}_4\text{FAq}$  or alcohol; heating in air leaves  $\text{Cr}_2\text{O}_3$ . Poulenc (*C. R.* 116, 253 [1893]) obtained  $\text{CrF}_3$  in green crystals by heating  $\text{CrCl}_3$ ,  $\text{Cr}_2\text{O}_3$ , or  $\text{CrF}_3 \cdot x\text{H}_2\text{O}$  in  $\text{HF}$ .

**Chromous fluoride.** According to Poulenc (*l.c.*),  $\text{CrF}_2$  is formed by heating  $\text{Cr}$  to redness in  $\text{HF}$ , or by the interaction of  $\text{CrCl}_3$  and  $\text{HF}$  at the ordinary temperature.  $\text{CrF}_2$ , after fusion, is described as a transparent, green, crystalline mass; S.G. 4.11; slightly sol. water, insol. alcohol. Heated in air it gives  $\text{Cr}_2\text{O}_3$ . (For more details *v. abstract in C. J.* 64 [11], 281 [1893].)

**Chromic oxide**  $\text{Cr}_2\text{O}_3$  (vol. ii. p. 464). Moissan (*C. R.* 115, 1034 [1892]) found that  $\text{Cr}_2\text{O}_3$  melted to a black mass, dotted with black crystals, in an electric furnace, using a current of 55 volts and 30 amperes.

**Chromium trioxide**  $\text{CrO}_3$  (vol. ii. p. 164). For action of water *v. CHROMIC ACID*, p. 905. Reduced to  $\text{Cr}_2\text{O}_3$  by  $\text{NO}$  at the ordinary temperature (Senderens *a. Sabatier, C. R.* 114, 1476 [1892]). For the reaction of  $\text{CrO}_3\text{Aq}$  with  $\text{Q}$  and  $\text{BaO}_2\text{H}_2\text{Aq}$ —said to give a ppt. approximately  $\text{BaCrO}_4$ —*v. Pichard, C. R.* 113, 39 (*abstract in C. J.* 60, 1431 [1891]).

**Chromium salts** (vol. ii. p. 167). According to Recoura (*C. R.* 112, 1439; *abstract in C. J.* 60, 1430 [1891]), the green solutions obtained by heating solutions of the normal violet chromic salts contain free acid and a soluble basic salt; in the case of the sulphate this soluble basic salt is said to be  $2\text{Cr}_2\text{O}_3 \cdot 5\text{SO}_4$ . For preparation of green soluble normal sulphates *v. Recoura, C. R.* 112, 857 (*abstract in C. J.* 62, 411 [1892]).

**CHROM-AMMONIUM COMPOUNDS** (vol. ii. p. 158). Petersen (*Z. P. C.* 10, 580 [1892]) finds, by cryoscopic determinations, that the formulae usually assigned to the chief salts of this class are probably molecular. For a discussion of the constitution of these salts *v. Jørgensen (J. pr.* [2] 42, 206; 45, 274).

**CHROMATES; and derivatives** (vol. iit p. 154).

**Ammonium chromates.** According to Jäger *a. Krüss (B.* 22, 2028 [1889]), normal ammonium chromate has not hitherto been obtained pure; they prepare the pure salt by adding excess of  $\text{NH}_3\text{Aq}$  S.G. 9 to  $\text{CrO}_3\text{Aq}$  free from  $\text{H}_2\text{SO}_4\text{Aq}$ , warming until the solid that separates dissolves, and placing in a freezing mixture.  $(\text{NH}_4)_2\text{Cr}_2\text{O}_7$  crystallizes in long, monosymmetric, golden needles, *a:b:c* = 1.9603:1.24452; S.G. 1.886 at 11°.

**Ammonium trichromate**  $(\text{NH}_4)_3\text{Cr}_2\text{O}_7$  is prepared by J. a. K. (*l.c.*) by dissolving  $(\text{NH}_4)_2\text{Cr}_2\text{O}_7$  in hot conc.  $\text{CrO}_3\text{Aq}$ , concentrating, and drying at 100° the fed crystals that separate on cooling; S.G. 2.342 at 13°; explodes at 190°, giving off  $\text{NO}_2$  and leaving  $\text{Cr}_2\text{O}_3$ .

**Ammonium tetrachromate**  $(\text{NH}_4)_4\text{Cr}_2\text{O}_7$  is formed by dissolving the trichromate in warm  $\text{HNO}_3\text{Aq}$  S.G. 1.09, and letting cool slowly; S.G. 2.343 at 10°; melts at 170°, and suddenly decomposes at 175°, giving off  $\text{NO}$  and leaving  $\text{Cr}_2\text{O}_3$ . J. a. K. (*l.c.*) failed to obtain hexachromate; they say that no nitro-chromates are obtained by treating ammonium chromates with  $\text{HNO}_3\text{Aq}$ . (For more details *v. abstract in C. J.* 56, 1117 [1889].) Various double compounds of

$(\text{NH}_4)_2\text{Cr}_2\text{O}_7$  with  $\text{HgCl}_2$  are described by J. a. K. (*l.c.*).

**Ceric dichromate**  $\text{CeO}_2 \cdot 2\text{Cr}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ . Prepared by passing a current of 2.5 to 3 volts through a slightly acid solution formed by dissolving  $\text{Ce}_2(\text{SO}_4)_3$  in  $\text{CrO}_3\text{Aq}$ ; insoluble water; boiling water forms yellow  $\text{Ce}(\text{CrO}_4)_2$ , and then  $\text{CeO}_2 \cdot x\text{H}_2\text{O}$  (Bricout, *C. R.* 118, 145 [1894]).

**Lead chromates.** For double compounds of  $\text{PbCrO}_4$  with  $\text{Li}_2\text{CrO}_4$ ,  $\text{K}_2\text{CrO}_4$ , and  $\text{Na}_2\text{CrO}_4$ , *v. Lachaud a. Lepierre, C. R.* 110, 1035 (*abstract in C. J.* 58, 1065 [1890]).

**Mercury chromates.** For basic mercuric chromates and a double compound of  $\text{HgCrO}_4$  with  $\text{NH}_4\text{HgCl}$  *v. Jäger a. Krüss, B.* 22, 2028 (*abstract in C. J.* 56, 1120 [1889]).

**Potassium chromates.** Jäger *a. Krüss (l.c.)* prepare potassium trichromate  $\text{K}_2\text{Cr}_2\text{O}_7$  by treating  $\text{K}_2\text{Cr}_2\text{O}_7$  with  $\text{HNO}_3\text{Aq}$  S.G. 1.19, pouring off from  $\text{KNO}_3$  that separates, and crystallizing; S.G. 2.648 at 11°.  $\text{K}_2\text{Cr}_2\text{O}_7$  is quickly decomposed by water to  $\text{CrO}_3\text{Aq}$  and  $\text{K}_2\text{CrO}_4\text{Aq}$ ; melts at 250°. Potassium tetrachromate  $\text{K}_4\text{Cr}_2\text{O}_7$  is prepared by J. a. K. (*l.c.*) by dissolving  $\text{K}_2\text{Cr}_2\text{O}_7$  in hot conc.  $\text{HNO}_3\text{Aq}$  S.G. 1.41; S.G. 2.649 at 11°; not deliquescent; decomposed by water; crystallizes unchanged from  $\text{HNO}_3\text{Aq}$  S.G. 1.41. Schmidt (*B.* 25, 2917 [1893]) says that no nitrochromate is obtained by the action of  $\text{HNO}_3\text{Aq}$  on  $\text{K}_2\text{Cr}_2\text{O}_7$ ; the substances obtained by Darmstadtler (*v. vol. ii. p. 158*) were mixtures of  $\text{KNO}_3$  and  $\text{K}_2\text{Cr}_2\text{O}_7$ .

**Silver chromates.** Pure silver chromate  $\text{Ag}_2\text{CrO}_4$  is prepared by J. a. K. (*l.c.*) by repeatedly boiling  $\text{Ag}_2\text{CrO}_4$  with water as long as anything dissolves; it is a deep-green solid, insol. water.

**Sodium perchromate.** Häussermann (*J. pr.* [2] 48, 70; *abstract in C. J.* 64 [11], 471) describes a salt  $\text{Na}_2\text{Cr}_2\text{O}_7 \cdot 2\text{Naq}$ , prepared by adding  $\text{Na}_2\text{O}_2$  to a thin paste of  $\text{CrO}_3\text{H}$  and water, kept at 10°–20°.

**Thallium chromates.** For preparation of  $\text{Tl}_2\text{CrO}_4$  and the double compound  $\text{Tl}_2\text{CrO}_4 \cdot \text{K}_2\text{CrO}_4$ , *v. Lachaud a. Lepierre, Bl.* [3] 6, 232 (*abstract in C. J.* 62, 467 [1892]).

**Uranium chromates.** For double uranyl chromates *v. Formánek, A.* 257, 102 (*abstract in C. J.* 58, 852 [1890]).

**IODOCHROMATES** (vol. ii. p. 157). A series of salts of the forms  $\text{IO}_3 \cdot \text{O} \cdot \text{CrO}_3 \cdot \text{OM}^+$  and  $(\text{IO}_3 \cdot \text{O} \cdot \text{CrO}_3 \cdot \text{O}) \cdot \text{M}^{++}$  has been obtained by Berg (*C. R.* 104, 1511 [1887]; 111, 42 [1890]);  $\text{M}^+ = \text{NH}_4$ ,  $\text{Li}$ ,  $\text{K}$ ,  $\text{Ag}$ , and  $\text{Na}$ ;  $\text{M}^{++} = \text{Co}$ ,  $\text{Cu}$ ,  $\text{Mg}$ , and  $\text{Ni}$ . Most of the alkali salts were formed by dissolving the alkali iodate in excess of  $\text{CrO}_3\text{Aq}$  and crystallizing; the other salts were usually prepared by dissolving the oxide or carbonate of the metal in excess of  $\text{CrO}_3\text{Aq}$  and adding  $\text{HIO}_3\text{Aq}$ . (For details *v. abstracts in C. J.* 55, 976 [1887]; 58, 1378 [1890].)

**PHOSPHOCHROMATES.** By adding conc.  $\text{H}_3\text{PO}_4\text{Aq}$  +  $\text{CrO}_3\text{Aq}$  to  $\text{K}_2\text{CO}_3\text{Aq}$ , Blondel (*C. R.* 115, 194; *abstract in C. J.* 66 [11], 193 [1894]) obtained compounds of the form  $m\text{K}_2\text{O} \cdot p\text{P}_2\text{O}_5 \cdot n\text{CrO}_3 \cdot x\text{aq}$ ,  $m$  being 2 and 3,  $n$  4 and 8, and  $x$  being 0 or 1.

**SULFOCHROMATES.** In 1882 Cross *a. Higginf* described a compound of  $\text{Cr}_2\text{O}_3$ ,  $\text{SO}_3$ , and  $\text{H}_2\text{O}$  (*C. J.* 51, 113), and also compounds of  $\text{Cr}_2\text{O}_3$ ,  $\text{SO}_3$ ,  $\text{K}_2\text{O}$  and  $\text{H}_2\text{O}$ . Recoura (*C. R.* 114, 477

[1892]; 116, 1367; 117, 37, 101 [1893]) has made a more complete examination of these and allied compounds. By evaporating, at  $100^{\circ}$ , solutions containing violet  $\text{Cr}_2(\text{SO}_4)_3$  and  $\text{H}_2\text{SO}_4$  in the molecular ratio 1:1, 1:2, and 1:3, he obtained chromosulphuric acid  $\text{H}_2\text{Cr}_2(\text{SO}_4)_4$ , chromodisulphuric acid  $\text{H}_2\text{Cr}_2(\text{SO}_4)_5$ , and chromotrisulphuric acid  $\text{H}_2\text{Cr}_2(\text{SO}_4)_6$ ; by using various sulphates in place of  $\text{H}_2\text{SO}_4$ , he obtained chromosulphates, chromodisulphates, and chromotrisulphates. The acids are green powders, easily sol. in water; they gradually decompose in solution; dilute  $\text{BaCl}_2$  aq. ppt. Ba chromosulphates, but conc.  $\text{BaCl}_2$  aq. gives  $\text{BaSO}_4$ . R. obtained chromopyrosulphuric acid  $\text{Cr}(\text{OH})(\text{S}_2\text{O}_8)_2$  by evaporating a solution of  $\text{Cr}_2(\text{SO}_4)_3$  and  $\text{H}_2\text{SO}_4$  in the molecular ratio 1:5, at  $100^{\circ}$ , and heating the dark-green syrupy liquid so obtained to  $140^{\circ}$ – $115^{\circ}$  for some days. The acid forms brittle, transparent, pale-green laminae. Salts of the form  $\text{Cr}_2(\text{S}_2\text{O}_8)_2(\text{OM})_2$  are obtained by adding alkalis to the acid in solution; these salts R. calls pyrosulphochromites. By adding conc.  $\text{HCl}$  aq. or  $\text{H}_2\text{SO}_4$  to a solution of chromopyrosulphuric acid, R. obtained a compound  $\text{Cr}_2(\text{OH})(\text{S}_2\text{O}_8)_2$ , pyrosulphochromic hydrate, isomeric with chromosulphuric acid  $\text{Cr}_2(\text{SO}_4)_3 \cdot \text{H}_2\text{O}$ . (For more details v. abstracts in *C. J.* 62, 783 [1892]; 64 [11], 470, 528 [1893].)

**COBALT**, vol. ii. p. 217. Winkler has re-determined at. w. of Co, (1) by dissolving electrolytically deposited Co in  $\text{HCl}$  aq., evaporating to dryness, and determining Cl in the  $\text{CoCl}_2$  obtained (*Zeit. f. anorg. Chemie*, 4, 10 [1893]); (2) by finding the quantity of Ag deposited from solution of  $\text{Ag}_2\text{SO}_4$  by electrolytically deposited Co (l.c. p. 462). The values obtained were 51.1 about 59.6 ( $\text{Ag} = 107.66$ ).

*Alleged decomposition of cobalt.* Krüss a. Schmidt (*B. 22*, 11, 2026 [1889]) supposed they had separated Ni into two constituents, (r. vol. iii. p. 500); and they thought that Co also was probably not a homogeneous substance. Remmler, in 1893, obtained a number of specimens of  $\text{Co}_2\text{O}_3$  by pptg.  $\text{CoCl}_2$  aq. by  $\text{KOH}$  aq. and Br water, treating the pp. with  $\text{NH}_4\text{Ag}$ , which gradually dissolves it, decanting off the ammoniacal solution at intervals during 9 months, evaporating each and heating in  $\text{CO}_2$ ; the different specimens of  $\text{Co}_2\text{O}_3$  were heated in H, and the quantity of Co obtained in each case was determined. The values thus obtained for the at. w. of Co varied from 59.53 to 58.3. R. concluded that Co purified by the ordinary methods is not a homogeneous substance. Winkler's determinations of the at. w. (v. *supra*), however, gave very constant values.

*Reactions.*—Heated in  $\text{NO}$  to  $750^{\circ}$ , CoO is formed (Sabatier a. Senderens, *C. R.* 114, 1429 [1892]); finely divided Co burns in  $\text{NO}_2$  at the ordinary temperature, giving  $\text{Co}_2\text{O}_3$ ; but if  $\text{NO}_2$  is largely diluted with N, a black compound is formed,  $\text{Co}_2\text{NO}_2$ , called by S. a. S. (*C. R.* 115, 236 [1892]) *nitro-cobalt*. This compound reacts rapidly with  $\text{H}_2\text{O}$ , giving off  $\text{NO}$ , and forming a solution containing  $\text{Co}(\text{NO}_2)_2$ , with a very little  $\text{Co}(\text{NO}_3)_2$ , Co remaining insoluble, and sometimes also a basic nitrite; when heated in  $\text{N}_2$  oxides of N are given off and then rapid decomposition occurs with formation of Co and oxides of Co, when mixed with combustible substances,  $\text{Co}_2\text{NO}_2$

explodes (S. a. S. *ibid.* [3], v. 609 [1893]). Montemartini (*G. 22* [1], 250) finds that the gases produced by the interaction of Co and excess of  $\text{HNO}_3$  aq. (27.5 p.c.) are  $\text{NH}_3$ ,  $\text{N}_2\text{O}$ , and N (v. abstract in *C. J.* 62, 1278 [1892]).

**Cobalt chloride** (vol. ii. p. 219). For the solubility of  $\text{CoCl}_2$  in water, and the changes of colour produced by digesting the solution, with a discussion of the hydrations and dehydrations that accompany these changes, v. Etard, *C. R.* 113, 609 (abstract in *C. J.* 62, 378 [1892]); Engel, *Bl.* [3] 239 (abstract in *C. J.* 62, 569 [1892]); and Potilizin, *Bl.* [3] 6, 264 (abstract in *C. J.*, l.c. p. 571). The double compounds  $\text{CoCl}_2 \cdot \text{HCl}$  3aq.,  $\text{CoCl}_2 \cdot \text{LiCl}$  3aq., and  $\text{CoCl}_2 \cdot \text{NH}_4\text{Cl}$  6aq. are described by Chassevant (*J. Ch.* [6] 30, 5 [1893]).

**Cobalt fluoride** (vol. ii. p. 220). Pouleno (*C. R.* 114, 1426; v. abstract in *C. J.* 62, 1159 [1892]) prepares  $\text{CoF}_3$  by heating  $\text{CoCl}_2$  with excess of  $\text{NH}_4\text{F}$  for 15 minutes, and repeatedly washing the double fluoride  $\text{CoF}_2 \cdot 2\text{NH}_4\text{F}$  thus obtained with boiling alcohol. By heating  $\text{CoF}_3$  to  $1200^{\circ}$ – $1300^{\circ}$  in  $\text{HF}$ , the salt is obtained in small, rose-red prisms; S.G. 4.13. The double compound  $\text{CoCl}_2 \cdot 2\text{KF}$  is formed by heating  $\text{CoCl}_2$  with  $\text{KHF}_2$  (l.c. p. 746; abstract, l.c. p. 781).

**Cobalt iodide** (vol. ii. p. 220). For solubility in water of  $\text{CoI}_2$ , and the formation of various hydrates attending solution, v. Etard, *C. R.* 113, 639 (abstract in *C. J.* 62, 278 [1892]).

**Cobaltous oxide**  $\text{CoO}$  (vol. ii. p. 220). This oxide melts in the electric furnace, and forms rose-coloured crystals (Moissan, *C. R.* 115, 1034 [1892]).

**Cobaltous hydroxide**  $\text{CoO} \cdot \text{H}_2\text{O}$  (vol. ii. p. 220). A. de Schulten (*C. R.* 109, 266 [1889]) obtained this compound in microscopic, brownish-red, four-sided prisms, S.G. 3.597 n° 15°, by heating 10 g.  $\text{CoCl}_2$  6aq. in 60 c.c. water with 250 g.  $\text{KOH}$ , in a flask filled with con-gas, letting stand for 24 hours, and washing away the lighter amorphous products of the reaction.

**Cobalto-cobaltic oxides** (vol. ii. p. 221). Regarding  $\text{Co}_2\text{O}_3$  and oxides intermediate between this and  $\text{Co}_3\text{O}_4$ , v. Schröder, *C. R.* 1890, [1] 931 (abstract in *C. J.* 58, 1213 [1890]).  $\text{Co}_2\text{O}_3$  heated to c.  $1750^{\circ}$  loses all its O, and leaves Co (Read, *C. J.* 65, 313 [1891]).

**Cobalt, dioxide of.** By the reaction of  $\text{IAg}$  and  $\text{NaOH}$  aq. on  $\text{CoSO}_4$  aq., filtering, and acidifying with acetic acid, Vortmann (*B. 24*, 2741, abstract in *C. J.* 60, 1429 [1891]) obtained a greenish-black pp. nearly agreeing with the formula  $\text{Co}_2\text{O}_3$ . For compounds of  $\text{Co}_2\text{O}_3$  with  $\text{BaO}$  v. Roussan, *C. R.* 104, 614 (abstract in *C. J.* 56, 1115 [1889]).

**Cobalt, salts of** (vol. ii. p. 221). Marshall (*C. J.* 59, 760 [1891]) has prepared the salts  $\text{Co}_2(\text{NO}_3)_4$ , 18aq. and  $\text{Co}_2(\text{C}_2\text{O}_4)_3 \cdot 3(\text{NH}_4)_2\text{C}_2\text{O}_4$  6aq. by electrolyzing a solution of  $\text{CoSO}_4$  in  $\text{H}_2\text{SO}_4$  aq. and of  $\text{Co}_2\text{O}_3$  aq. containing  $(\text{NH}_4)_2\text{C}_2\text{O}_4$ .

**COBALTAMMINES** (vol. ii. p. 222). By cryoscopic determinations, Petersen (*Z. P. C.* 10, 580 [1892]) concludes that the formulae generally given to the chief cobaltamines are molecular. For a discussion of the constitution of these compounds, v. Jørgensen (*J. pr.* [2] 41, 429, 440 [1890]; 42, 206; 45, 274 [1891–92]). For various octamines, v. Vortmann a. Blasberg (*B. 22*, 2649), and V. a. Magdeburg (*B. 22*,

2680; *abstracts* in *C. J.* 58, 14 [1890]. V. a. Morgulis (*B.* 22, 2644; *abstract* in *C. J.* 58, 13 [1890]), describe several *mercuricobaltammines*. A number of *croceo-, luteo-, and xantho-salts*, and also several *flavo-salts* isomeric with the *croceo-salts*, are described by Jørgensen in *Zeit. f. anorg. Chemie*, 5, 147 (*abstract* in *C. J.* 65 [11], 50 [1894]).

**COPPER** (vol. ii. p. 251). An elaborate investigation of the at. w. of Cu has been made by Richards, *P. Am. A.* 26, 240 [1891] (*v. C. N.* 65, 236, &c.; *abstract* in *C. J.* 64 [11], 12 [1893]).  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  was analysed and synthesised, and  $\text{CuO}$  was analysed; the final value obtained by R. is 63.604 ( $Q = 16$ ), or 63.44 ( $O = 15.96$ ). The molecule of Cu in dilute solution in tin is probably monatomic (Heycock & Neville, *C. J.* 57, 376 [1890]). For the absorption spectra of solutions of  $\text{CuCl}_2$ ,  $\text{CuSO}_4$ , and  $\text{Cu}(\text{NO}_3)_2$ , v. Evan, *P. M.* [5] 33, 317 (*abstract* in *C. J.* 64 [11], 149 [1893]).

**Preparation.**—For the preparation by electrolysis of pure copper v. Richards (*P. Am. A.* 25, 199, 206 [1890]).

**Reactions.**—Heated in the electric furnace, using a current of 70 volts and 350 amperes, Cu rapidly volatilises, and the vapour forms  $\text{CuO}$  in the air (Moissan, *C. R.* 116, 1429 [1893]). According to Neumann (*M.* 13, 40 [1893]), the H occluded in Cu prepared by reducing  $\text{CuO}$  by H, cannot be wholly expelled by heating in a stream of  $\text{CO}_2$ ; some of the  $\text{CO}_2$  is also absorbed by the Cu. N. also says that Cu reduced by vapour of  $\text{MeOH}$  or  $\text{EtOH}$ , or by coal gas, retains very small traces of C and H after being heated to  $220^\circ$ . Montemartini (*G.* 22, 384, 377, 426 [1892]) says that the reaction between Cu and  $\text{HNO}_3$  aq of less than 30 p.c. produces  $\text{Cu}(\text{NO}_3)_2$  and  $\text{HNO}_2$ , the  $\text{HNO}_2$  then decomposing to  $\text{HNO}$ ,  $\text{NO}$ , and  $\text{H}_2\text{O}$ ; with acid more conc. than 30 p.c.  $\text{HNO}_3$ , some  $\text{NO}$  is produced with a little  $\text{N}_2\text{O}$ , and with 70 p.c. acid only  $\text{NO}$  is given off; no appreciable quantity of  $\text{NH}_3$  is produced with acid from 3 to 27.5 p.c.  $\text{HNO}_3$ . According to Freer & Higley (*Am.* 15, 71 [1893]), the only gaseous products of the reaction of Cu with excess of  $\text{HNO}_3$  aq S.G. 1.4 (c. 65 p.c.  $\text{HNO}_3$ ) are  $\text{NO}_2$  and  $\text{N}_2\text{O}$ , c. 90 p.c.  $\text{NO}_2$  and 10 p.c.  $\text{N}_2\text{O}$ . Cu is superficially oxidised in  $\text{NO}$  at a dull red heat (Sabatier & Senderens, *C. R.* 114, 1429 [1892]). Reduced Cu absorbs  $\text{NO}_2$  at the ordinary temperature, forming a brownish powder  $\text{Cu}_2\text{NO}_2$  (S. a. S., *C. R.* 115, 236 [1893]). For the reactions of this nitro-copper v. S. a. S., *C. R.* 116, 756 (*abstract* in *C. J.* 64 [11], 874 [1893]).

**Copper, alloys of** (vol. i. p. 253). For a description of alloys of Cu with  $\text{O}_2$ , Sn, and Zn, prepared by immersing plates of Cd, Sn, or Zn, in solutions of salts of Cu, v. Mylius & Fromm, *B.* 27, 630 (*abstract* in *C. J.* 65 [11], 235 [1894]).

**Cupric bromide** (vol. ii. p. 254). According to Sabatier (*C. R.* 118, 980 [1891]), the green crystals that separate from  $\text{CuBr}_2$  aq are  $\text{CuBr}_2 \cdot 2\text{aq}$ . A solution of  $\text{CuBr}_2$  in conc.  $\text{HBr}$  aq has an intense purple colour which becomes less marked on dilution, but even with 0.015 mgm. Cu in solution the colour can be detected (S., *l.c.*) The double salts  $\text{CuBr}_2 \cdot \text{CsBr}$  and  $\text{CuBr}_2 \cdot 2\text{CsBr}$  are described by Wells & Walden

(*Zeit. f. anorg. Chem.*, 6, 304; *abstract* in *C. J.* 66 [11], 47 [1894]).

**Cupric chloride** (vol. ii. p. 255). Tsuchanoff (*J. R.* 25, 151; *abstract* in *C. J.* 66 [11], 47 [1894]) finds that the E.C. of dilute blue-coloured  $\text{CuCl}_2$  aq increases with increase of concentration to a maximum, after which it decreases while the colour changes to yellowish-brown. For heats of solution and dilution of  $\text{CuCl}_2 \cdot 2\text{aq}$ , v. Reichert & Deventer (*Z. P. C.* 5, 559 [1890]).

**Double salts.**— $\text{CuCl}_2 \cdot \text{HCl}$ , 3aq,  $\text{CuCl}_2 \cdot \text{LiCl}$ , 2aq,  $\text{CuCl}_2 \cdot \text{NH}_4\text{Cl}$ ,  $\text{CuCl}_2 \cdot 2\text{NH}_4\text{Cl}$ , 2aq,  $\text{CuCl}_2 \cdot \text{KCl}$ , and  $\text{CuCl}_2 \cdot 2\text{KCl}$ , 2aq (Chassevant, *Ch.* [6] 80, 5 [1893]);  $\text{CuCl}_2 \cdot \text{CsCl}$ ,  $\text{CuCl}_2 \cdot 2\text{CsCl}$ , 2aq ( $x = 0$  and 2), and  $2\text{CuCl}_2 \cdot 3\text{CsCl}$  (Wells & Dupree, *Zeit. f. anorg. Chemie*, 5, 300 [1893]).

**Cuprous chloride** (vol. ii. p. 255). Wells (*l.c.*, p. 306) describes the double salts  $2\text{CuCl} \cdot \text{CsCl}$ ,  $2\text{CuCl} \cdot 3\text{CsCl}$ , and  $\text{CuCl} \cdot 3\text{CsCl}$  aq.

**Cupric fluoride** (vol. ii. p. 256). Poulenc (*C. R.* 116, 1446; *abstract* in *C. J.* 64 [11], 525 [1893]) prepares  $\text{CuF}_2$ , as a white amorphous powder, by heating  $\text{NH}_4\text{F}$  with  $\text{CuF}_2 \cdot 2\text{aq}$ ; by heating in  $\text{HF}$  at  $500^\circ$  (not above) the  $\text{CuF}_2$  becomes crystalline. Crystalline  $\text{CuF}_2$  is also obtained by heating  $\text{CuO}$ , or  $\text{CuF}_2 \cdot 2\text{aq}$ , in  $\text{HF}$  at  $400^\circ$  (P., *l.c.*). Heated to  $800^\circ$  in air  $\text{CuO}$  is formed; heating in steam gives  $\text{CuO}$  and  $\text{HF}$ ;  $\text{H}_2\text{S}$  forms  $\text{CuS}$  and  $\text{HF}$ ;  $\text{HCl}$  forms  $\text{CuCl}_2$ .  $\text{CuF}_2$  absorbs water from the air, and becomes blue. H. von Helmholtz (*Zeit. f. anorg. Chemie*, 3, 115 [1892]) describes the double salts  $\text{CuF}_2 \cdot \text{KF}$ ,  $\text{CuF}_2 \cdot \text{RbF}$ ,  $\text{CuF}_2 \cdot \text{AmF}$ , 2aq, and  $\text{CuF}_2 \cdot 2\text{AmF}$ , 2aq.

**Cuprous fluoride** (vol. ii. p. 256). According to Mauro (*Real. Acad. Lincei*, 1892 [1], 194; *abstract* in *C. J.* 64 [11], 124 [1893]),  $\text{Cu}_2\text{F}_2$  does not exist, and the substance obtained by Berzelius was almost certainly merely impure copper. Poulenc, however (*C. R.* 116, 1446; *abstract* in *C. J.* 64 [11], 525 [1893]), says that  $\text{Cu}_2\text{F}_2$  is formed by heating  $\text{Cu}_2\text{Cl}_2$  to dull redness in  $\text{HF}$  (the action is not complete until  $1100^\circ$ – $1200^\circ$ ); also by heating  $\text{CuF}_2$  in  $\text{HF}$  at c.  $600^\circ$ , raising the temperature to  $1100^\circ$ – $1200^\circ$  towards the end of the reaction. P. describes  $\text{Cu}_2\text{F}_2$  that has been fused as a ruby-red, transparent solid, with a crystalline fracture; exposed to moist air it changes to  $\text{CuF}_2 \cdot \text{aq}$ ; it is easily reduced by H at a red heat.

**Cuprous iodide** (vol. ii. p. 256). Brun (*G. R.* 114, 667; *abstract* in *C. J.* 62, 1157 [1893]) describes double compounds with  $(\text{NH}_4)_2\text{S}_2\text{O}_8$  and  $\text{NH}_4\text{I}$ , and also with  $(\text{NH}_4)_2\text{S}_2\text{O}_8$  and  $\text{Cu}_2\text{S}_2\text{O}_8$ .

**Cuprous oxide** (vol. ii. p. 258). Russell (*C. N.* 62, 308 [1893]) prepares  $\text{Cu}_2\text{O}$  by completely reducing  $\text{Cu}_2\text{NO}$  aq mixed with excess of  $\text{NaCl}$  by  $\text{SO}_2$ , heating till excess of  $\text{SO}_2$  is removed, and then ppg. by  $\text{Na}_2\text{CO}_3$ , added solid at the hot solution. With  $\text{HFA}$ ,  $\text{CuF}_2$  aq and Cu are formed (Poulenc, *C. R.* 116, 1446 [1893]).

**Cupric oxide** (vol. ii. p. 258). Moissan (*C. R.* 115, 1034 [1893]) says that  $\text{CuO}$  is entirely decomposed in the electric furnace at c.  $2500^\circ$ , yielding Cu and a crystalline compound of  $\text{CuO}$  and  $\text{CaO}$  (the reaction was effected in a block of  $\text{CaO}$ ). By heating  $\text{CuO}$  to whiteness, in a Metcher injector-furnace, in an oxidising atmosphere, Bailey & Hopkins (*C. J.* 57, 269 [1890]) obtained a very hard, yellowish-red

solid agreeing with the formula  $\text{Cu}_2\text{O}$ . Richards (P. Am. A. 26, 281 [1891]) found that  $\text{CuO}$  excludes gas, chiefly N; when prepared by heating  $\text{Cu}(\text{NO}_3)_2$ , the oxide retained c. .08 p.c. of its weight of N, which could not be removed by heating. For experiments on the dehydration of  $\text{CuO} \cdot x\text{H}_2\text{O}$  v. Spring a. Lucion (Zeit. f. anorg. Chemie, 2, 195; abstract in C. J. 64 [11], 210 [1893]). For colloidal, jelly-like  $\text{CuO} \cdot x\text{H}_2\text{O}$  v. J. van Bemmelen (Zeit. f. anorg. Chemie, 5, 466; abstract in C. J. 65 [11], 191 [1894]).

**Copper, oxybromides** of (vol. ii. p. 260). Dupont a. Jensen (Bl. [3] 9, 193; abstract in C. J. 64 [11], 463 [1893]) obtained the salt  $3\text{CuO} \cdot \text{CuBr}_2 \cdot 3\text{aq}$  by heating  $\text{CuBr}_2 \cdot \text{aq}$  with  $\text{CuO}$  in a sealed tube at  $200^\circ$ , or, better, by heating neutral dilute  $\text{CuBr}_2 \cdot \text{aq}$  at  $225^\circ$ ; the compound crystallised in green rhombohedral plates, S.G. 4.39.

**Copper, oxychlorides** of (vol. ii. p. 260), v. Roussseau, C. R. 110, 1261 (abstract in C. J. 58, 1058 [1890]).

**Copper, oxysulphides** of (vol. ii. p. 260), v. Cliche, Ar. Ph. 228, 374 (abstract in C. J. 58, 1211 [1890]).

**Copper, phosphides** of (vol. ii. p. 260). For descriptions of  $\text{Cu}_3\text{P}_2$  and  $\text{Cu}_2\text{P}$ , prepared by heating Cu in vapour of P, v. Granger, C. R. 113, 1401; and for  $\text{Cu}_3\text{P}_2$ , prepared by heating red P with excess of Cu phosphite and water, v. G., C. R. 117, 237 (abstracts in C. J. 62, 410 [1892]; and 64 [11], 526 [1893]).

**Cupric sulphide**. From experiments on the interaction of  $\text{H}_2\text{S}$  and  $\text{CuSO}_4 \cdot \text{aq}$  and  $\text{CuSO}_4$  in presence of acetic acid, Linder a. Pictet (C. J. 61, 120 [1892]) conclude that a compound  $7\text{CuS} \cdot 11\text{S}$  is formed, and that then such compounds as  $9\text{CuS} \cdot 11\text{S}$  and  $22\text{CuS} \cdot 11\text{S}$  are produced, and finally  $(\text{CuS})_n$  is formed.

**COPPER-AMMONIUM COMPOUNDS** (vol. ii. p. 262). Several derivatives of cupriammonium bromide are described by Richards a. Shaw (P. Am. A. 28, 247 [1893]).

#### FERRICYANIDES.

**Barium ferricyanide** (vol. ii. p. 337); v. Raimelsberg, J. pr. [2] 39, 455 (abstract in C. J. 56, 950 [1889]).

**Lead ferricyanide** (vol. ii. p. 330); v. Raimelsberg (l.c.).

**Potassium ferricyanide** (vol. ii. p. 339); v. Kassner, Chem. Zeit. 13, 1701 (abstract in C. J. 58, 352 [1890]).

**DIDYMIUM** (vol. ii. p. 382). For an investigation into the separation of Di and Er, v. Krüss, A. 265, 1 (abstract in C. J. 63, 1421 [1891]). For the emission spectra of oxides of neodymium and praseodymium, v. Hattinger, M. 12, 362 (abstract in C. J. 62, 2 [1892]). Read (C. J. 65, 313 [1894]) says that  $\text{Di}_2\text{O}_3$  is unchanged at c.  $1750^\circ$ .

**ERBIUM** (vol. ii. p. 456). For the separation of compounds of Er and Di, v. Krüss, A. 265, 1 (abstract in C. J. 60, 1424 [1891]).

**FERRITES** (vol. ii. p. 547). J. van Bemmelen a. Hobbs (J. pr. [2] 46, 497 [1892]) say that  $\text{Fe}_2\text{O}_3 \cdot \text{K}_2\text{O}$  and  $\text{Fe}_2\text{O}_3 \cdot \text{Na}_2\text{O}$  are obtained, in crystals, by continued heating  $\text{Fe}_2\text{O}_3$  with conc.  $\text{KOH aq}$  and  $\text{NaOH aq}$  respectively; these

ferrites are decomposed by water, giving  $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ .

**FLAME** (vol. ii. p. 549). Reference should be made to Smithells a. Ingle on 'The Structure and Chemistry of Flames' in C. J. 61, 204 [1892], and to Lewis on 'The Luminosity of Coal-gas Flames' in ibid. p. 322.

**FLUORHYDROIC ACID** (vol. ii. p. 558). Berthelot a. Moissan (C. R. 109, 209 [1889]) give the thermal data  $[\text{H.F.}] = 37,600$ ;  $[\text{H.F.Aq}] = 49,400$ . For the description of an apparatus for purifying  $\text{HFAq}$ , v. Hquilton (C. N. 60, 252 [1889]).

**FLUORINE** (vol. ii. p. 560). Moissan (C. R. 111, 370 [1890]) determined the at. w. (1) by converting  $\text{Na}_2\text{C}_2\text{O}_4$  into  $\text{NaF}$ , and this into  $\text{Na}_2\text{SO}_4$ ; (2) by converting  $\text{CaF}_2$  into  $\text{CaSO}_4$ , and (3) by converting  $\text{BaF}_2$  into  $\text{BaSO}_4$ ; the mean of the results regarded by M. as the most trustworthy was 19.05. V.D. at the ordinary temperature,  $18.3$  (Moissan, C. R. 109, 861; v. abstract in C. J. 58, 204 [1890]). A column of F one metre long shows no definite absorption bands (M., l.c. p. 937); for the emission spectrum v. M. (l.c., abstract in C. J. 58, 329 [1890]). F does not liquefy at  $-95^\circ$  at the ordinary pressure (M., A. Ch. [6] 25, 125 [1893]). Gladstone (P. M. [5] 31, 1 [1891]) has determined the atomic refraction of F in  $\text{O}_2\text{H}_2\text{F}$  to be as follows for the different lines of the solar spectrum, at  $22.8^\circ$ :—

A C D E F G H

at. refraction .63 .63 .53 .48 .44 .35  
The values are much smaller than those for Cl, Br, or I, which are 10.0, 15.23, and 25.2 for the line A.

**Formation**.—According to Brauner, (C. J. 65, 393 [1894]), F is given off when  $3\text{KF} \cdot \text{PbF}_2 \cdot \text{HF}$  (or LEAD TETRAFLUORIDE, p. 125) is heated to dull redness.

**Reactions**.—F combines with the more porous forms of carbon at the ordinary temperature, with incandescence, forming  $\text{CF}_4$ ; the denser forms of C combine with incandescence at from  $50^\circ$  to  $100^\circ$  (Moissan, C. R. 110, 276; abstract in C. J. 58, 557 [1890]). For a discussion of the chemical relations of F, v. Moissan, Bl. [3] 5, 880 [1891].

**GALLIUM** (vol. ii. p. 597). Lecocq de Boisbaudran (C. R. 114, 815; abstract in C. J. 62, 930 [1892]) gives measurements of the chief lines in the spark emission spectrum of Ga; the spectrum varies much according to the conditions under which the spark is applied.

**GERMANIUM** (vol. ii. p. 610). A new mineral from Bolivia, *senfildite*,  $\text{Ag}_2\text{GeS}_4$ , identical in composition with *argyrodite* from Freiberg, but crystallising in isometric forms (the form of *argyrodite* is monoclinic), is described by Field in Am. S. [3] 46, 107 (abstract in C. J. 66 [11], 19 [1894]).

**GOLD** (vol. ii. p. 647). Melet (Pr. 46, 71; abstract in C. J. 58, 708 [1890]) has re-determined the at. w. of gold by various methods; the mean value obtained is 196.9, but the value 196.88 M. thinks is more trustworthy. The molecule of gold in dilute solution in this is probably monatomic (Heycock a. Neville, C. J. 57, 376 [1890]). Gold volatilises considerably in the electric furnace with a current of 70 volts and 860 amperes (Moissan, C. R. 116, 1429 [1893]).

Concerning the volatilisation of gold v. Rose (*C. J.* 63, 714 [1893]). Neumann (*M.* 13, 40 [1892]) says that gold absorbs from 33 to 48.5 times its volume of O at c. 450°. According to Petersen (*Z. P. C.* 8, 601 [1891]), the heats of formation of  $\text{Au}_2\text{O}_3$  and  $\text{Au}_2\text{O}$  from gold (1) reduced from  $\text{AuCl}_3$ , (2) from  $\text{AuHBr}_2$ , and (3) from  $\text{AuBr}$ , differ very markedly. From the results of many experiments on the reaction between gold and  $\text{KCN}$ , Maclaurin (*G. J.* 63, 724 [1893]) concludes that O must be present to accomplish solution, and that the equation  $4\text{Au} + 8\text{KCN} + \text{O}_2 + 2\text{H}_2\text{O} = 4(\text{AuCN.KCN}) + 4\text{KOH}$  (Elsner, *J. pr.* 37, 323 [1849]) expresses the proportion between K and Au in the solution.

**Gold, alloys of** (vol. ii. p. 648). For an alloy with Cd, AuCd, v. Heycock & Neville (*G. J.* 61, 914 [1892]). For alloys with Cd and Sn, v. H. a. N. (*C. J.* 59, 936 [1891]). For alloys with Al and Sn, Cd and Bi, Cd and Pb, and Cd and Ti, v. H. a. N. (*C. J.* 65, 65 [1894]). For alloys with Cd and with Zn, prepared by immersing plates of Cd and Zn in solution of a salt of gold, v. Mylius & Fromm (*B.* 27, 630; abstract in *C. J.* 66 [11], 235 [1894]).

**Gold, bromides of** (vol. ii. p. 648). Petersen (*J. pr.* [2] 46, 328) upholds the existence of  $\text{AuBr}$ , against the statements of Krüss & Schmitt (*B.* 20, 244; in a later paper (*J. pr.* [2] 47, 301) K. a. S. still maintain that  $\text{AuBr}$  is the ultimate product of the reaction of Br with gold (v. abstracts in *C. J.* 64 [11], 126, 284). For the double salts  $\text{AuBr}_2$ ,  $\text{CsBr}$  and  $\text{AuBr}_2$ ,  $\text{RbBr}$ , v. Wells a. Wheeler (*Am. S.* [3] 44, 157 [1892]).

**Gold, chlorides of** (vol. ii. p. 649). Petersen (*G. pr.* [2] 46, 328; 48, 88) maintains that  $\text{AuCl}_3$  is a definite compound; Krüss & Schmitt (*J. pr.* [2] 47, 301; *Zeit. f. anorg. Chemie*, 3 421) say this substance is a mixture (v. abstracts in *C. J.* 64 [11], 126, 284, 474 [1893]).

**Double salts of  $\text{AuCl}_3$  with  $\text{CsCl}$  and  $\text{RbCl}$**  are described by Wells a. Wheeler (*l.c.*); for a double salt  $\text{AuCl}_3$ ,  $\text{AgCl}$ , v. Hermann (*B.* 27, 596; abstract in *C. J.* 66 [11], 234 [1894]).

**Gold, sulphides of** (vol. ii. p. 651). Concerning the conditions of formation of  $\text{Au}_2\text{S}_3$ , v. Antony a. Lucchesi (*G.* 19, 545; abstract in *C. J.* 58, 1216 [1890]).

**Auric sulphide  $\text{Au}_2\text{S}_3$ .** This compound is formed, according to A. a. L. (*G.* 20, 601; 21 [11], 209; abstracts in *C. J.* 60, 526; 62, 430 [1892]), by passing  $\text{H}_2\text{S}$  into a solution of  $\text{AuCl}_3$ ,  $\text{LiCl}$  kept at  $-10^\circ$ , extracting  $\text{LiCl}$  by absolute alcohol, and drying in N at  $70^\circ$ .  $\text{Au}_2\text{S}_3$  is a black, amorphous solid; decomposed by heat at  $200^\circ$ – $205^\circ$  to Au and S (for other reactions v. abstracts, *l.c.*).

Schneider (*U. S. Geol. Survey Bull.* No. 90, 56, [1892]) obtained aqueous solutions of colloidal  $\text{AuS}$  and  $\text{Au}_2\text{S}_3$ .

#### HYDRAZONIC ACID (v. p. 919, Addenda).

**HYDROGEN** (vol. ii. p. 719). The ratio between the densities of H and O is 1:15.832; the weight in grams of 1 litre of H is .08991 (Rayleigh, *Phil. Mag.*, 134 [1893]). For solubility in water, and in alcohol, v. Timofeff (*Z. P. C.* 6, 141); Winkler (*B.* 24, 89); Henrich (*Z. P. C.* 9, 435); (abstracts in *C. J.* 60, 15, 384 [1891]; 62, 1043 [1892]). For the line spectrum of H, v.

Anges (*L. M.* [5] 30, 48 [1890]); and cf. Grünwald (*M.* 13, 111; abstract in *C. J.* 62, 1381 [1892]).

Wilm (*B.* 25, 217; abstract in *C. J.* 62, 563 [1892]) describes a lecture experiment to show the occlusion of H by Pd. Regarding the occlusion of H by other metals v. Streintz (*M.* 12, 642; abstract in *C. J.* 62, 567 [1892]).

Baker (*C. J.* 65, 611 [1894]) found that a mixture of equal volumes of dry H and dry Cl did not explode in bright sunlight, and that more than a quarter of the mixed gases remained uncombined after exposure for two days to diffused light and two days to bright sunshine.

**Reactions.**—Neumann (*Z. P. C.* 14, 193 [1894]) has examined the reducing action of H occluded by Pt on solutions of salts of Al, Sb, As, Bi, Cd, Cu, Co, Au, Fe, Pb, Mg, Mn, Hg, Ni, Pd, Ag, Sn, Ti, and Zn. Regarding the rate of combination of H and O, v. WATKIN (p. 860). Regarding the explosion of mixtures of H with O and Cl, v. CHLOPINE (*Addenda*, pp. 904, 905).

**Hydrogen dioxide** (vol. ii. p. 722). Schöne (*B.* 26, 3011; 27, 1233 [1893-4]) affirms the occurrence of  $\text{H}_2\text{O}_2$  in the atmosphere against the contention of Ilsva (*B.* 27, 920).

**Formation.**—Regarding the formation from ether v. Dunstan a. Dymond (*C. J.* 57, 574, 988 [1890]).  $\text{H}_2\text{O}_2$  is formed by the action of light on  $\text{H}_2\text{C}_2\text{O}_4$ , excess of O being present (Richardson, *C. J.* 65, 450 [1894]). Richardson (*C. J.* 63, 1110 [1893]) has examined the formation of  $\text{H}_2\text{O}_2$  in urine exposed to sunlight.

**Preparation.**—By making commercial 3 p.c.  $\text{H}_2\text{O}_2$  distinctly alkaline by  $\text{Na}_2\text{CO}_3$ , filtering, soaking with 10–12 vols. of ether, separating the ethereal solution, evaporating this to .01–.0025 of its original volume on a water-bath, and removing the rest of the ether by standing in a bell-jar over solid paraffin, Shiloff (*J. R.* 25, 293; abstract in *C. J.* 66 [11], 186 [1894]) obtained a thick, transparent, slightly acid liquid, S.G. 1.2475, containing 79.6 g.  $\text{H}_2\text{O}_2$  in 100 c.c. For preparation of conc.  $\text{H}_2\text{O}_2$  v. Talbot a. Moody (abstract in *C. J.* 64 [11], 369 [1893]).

**Molecular weight.** Tamman in 1889 (*Z. P. C.* 4, 411) by cryoscopic measurements determined mol. formula to be  $\text{H}_2\text{O}_2$ ; but T.'s results were called in question by Carr in 1893 (*G.* 22 [1], 341), who found mol. w. 33.92 ( $\text{H}_2\text{O}_2$ ) from cryoscopic measurements, and this result was confirmed by Orndorff a. White (*Am.* 15, 347, [1893]), and also by Tamman himself (*Z. P. C.* 12, 431 [1893]).

**Reactions.**—Regarding the reaction between  $\text{H}_2\text{O}_2$ ,  $\text{Ag}$  and  $\text{KMnO}_4$ , v. Engel (*B.* [3] 6, 17; abstract in *C. J.* 62, 277 [1892]).

**Hydrogen sulphide** (vol. ii. p. 725). Henrich (*Z. P. C.* 9, 435 [1892]) gives the absorption coefficient of  $\text{H}_2\text{S}$  by water as 4.4015–.089117 + .00061954t. Hughes (*P. M.* [5] 33, 471 [1892]) says that  $\text{H}_2\text{S}$  dried by  $\text{CaCl}_2$  and  $\text{P}_2\text{O}_5$  does not redden dry litmus paper, and does not react with  $\text{BaO}$  or  $\text{Fe}_2\text{O}_3$ , nor with salts of Sb, As, Bi, Cd, Co, Cu, Pb, Hg, Ag, or Sn. According to Pöller (*C. J.* 57, 625 [1890]), the equation  $2\text{H}_2\text{S} + 3\text{O}_2 = 2\text{SO}_2 + 2\text{H}_2\text{O}$  correctly represents the explosion of  $\text{H}_2\text{S}$  and air or  $\text{O}$ .

**HYDROXYLAMINE** (vol. ii. p. 734).  $\text{NH}_2\text{OH}$  has been isolated as a solid by Schmitt &

(R. T. O. *U*, 100; 11, 15, *abstracts in C. J.* 62, 402, 1891 [1892]).  $\text{NH}_4\text{OH} \cdot \text{HCl}$  dissolved in  $\text{MeOH}$  is treated with  $\text{CH}_3\text{ONa}$  solution, and most of the  $\text{MeOH}$  is distilled off at 100 mm. pressure; the residue is distilled in small portions at 40 mm. pressure (for details v. C. J., *l.c.*). For the preparation from  $2\text{NH}_4\text{OH} \cdot \text{ZnCl}_2$  v. Crismer, *Bl.* [3] 6, 793 (*abstract in C. J.* 62, 771 [1892]). For details of suitable apparatus for the fractionation of  $\text{NH}_4\text{OH}$  *in vacuo*, v. Brühl (*B.* 26, 2508 [1893]; cf. L. de B., *B.* 27, 307, and reply by Berthelot a. André (*C. R.* 110, 830; *abstract in C. J.* 58, 934 [1890]). Hydroxylamine is a white, odorless solid, melting at  $-33^\circ$ , and remaining supercooled at  $0^\circ$ ; boils at  $58^\circ$  under 22 mm. pressure; decomposes at  $90^\circ$ – $100^\circ$ , and detonates at a higher temperature. S.G. 1.35; S.G. when liquid, 1.23. A drop heated in a test tube explodes very violently (v. Brühl, *l.c.*). B., *l.c.*, discusses the molecular refraction of  $\text{NH}_4\text{OH}$ .  $\text{NH}_4\text{OH}$  is fairly stable up to  $15^\circ$ , then gradual decomposition occurs, giving  $\text{NH}_3$ ,  $\text{HNO}_2$ , and  $\text{H}_2\text{N}_2\text{O}_2$ , which react with unchanged  $\text{NH}_4\text{OH}$  producing  $\text{O}$  and  $\text{N}_2$ . L. de B., *B.* 27, 967; *abstract in C. J.* 66 [11], 278 [1891]). For a full account of the reactions of  $\text{NH}_4\text{OH}$  v. Lobry de Bruyn (*l.c.*; *abstract in C. J.* 62, 1391 [1892]).  $\text{H}_2\text{N}_2\text{O}_2 \cdot \text{HCl}$  in water and  $\text{NaNO}_2$  aq react to form  $\text{NaNO}_2$  aq (v. Tarnier, *J. R.* 25, 312; *abstract in C. J.* 66 [11], 136 [1891]; cf. Vislicenus, *B.* 26, 771; *abstract in C. J.* 64, 18 [1892]). For the reactions of  $2\text{NH}_4\text{OH} \cdot \text{H}_2\text{SO}_4$  with  $\text{NaOH}$  aq v. Kolotoff (*J. R.* 25, 295; *abstract in C. J.* 66 [11], 187 [1891]). For compounds of  $\text{NH}_4\text{OH}$  with metallic salts, v. Crismer, *Bl.* [3] 8, 114; Goldschmidt a. Syngros (*Z. anorg. Chemie*, 5, 129); and Feldt (*B.* 27, 401) (*abstracts in C. J.* 58, 558 [1890]; 66 [11], 15, 187 [1894]). Kolotoff discusses the constitution of  $\text{NH}_4\text{OH}$  in *J. R.* 23, 3 (*abstract in C. J.* 64 [11], 114 [1893]). Kjellin (*B.* 26, 2377) describes  $\text{NH}_4\text{F} \cdot \text{OH}$  and  $\text{NHMe} \cdot \text{OH}$  (*abstract in C. J.* 66 [11], 9 [1894]).

**INDIUM** (vol. iii. p. 1). The molecule of indium in dilute solution is tin is perhaps diatomic (v. Heycock a. Neville, *C. J.* 57, 376 [1890]). Linder a. Picton (*C. J.* 61, 131 [1892]) failed to isolate indium hydrosulphide, but they think that it is formed by passing  $\text{H}_2\text{S}$  into water with  $\text{In}_2\text{O}_3 \cdot \text{H}_2\text{O}$  in suspension; the continued passage of  $\text{H}_2\text{S}$  produces  $\text{In}_2\text{S}_3$ . Read (*C. J.* 65, 313 [1894]) found that indium sesquioxide,  $\text{In}_2\text{O}_3$ , is unchanged at  $675^\circ$ .

**IODHYDRIC ACID** (vol. iii. p. 11). For the Mol. R. of  $\text{HIAg}$  from 20.77 to 67.92 p.c., v. Perkin (*C. J.* 55, 708 [1889]). For a research on the dissociation of  $\text{HI}$ , v. Bodenstein (*Z. P. K.* 33, 56 [1894]; *abstracts in C. J.* 61 [11], 369; 66 [14], 12 [1893-4]). Nickling (*B.* 26, 2007) has isolated three hydrates of  $\text{HI}$ :  $\text{HI} \cdot 2\text{H}_2\text{O}$ , melting at  $-43^\circ$ ;  $\text{HI} \cdot 3\text{H}_2\text{O}$ , melting at  $-48^\circ$ ; and  $\text{HI} \cdot 4\text{H}_2\text{O}$ , melting at  $-36.5^\circ$ .

**IODINE** (vol. iii. p. 14). The mol. w. of iodine dissolved in  $\text{Et}_2\text{O}$  or  $\text{CS}_2$  was found by Beckmann (*Z. P. K.* 5, 76 [1890]) to be 254, from determinations of the boiling-point; the results were confirmed by Sakurai (*C. J.* 51, 99 [1892]). By determining the lowering of the f.p. of naphthalene by solution therein of  $\text{I}_2$ ,

Hertz (*Z. P. O.* 3, 358 [1890]) found the value 254 for the mol. w. of iodine.

According to Meineke (*Chem. Zeitung*, 10, 121, 1230), very pure  $\text{I}_2$  is prepared by covering ordinary  $\text{I}_2$  with a solution of  $\text{CaCl}_2$ , S.G. 1.85, mixed with a little conc.  $\text{KIAg}$  and a few drops of  $\text{HCl}$  aq, heating until the  $\text{I}_2$  fuses, letting cool, washing the  $\text{I}_2$ , drying, and subliming it twice, the first time with addition of a little  $\text{BaO}$ .

For the reactions of  $\text{I}_2$  with  $\text{KClO}_3$ , and with  $\text{KClO}_4$  and water, v. POTASSIUM CHLORATE (*Addenda*, p. 905).

**Iodine monochloride** (vol. iii. p. 17). For thermal data bearing on the two forms of  $\text{ICl}$ , v. Stortenbecker (*Z. P. C.* 10, 183; *abstract in C. J.* 62, 1387 [1892]). Tarnier (*J. R.* 25, 97; *abstract in C. J.* 64 [11], 514) gives details of the methods for preparing the two forms of  $\text{ICl}$ .

**Iodates** (vol. iii. p. 21). For *iodates of cesium* and *rubidium*, v. Wheeler, *Am. S.* [3] 44, 123 (*abstract in C. J.* 64 [11], 68 [1894]). Pure potassium iodate is prepared, according to Gröger (*Zeit. angew. Chemie*, 1891, 13), by heating to  $100^\circ$  for 20–30 minutes 20 g.  $\text{KI}$  in as little water as possible mixed with 40 g. pure  $\text{KMnO}_4$ , in 1,000 c.c. water, reducing excess of  $\text{KMnO}_4$  by cautious addition of alcohol, filtering, adding acetic acid till acid, evaporating to c. 50 c.c., washing the crystals of  $\text{KIO}_3$  with conc. alcohol, and drying. By heating  $\text{KIO}_3$  till it fuses,  $\text{O}$  and some  $\text{I}_2$  are given off, and  $\text{K}_2\text{O}$  finally remains; no other oxy-compounds are formed (Cook, *C. J.* 65, 802 [1894]).

**IRIDIUM** (vol. iii. p. 46). For analyses of the salts  $\text{IrCl}_3 \cdot 3\text{KCl}$  aq and  $\text{IrCl}_3 \cdot 3\text{NH}_4\text{Cl}$  aq, July deduced the value 192.75 for the at. w. of  $\text{Ir}$  (*C. R.* 110, 1131 [1890]). According to Prinz (*C. R.* 116, 392 [1893]),  $\text{Ir}$  crystallises in regular octahedra and in forms derived therefrom. Milius a. Foerster (*B.* 25, 665 [1892]) stated that  $\text{Ir}$  is slightly volatilised when heated in a current of  $\text{CO}$  and  $\text{Cl}_2$  to c.  $238^\circ$ ; Antony, however (*C. R.* [11], 517 [1893]), asserts that no trace of any volatile compound of  $\text{Ir}$  is formed under these conditions.

**Irid-ammonium salts** (vol. iii. p. 47). Palmæ (*B.* 22, 15; 23, 3910 [1889-90]) describes a number of irido-ammonium compounds. He calls them *iridopentammine salts*, and formulates them as  $\text{Ir}(\text{NH}_3)_5\text{X}_2$ ; compounds are described where  $\text{X}_2 = \text{Cl}_2$ ,  $\text{ClBr}$ ,  $\text{ClI}$ ,  $\text{ClSO}_3$ ,  $\text{Cl}(\text{NO}_2)$ ,  $\text{Cl}(\text{NO}_2)_2$ ,  $\text{Cl}(\text{CO})$ ,  $\text{ClP}(\text{Cl})_2$ ; also where  $\text{X}_2 = \text{Br}$ ,  $\text{BrSO}_3$ , and  $\text{Br}(\text{NO}_2)$ . One-third of the  $\text{Cl}$  in the salt when  $\text{X}_2 = \text{Cl}_2$  is not removed by the action of cold  $\text{H}_2\text{SO}_4$  aq or cold  $\text{AgNO}_3$  aq; the reactions of the salts are similar to those of the purple cobaltammines (v. vol. ii. p. 227) (*abstracts in C. J.* 56, 252 [1889]; 60, 402 [1891]). In *B.* 21, 2099 (v. *abstract in C. J.* 60, 11 [1889]) P. describes compounds analogous with the rose-cobaltic salts  $\text{Co}(\text{NH}_3)_6(\text{H}_2\text{O})_2\text{X}_2$ ; as the  $\text{I}$  salts are almost colorless, P. thinks the prefix *rosco-* is unsuitable; he calls them *iridium aquoferrammines*, and formulates them as  $\text{Ir}(\text{NH}_3)_6(\text{H}_2\text{O})\text{X}_2$ . Salts are described in which  $\text{X}_2 = \text{Br}_2$ ,  $\text{Cl}_2$ , and  $(\text{NO}_2)_2$ . The chloride  $\text{Ir}(\text{NH}_3)_6(\text{H}_2\text{O})\text{Cl}_2$  is formed by boiling, for five hours, 5 g.  $\text{Ir}(\text{NH}_3)_4\text{Cl}_3$  with 14 times the calculated weight of  $\text{KOH}$  in 50 c.c. water, filtering, partially freezing the filtrate, adding 30 c.c. fuming  $\text{HCl}$  aq, washing the pp. thus formed

with 22 p.c. cold HClAq and then with alcohol, dissolving in water, and again ppg. by conc. HClAq (for details v. *abstract in C. J.* 60, 1486 [1891]).

**Iridium tribromide** (vol. iii, p. 48). Compounds of this bromide with PBr<sub>3</sub> are described by Geisenheimer (*C. R.* 111, 40; *abstract in C. J.* 58, 1883 [1890]). By heating IrO<sub>3</sub>.xH<sub>2</sub>O with IrBr<sub>3</sub> and PBr<sub>3</sub>, red needles of IrBr<sub>3</sub>.3PBr<sub>3</sub> are formed; by heating this with PBr<sub>3</sub>, black crystals of IrBr<sub>3</sub>.2PBr<sub>3</sub> are produced.

**Iridium tetrabromide** (vol. iii, p. 48). Geisenheimer (*loc.*) describes the compound IrBr<sub>3</sub>.2PBr<sub>3</sub>, obtained by heating IrBr<sub>3</sub>.3PBr<sub>3</sub> with PCl<sub>3</sub>.

**Iridium trichloride** (vol. iii, p. 48). The following compounds with PCl<sub>3</sub> are described by Geisenheimer (*C. R.* 110, 1004; *abstract in C. J.* 58, 1068 [1890]). IrCl<sub>3</sub>.3PCl<sub>3</sub>; IrCl<sub>3</sub>.2PCl<sub>3</sub>; IrCl<sub>3</sub>.PCl<sub>3</sub>.2PCl<sub>3</sub>; IrCl<sub>3</sub>.PCl<sub>3</sub>.PCl<sub>3</sub>. Various compounds of IrCl<sub>3</sub> with H<sub>3</sub>PO<sub>4</sub> and H<sub>2</sub>PO<sub>3</sub> and salts of these, are also described. G. (*C. R.* 110, 1336; *abstract in C. J.* 58, 1069 [1890]) also describes the complex compounds 2IrP<sub>2</sub>Cl<sub>5</sub>.5AsCl<sub>3</sub> and IrCl<sub>3</sub>.2PCl<sub>3</sub>.2AsCl<sub>3</sub>. For the salts IrCl<sub>3</sub>.3KCl. aq and IrCl<sub>3</sub>.3MnCl<sub>2</sub>. aq. v. Joly (*C. R.* 110, 1131; *abstract in C. J.* 58, 1067 [1890]). For a description of IrCl<sub>3</sub>.3TiCl<sub>3</sub>.2aq. v. Lisony (*G.* 23 [1], 190; *abstract in C. J.* 64 [11], 880 [1893]). According to A. (*G.* 23 [1], 184; *abstract in C. J.* 64 [11], 879 [1890]), the passage of H<sub>2</sub>S through a 2 p.c. solution of IrCl<sub>3</sub>.3KCl produces pps. which are mixtures of Ir<sub>2</sub>S<sub>3</sub> and IrS.

**Iridium dioxide** (vol. iii, p. 50). For methods of preparing IrO<sub>2</sub>, v. Geisenheimer (*C. R.* 110, 865; *abstract in C. J.* 58, 948 [1890]).

**Iridium disulphide** (vol. iii, p. 50). IrS<sub>2</sub> is obtained by passing H<sub>2</sub>S over IrCl<sub>3</sub>.3LiCl at 4° to 7°, washing with absolute alcohol, and drying at 90° to 100° in a current of CO<sub>2</sub> (Antony, *G.* 23 [1], 190; *abstract in C. J.* 64 [11], 380 [1893]).

**IRON** (vol. iii, p. 51). Lockyer (*Pr.* 54, 359 [1893]) gives the emission spectrum obtained by using very fine electrolytically deposited iron as the poles of an electric lamp.

**Properties and Reactions.**—Iron volatilises in the electric furnace, using a current of 850 amperes and 50 volts (Moissan, *C. R.* 116, 1429 [1893]). Iron is superficially oxidised by heating to dull redness in NO (Sabatier a. Senderens, *C. R.* 114, 1429 [1892]); heated in NO<sub>2</sub> to c. 350°, reduced iron is oxidised with incandescence to Fe<sub>2</sub>O<sub>3</sub> (S. a. S., *C. R.* 115, 236 [1892]; cf. *abstract in C. J.* 66 [11], 95 [1894]). Montemartini (*G.* 22, [1], 350) says that NH<sub>3</sub>, N<sub>2</sub>O, and N are formed by the solution of iron in excess of 27.5 p.c. HNO<sub>3</sub> (for quantities, v. *abstract in C. J.* 62, 1278 [1892]). For quantities of iron dissolved by HNO<sub>3</sub> of different concentrations, v. Gautier a. Charpy (*C. R.* 112, 1461; *abstract in C. J.* 60, 1496 [1891]).

**Passivity of iron.** Concerning the passivities of steel and wrought iron to HNO<sub>3</sub> Aq, v. Andrews (*Pr.* 48, 116; 49, 481; *abstracts in C. J.* 60, 250, and 64 [11], 16 [1891 and 1893]).

**Iron, bromochloride of.** The compound FeBrCl was obtained by Lenormand (*J. R.* 118, 820; *abstract in C. J.* 64 [11], 877) by heating FeCl<sub>3</sub> with excess of Br in a sealed tube at c. 100°. The compound is opaque in thin

sections, and green by reflected light; very deliquescent; crystallises probably in hexagonal plates; easily sol. alcohol and ether, CS<sub>2</sub>, &c., can be sublimed by heating in a tube containing a little Br.

**Iron carbide.** Arnold a. Read (*C. J.* 55, 798 [1894]) confirm the existence of Fe<sub>3</sub>C in steel (v. Abel, *Proc. Inst. Mechan. Engineers*, 1885, 10; also Müller, *Stahl und Eisen*, No. 3); J. a. B. say that two forms of Fe<sub>3</sub>C are found in steel.

**Iron carbonyls.** In 1891 Mond a. Quincke (*C. J.* 59, 604) obtained a compound of Fe with CO; further investigation of the reaction by Mond a. Langer (*C. J.* 59, 1090 [1891]) led to the isolation of two compounds.

**Ferropentacarbonyl** Fe<sub>5</sub>(CO)<sub>5</sub>. Mol. w. 195.55. V.D. at 142° ± 93.2, S.G.<sub>15°</sub> = 1.4664; distils completely, without decomposition, at 102.8° under 749 mm. pressure; solidifies at -21°.

**Preparation.**—FeC<sub>2</sub>O<sub>4</sub> ppd. by adding a slight excess of K<sub>2</sub>C<sub>2</sub>O<sub>4</sub> Aq to hot FeSO<sub>4</sub> Aq, is well washed, and dried at 120°; it is then heated in a slow stream of H<sub>2</sub>, temperature being raised until the substance in the tube is black, and then kept constant until gas ceases to come off, when the current of H<sub>2</sub> is stopped; the product is allowed to cool in H<sub>2</sub>, placed in water without coming into the air, and treated with successive quantities of boiling water until sulphate is removed; it is then quickly dried on plates of gypsum, placed in the combustion tube, heated to c. 300° in H<sub>2</sub> till quite dry, and allowed to cool in H<sub>2</sub>. The tube is then connected with a gas-holder containing CO, and the H<sub>2</sub> is completely displaced by CO; one end of the tube is then sealed, and the open end is kept in connection with the supply of CO. After 24 hours the tube is heated to c. 120°, while a slow current of CO is passed through it, and the issuing gases are passed through a tube kept at -20°. When iron carbonyl ceases to come over, the tube is let cool, and is then again put in connection with the CO supply. These processes are repeated many times; the daily yield of the carbonyl is not more than c. 1 g. from 100 g. iron.

**Properties.**—A pale-yellow, somewhat viscous liquid; unchanged in the dark, but in sunlight gives solid Fe<sub>2</sub>(CO)<sub>9</sub> (v. *infra*); slowly decomposed on exposure to air, giving chiefly Fe<sub>2</sub>O<sub>3</sub>.xH<sub>2</sub>O; completely decomposed at 180° to Fe and CO; soluble in EtOH, Et<sub>2</sub>O, C<sub>2</sub>H<sub>4</sub>, mineral oils, &c. (For S.G., V.D., &c., v. *supra*). Fe(CO)<sub>5</sub> is not acted on by dilute H<sub>2</sub>SO<sub>4</sub> Aq, HClAq, or HNO<sub>3</sub> Aq at the ordinary temperature; but is rapidly decomposed to Fe(NO)<sub>3</sub> Aq, FeCl<sub>3</sub> Aq, or FeBr<sub>3</sub> Aq by conc. HNO<sub>3</sub> Aq, ClAq, and BrAq.

**Diferroheptacarbonyl** Fe<sub>2</sub>(CO)<sub>7</sub>. Obtained by expunging Fe(CO)<sub>5</sub> in a sealed tube to sunlight for some hours, collecting the solid that forms, washing with ether, and drying over H<sub>2</sub>SO<sub>4</sub> for a short time. Yellow, lustrous flakes; gradually decomposed by exposure to air, turning brown. Not solid on by H<sub>2</sub>SO<sub>4</sub> Aq or HClAq at the ordinary temperature; decomposed by HNO<sub>3</sub> Aq, Cl or Br.

Iron carbonyls seem to be present in water-

also sometimes in compressed coal-gas. See a Scudder, *C. J. Proc.* 1891. No. 101).  
**Ferrous chloride** (vol. iii. p. 53). Chasse-  
 rant (*A. Ch.* [6] 30, 5, [1893]) describes the  
 double salts  $\text{FeCl}_2 \cdot 2\text{AmCl}$ ,  $\text{FeCl}_2 \cdot \text{LiCl}$ ,  $\text{FeCl}_2 \cdot \text{NaCl}$ , and  
 $\text{FeCl}_2 \cdot 2\text{KCl}$ .

**Ferric chloride** (vol. iii. p. 54). By deter-  
 mining the rise of b.p. of alcohol and ether when  
 $\text{FeCl}_3$  is dissolved in these solvents, Müller  
 (*C. R.* 118, 644; *abstract in C. J.* 66 [11], 282  
 [1894]) finds that the molecular formula of the  
 chloride in these solutions is  $\text{FeCl}_3$ .  $\text{FeCl}_3$  in  
 reacts with many metallic sulphides, when  
 heated therewith in sealed tubes;  $\text{FeCl}_3$  in  
 and a chloride of the metal of the sulphide are  
 generally formed (Caumener, *C. C.* 291 [11],  
 370; *abstract in C. J.* 62, 18 [1892]). Seubert  
 a. Dorner (*Zeit. f. anorg. Chem.*, 5, 339, 41;  
*v. abstracts in C. J.* 66 [11], 140, 190 [1894]) have  
 made a full investigation of the interaction  
 of  $\text{FeCl}_3$  and  $\text{KIAq}$ ; their results are in  
 keeping with the hypothesis that the direct re-  
 action  $\text{FeCl}_3 + \text{KIAq} = \text{FeCl}_2 + \text{KCl} + \text{IAq}$   
 is counterbalanced by the reverse reaction  
 $\text{FeCl}_2 + \text{KCl} + \text{IAq} = \text{FeCl}_3 + \text{KIAq}$ .  
 S. a. D. think that the first stage of the re-  
 action is to produce an iodochloride; thus  
 $\text{FeCl}_3 + \text{KIAq} = \text{FeCl}_2 + \text{KCl} + \text{IAq}$ ; that this  
 then decomposes, more or less completely  
 (according to conditions of concentration, time,  
 temperature, and mass), into  $\text{FeCl}_2$  and  $\text{IAq}$ ;  
 and that  $\text{FeCl}_2$  and probably  $\text{FeCl}_3$  are  
 re-formed until equilibrium is established.  
 S. a. D. do not agree with the explanation of the  
 mechanism of the reaction given by Carnegie  
 (v. vol. iii. p. 55). Roozeboom (*Z. P. C.* 10, 477  
 [1892]) has investigated the conditions of equi-  
 librium in aqueous solution of the hydrates of  
 $\text{FeCl}_3$ ; he has isolated hydrates  $2\text{FeCl}_3 \cdot x\text{H}_2\text{O}$   
 where  $x = 4, 5, 7$ , and 12. (For details, v.  
*abstract in C. J.* 64 [11], 119 [1893]). For a  
 study of the interaction of  $\text{FeCl}_3$  and  
 oxalic acid, v. Lemoine, *C. R.* 116, 981 (*abstract in*  
*C. J.* 64 [11], 405 [1893]). A compound of  
 $\text{FeCl}_3$  with nitrosyl chloride,  $\text{FeCl}_3 \cdot \text{NOCl}$ , was  
 obtained by Sudborough (*C. J.* 59, 660 [1891]),  
 by immersing iron in liquid  $\text{NOCl}$ , and letting  
 the liquid stand over  $\text{H}_2\text{SO}_4$ ; the compound  
 forms small golden-brown, deliquescent crystals  
 (cf. vol. iii. p. 56; *Combinations*, No. 7).

**Ferrous fluoride** (vol. iii. p. 56).  $\text{FeF}_2$  was  
 obtained by Poulenc (*C. R.* 115, 941; *abstract in*  
*C. J.* 64 [11], 122 [1893]) by passing anhydrous  
 $\text{HF}$  over red-hot iron or dry  $\text{FeCl}_3$ ; small, white,  
 rhombic prisms; S.G. 4.09; decomposed by  
 heating with  $\text{H}_2\text{SO}_4$ ,  $\text{Na}_2\text{CO}_3$ , steam, air,  $\text{HCl}$ ,  
 or  $\text{H}$ .

**Ferric fluoride** (vol. iii. p. 56). Poulenc (*loc.*)  
 obtained  $\text{FeF}_3$  in small, very refractive, greenish  
 crystals, S.G. 3.87, by passing  $\text{HF}$  over red-hot  
 iron,  $\text{Fe}_2\text{O}_3$ ,  $\text{FeF}_2$ , or  $\text{FeCl}_3$ ; also by dropping  
 $\text{FeF}_2$  into fused  $\text{AmCl}$  and heating in a cur-  
 rent of an inert gas.  $\text{FeF}_3$  does not fuse at  
 $1000^\circ$ ; but is decomposed by heating in air, also  
 by fusion with  $\text{Na}_2\text{CO}_3$ , by heating in steam, or  
 with  $\text{HCl}$  or  $\text{H}_2$ . According to Sperazsky  
 (*J. R.* 24, 304; *abstract in C. J.* 64 [11], 314  
 [1893]),  $\text{FeF}_3$  shows a very small electrical  
 conductivity; there is, therefore, no appreciable  
 electrolytic dissociation; as the solution scarcely  
 effects any inversion of cane sugar, S. concludes

that there is practically no hydrolytic dissociation.  
 Cryoscopic determinations showed that  
 the molecules in a dilute aqueous solution are  
 chiefly  $\text{FeF}_3$ , but indicated the existence of  $\text{Fe}_2\text{F}_6$   
 in more conc. solutions.

**Iron, nitrides** (vol. iii. p. 59). Fowler  
 (*C. N.* 63, 158 [1893]) obtained  $\text{Fe}_3\text{N}$  by heating  
 reduced iron in a rapid stream of  $\text{NH}_3$ . (For  
 details v. *abstract in C. J.* 66 [11], 50 [1894]).

**Ferric oxide** (vol. iii. p. 61; also p. 57 for  
 hydrates). At  $1750^\circ$   $\text{Fe}_2\text{O}_3$  is completely changed  
 to  $\text{Fe}_3\text{O}_4$  (Read, *C. J.* 65, 313 [1894]); in the elec-  
 tric furnace  $\text{Fe}_2\text{O}_3$  is formed, partly melted and  
 partly crystallised (Moissan, *C. R.* 115, 1034  
 [1892]). According to J. van Bemmelen a.  
 Klobbie (*J. pr.* [2] 46, 497 [1893]), crystallised  
 $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$  is obtained by treating with water the  
 hexagonal crystals of  $\text{Fe}_2\text{O}_3 \cdot \text{Na}_2\text{O}$  formed by  
 heating  $\text{Fe}_2\text{O}_3$  for some time with conc.  $\text{NaOH}$  aq.;  
 the crystalline  $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$  is not hygroscopic;  
 $\text{H}_2\text{O}$  is given off below  $100^\circ$ .

**Iron, oxychlorides** (vol. iii. p. 62). Rousseau  
 (*C. R.* 110, 1032; 113, 643; 116, 392; *abstracts in*  
*C. J.* 58, 1093 [1890]; 62, 119 [1892]; 64 [11]  
 280 [1893]) describes compounds  $x\text{FeCl}_2 \cdot y\text{Fe}_2\text{O}_3$ ,  
 some crystalline and some amorphous, formed by  
 heating  $\text{FeCl}_2$  aq. at different temperatures, and  
 also by the interaction of  $\text{FeCl}_2$  and steam.

**LANTHANUM** (vol. iii. p. 116). Betendorff  
 (*A.* 256, 159 [1890]) obtained the value 438.23  
 for the at. w.; and Brauner (*B.* 24, 1378 [1891])  
 the value 138.21 (0 - 16).

Winkler (*B.* 24, 873 [1891]) obtained results,  
 by heating  $\text{La}_2\text{O}_3$  with  $\text{Mg}$  in  $\text{H}$ , which pointed  
 to the existence of a hydride of  $\text{La}$  (cf. Brauner,  
*loc.*).

**LEAD** (vol. iii. p. 122). The molecule in  
 dilute solution in tin is probably monatomic  
 (Heycock a. Neville, *C. J.* 57, 376 [1890]). The  
 m.p. of lead was found by Griffiths a. Calender  
 (using a Pt thermometer) to be  $327.69^\circ$  (*C. N.*  
 63, 1 [1891]). Lehmann (*Z. K.* 17, 274 [1890])  
 says that lead separated electrolytically by a  
 weak current, crystallises in leadlets that are  
 probably monosymmetric, but that the crystals  
 are regular octahedra when separated by a  
 strong current. Veley (*S. C. I.* 10, 206; sum-  
 mary of conclusions in *C. J.* 62, 410 [1892]) has  
 examined the interaction of lead and nitric acid:  
 an acid of intermediate concentration acts most  
 rapidly; when  $\text{HNO}_2$  is present the action in-  
 creases. Montemartini (*G.* 22, 384, 397, 426  
 [1892]) found that a little  $\text{NH}_3$  was produced,  
 especially with dilute  $\text{HNO}_3$  aq. Lead rapidly  
 oxidises to  $\text{PbO}$  when heated in  $\text{NO}$ ; oxidation  
 occurs at  $c. 200^\circ$  in  $\text{NO}_2$ , with formation of a  
 basic nitrate (Sabatier a. Senderens, *C. R.* 114,  
 1429 - 115, 236 [1892]).

**Lead, bromide** of (vol. iii. p. 125). Several  
 double compounds of  $\text{PbBr}_2$  with alkali bromides  
 have been described. For  $\text{PbBr}_2 \cdot \text{AmBr}$  aq. and  
 $2\text{PbBr}_2 \cdot \text{AmBr}$ , v. Wells a. Johnston, *Am. S.* [8]  
 46, 25 (*abstract in C. J.* 63 [11], 523 [1893]); for  
 $\text{PbBr}_2 \cdot \text{KBr}$  aq. and  $\text{PbBr}_2 \cdot 2\text{KBr}$  aq. v. Herty,  
*Am. S.* 15, 357 (*abstract in C. J.* 66 [11], 465  
 [1894]); for  $2\text{PbBr}_2 \cdot \text{RbBr}$  and  $2(\text{PbBr}_2 \cdot 2\text{RbBr})$  aq.  
 v. Wells a. Johnston, *Am. S.* [8] 46, 34 (*abstract in C. J.* 66  
 [11], 324 [1893]); and for  $\text{K}_2\text{PbBr}_4$  aq. and  
 $\text{K}_2\text{Pb}(\text{Br})_4$ , 4aq. v. Wells, *loc. p.* 190 (*abstract*  
*loc. p.* 524).

**Lead, chlorides of** (vol. iii. p. 125). The statement, on p. 125 (vol. iii.), that only one chloride has been isolated is no longer true;  $\text{PbCl}_2$  was prepared by Friedrich in 1893.

**Lead tetrachloride** (vol. iii. p. 126).  $\text{PbCl}_4$  has been obtained by Friedrich (*B.* 26, 1434; *abstract in C. J.* 64 [11], 415 [1893]; *cf. M.* 14, 505; *abstract in C. J.* 66 [11], 16 [1894]), by passing  $\text{Cl}$  into  $\text{HClAq}$  containing  $\text{PbCl}_2$  in suspension, adding  $\text{NH}_4\text{Cl}$  to the solution thus obtained, separating and drying the compound  $\text{PbCl}_2 \cdot 2\text{NH}_4\text{Cl}$  thus formed, adding it to conc. cooled  $\text{H}_2\text{SO}_4$ , allowing the oily drops that formed to collect at the bottom of the vessel, and shaking these drops repeatedly (and quickly) with conc.  $\text{H}_2\text{SO}_4$ .  $\text{PbCl}_4$  is a transparent, yellow, very refractive liquid, fuming in moist air with formation of  $\text{PbCl}_2$  and  $\text{Cl}$ ; it is unchanged in contact with cold conc.  $\text{H}_2\text{SO}_4$ , but when heated with the acid it decomposes explosively to  $\text{PbCl}_2$  and  $\text{Cl}$ ; when heated with conc.  $\text{H}_2\text{SO}_4$ , in a current of  $\text{Cl}$ , some  $\text{PbCl}_4$  passes over, but at c.  $105^\circ$  explosion occurs.  $\text{PbCl}_4$  has S.G. 3.18 at  $0^\circ$ ; at c.  $-15^\circ$  it solidifies to a yellowish, crystalline mass. A hydrate is formed with a little water; but addition of much water produces  $\text{HClAq}$  and  $\text{PbO}_2$ . By adding  $\text{PbCl}_4$  to a little cooled conc.  $\text{HClAq}$ , a crystalline compound, probably  $\text{PbCl}_4 \cdot 2\text{HCl}$ , is formed.

Several double salts of  $\text{PbCl}_4$  with alkali chlorides have been isolated. Classen & Zahorski (*Zelt. f. anorg. Chemie*, 4, 100) give the formula  $2\text{PbCl}_4 \cdot 5\text{AmCl}$  to the salt formed by digesting  $\text{PbCl}_4$  with liquid  $\text{Cl}$  and fuming  $\text{HClAq}$ , and adding  $\text{AmCl}$ ; but Friedrich (*loc. cit.*) says the compound is  $\text{PbCl}_4 \cdot 2\text{NH}_4\text{Cl}$ . For compounds  $\text{PbCl}_4 \cdot 2\text{MCl}$ , when  $\text{M} = \text{NH}_4$ ,  $\text{Cs}$ ,  $\text{K}$ , and  $\text{Rb}$ , v. Wells (*Ann. S.* [3] 46, 180; *abstract in C. J.* 64 [11], 523 [1893]); C. A. Z. (*loc. cit.*) describe compounds of  $\text{PbCl}_4$  with the hydrochlorides of pyridine and quinoline (*abstract in C. J.* 64 [11], 46 [1893]).

**Lead dichloride** (vol. iii. p. 125). Several double compounds with alkali chlorides are described by Randall (*Ann.* 15, 494 [1893]); Wells & Johnston (*Ann. S.* [3] 46, 25 [1893]); and Wells (*loc. cit.* p. 34). The compounds are of the forms  $\text{PbCl}_4 \cdot 2\text{MCl}$ ,  $\text{PbCl}_4 \cdot 3\text{MCl}$ ,  $\text{aq.}$ , and  $2\text{PbCl}_4 \cdot \text{MCl}$  (v. *abstracts in C. J.* 64 [11], 523, 524 [1893]).

**Lead, fluorides of** (vol. iii. p. 127). Brauner (*C. J.* 65, 393 [1894]) has prepared the compound  $\text{PbF}_4 \cdot 3\text{KF} \cdot \text{HF}$  in various ways; the simplest process being to dissolve  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$  (v. *REP OXIDE OF LEAD, Addenda, infra*) in conc.  $\text{HFAq}$  and add  $\text{KF}$ . By acting on this salt with conc.  $\text{H}_2\text{SO}_4$ , B. obtained evidence of the formation of lead tetrafluoride,  $\text{PbF}_4$ , but he did not succeed in isolating the compound.

**Lead, iodide of** (vol. iii. p. 127). Several double compounds of  $\text{PbI}_4$  with alkali iodides have been isolated by Wells & Johnston, and Herty (v. *References under LEAD, Bromine, p. 913*). For the compound  $\text{PbI}_4 \cdot 2\text{MgI}_2 \cdot 16\text{aq.}$ , v. Otto & Drewes (*Ar. P.* 229, 179; *abstract in C. J.* 64 [11], 984 [1893]).

**Lead iodobromide and iodochlorides** (vol. iii. p. 128). Miss Field (*C. J.* 63, 540 [1893]) has described the compounds  $2\text{PbI}_2 \cdot \text{PbI}_2$ ,  $2\text{PbCl}_2 \cdot \text{PbI}_2$ , and  $6\text{PbCl}_2 \cdot \text{PbI}_2$ .

**Lead protoxide** (vol. iii. p. 128).  $\text{PbO}$  is unchanged at c.  $1750^\circ$  (Read, *C. J.* 65, 818

[1894]). The hydrate  $2\text{PbO} \cdot \text{H}_2\text{O}$  (v. *loc. cit.* p. 128) is obtained in large crystals by allowing a solution of  $\text{PbO}$  in  $\text{KOHaq}$  to cool in the air;  $\text{CO}$  is absorbed, and the hydrate is deposited in colourless, tetragonal crystals,  $a:b:c = 1:1.42$  (Luedeking, *Ann.* 13, 120 [1891]).

**Red oxide of lead** (vol. iii. p. 130). Hutchinson & Pollard (*C. J.* 63, 1136 [1893]) have examined the reaction of  $\text{Pb}_2\text{O}_3$  with glacial acetic acid, and have isolated lead tetrachloride  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_4$ , melting at c.  $175^\circ$ , and decomposing a little above that temperature.

**Note.**—The formula  $\text{PbO}(\text{OC}_2\text{H}_3\text{O})_2$  said to be assigned by Jacquelin to the salt obtained by him (vol. iii. p. 130, *dbl.* 2, line 28 from top; and p. 131, *col.* 2, line 24 from bottom) should have been given as  $\text{PbO}(\text{C}_2\text{H}_3\text{O})_2$ , *old notation*.

**Plumbates** (vol. iii. p. 132). Kassner (*Ar. P.* [3] 28, 109; *abstract in C. J.* 58, 561 [1890]) describes plumbates of Ba, Ca, and Sr. Regarding the dissociation of Ca plumbate, v. Le Chatelier (*C. R.* 117, 109; *abstract in C. J.* 64 [11], 524 [1893]).

**Lead oxyiodides** (vol. iii. p. 132). Gröger (*M.* 13, 510; *abstract in C. J.* 62, 1892) describes the compound  $\text{PbO} \cdot \text{PbI}_2$ .

**Lead, salts of** (vol. iii. p. 132). The salt  $\text{Pb}(\text{O}_2\text{H})_2$  (v. *supra*, *Red oxide of lead*) belongs to the type  $\text{PbX}_2$ , to which form  $\text{PbCl}_2$  also belongs.

**Lead, sulphide of** (vol. iii. p. 151). According to Hannay (*C. J. Proc.*, Nos. 139, 141 [1894]), when air is passed into molten  $\text{PbS}$ , one half of the lead remains as lead, and one half is volatilised, and deposited as  $\text{PbS}$ ; H. accounts for this change by supposing the reaction to be  $2\text{PbS} + \text{O}_2 = \text{Pb} + \text{PbS} \cdot \text{SO}_2$ , the volatile  $\text{PbS} \cdot \text{SO}_2$  being decomposed in the colder part of the apparatus to  $\text{PbS}$  and  $\text{SO}_2$ .

**Lead sulphobromide and sulphochloride** (vol. iii. p. 133). Parmentier (*C. R.* 114, 298; *abstract in C. J.* 62, 685 [1892]) obtained the compounds  $\text{PbS} \cdot \text{PbBr}_2$  and  $\text{PbS} \cdot \text{PbCl}_2$  by dissolving the halides in their acids and shaking the liquids while  $\text{H}_2\text{S}$  was passed over the surfaces of the solutions.

**LITHIUM** (vol. iii. p. 147). Guntz (*C. R.* 117, 732 [1893]) recommends to use a mixture of equal weights of  $\text{LiCl}$  and  $\text{KCl}$  for the electrolytic preparation of the metal; the mixture melts at  $450^\circ$  and the m.p. decreases as electrolysis proceeds. (For details as to size of electrodes, strength of current, &c., v. *abstract in C. J.* 66 [11], 91 [1894].) Holt & Sims, *C. J.* 65, 445 [1894], find that traces of a peroxide are formed, along with  $\text{Li}_2\text{O}$ , by burning  $\text{Li}$  in  $\text{O}$ .

**Lithium, amide of**,  $\text{LiNH}_2$ . Formed by gently heating clean  $\text{Li}$  in a stream of  $\text{NH}_3$  until violent action ceases, and then heating to c.  $400^\circ$  until the reaction is finished. A white, crystalline, transparent solid; melts between  $380^\circ$  and  $400^\circ$ ; decomposes in cold water slowly, giving  $\text{LiOHaq}$  and  $\text{NH}_3$ ; decomposed by heating in air, but without taking fire (Titherley, *C. J.* 65, 504 [1894]; q. v. for further reactions).

**Lithium, bromide of** (vol. iii. p. 150). The hydrates  $\text{LiBr} \cdot \text{aq.}$ , where  $x = 1$  and 2, are described by Bogorodsky (*J. R.* 25, 3.3 [1893]).

**Lithium, chloride of** (vol. iii. p. 150). For  $\text{LiCl} \cdot \text{aq.}$  and  $\text{LiCl} \cdot 2\text{aq.}$  v. Bogorodsky (*loc. cit.*). For the double compounds  $\text{LiCl} \cdot \text{MCl} \cdot \text{aq.}$ , where

**Mn-Ox.** *Os. Fe. Mn. or Ni.* Chassevant (*C. R.* 112, 646; 115, 111; abstracts in *C. J.* 62, 118, 1278 [1892]).

**Lithium fluoride** of (vol. iii. p. 150). Poulenc (*Bull.* [3] 11, 15 [1894]) obtained LiF in regular octahedra by heating the amorphous fluoride with KHF<sub>2</sub> and KCl, and washing with water; sl. sol. water, insol. 95 p.c. alcohol; melts at c. 1000° in H<sub>2</sub>, and partially volatilises at 1100°-1200°.

**Lithium hydroxide** of (vol. iii. p. 150). For the freezing-points of aqueous solutions of LiOH v. Pickering (*C. J.* 65, 899 [1893]).

**Lithium nitride** of. Ouvrard (*C. R.* 114, 120 [1892]) obtained a black solid, probably Li<sub>3</sub>N, by heating commercial Li to dull redness in N<sub>2</sub>.

**Lithium oxides** of (vol. iii. p. 151). Almost the only products of heating Li in O is Li<sub>2</sub>O; only traces of a peroxide are formed (Holtz & Sims, *C. J.* 65, 443 [1894]).

**Magnesium** (vol. iii. p. 157). Burton & Vorce (*Am.* 12, 219 [1890]) obtained the value 24.22 (O = 15.96) for at. w., by converting pure Mg into Mg(NO<sub>3</sub>)<sub>2</sub> and this to MgO. The molecule of Mg in dilute solution in tin is probably monatomic (Heycock & Neville, *C. J.* 57, 376 [1896]). Mg crystallises in holohedral hexagonal ferrus,  $a:b:c = 1.1:1.0202$ , isomorphous with Zn and Be (H. a. V., l.c.).

According to Montemagni (*C.* 22, 381, 397, 426 [1892]), a considerable quantity of H is given off when Mg interacts with HNO<sub>3</sub> (c. 13 p.c.); the quantity of NH<sub>3</sub> formed increases with concentration of the acid up to 40 p.c. HNO<sub>3</sub>, after which it decreases. Mg burns in NO at a dull red heat (Sabatier & Senderens, *C. R.* 115, 236 [1892]). Georgis (*G.* 21, 510 [1891]) says that Mg dissolves in water saturated with CO<sub>2</sub>; that H is given off, and crystals of MgCO<sub>3</sub>·3aq are deposited. For the interactions of Mg and chlorides v. Suwert & Schmidt (*A.* 267, 219; abstract in *C. J.* 62, 776 [1892]). Winkler has made an extended examination of the interactions of Mg and oxides (*B.* 23, 44, 120, 772, 2642; 24, 873, 1966; abstracts in *C. J.* 53, 331, 451, 693, 1372 [1890]; 60, 801, 155 [1891]).

**Magnesium bromide** of (vol. iii. p. 159). Beketoff (v. abstract in *C. J.* 62, 764 [1892]) gives H.F. [Mg.Br<sup>+</sup>] = 121,700. The double salt 2MgBr<sub>2</sub>·PbBr<sub>2</sub>·16aq is described by Otto & Drewes (*Ar. Ph.* 229, 585; abstract in *C. J.* 62, 566 [1892]).

**Magnesium chloride** of (vol. iii. p. 159). Skinner (*C. J.* 61, 341 [1892]) gives the boiling-points of solutions of MgCl<sub>2</sub> in water and alcohol, from 4.5 to c. 14.5 p.c. MgCl<sub>2</sub>.

**Magnesium iodide** of (vol. iii. p. 161). Beketoff (l.c.) gives H.F. [Mg.I<sup>+</sup>] = 64,800.

**Magnesium nitride** of (vol. iii. p. 161). For description of an experiment to demonstrate the formation of Mg<sub>3</sub>N<sub>2</sub> v. Merz (*B.* 24, 8,940; abstract in *C. J.* 62, 409 [1892]).

**Magnesium oxide** of (vol. iii. p. 161). MgO is unchanged at c. 1750° (Read, *C. J.* 65, 313 [1894]); heated in the electric furnace, it melts with a current of 70 volts and 350 amperes (Moissan, *C. R.* 115, 1034; cf. *C. R.* 116, 1429 [1892-3]). Richards & Rogers (*P. Am.* 28, 300 [1893]) found that MgO, prepared by evaporating MgCO<sub>3</sub> or Mg, with HNO<sub>3</sub> and heat-

ing very strongly, retained c. 10 times its volume of gas, chiefly O and N.

**Magnesium silicides** of (vol. iii. p. 163). Regarding the formation of compounds by heating together Mg and Si, v. Winkler (*B.* 23, 2842; abstract in *C. J.* 58, 1873 [1890]).

**MANGANESE** (vol. iii. p. 177). Moissan (*C. R.* 116, 849 [1893]) obtained Mn containing 4 to 5 p.c. O, by fusing MnO with charcoal (keeping MnO in excess) by means of a current of 60 volts and 800 amperes. Prelinger (*M.* 14, 353; abstract in *C. J.* 66 [11], 49 [1894]) prepared pure Mn by fusing Mn amalgam (formed by electrolysis MnCl<sub>2</sub>Aq using a cathode of Hg) in pure H<sub>2</sub>.

Mn is described by P (l.c.) as a grey porous metal; unchanged in dry air; reacts slowly with cold, rapidly with warm, water; dissolves in NH<sub>4</sub>Cl, giving off NH<sub>3</sub> and H<sub>2</sub>; S.G. 7.4212 referred to water at 4°. Moissan (*C. R.* 116, 1429 [1893]) found that Mn volatilises readily in the electric furnace, using a current of 80 volts and 380 amperes. Montemagni (*C.* 22, 384, 397, 426 [1892]) says that the gaseous products of the interaction of Mn and HNO<sub>3</sub> are H<sub>2</sub>, NH<sub>3</sub>, N<sub>2</sub>, and N<sub>2</sub>O. Finely divided Mn reacts with CO at c. 400°, producing MnO and C (Guntz, *C. R.* 114, 115 [1892]).

**Manganese alloys** of. The presence of 6.5 p.c. Mn in iron or steel scarcely affects the properties, except by slightly increasing the tenacity and malleability; a very hard tool-steel is formed with c. 13 p.c. Mn. Alloys with iron containing from 7 to 30 p.c. Mn are extremely hard and tough.

**Manganese amalgams** of (vol. iii. p. 179). Prelinger (*M.* 14, 353; abstract in *C. J.* 66 [11], 49 [1894]) prepared Mn<sub>2</sub>Hg, by passing a current from a cathode of Hg through saturated MnCl<sub>2</sub>Aq to an anode of C, or Pt-Ir, in a porous vessel, washing in running water, squeezing out excess of Hg, and drying in H over CaCl<sub>2</sub>. By heating gently in a stream of pure, dry H<sub>2</sub>, pure Mn was obtained.

**Manganous chloride** (vol. iii. p. 179). Chassevant (*A. Ch.* [6] 30, 5 [1893]) describes several double salts of MnCl<sub>2</sub>; viz. MnCl<sub>2</sub>·AmCl<sub>2</sub>·2aq, MnCl<sub>2</sub>·2AmCl<sub>2</sub>·aq, and MnCl<sub>2</sub>·LiCl<sub>3</sub>·3aq. For the double salts M.KCl·2aq, M.CsCl·2aq; M·2XCl·2aq, X = NH<sub>4</sub>, Cs, Rb; 2M·MgCl<sub>2</sub>·12aq (M = MnCl<sub>2</sub>), v. Saunders (*Am.* 14, 127; abstract in *C. J.* 62, 780 [1892]).

**Manganic chlorides** (vol. iii. p. 180). Regarding the composition of the chloride in the solution obtained by dissolving MnO<sub>2</sub> in HClAq, v. Vernon (*P. M.* [5] 31, 469), and Pickering (*P. M.* [5] 33, 284) (abstracts in *C. J.* 62, 19, 687 [1892]).

**Manganese peroxide** (vol. iii. p. 183). Regarding the compositions of the hydrated oxides, approximately MnO<sub>2</sub>·2aq, prepared by different methods, v. Goëu (*B.* [3] 4, 16 [1891]). *C.* (*C. R.* 110, 877; abstract in *C. J.* 58, 946 [1890]) gives some details regarding the interaction of MnO<sub>2</sub>·2aq and H<sub>2</sub>O<sub>2</sub>·aq. Heated in the electric furnace, MnO<sub>2</sub> melts, gives off O, and leaves MnO (Moissan, *C. R.* 115, 1034 [1892]). MnO<sub>2</sub> is said to be formed by heating MnO, to c. 400° in NO (Sabatier & Senderens, *C. R.* 114, 1476 [1892]). McLeod (*C. J.* 65, 202 [1894]) has confirmed his former observation that O is

given off when  $\text{MnO}_2$  and  $\text{KClO}_4$  are heated together. Regarding compounds of  $\text{MnO}_2$  with basic oxides, v. Rousseau (*C. R.* 112, 525; 114, 72; 116, 1060; *abstracts in C. J.* 60, 645 [1891]; 69, 569 [1892]; 64 [11], 416 [1893]).

**Permanganates** (vol. iii. p. 186). Regarding the interaction of permanganates with  $\text{H}_2\text{O}_2$ , v. Gorgou (*C. R.* 110, 958; *abstract in C. J.* 58, 1062 [1890]). Klobb (*Bull.* [3] 3, 502; *abstract in C. J.* 58, 947 [1890]) describes compounds of  $\text{NH}_3$  with permanganates of Cd, Cu, Ni, and Zn.

**Barium permanganate**  $\text{BaMnO}_4$  (the formula is wrongly printed  $\text{BaMnO}_3$  in vol. iii. p. 186). For the preparation of this salt from  $\text{KMnO}_4$  and  $\text{Ba(NO}_3)_2$ , v. Muthmann (*B. Z.* 26, 1016; *abstract in C. J.* 64 [11], 324 [1893]).

**Calcium permanganate**. The formula given on p. 186 of vol. iii. is wrong; it should be  $\text{CaMnO}_4 \cdot 5\text{H}_2\text{O}$ .

**Potassium permanganate** (vol. iii. p. 186). Tivoli (*G. Z.* 19, 630 [1890]) gives the following as the reactions that occur when pure  $\text{AsH}_3$  is passed into dilute  $\text{KMnO}_4$ : (1)  $2\text{KMnO}_4 + \text{AsH}_3 = \text{K}_2\text{HASO}_4 + \text{Mn}_2\text{O}_3 + \text{H}_2\text{O}$ ; (2)  $2\text{KMnO}_4 + \text{AsH}_3 = \text{K}_2\text{HASO}_4 + 2\text{MnO}_2 + \text{H}_2\text{O}$ .

**Silver permanganate** (vol. iii. p. 187).  $\text{AgMnO}_4$  decomposes slowly at the ordinary temperature, rapidly at  $100^\circ$ , and very rapidly at  $125^\circ$  (Gorgou, *C. R.* 114, 912; *abstract in C. J.* 62, 942 [1892]).

**Manganese sulphide** (vol. iii. p. 188). The pp. produced by adding  $(\text{NH}_4)_2\text{HSAq}$  to an ammoniacal solution of a Mn salt, after washing in an atmosphere of  $\text{H}_2\text{S}$  and drying in  $\text{CO}_2$  at  $70^\circ$ , is  $\text{MnS}$ ;  $\text{S.G.}_{17}^{17} = 3.55$ . By heating to  $300^\circ$ – $320^\circ$ , or by leaving in contact with  $(\text{NH}_4)_2\text{HSAq}$  for some days, the reddish  $\text{MnS}$  becomes green without changing its composition; the green form of  $\text{MnS}$  is crystalline,  $\text{S.G.}_{17}^{17} = 3.63$  (Antony a. Donnini, *G. Z.* 23 [1], 560 [1892]).

**MASRIUM**. In 1892 (*C. J.* 61, 491) Richmond a. Husseinoff obtained indications of the existence of an element before unknown in specimens of Egyptian fibrous alums. The supposed new element gave reactions indicating analogies with Be, Ca, and Zn; the results obtained by decomposing the oxalate by heat led to the at. w. of c. 228. The authors suggested the name *masrium*, from the Arabic name for Egypt.

**MERCURAMMONIUM COMPOUNDS** (vol. iii. p. 206).

**Mercurio-ammonium salts**  $\text{NH}_4\text{Hg}_2\text{X}$  (vol. iii. p. 207). Barfoed's conclusion that the supposed compounds are really mixtures of mercurio-compounds and Hg is confirmed by Pesci (*G. Z.* 21 [11], 569 [1891]). The product of the interaction of  $\text{HgCl}_2$  and  $\text{NH}_4\text{Aq}$ , described as *dimercurio-ammonium chloride*  $\text{NH}_4\text{Hg}_2\text{Cl}$  in vol. iii. (p. 208), leaves azetlic Hg when treated with ammoniacal  $(\text{NH}_4)_2\text{SO}_4$  according to P. When the reaction of  $\text{HgCl}_2$  with  $\text{NH}_4\text{Aq}$  proceeds out of the light, P. says that the change is  $2\text{HgCl}_2 + 4\text{NH}_4\text{Aq} = (\text{NH}_4)_2\text{Cl}_2\text{NH}_4\text{Cl} + 2\text{NH}_4\text{ClAq} + 2\text{H}_2$ . Similarly the reaction of  $\text{NH}_4\text{Aq}$  with  $\text{Hg}_2\text{SO}_4$  produces a double compound of dimercurio-ammonium sulphate  $(\text{NH}_4)_2\text{SO}_4 \cdot (\text{NH}_4)_2\text{SO}_4$  and  $\text{Hg}_2$ ; and

$(\text{NH}_4)_2\text{NO}_3$ ,  $\text{NH}_4\text{NO}_3$ , and Hg are formed, according to P., when  $\text{HgNO}_3\text{Aq}$  is treated with  $\text{NH}_4\text{Aq}$ .

**Mercurio-ammonium salts**  $\text{NH}_4\text{Hg}_2\text{X}$ . Regarding the conditions of formation of compounds of mercurio-ammonium chloride  $\text{NH}_4\text{Hg}_2\text{Cl}$  (vol. iii. p. 208) with  $\text{HgCl}_2$  and  $\text{NH}_4(\text{Hg}_2\text{O})\text{Cl}_2$ , v. Balestra (*J. Z.* 21 [11], 294; *abstract in C. J.* 62, 276 [1892]).

**Dimercurio-ammonium salts**  $\text{NH}_4\text{Hg}_2\text{X}$  (vol. iii. p. 209). Pesci (*G. Z.* 20, 485 [1890]) has examined the conditions of formation of various salts of this class, especially the *nitrate*  $\text{NH}_4\text{Hg}_2\text{NO}_3$  and compounds of this with  $\text{NH}_4\text{NO}_3$ . The *sulphate*  $(\text{NH}_4)_2\text{SO}_4$  was formed by saturating conc.  $\text{NH}_4\text{Aq}$  with  $\text{HgSO}_4$ , allowing the solution to evaporate in an atmosphere of  $\text{NH}_3$  over  $\text{CaO}$ , and collecting the first crop of crystals; various compounds of  $(\text{NH}_4)_2\text{SO}_4$  with  $(\text{NH}_4)_2\text{SO}_4$  are also described (v. *abstract in C. J.* 60, 268 [1891]).

**MERCURY** (vol. iii. p. 212). Heycock a. Noville's results (*J. Z.* 57, 876 [1890]) show that some condensation from monatomic molecules perhaps occurs in dilute solutions of Hg in tin. For corrected tables of the vapour pressures of Hg for each  $10^\circ$  from  $180^\circ$  to  $480^\circ$ , and each  $1^\circ$  from  $830^\circ$  to  $860^\circ$ , v. Young (*C. J.* 59, 629 [1891]).

Jäger (*W. Z.* 48, 209 [1893]) recommends to prepare pure Hg by converting Hg that has been distilled *in vacuo* into  $\text{HgNO}_3$  and electrolysis a solution of the salt, using Pt as anode and distilled Hg as anode. Sherstone (*J. Z.* 61, 452 [1892]) noticed that Hg adheres to glass when brought into contact with Cl, Br, or I. Montmartini (*G. Z.* 23, 884, 397, 426 [1891]) finds that the amount of NO produced by the interaction of Hg and  $\text{HNO}_3$  decreases as concentration of the acid increases; that  $\text{NO}_2$  is produced with acid more conc. than 27.5 p.c.  $\text{HNO}_3$ ;  $\text{HgNO}_3$  is formed with 25 p.c. acid, but  $\text{Hg(NO}_3)_2$  with 50 to 70 p.c. acid; no  $\text{NH}_3$  is formed with 27 and 50 p.c. acid.

**Mercuric bromide** (vol. iii. p. 215).  $\text{HgBr}_2$  boils at  $325^\circ$ , according to Freyer a. V. Meyer (*Zeit. f. anorg. Chemie*, 2, 1 [1892]).

**Mercurous chloride** (vol. iii. p. 215). Harris a. V. Meyer have re-determined the V.D. of calomel at  $448^\circ$  and  $518^\circ$ ; the value obtained was 117.5. H. a. M. obtained considerable quantities of Hg and  $\text{HgCl}_2$  by allowing the vapours obtained by heating calomel to c.  $465^\circ$  to diffuse along a glass tube; also by heating calomel at  $420^\circ$  for half an hour in a distillation flask at 33 mm. pressure. By heating calomel to  $540^\circ$ – $560^\circ$ , and bringing a piece of KOH, which had been heated to c.  $250^\circ$ , into the vapour, they noticed that the surface of the KOH at once became covered with yellow  $\text{HgO}$ ; they also found that a piece of gold leaf held for a moment in the vapour was amalgamated (if kept for some time in the hot vapour the yellow colour was restored). H. a. M. think their results leave no doubt that the vapour obtained by heating calomel is  $\text{Hg} + \text{HgCl}_2$ , and that the molecular formula of calomel is  $\text{HgCl}_2$ .

The reaction of  $\text{HgCl}_2$  with  $\text{NH}_4\text{Aq}$  gives  $(\text{NH}_4)_2\text{Cl}_2\text{NH}_4\text{Cl}$  and Hg, according to Pesci (v. *supra*). **MERCURIO-AMMONIUM SALTS**.

**Mercuric chloride** (vol. iii. p. 217).  $\text{HgCl}_2$  boils at  $307^\circ$  (Freyer a. V. Meyer, *Zeit. f. anorg. Chemie*, 2, 1 [1892]). The white substance

processes by the reduction of  $\text{HgCl}_2\text{Aq}$  with a silver photographic image, or with pulverulent Ag, in  $\text{HgCl}_2$ , according to Jones (S. C. M. 12, 985; abstract in C. J. 66 [11], 188 [1894]).

**Mercuric cyanide**, for an account of the conditions of formation and properties of the double mercury-zinc cyanide, v. Dunstan (C. U. 62, 666 [1892]).

**Mercury, haloid compounds of** (vol. iii. p. 219). Wells (Am. S. [3] 44, 221; abstract in C. J. 64 [11], 68 [1893]) describes a number of double compounds of mercury and cesium halides; the compounds belong to the forms (1)  $\text{Cs}_2\text{HgX}_4$ , (2)  $\text{Cs}_2\text{HgX}_6$ , (3)  $\text{Cs}_4\text{HgX}_{10}$ , (4)  $\text{CsHgX}_3$ , (5)  $\text{CsHgX}_5$ , (6)  $\text{CsHg}_2\text{X}_7$ ; X = Cl, Br or I; in some cases the total X atoms comprise two different halogens.

**Mercury hydrosulphide**; for experimental attempts to prepare a definite compound, v. Linder a. Pietsch (C. J. 61, 123 [1892]).

**Mercury phosphide** (vol. iii. p. 223). By heating Hg and P, in a sealed tube for many hours at  $275^\circ\text{--}300^\circ$ , and removing HgI, by treatment with  $\text{KIaq}$ , Granger (C. R. 115, 229 [1892]) obtained  $\text{Hg}_3\text{P}_2$  in lustrous, metal-like, hexagonal crystals, appearing red by transmitted light, and giving a brown powder. The compound gives Hg and P when heated; heated in air it burns; detonates when mixed with  $\text{KClO}_4$  and struck; burns in Cl; dissolved by aqua regia.

**Mercurous sulphide** (vol. iii. p. 224). Antony a. Sestini (G. 24 [1], 193 [1894]) obtained a black powder by passing dry  $\text{H}_2\text{S}$ , diluted with  $\text{CO}_2$ , over dry  $\text{Hg}_2\text{Cl}_2$  or  $\text{Hg}(\text{C}_2\text{H}_3\text{O}_2)_2$ , kept at  $-10^\circ$ ; when freshly prepared the black powder was scarcely changed in dry  $\text{HCl}$  at  $-18^\circ$ , but at a somewhat higher temperature (below  $0^\circ$ )  $\text{Hg}_2\text{Cl}_2$  was quickly formed. The substance dissolved in cold  $\text{K}_2\text{SAq}$  or  $\text{NaSAq}$ , but when temperature rose above  $0^\circ$  the solution became turbid and pptd. Hg. A. a. S. think their results show that  $\text{Hg}_2\text{S}$  exists at low temperatures (abstract in C. J. 66 [11], 318 [1894]).

**Mercury sulphochloride** (vol. iii. p. 225). The compound  $2\text{HgS} \cdot \text{HgCl}_2$  is formed, according to Colson (C. R. 115, 657 [1892]), by passing  $\text{H}_2\text{S}$  into a solution of  $\text{HgCl}_2$  in dry benzene.

**MOLYBDENUM** (vol. iii. p. 421). Smith a. Maas (A. C. J. 15, 897 [1894]) obtained the mean value 95.85 (O = 15.96) for the at. w. of Mo, by heating  $\text{Na}_2\text{MoO}_4$  in a current of dry  $\text{HCl}$  and weighing the NaCl that remained ( $\text{MoO}_3 \cdot 2\text{HCl}$  and  $\text{H}_2\text{O}$  were formed and removed). Smith a. Oberholtzer (Zeit. f. anorg. Chemie, 2, 63 [1893]) say that a mixture of  $\text{MoOC}_2$  and  $\text{Mo(CO)}_6$  is formed by heating Mo to  $150^\circ\text{--}200^\circ$  in  $\text{COCl}_2$ ; and that  $\text{Mo}_2\text{S}_2\text{Cl}_4$  is produced by heating Mo to wedness in  $\text{S}_2\text{Cl}_2$ . Mo is said to ppt. Ag from  $\text{AgNO}_3\text{Aq}$ , Au from  $\text{AuCl}_3\text{Aq}$ ,  $\text{HgCl}_2$  and then Hg from  $\text{HgCl}_2\text{Aq}$ , and Cu from solutions of its salts (Smith, Zeit. f. anorg. Chemie, 1, 860 [1891]). Montemartini (G. 22, 884, 897, 426 [1891]) finds that no  $\text{NH}_3$  is formed in the interaction of Mo and  $\text{HNO}_3\text{Aq}$  with from 8 to 70 p.c.  $\text{HNO}_3$ ; the most vigorous action occurs with acid c. 50 p.c., but the whole of the metal is not oxidised to  $\text{MoO}_3$ , a nitrate being probably formed; the gaseous products are  $\text{SO}$  and  $\text{NO}$ , the quantity of  $\text{NO}$  decreasing as the concentration of the acid increases.

**Molybdenum, carbides of**. By heating a mixture of  $\text{MoO}_3$  and charcoal in the electric furnace, Moissan (C. R. 116, 1235 [1893]) obtained a very hard carbide, containing from 9.77 to 9.9 p.c. C; S.G. 8.8.

**Molybdenum sesquioxide** (vol. iii. p. 431). Heating  $\text{Mo}_2\text{O}_3$  in  $\text{NO}$  produces  $\text{MoO}_3$  (Sabatier a. Senderens, C. R. 114, 1429 [1892]).

**Molybdenum trioxide** (vol. iii. p. 432).  $\text{MoO}_3$ , partially volatilises, and is partially reduced to one of the blue oxides, at c.  $1750^\circ$  (Read, C. J. 65, 813 [1894]). According to Smith a. Oberholtzer (Zeit. f. anorg. Chemie, 4, 236 [1893]), the products of heating  $\text{MoO}_3$  in  $\text{HBr}$  are (1)  $\text{MoO}_3 \cdot 3\text{HBr}$ , and (2)  $\text{Mo}_2\text{O}_5\text{Br}_2$ ; when  $\text{HI}$  is used and the temperature kept at  $105^\circ\text{--}120^\circ$ , a blue oxide  $\text{Mo}_2\text{O}_5$  is formed;  $\text{H}_2$  at  $300^\circ\text{--}400^\circ$  forms  $\text{Mo}_2\text{O}_5\text{F}_2$  (v. abstract in C. J. 64 [11], 471 [1893]). Cammerer (Chem. Zeit. 15, 967; abstract in C. U. 62, 944 [1892]) says that  $2\text{MoO}_3 \cdot \text{H}_2\text{O} \cdot \text{H}_2\text{O}$  is formed by boiling  $\text{MoO}_3$  with  $\text{H}_2\text{Oaq}$ .

**Molybdenum, oxybromides of** (vol. iii. p. 433). Smith a. Oberholtzer (Zeit. f. anorg. Chemie, 4, 236 [1893]) describe  $\text{Mo}_2\text{O}_5\text{Br}_2$ , square plates, color of  $\text{KMnO}_4$ . Formed, along with  $\text{MoO}_3 \cdot 3\text{HBr}$ , by heating  $\text{MoO}_3$  in  $\text{HBr}$ .

**Molybdenum, oxyfluorides of** (vol. iii. p. 433). For the products of the interaction of  $\text{MoO}_3\text{Cl}_3$  and  $\text{NH}_3$ , v. Smith a. Lehner (Zeit. f. anorg. Chemie, 4, 374; abstract in C. J. 64 [11], 629 [1893]).

**Molybdenum, oxycyanide of**. By dissolving  $\text{MoO}_3$  in  $\text{KCyAq}$ , and adding a strong acid, Pechard (C. R. 118, 804 [1894]) obtained  $\text{MoO}_3\text{Cy}_2$ . Easily decomposed by contact with acids; double compounds with  $\text{KCy}$  and  $\text{AgCy}$  are also described.

**Molybdenum, oxyfluorides of** (vol. iii. p. 433). For  $\text{Mo}_2\text{O}_5\text{F}_2$ , a white, crystalline, deliquescent solid, obtained by heating  $\text{MoO}_3$  in  $\text{HF}$  at  $300^\circ\text{--}400^\circ$ , v. Smith a. Oberholtzer (l.c.).

**Molybdenum, thioclauride of**. For  $\text{Mo}_2\text{S}_2\text{Cl}_4$ , v. S. a. O. (l.c. 5, 63).

**Molybdates, and derivatives thereof** (vol. iii. p. 423). For compounds of molybdates of  $\text{NH}_4$  and K with  $\text{SO}_2$  and  $\text{SeO}_2$ , v. Pechard (C. R. 116, 1441; 117, 104; abstracts in C. J. 64 [11], 530 [1893]).

**Perrymolybdates**. By the reaction of  $\text{H}_2\text{O}_2\text{Aq}$  with  $\text{K}_2\text{MoO}_4\text{Aq}$ , Pechard (C. R. 112, 720; abstract in C. J. 60, 988 [1891]) obtained potassium perrymolybdate  $\text{K}_2\text{MoO}_4 \cdot 4\text{aq}$ ; the corresponding  $\text{NH}_4$  salt was also formed.

**Arseno-molybdates** (vol. iii. p. 425). For salts of this class, v. Friedheim (Zeit. f. anorg. Chemie, 2, 814; 6, 11, 27; abstracts in C. J. 64 [11], 283; 66 [11], 238 [1893, 4]).

**Iodomolybdates**. A great many salts of the form  $x\text{MoO}_3 \cdot y\text{I}_2 \cdot z\text{H}_2\text{O}$  are described by Blomstrand (Zeit. f. anorg. Chemie, 1, 10; abstract in C. J. 64 [11], 122 [1893]).

**Phosphomolybdates** (vol. iii. p. 426). Friedheim (Zeit. f. anorg. Chemie, 4, 276; 6, 11, 27; abstracts in C. J. 64 [11], 472; 66 [11], 288 [1893, 4]) describes several salts of this class.

**Fluomolybdates** (vol. iii. p. 425). v. Piccini (Real. Acad. Lincei, 7 [1], 267; abstract in C. J. 62, 434 [1892]), and Mauro (l.c., 1892 [1], 194; abstract in C. J. 64 [11], 124 [1893]).

**NICKEL** (vol. iii. p. 498). The *sat. w.* has been re-determined (1) by Schützenberger, by reducing oxides of Ni in H<sub>2</sub> (C. R. 114, 1149 [1892]); (2) by Winkler, by estimating Cl in NiCl<sub>2</sub> prepared from electrolytically deposited Ni (Zeit. f. anorg. Chemie, 4, 10 [1893]). Schützenberger's values varied from 58.5% to 59.8; Winkler's mean value from the gravimetric determinations was 58.903, and from the volumetric determinations 58.910 (Cl = 35.37, Ag = 107.66). Krüss a. Schmidt (Zeit. f. anorg. Chemie, 2, 235 [1892]) insist that the substance called nickel is not an element, but Winkler (i.e.) controverts this statement (v. abstracts in C. J. 64 [11], 212, 469 [1893]). The molecule of Ni in dilute solution in tin is probably monatomic (Heycock a. Neville, C. J. 57, 376 [1890]). Schützenberger (C. R. 113, 177 [1891]) says that a volatile compound is formed by passing dry HCl over finely divided Ni heated to a dull redness. Montmartini (G. 22 [1], 253; abstract in C. J. 62, 1278 [1892]) gives the quantities of NH<sub>3</sub>, N<sub>2</sub>O, N, and HNO<sub>2</sub> (no NO) produced by the reaction of excess of HNO<sub>3</sub>Aq (27.5 p.c.) with Ni. Heated to 200° in NO, the oxide NiO is formed without any Ni<sub>2</sub>O (Sabatier a. Sendgrens, C. R. 114, 1429 [1892]). By passing NO<sub>2</sub>, diluted with N, over reduced Ni, nitro-nickel (or Ni<sub>2</sub>NO<sub>2</sub>) is obtained; it resembles nitro-cobalt (see p. 908) (S. a. S., Bl. [3] 9, 669 [1893]).

**Nickel carbonyl** Ni(CO)<sub>4</sub> (Nickel carbonyl, vol. iii. p. 501). Mol. w. was confirmed by Mond a. Nasini (Z. P. C. 8, 150 [1891]), by finding the depression of the freezing-point of benzene. S.G. 1.35613 at 0°, 1.27132 at 36° (water at 4° = 1); S.G. at b.p. = 1.25406; molecular weight = 186.04; critical temp. = 151°. For some reactions v. Berthelot (C. R. 112, 1343; abstract in C. J. 60, 1427 [1890]).

**Nickel, chloride of** (vol. iii. p. 501). A volatile substance, decomposed by heating, is said to be formed by passing dry HCl over dry NiCl<sub>2</sub> at dull redness (Schützenberger, C. R. 113, 177; v. abstract in C. J. 60, 1429 [1890]). Chassevant (A. Ch. [6] 30, 5 [1893]) describes the double compounds NiCl<sub>2</sub>.AmCl.6aq and NiCl<sub>2</sub>.K<sup>+</sup>Cl.3aq.

**Nickel, fluoride of** (vol. iii. p. 502). Poulenc (C. R. 114, 1426 [1892]) obtained amorphous NiF<sub>2</sub> by heating NiCl<sub>2</sub> with excess of NH<sub>4</sub>F, and washing away NH<sub>4</sub>Cl with boiling alcohol; by heating in HF to 1200°-1300°, the amorphous MF<sub>2</sub> became crystalline, forming green crystals, S.G. 4.63, not acted on by warm HNO<sub>3</sub>Aq, HClAq, or H<sub>2</sub>SO<sub>4</sub>Aq. Heated in air, NiF<sub>2</sub> gives NiO; heated with S it gives NiS; and with H<sub>2</sub> it is reduced to Ni (for other reactions, v. abstract in C. J. 62, 1159 [1892]). The double salt NiF<sub>2</sub>.KF is formed by heating NiCl<sub>2</sub> with KHF<sub>2</sub>, and washing away KCl by water (P., C. R. 114, 746 [1892]).

**Nickel monoxide** (vol. iii. p. 502). NiO melts and forms green crystals in the electric furnace (Moissan, C. R. 115, 1034 [1892]). NiO occludes small quantities of N and O (Richards a. Rogers, P. Am. A. 28, 200 [1893]).

**Nickel sesquioxide** (vol. iii. p. 502). Ni<sub>2</sub>O fuses, gives up all its O, and leaves Ni at c. 1750° (Read, C. J. 16, 313 [1894]).

**Nickel peroxide** (vol. iii. p. 503). Campbell a. Trowbridge (J. Anal. and App. Chem. 7, 301;

abstract in C. J. 46 [11], 288 [1894]) conclude that an oxide with more O than Ni<sub>2</sub>O can be obtained by ppg. NiSO<sub>4</sub>Aq by Na<sub>2</sub>CO<sub>3</sub>Aq in presence of Br at different temperatures.

**Nickel monosulphide** (vol. iii. p. 503). Regarding the oxidation of this salt in air, to NiSO<sub>4</sub>.6NiO, v. P. de Clermont (C. R. 117, 229; abstract in C. J. 64 [11], 528 [1894]).

**NIYBIUM** (vol. iii. p. 505). Nb<sub>2</sub>O<sub>5</sub> is not changed at c. 1750° (Read, C. J. 16, 313 [1894]). Piccini (Zeit. f. anorg. Chemie, 2, 21 [1892]) has prepared potassium fluoroniobate K<sub>2</sub>NbO<sub>5</sub>.2KF.aq.

**NITRAMIDE** NO<sub>2</sub>(NH<sub>2</sub>). Thiele a. Lachman (B. 27, 1909 [1894]) obtained this compound by throwing NO<sub>2</sub>.NK.CO<sub>2</sub>K (potassium nitro-carbamate) into a mixture of ice and excess of H<sub>2</sub>SO<sub>4</sub>, extracting with ether, and evaporating in a stream of air. Crystals in clear prisms, which melt at 72° with decomposition; decomposed instantly to N<sub>2</sub>O and H<sub>2</sub>O by alkalis, alkali carbonates, borax, or Na acetate.

**NITRATES** (vol. iii. p. 509). Rolsseau a. Tite (C. R. 115, 174 [1892]) find that many basic nitrates are completely decomposed by heating with water at 150°-200°. Regarding the formation of basic nitrates of Cd, Ca, Ni, and Zn, v. R. a. T. (C. R. 114, 1184); Riban (C. R. 114, 1357); and Werner (C. R. 115, 169); (abstracts in C. J. 62, 1156, 1157, 1276 [1892]).

**NITRIC ACID** (vol. iii. p. 517). Regarding the colours produced by diluting and fuming, HNO<sub>3</sub>Aq v. Marchlewski (B. 24, 3271 [1891]). For revised tables showing the composition of HNO<sub>3</sub>Aq of different concentrations v. Lunge a. Rey (S. C. I. 1891, 543). Regarding the magnetic rotations of HNO<sub>3</sub>Aq v. Porkin (S. J. 63, 57 [1893]). Hall (Am. 13, 554) has examined the rate of production of H<sub>2</sub>O and the effect on the concentration of the acid, by the slow and steady electrolysis of HNO<sub>3</sub>Aq (abstract in C. J. 62, 680 [1892]). The interactions of HNO<sub>3</sub>Aq with many metals have been examined by Montmartini (G. 22 [1], 250, 277, 384, 397, 426 [1891]; abstracts in C. J. 62, 1278, 1402 [1892]), Veley (S. C. I. 10, 206; and elsewhere), and others; the results are noted under various metals. Pickering (C. J. 63, 436 [1893]) has isolated the hydrates HNO<sub>3</sub>.H<sub>2</sub>O and HNO<sub>3</sub>.3H<sub>2</sub>O; the freezing-points of HNO<sub>3</sub>Aq, from 1.82 to 86.19 p.c. HNO<sub>3</sub>, are given by P.

**NITROGEN** (vol. iii. p. 546). S.G. of N<sub>2</sub> (at 0°) = 1.257209; 1 litre weighs 1.25749 g. (Rayleigh, P. 1, 53, 134 [1893]).  $\mu_D = 1.2053$  at -190° (liquid N, containing 5 p.c. O) (Livinge a. Dewar, P. M. [5] 36, 929 [1893]). Absorption coefficient in alcohol, v. Menrich (Z. P. C. 9, 435 [1892]). Diffusion in water, v. Duncanson a. Hoppe-Seyler (Zeit. physiol. Chemie, 17, 147 [1893]).

**Preparations of pure nitrogen**. Threlfall (S. M. [5] 33, 1 [1893]) gives minute directions for preparing pure N by passing air and NH<sub>3</sub> over hot Cu, and absorbing traces of O by CrCl<sub>3</sub>Aq; exact directions for preparing the CrCl<sub>3</sub>Aq are given, and the paper contains numerous details regarding the purifications of the reagents used in the process.

**Supposed allotropic form of nitrogen**. Threlfall (i.e.) has repeated experiments on sparking extremely pure N (v. vol. iii. p. 57); no condensation occurred down to -10° and c. 8 mm.

pressure, but when  $Hg_2$  is present a compound of N and Hg is formed (probably  $Hg_2N_2$ , v. vol. iii. p. 221). Regarding the fixation of nitrogen by growing plants, cf. Beyerinck, also Schloesing & Laurent (abstracts in C. J. 62, 1019, 1021 [1892]).

Nitrogen, hydrides of (vol. iii. p. 559).

Hydrazic acid  $N_2H_4$ . For new methods of preparing  $N_2H_4$  v. Curtius (B. 24, 3341; 26, 1263; abstracts in C. J. 62, 112; 64 [11], 463 [1892-3]). Wislicenus (B. 25, 2084 [1892]) has obtained  $N_2H_4$  by the interaction of  $NH_3$  and  $N_2O_3$ . From 1 g. to 1 g. Na is heated in a stream of  $NH_3$ , until all is converted into  $NaNH_2$ ; a current of dry  $N_2O$  is then passed over the  $NaNH_2$  at 150°-250° as long as  $NH_3$  is given off ( $2NaNH_2 + N_2O = NaN_3 + NaOH + NH_3$ ). By dissolving the product in water, filtering, decomposing by dilute  $H_2SO_4$ , and distilling,  $N_2H_4$  is obtained.

The following salts are described by Curtius (B. 24, 3341; abstract in C. J. 62, 112 [1892]):  $(NH_4)_2N_2$ ,  $Pb(N_2)_2$ ,  $HgN_2$ ,  $NaN_3$ .

Nitrogen, iodides of (vol. iii. p. 560). Diiodamine,  $NH_2I$ , is the product of adding excess of  $NH_3$  to a conc. solution of I in conc.  $KIAg$ ; by suspending  $NH_3$  in water, and adding an ammoniacal solution of  $AgNO_3$  or  $Ag_2O$ , a black compound  $NaI_2$  is obtained which explodes when dry (Sazhaya, B. 26, 1433; abstract in C. J. 64 [11], 568 [1893]; cf. Selivanoff, B. 27, 1012; abstract in C. J. 66 [11], 312 [1894]).

Nitrous oxide (vol. iii. p. 561). Ramsay & Shields (C. 63, 833 [1893]) give the m.p. of  $N_2O$  as  $-102.3^\circ$ , and the b.p. as  $-89.8^\circ$ . Villard (C. R. 118, 1096 [1894]) gives the following data for the S.G. of liquid  $N_2O$ : 1.05 at  $0^\circ$ , 1.05 at  $5^\circ$ , 1.05 at  $10^\circ$ , 1.04 at  $17.5^\circ$ , 1.03 at  $26.5^\circ$ , 1.02 at  $32.9^\circ$ , 1.01 at  $34.9^\circ$ , 1.00 at  $36.3^\circ$ . Livinge & Dewar (P. M. [5] 34, 205 [1892]) give

$$\mu_D - 1 = .2634, \text{ and } \frac{\mu^2 - 1}{(\mu^2 + 2)^2} = .163 \text{ at } -90^\circ.$$

Smith (S. C. 1, 11, 867; 12, 10 [1893]) says that a regular stream of  $N_2O$  is obtained by heating to  $240^\circ$ - $260^\circ$  a mixture of 1 pt. dry  $NaNO_3$  with c. 1 pt. dry  $(NH_4)_2SO_4$ . By passing  $N_2O$ , mixed with a little H, over Pd black, the H is entirely converted to  $H_2O$ , with formation of N (Montemartini, Real. Acad. Lincei, 7 [11], 219 [1892]).

Nitric oxide (vol. iii. p. 562). Very pure NO is obtained, according to Emich (J. 13, 73 [1892]), by the interaction of copper and a mixture of  $H_2SO_4$  and  $HNO_3$ . Emich (l.c., p. 78) finds that NO is completely decomposed to N and O by passing over nets of Pt or Pd wire kept very hot by an electric current. Emich (l.c. p. 86) says that NO and O unite after being dried by long contact with  $P_2O_5$ ; but Baker (C. J. 65, 611 [1894]) finds that dry NO and dry O do not combine at the ordinary temperature. Regarding the reactions between NO and metals and metallic oxides, v. Salatierr & Senderens (C. R. 114, 1420; 1470; abstracts in C. J. 62, 1151, 1271 [1892]); results are noted under the different metals and oxides in Addenda.

Nitrogen dioxide (vol. iii. p. 565). For the reactions of  $N_2O_4$  with various metals and oxides v. S. a. C. (J. 115, 286; abstracts in C. J. 62, 1390 [1892]); results are noted under the different metals and oxides in Addenda.

Nitrogen tetroxide (vol. iii. p. 565). For preparation of  $N_2O_4$  v. Cundall (C. J. 59, 1076 [1891]). O. (l.c.) has measured the dissociation of liquid  $N_2O_4$  in  $CHCl_3$  up to c.  $35^\circ$ ; Ostwald (C. J. 61, 242 [1892]) shows that the dissociation follows van't Hoff's law for dilute solutions.

Nitrous acid (vol. iii. p. 567). Regarding the formation of  $HNO_2$  in solution in  $HNO_3$ , v. Veley (P. 52, 27; abstract in C. J. 64 [11], 415 [1893]).

Hyponitrous acid (vol. iii. p. 568). Tanatar (J. R. 25, 342; abstract in C. J. 66 [11], 186 [1894]) prepared  $Ag_2N_2O_2$  by adding CaO to fairly conc.  $KNO_3$  in the ratio  $CaO:KNO_3$ , then an equivalent of solid  $NH_4OH.HCl$ , heating to  $50^\circ$ , letting stand for a few days at the ordinary temperature, filtering, acidifying with acetic acid, ppg. by  $AgNO_3$ , dissolving  $Ag_2N_2O_2$  in  $HNO_3$  (which leaves  $AgCl$ ), and ppg. again by Na acet.

Osmium (vol. iii. p. 611). Os fuses readily in the electric arc in a carbon capsule; when fused it has a crystalline fracture, and scratches quartz, but is scratched by topaz (Joly & Vézès, C. R. 116, 577 [1893]).

Osmic acid (vol. iii. p. 640). Morah (a. Wischin (Zeit. f. anorg. Chemie, 3, 153; abstract in C. J. 64 [11], 380 [1893]) say that the black powder obtained by the interaction of osmium and  $K_2OsO_4$  (vol. iii. p. 645), when dried over  $P_2O_5$  in *vacuo* till it ceases to lose weight, is osmic acid  $H_2OsO_4$ . M. a. W. describe the compound as a sooty black powder, smelling of  $OsO_3$  in moist air, but unchanged under water containing alcohol. By passing  $H_2S$  over  $H_2OsO_4$ , a violent reaction occurs, and  $OsO_3.S.H_2O$  is formed. Heated with conc.  $HCl$  for many hours with a little alcohol, and evaporated,  $OsCl_4$  was obtained; an alcoholic solution of this substance with  $KClAq$  gave  $K_2OsCl_6$ , and the filtrate yielded  $OsCl_4$  3nq; the substance  $OsCl_4$  is therefore supposed by M. a. W. to be a mixture of  $OsCl_4$  and  $OsCl_3$ . By heating  $H_2OsO_4$  with  $HIAq$ , violet black crystals, probably  $OsI_4$ , were obtained. No action occurs when Os is heated with I, or with Br.

Potassium osmiumate (vol. iii. p. 645). Joly (C. R. 112, 1442 [1891]) prepares this salt by dissolving 100 pts. Os, in a solution of 100 pts.  $KOH$  in 50 pts.  $H_2O$ , keeping the solution at c.  $40^\circ$ , and adding 40 c.c.  $NH_3$ ; after a time the brown liquid becomes colourless, and a yellow crystalline pp. is formed. J. gives the formula  $KNOsO_4$  to this salt. Heated in *vacuo* it is rapidly decomposed above  $200^\circ$ , and at  $440^\circ$  almost all the N is given off, the solid products being  $K_2O$ ,  $OsO_3$ , and  $KOsO_4$  (v. abstract in C. J. 60, 1433 [1891]).

Oxides (vol. iii. p. 658). Regarding the connections between the stability of oxides when heated and the periodic classification of the elements, v. Bailey (C. J. 65, 106, 321 [1894]).

Oxygen (vol. iii. p. 703). Atomic weight of oxygen (vol. iii. p. 705). Dumas & Henderson (C. N. 87, 127, 139, 151, 164; abstract in C. J. 64 [11], 410 [1893]) from careful determinations made by passing H over hot  $CuO$ , and weighing the water and  $Cu$  produced, adopt the value 15.87 for the at. w. of O. By measurements of the combining volumes of O and H, combi

ning the results with Rayleigh's determination of the S.G. of O, Scott (Z. 184, 648 [1898]) got the value 15.862. The following values summarise the most recent determinations (v. D. a. H., l.c.), Cooke a. Richards, 15.868; Noyes, 15.885; Rayleigh (Pr. 45, 426 [1890]), 15.89; Keiser, 15.949; Ledue (C. R. 146, 1248 [1898]), 15.88; D. a. H., 15.97; Scott, 15.862. The value adopted in this Dictionary, 15.90, is almost certainly too high; the mean of the values obtained by C. a. R., N., R., D. a. H., and S., is 15.875.

The ratio of the combining volumes of O and H was determined by Scott (l.c.) to be 2.00245:1 (v. WATER, this vol. p. 861). S.G. of O referred to H = 15.882 (Rayleigh, Pr. 50, 448 [1892]). For an examination of the whole of the spectrum of O, v. Eisig (W. 61, 747: abstract in C. J. 66 [11], 265 [1894]). Livinge a. Dewar (P. M. [5] 84, 205 [1892]) determined  $\frac{\mu-1}{d}$  to be 1.389, and

$\frac{\mu^2-1}{(\mu^2+2)d}$  to be 1.265, at  $-182^\circ$  (cf. Olszewski a. Witkowski; abstract in C. J. 64\* [11], 853 [1893]). For diffusion of O in water, v. Dugan a. Hoppe-Seyler (Zeit. physikalische Chemie, 17, 147 [1892]).

Regarding the division of O between H and O<sub>2</sub> when mixtures of these gases are exploded, v. Harker (Z. P. C. 9, 673 [1892]). Dry O does not combine with Ar, NO at the ordinary temperature (Baker, C. J. 65, 611 [1894]); nor with dry K or Na, even when these metals are distilled in the gas (Holt a. Sims, C. J. 65, 440 [1894]).

**OZONE** (vol. iii. p. 788). Regarding the conditions of ozonification of oxygen, v. Shenstone a. Pries (C. J. 68, 938 [1893]). Baker (C. J. 65, 611 [1894]) confirms the observation of Shenstone a. Cundall (C. J. 81, 610 [1887]) that dry O is ozonised as rapidly as moderately dry O.

**PALLADIUM** (vol. iii. p. 792). The at. w. of Pd has been re-determined (1) by Bailey a. Lamb (C. J. 61, 745 [1892]), by analyses of Pd(NH<sub>4</sub>Cl)<sub>2</sub>; (2) by Kellera. Smith (Am. 14, 423 [1892]), by electrolytically from a solution of Pd(NH<sub>4</sub>Cl)<sub>2</sub> in NH<sub>4</sub>Aq; (3) by Joly a. Leidió (C. R. 116, 146 [1893]), by electrolysis of K<sub>2</sub>PdCl<sub>4</sub> in HClAq; (4) by Keiser a. Breed (Am. 16, 20 [1894]), by determining the ratio of Pd to Cl in Pd(NH<sub>4</sub>Cl)<sub>2</sub>. B. a. L. obtained the value 105.459; K. a. S. the value 106.35; J. a. L. the value 105.665; and K. a. B. the value 106.27 (Cl = 35.47; Ag = 107.66; N = 14.01; O = 15.96). The molecule of Pd in dilute solution in tin is probably monatomic (Heycock a. Neville, C. J. 67, 376 [1890]). Regarding the preparation of pure Pd, v. the memoirs referred to *supra*. Pd absorbs O at 450°, forming PdO (Neumann, M. 18, 40 [1892]), but when Pd sponge is heated in dry O till the weight is constant Pd<sub>2</sub>O is formed (Wilm, B. 25, 220 [1892]). Heated to 120° in NO, Pd sponge that has been saturated with H becomes incandescent and the NO is completely changed to H<sub>2</sub>O and NH<sub>3</sub>, but oxidation of the Pd does not occur (Sabatier a. Senderens (C. R. 114, 1429 [1892])). Regarding palladium sulphides, v. Petrenko a. Arisohenko (Zeit. f. anorg. Chemie, 4, 247; abstract in C. J. 64 [11], 475 [1893]). Phosphopalladous compounds, PdCl<sub>2</sub>PO<sub>4</sub> and

PdCl<sub>2</sub>P(OH)<sub>2</sub>, are described by Fink (C. M. 129, 176; abstract in C. J. 63, 1285 [1892]). Vases (C. R. 115, 111) describes polypodium palladoschloronitride K<sub>2</sub>Pd(NO<sub>3</sub>)<sub>2</sub>Cl<sub>2</sub> (abstract in C. J. 63, 1284 [1892]).

**PHOSPHATES** (vol. iv. p. 106). Rosell a. Frank (B. 27, 62) say that P is obtained by heating Na<sub>3</sub>PO<sub>3</sub> or any phosphate of Ca or Mg, with Al in a current of H.

Dipotassium-hydrogen-orthophosphate (vol. iv. p. 111). According to Staudenmaier (Zeit. f. anorg. Chemie, 5, 893 [1896]), K<sub>2</sub>HPO<sub>4</sub> cannot be isolated. S. (l.c.) describes acid salts, K<sub>3</sub>H<sub>2</sub>(PO<sub>4</sub>)<sub>3</sub> aq, K<sub>2</sub>H<sub>2</sub>(PO<sub>4</sub>)<sub>2</sub> 2aq, and KH<sub>2</sub>(PO<sub>4</sub>)<sub>2</sub>. Thorium orthophosphates (vol. iv. p. 112). Velok (Zeit. f. anorg. Chemie, 6, 161 [1894]) obtained Th(HPO<sub>4</sub>)<sub>2</sub> aq by adding dilute H<sub>2</sub>PO<sub>4</sub> aq to ThCl<sub>4</sub> aq.

Sodium pyrophosphate (vol. iv. p. 114). For a study of the reaction of HClAq with Na<sub>2</sub>P<sub>2</sub>O<sub>7</sub>, v. Watson (S. C. I. 11, 224; abstract in C. J. 64 [11], 272 [1893]).

**ORTHOPHOSPHORIC ACID** (vol. iv. p. 125). According to Watson (C. N. 68, 199 [1893]), H<sub>3</sub>PO<sub>4</sub> is changed completely to H<sub>2</sub>P<sub>2</sub>O<sub>7</sub> at 255°-260°, and HPO<sub>3</sub> begins to form at 290°-300°.

**PHOSPHORUS** (vol. iv. p. 126). Regarding the action of light and heat on ordinary phosphorus, v. Retgers (Z. P. C. 5, 211; abstract in C. J. 66 [11], [1894]).

Phosphorus hydride (vol. iv. p. 136). PH<sub>3</sub> and O react at a low pressure to form H<sub>3</sub>PO<sub>2</sub> (2PH<sub>3</sub> + 3O<sub>2</sub> = 2H<sub>3</sub>PO<sub>2</sub>); when the gases are allowed to diffuse with one another at less than 50 mm. pressure, the reaction is PH<sub>3</sub> + O<sub>2</sub> = H<sub>2</sub> + HPO<sub>2</sub>; slow oxidation at greater pressures proceeds approximately according to the equation 4PH<sub>3</sub> + 5O<sub>2</sub> = 2HPO<sub>3</sub> + 2H<sub>2</sub>PO<sub>3</sub> + 2H<sub>2</sub> (H. J. van de Stadt, Z. P. C. 12, 822 [1893]). According to van de S., explosion occurs at a certain low pressure, and this pressure depends much on the amount of moisture present, the moisture preventing and retarding the explosion. Edvi (Z. P. C. 12, 155 [1893]) has examined the rate of decomposition of PH<sub>3</sub> by heat. For the reaction of PH<sub>3</sub> with AgNO<sub>3</sub> aq v. Vitafi (abstract in C. J. 64 [11], 206 [1893]).

Phosphoric oxide (vol. iv. p. 141). For details regarding the preparation of pure P<sub>2</sub>O<sub>5</sub>, and for methods of detecting traces of P in P<sub>2</sub>O<sub>5</sub>, v. Threlfall (P. M. [5] 35, 14 [1893]).

Phosphorus suboxide (vol. iv. p. 139). B. (B. 27, 1257 [1894]) thinks that P<sub>2</sub>O is formed by the interaction of P<sub>2</sub>O<sub>5</sub> and NH<sub>3</sub>.

Phosphorus sulphides (vol. iv. p. 145). Helff (Z. F. C. 12, 490 [1893]) confirms the statement that there are no definite compounds P<sub>2</sub>S and P<sub>4</sub>S; by heating together red P and S, he obtained P<sub>2</sub>S, P<sub>3</sub>S, P<sub>4</sub>S, and P<sub>5</sub>S.

Phosphorus sulphoxide of Oüvrad (C. R. 125, 1801; abstract in C. J. 64 [11], 164 [1893]) obtained P<sub>2</sub>S<sub>2</sub>O by heating P<sub>4</sub> in H<sub>2</sub>S at 110°-120°; also by evaporating a solution of the three elements in the proper proportion in CS<sub>2</sub> and heating the residue to 120° in an inert gas; also by dissolving P<sub>4</sub> in a solution of P<sub>2</sub>S in CS<sub>2</sub>. The compound crystallises from CS<sub>2</sub> in golden-yellow prisms; it is unchanged in dry air, but slowly decomposed in moist air, giving off H<sub>2</sub>S; it sol. in CHCl<sub>3</sub>, CCl<sub>4</sub>, EtOH, or Et<sub>2</sub>O; burns at c. 800°, giving P<sub>2</sub>O<sub>5</sub>, SO<sub>2</sub>, and S; at c. 800° in vacuum it

separates into I and P<sub>2</sub>S<sub>5</sub>; decomposed by hot water, and explosively by fuming HNO<sub>3</sub>.

• Potassium hypophosphates (vol. iv. p. 163). Bansa (*Zeit. f. anorg. Chemie*, 6, 128 [1894]) describes many double salts of K<sub>2</sub>H<sub>2</sub>P<sub>2</sub>O<sub>4</sub> with (M<sub>2</sub>H<sub>2</sub>P<sub>2</sub>O<sub>4</sub>), where M = Cd, Co, Cu, Mn, Ni, or Zn; also double salts MK<sub>2</sub>P<sub>2</sub>O<sub>4</sub>, where M = Co or Ni. The double salt K<sub>2</sub>Na<sub>2</sub>P<sub>2</sub>O<sub>4</sub>·2aq is also described (abstract in *C. J.* 66 [11], 279 [1894]).

• Thallium hypophosphates. Joly (*C. R.* 118, 649 [1894]) obtained the normal salt Tl<sub>2</sub>H<sub>2</sub>P<sub>2</sub>O<sub>4</sub> and the acid salt Tl<sub>2</sub>H<sub>2</sub>P<sub>2</sub>O<sub>4</sub> (abstract in *C. J.* 66 [11], 282 [1894]).

• PLATINATES (vol. iv. p. 281).

Sodium thioplatinates. Schneider has obtained the salts Na<sub>2</sub>PtS<sub>2</sub> and Na<sub>2</sub>S<sub>2</sub>PtS<sub>2</sub>PtS<sub>2</sub> (*J. pr.* [2] 48, 411 [1894]).

Platino-oxalates (vol. iv. p. 285). Regarding the constitutional formulae of the K salts, v. Werner (*Zeit. f. anorg. Chemie*, 3, 267), and Söderbaum (*ibid.* 6, 45 [1894]).

• PLATINUM-AMMONIUM COMPOUNDS (vol. iv. p. 292). Petersen (*Z. P. C.* 10, 580 [1892]) finds, from cryoscopic determinations, that most of the formulae generally used for these compounds are molecular. For a discussion of the constitutions of several classes of these compounds, and for measurements of the electrical conductivities of aqueous solutions of some of them, v. Werner a. Molati (*Z. P. C.* 12, 35 [1893]).

• POTASSIUM (vol. iv. p. 297). Holt a. Sims (*C. J.* 65, 492 [1894]) found that K became soft at 54.5°, and remained soft to 60.5°, whereat it became brittle; complete melting occurred at 62.5°. H. a. S. say that dry K may be distilled in dry Q without the formation of any compound of the two elements. They found the products of the oxidation of K to be K<sub>2</sub>O, K<sub>2</sub>O<sub>2</sub>, and finally K<sub>2</sub>O<sub>3</sub> (v. Oxides, *infra*). Mixtures of KNO<sub>3</sub> and KNO<sub>2</sub> were formed by oxidising K in NO and in the red oxides of N.

Potassium amide (vol. iv. p. 299). Titherley (*C. J.* 65, 504 [1894]) says that KNH<sub>2</sub> is white and wax-like, melting at 270°-272°. It may be distilled without change in H at 400°-500°. T. says that KNH<sub>2</sub> is not decomposed by heating at c. 400° in a silver boat; if a glass vessel is used, NH<sub>3</sub> is given off with some N<sub>2</sub> and H<sub>2</sub>, and K silicate is formed; a small amount of decomposition occurs in a silver boat at c. 500°, and at a full red heat the amide distils with partial splitting up into its elements. For other reactions of KNH<sub>2</sub>, v. T. (*loc.*).

Potassammonium (vol. iv. p. 299). Joannis (*C. R. M.* 8, 713 [1894]) finds that there is no reaction between N and N<sub>2</sub>H<sub>4</sub>K<sub>2</sub>; he says that N<sub>2</sub>O produces KNH<sub>2</sub>, NH<sub>3</sub>, KOH, and N. For the action of O, v. J. (*C. R.* 118, 1370; abstract in *C. J.* 64 [11], 462 [1893]).

Potassium bromide (vol. iv. p. 299). The melting-point is given as 215° by V. Meyer a. Riddle (*B.* 26, 2443 [1893]).

Potassium chloride (vol. iv. p. 300). Melts at 766°, according to M. a. B. (*loc.*).

Potassium hydroxide (vol. iv. p. 302). Melts at 1045° (M. a. B. *loc.*).

Potassium iodide (vol. iv. p. 303). Melts at 126° (M. a. B. *loc.*). Regarding the interaction of KIAq and FeCl<sub>3</sub>aq, v. Ferrous compounds, *addenda*, p. 913.

Potassium tri-iodide (vol. iv. p. 304). Jakovkin (*Z. P. C.* 13, 539 [1894]) has made an examination of the dissociation of KI<sub>3</sub> in aqueous solution to KIAq and IAq (abstract in *C. J.* 66 [11], 271 [1894]).

• Potassium nitride (vol. iv. p. 304). The experiments of Titherley (*C. J.* 65, 518 [1894]) show that K<sub>2</sub>N does not exist.

Potassium oxide (vol. iv. p. 304). Holt a. Sims (*C. J.* 66, 432 [1894]) failed to obtain the monoxide K<sub>2</sub>O by any of the methods said to give this compound, but they say that when K<sub>2</sub>O is kept at a red heat it loses O and gives a substance the composition of which approaches that of K<sub>2</sub>O. By heating K in a fairly dry mixture of O and N, oxidation proceeded until K<sub>2</sub>O was formed (dry O is without action on K); when kept in water-vapour K<sub>2</sub>O gave off O, and formed K<sub>2</sub>O<sub>2</sub>; and by heating K in N<sub>2</sub>O, H. a. S. obtained K<sub>2</sub>O<sub>3</sub>, which on exposure to air became K<sub>2</sub>O<sub>2</sub>.

## RUBIDIUM.

Rubidium haloid compounds (vol. iv. p. 413). Wheelgr (*Ann. S.* [3] 46, 88 [1893]) has prepared double compounds of the forms 3RbX.AsX<sub>3</sub> and RbX.AsX<sub>3</sub>; and (*loc.* p. 269) various compounds of RbX with SbX<sub>3</sub>. For physical properties of various salts of Rb, v. Erdmann, *Ar. Ph.* 232, 3 (abstract in *C. J.* 66 [11], 351 [1894]).

SELENATES (vol. iv. p. 413). Basic salts of Co and Cu are described by Bogdan (*Bl.* [8] 9, 584; abstract in *C. J.* 66 [11], 16 [1894]); the compositions given are 4CoO.3SeO<sub>3</sub>aq and 3CuO.2SeO<sub>3</sub>·4aq.

SILICON CHLORIDES (vol. iv. p. 458). In *B.* 27, 1943 [1894] Gattermann a. Weimig detail the best conditions for preparing SiCl<sub>4</sub>, SiHCl<sub>3</sub>, and SiCl<sub>3</sub> from crude Si obtained by the interaction of SiO<sub>2</sub> and Mg powder (v. vol. iv. p. 455). SiCl<sub>4</sub> melts at -12° with NH<sub>3</sub>Aq it gives off H and forms SiO<sub>2</sub>·xH<sub>2</sub>O (O. a. W. *loc.*).

Silicon octochloride Si<sub>2</sub>Cl<sub>8</sub>. Mol. w. 860.9, V.D. 187.7. Obtained by G. a. W. (*loc.*) by fractionating crude Si chlorides; boils from 220° to 215°; does not solidify at -12°.

SILVER (vol. iv. p. 464). The molecule of Ag in dilute solution in tin is probably monatomic (Heycock a. Neville, *C. J.* 57, 376 [1890]). According to Lütke (*W.* 50, 678; abstract in *C. J.* 66 [11], 92 [1894]), thin deposits of Ag on glass, mica, &c., are allotropic forms of the metal. Regarding alloys of Ag with cadmium, v. Heycock a. Neville (*C. J.* 65, 65 [1894]); v. also Mylius a. Fromm (*B.* 27, 630 [1894]).

• Silver chloride (vol. iv. p. 468). By the action of AgCl<sub>2</sub>Aq on pulverulent silver, Jones (*S. C. I.* 12, 983; abstract in *C. J.* 66 [11], 188 [1894]) obtained the compound Ag<sub>2</sub>HgCl<sub>4</sub>.

• SODIUM (vol. iv. p. 473). The molecule of sodium in dilute solution in tin is probably monatomic (Heycock a. Neville, *C. J.* 57, 376 [1890]). Holt a. Sims (*C. J.* 65, 440 [1894]) found that dry sodium may be distilled unchanged in dry O; in ordinary O the products are Na<sub>2</sub>O and Na<sub>2</sub>O<sub>2</sub>. Heating to 180°-200° in a limited volume of N<sub>2</sub>O forms Na<sub>2</sub>O<sub>3</sub>; heating in NO or the red oxides of N produces a mixture of NaNO<sub>2</sub> and Na<sub>2</sub>O (H. a. S. *loc.*).

**Sodium amide** (vol. iv. p. 475). Titherley (*C. J.* 65, 504 [1894]) describes  $\text{NaNH}_2$  as a white, transparent solid, with a crystalline structure; softens at  $149^\circ$  and is completely melted at  $255^\circ$  to a colourless liquid.  $\text{NaNH}_2$  is obtained in transparent, crystalline needles by heating Na in  $\text{NH}_3$  at  $400^\circ$ , allowing the product to sublime through a narrow tube, and again subliming by warming gently.  $\text{NaNH}_2$  decomposes at a red heat into Na, N, and  $\text{H}_2$ . It does not give  $\text{NaN}_3$ , as generally stated (T., l.c.); no decomposition occurs at  $300^\circ$ – $400^\circ$ .

**Sodium bromide** (vol. iv. p. 476). Panfiloff (*J. R.* 25, 272 [1893]) obtained NaBr. 5aq by exposing conc.  $\text{NaBrAq}$  out of doors in winter in Russia; decomposed at  $-25^\circ$  to the dihydrate and water.

**Sodium iodide** (vol. iv. p. 481). NaI. 5aq separates from a solution of 100 g. NaI in 50 c.c. water at  $-14^\circ$ ; at  $-10^\circ$  it gives NaI. 2aq and water (P., l.c.).

**Sodium nitride** (vol. iv. p. 482).  $\text{NaN}_3$  is not formed by the interaction of Na or  $\text{Na}_2\text{O}$  and  $\text{NH}_3$ , or Na and N, according to Titherley (*C. J.* 65, 507; cf. *Sodium amide*, *supra*).

**Sodium monoxide** (vol. iv. p. 482).  $\text{Na}_2\text{O}$  is formed by heating Na in a limited volume of  $\text{O}_2$  at a temperature below  $180^\circ$ ; also by heating Na in a limited volume of  $\text{N}_2\text{O}$  at  $180^\circ$ – $200^\circ$  (Holt a. Spence, *C. J.* 65, 142 [1894]). Heated in excess of  $\text{O}_2$  the peroxide  $\text{Na}_2\text{O}_2$  is formed. H. a. S. say  $\text{Na}_2\text{O}$  is greyish white.  $\text{NH}_3$  reacts with gently heated  $\text{Na}_2\text{O}$  to form  $\text{NaNH}_2$  and  $\text{H}_2\text{O}$  (Titherley, *C. J.* 65, 510).

**Sodium dioxide** (vol. iv. p. 483).  $\text{Na}_2\text{O}_2$  does not combine with O when heated therein (H. a. S., l.c.). Regarding the interaction of  $\text{Na}_2\text{O}_2$  and an alcoholic solution of  $\text{HCl}$ , cf. Tafel (*B.* 27, 816 [1894]). For reactions of  $\text{Na}_2\text{O}_2$ , cf. Poleck, *B.* 27, 2051 (abstract in *C. J.* 66 [11], 818).

**STRONTIUM**. For *Strontium carbide*, cf. Moissan, *C. R.* 118, 688 (abstract in *C. J.* 66 [11], 818 [1894]).

**SULFATES** (vol. ix. p. 567).

**Chromium sulphates** (vol. iv. p. 570). Double salts of  $\text{Cr}(\text{SO}_4)_3$  and  $(\text{NH}_4)_2\text{SO}_4$  are described by Klobb (*B.* [3] 9, 668; abstract in *C. J.* 66 [11], 95 [1894]).

**Vanadium sulphates** (v. this vol. pp. 847, 848, 850).

**OXY-IMIDO SULPHONATES** (vol. iv. p. 602). Divers a. Haga have published a lengthy communication on these salts in *C. J.* 65, 523 [1894].

**SULPHUR** (vol. iv. p. 606). For measurements of the viscosity of molten S at different temperatures, cf. Brunhes a. Dussy, *C. R.* 118, 1045 (abstract in *C. J.* 66 [11], 348 [1894]).

**THALLIUM** (vol. iv. p. 674). The molecule of Tl in dilute solution in tin is probably monatomic (Heycock a. Neville, *C. J.* 57, 374 [1890]).

**Thallium tri-iodide  $\text{TlI}_3$** . Wells a. Penfield (*Zeit. f. anorg. Chemie*, 6, 312; abstract in *C. J.* 66 [11], 318 [1894]) obtained this compound, in rhombic crystals,  $a:b:c = 0.828:1:1.217$ , by digesting TlI and I with alcohol and evaporating over  $\text{H}_2\text{SO}_4$ .
